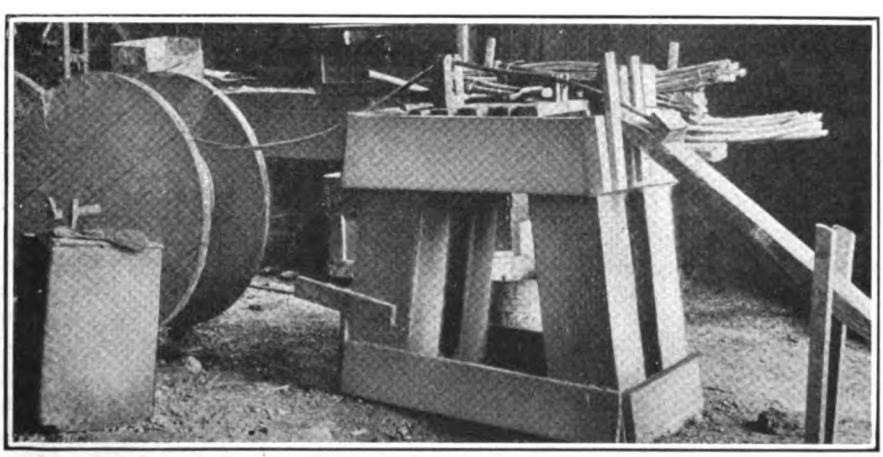
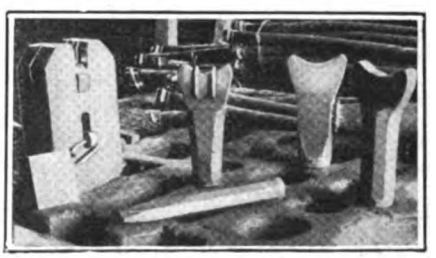
At Sublet, Wyo., the bed in which the No. 5 mine of the Kemmerer Coal Co. is opened outcrops at practically the top of a hill, the hoist house in fact being located slightly over the crest, at an elevation of nearly 8,000 ft. above tide. The somewhat peculiar situation and local topography make it possible to use a counterweight moving up and down a track laid on the surface.

Originally an electrically driven hoist was installed at this point which served the slope but without the assistance of any counterbalance. The Vulcan Iron Works of Wilkes-Barre, Pa., however, furnished a drum for controlling the counterweight. The present machine is shown in the accompanying illustration. As one rope winds off the drum serving the slope the other winds onto the other drum thus lifting the counterweight and vice versa.



Counterbalance on Hoist Almost Halves Load on Motor



As originally installed this machine was intended merely to haul trips out of, and lower them into, the slope as dead weight. The addition of a counterweight on the hillside and a means of controlling it materially decreased the power consumption, or what is the same thing, permitted the machine to handle 10-car trips whereas before it could handle trips of only 5 to 6 cars.

The power consumed in hoisting is thus materially reduced.

A small railroad car filled with rock and weighing approximately 90 tons serves as a back balance or counterweight. This moves up and down on a track laid on the hillside on an inclination of 12½ per cent. The relative speed of the two drums is such that the counterweight moves 1,600 ft. while the trip in the slope travels 2,500 ft. The speed of the trip in the slope when coming up is 1,200 ft. per minute and when going down 1,320 ft. per minute. Ten-car trips are handled. The weight of the cars, empty, is 2,500 lb. and they hold 5,000 lb. of coal each. The grade of the slope is 18 deg.

The present arrangement is quite flexible. It may be used for hoisting or lowering materials and supplies on the slope independent of the counterweight. The motor driving the hoist is a 500-hp. 2,300-volt induction machine operating at a no-load speed of 450 and a full-load speed of 442 r.p.m. Gomer Reese, the general superintendent of the company, states that this hoist now handles 10-car trips as easily and readily as it formerly handled 5- or 6-car trips before the counterweight and its drum equipment were added.

Electric Bonding "At Home"

The extensive bonding program of a large coal company prompted it to manufacture its own arc-weld bonds. Above is a close-up of die and tools used to apply copper-sheet terminals to the stranded wire. These bonds are for application by the copper-electrode method.

Should We Make Our Mine-Car Wheels Of Cast Steel or of Cast Iron?

I have been much interested in your editorial entitled "Lighter Wheels and Heavier Loads," appearing in *Coal Age*, Feb. 18, 1926, and in the criticism signed by "Wheelman" in your April 15 issue.

I began using cast-steel mine-car wheels when operating coal mines in Canada in 1910, and continued to use them up until I left the Dominion in 1917. After my arrival at Ansted, I ordered 100 sets of English cast-steel mine-car wheels. These were delivered about two years ago. The wheels I used in Canada were of 18-in. diameter, bronze-bushed, and were installed on a 3-ton mine car. We used sprags made from 1½-in. pipe; consequently, the service was severe, taking into consideration the extremes we would have in weather and also the steep grades.

Five Years and Still Working

In order to illustrate the good service we got from these English cast-steel wheels, I can state that we purchased eighty-four trucks and put them into service in 1912. I can vouch for the fact that upon my leaving in 1917 every wheel was in service, having been used continuously from the time it was installed, which covered a period of over five years. The results were so extraordinarily good that when I came to West Virginia I immediately began to look around for American-made cast-steel wheels. I was successful in getting some excellent wheels, which I put into service in 1918. These are still in use and giving splendid service.

As stated earlier in my letter, I have also installed one hundred sets of English cast-steel wheels of 14-in. diameter, equipped with bronze bushings. We have had some difficulty with these, which was due to no fault of the wheels themselves, but to the fact that we used too heavy grease in lubrication, causing some of the bushings to wear. These had to be replaced. They are all in service at the present time.

We have also just recently ordered from an American company fifty sets of cast-steel wheels, after having tried out ten of their wheels equipped with a special bearing. It is a fact —and we have experienced it—that when the thread of the cast-steel wheels is made too thin they will flatten between the spokes. I had one set of American-made cast-steel wheels which did this, and upon taking it up with the manufacturers they increased the thickness of the tread, and I am convinced now that the wheels will stand up well.

The writer of the letter printed in the issue of April 15 must have had experience with some very inferior cast-steel wheels, as he says that they wore out in one round trip. We have here extremely hard service, having an outside haul of over five miles—our cars being equipped with brakes—and in each trip the brakes are applied, causing slipping and sliding of the wheels. When cast-iron wheels slip on the rails the tread is often flattened and this action tends to increase on succeeding trips. When the brakes are applied to slip the cast-steel wheels little flattening is experienced—in fact upon close examination the cast-steel wheels do not flatten like a cast-iron wheel.

Weight Cut in Two

The statement in your editorial in regard to the difference in weight is conservative, as my experience has been in weighing several cast-iron wheels and cast-steel wheels, including the pedestals, a set of same-dimension cast-steel wheels will weigh approximately one-half as much as the cast-iron wheels and pedestals. As you mention in your editorial, this is an important item.

Having used cast-steel wheels over a period of sixteen years, I am thoroughly convinced that for mine service this wheel is far more economical than the cast-iron wheel.

West Virginia Won Doubtful Victory at Jacksonville

Many have been the declarations, appearing in *Coal Age*, of those whose business has been adversely affected by the Jacksonville agreement, but we in West Virginia can assure those in other states that we are not showing any signs of affluence as the outcome of that agreement. Nor were we helped by the anthracite strike which might have been expected to have aided all the bituminous operators whether working on the 1917 or any higher scale of wages.

The United Mine Workers perhaps intended that the anthracite strike should help the miners wherever production had been handicapped by the Jacksonville agreement. Whatever the union purposed, the Jacksonville signatories made little out of the strike and have been the first to feel the effect of the anthracite settlement and the slump that has followed. They are beginning to come to the 1917 scale, and when they do, competition with this state will be more intense. Thus the outlook in West Virginia is the darkest in many years.

Slow Progress in Merging

Consolidations might aid but any worth-while amalgamation seems unlikely. Some time ago an article on coal-company consolidations was published in the local papers and copied in New York and Chicago. The author made the statement that the main reasons why consolidations had not come to the relief of the industry were three:

First, that the promoters with the money worked under cover. Second, that the unfortunate mine owners with properties to consolidate were loath to advertise that they had "white elephants" on their hands which they desired to unload on someone else. Third, and perhaps the most important, that most of the coal men who were shaping the policies of the industry did not own the controlling stock and were drawing, relatively speaking, fairly good salaries to keep things going on as they were. They did not know where they would come out in a merger, so they sat still and said nothing.

For these reasons there was destined to be no more concerted action in the bituminous-coal business than in a government without a head. You can heap all the vitriol you please upon operators for not co-

Digitized by Google

operating, but it is pure communism to expect it. Ownership is the only sound basis for legitimate control of corporational activities.

When operating officials take this position, it is because they know that were their companies to go into a merger large enough to effect any improvement in the condition of the industry they would not be the presidents of them and would probably do well to get a superintendent's job. These are the facts, and everyone might just as well face the music.

Last year, if ever, should have been a profitable coal twelve months in West Virginia. The talk of profiteering among the operators certainly is disgusting, yet sufficient instances of coal companies trying to grab a little something out of the New England situation have occurred to lend it color. Egg went once to $3.50 per ton, but it went off almost immediately to $2.25.

WEST VIRGINIAN.

Back-Laid Fan Ill-Suited To Mine Ventilation

In the March 18 issue of *Coal Age* you published an article edited by Louis Huber setting forth many advantages of the fan with back-curved blades for mine ventilation. It is true that this fan has certain characteristics which are desirable in some special cases for the ventilation of mines, but it is my opinion that for such purposes the undesirable features of this fan overbalance its desirable qualities. Judging from inquiries received on this subject, the article has conveyed a wrong impression to the mine operator. Mr. Huber probably had in mind the use of fans for small volumes and high pressures, such as are adapted to forced draft, etc., for the data set forth do not state results obtained in the ventilating of mines.

WOULD FIGURE THUS

Let us investigate a 10 per cent drop in pressure as outlined on page 396. This means a 10 per cent drop in resistance for the volume passing. Suppose a fan is delivering 100,000 cu.ft. at 3 in. of water gage and a door is opened and the short circuit thus caused decreases the resistance 10 per cent for the above volume; the mine will then pass 100,000 cu.ft. at 2.7 in. of water gage. According to the premises in Mr. Huber's article, this fan is running at maximum efficiency and constant speed. Now the maximum volume which can be produced is found by the proportion

$$100{,}000^2 : x^2 :: 2.7 : 3 = 105{,}400 \text{ cu.ft.}$$

This is an increase in volume of 5,400 cu.ft. or 5.4 per cent instead of the 26 per cent increase stated in the article. The horsepower curve will show just about 5.6 per cent increase instead of 28 per cent.

The next item to consider is the effect on volume for a 10 per cent increase in resistance and consequently a 10 per cent increase in pressure for 100,000 cu.ft. at 3 in. of water gage. As there is a 10 per cent increase in resistance caused by falls, etc., for 100,000 cu.ft. it means that the resistance has been increased to 3.3 in. for 100,000 cu.ft. According to Mr. Huber's article the fan is running at constant speed at maximum efficiency, hence the problem is stated as follows:

$$100{,}000^2 : x^2 :: 3.3 : 3 = 95{,}300 \text{ cu.ft.}$$

The above proportion shows that a 10 per cent increase in resistance reduced the volume 4,700 cu.ft. or a decrease in volume of only 4.7 as against 84 per cent as stated in the article. The horsepower decrease will be approximately 4.6 as against the 64 per cent decrease stated by Mr. Huber.

PROVED BY PRACTICE

This shows conclusively that a 10 per cent drop in resistance or a 10 per cent increase in resistance is taken care of efficiently and effectively by a forward-curved bladed wheel. These data are obtained in actual practice, and it is in this fact that the mine operator is primarily concerned.

Mechanical efficiency is also important. It is stated that the efficiency of a backward-curved bladed fan is 15 to 20 per cent greater than with other types. I have conducted a long series of tests on both types of fans and have found that the backward-curved bladed wheel is no more efficient than any of the other types. An investigation of published data from other manufacturers who build both types of fans does not bear out the statement that the backward-curved bladed wheel is more efficient than the forward-curved bladed wheel of the same proportions.

There are two redeeming features with a backward-curved bladed wheel. The first is where a small volume of air is required, and this volume is to be delivered against a high resistance. This duty would permit direct connection to a motor of reasonable speed. The other is where a full backward-curved bladed wheel is used and a motor is provided at approximate maximum efficiency for the fan. Then no matter what conditions are encountered at this given fan speed, there is no danger of overloading the motor.

SLOWER, SAFER, CHEAPER

The forward-curved bladed wheel has distinct advantages. The normal ventilating resistance found in coal mines is equal to 3 in. of water gage. The necessary rim or peripheral speed of a forward-curved bladed fan for this pressure is approximately 5,300 ft. per minute, whereas the peripheral speed of a full backward-curved bladed wheel is approximately 8,000 ft. per minute. It must be evident to the operator that a fan wheel operating at 5,300 ft. per minute is a much safer installation than one operating at 8,000 ft. per minute. The assurance of reliability is a much greater asset than experimentation with high peripheral speeds for mine ventilation. A breakdown on the ventilating system puts the mine out of commission, and the direct loss through the shutdown is the main item to be considered, not the cost of repair to the ventilating equipment.

Another item which must be taken into consideration is the cost of the backward-curved-bladed wheel. Due to the unusually high peripheral speed, a much larger shaft must be provided, and great care must be exercised in the manufacture of the fan.

PERFECT BALANCE IMPERATIVE

No oil or foreign matter can be permitted to accumulate on blades which might jeopardize the balance of the wheel, and this calls for the highest class of bearings. It is found that the cost of this type of fan is from 50 to 75 per cent greater than that of a forward-curved-bladed fan of equal capacity.

Both types of fans are manufactured by the several fan builders and where conditions exist that call for a backward-curved-bladed fan, it will be specified. However, for the ventilation of the average mine, the forward-curved-bladed wheel will be found suitable for a wide range of pressures; efficient as to the volumes delivered and most reliable in operation.

Emergency Coal Control Now Allowed By Statute; Continuous Fact-Finding Unconstitutional, Gandy Testifies

Washington, D. C., April 27.—Authority to exercise emergency control over the coal industry already has been written into the federal statutes, according to Harry L. Gandy, executive secretary of the National Coal Association. "Additional legislation, therefore, such as is possible under the Constitution," he told members of the House committee on interstate and foreign commerce at the hearings on coal regulation yesterday, "could have only the effect of duplication or of transferring the authority from places where it is now lodged to some other department or commission of the government." Any program for continuous, compulsory fact-finding, he contended, would be clearly unconstitutional.

Compulsory arbitration also is beyond the power of the government. The organic law of the Department of Labor, however, authorizes the Secretary of Labor to act as a mediator and to appoint conciliators in labor disputes "whenever in his judgment the interests of industrial peace may require it to be done." That law, Mr. Gandy pointed out, is still in force, and probably represents the limits to which the government may go in intervening in labor troubles.

New Legislation Not Needed

Control of distribution during times of emergency is to be found in sections 15, 16 and 17 of the Transportation Act of 1920. The validity of that control, exercised by the Interstate Commerce Commission, has been sustained by the Supreme Court of the United States in *Advent vs. United States*, 220 U. S. 127, and in *Koenig Coal Co. vs. United States*, decided this month. "The placing of additional authority concerning distribution in any other department of the government," remarked Mr. Gandy, "would provide for duplication unless the authority should be withdrawn from the Interstate Commerce Commission. I submit that inasmuch as the law has been in existence for more than six years, additional legislation thereon is in no wise needed."

The recommendations of the United States Coal Commission, said the witness, embrace a wide range from fact-finding to control of distribution and the licensing of dealers. They rest upon the proposition that coal is clothed with a public interest and that the production and transportation of coal constitute a single service. But the Supreme Court has time and again contradicted that proposition, so that the recommendations "are at variance with the decisions of the highest tribunal of the land and hence outside the jurisdiction of Congress to legislate."

Mr. Gandy opened his presentation of the case for the bituminous operators with a review of the conflicting proposals and testimony given before the committee by proponents of further legislation. The only thing upon which there was agreement, he commented, was that there was no monopoly in bituminous coal. There was, he said, no danger of the exhaustion of our soft-coal resources for many generations yet unborn.

Compares Efficiency of Industries

Replying to the critics who have charged the industry with being inefficient and grossly overdeveloped, Mr. Gandy stated:

"If you will study the peaks and valleys of production in the manufacturing industries in the United States and compare them with the movement in the production of bituminous coal, you will find that the two lines approximately coincide. Until that person or that government arrives that can change the habits of the buying public and can underwrite continuous performance of manufacturing industry generally, there can be no complete stabilization of the load of production of bituminous coal."

Industry generally is developed to take care of peak loads. The so-called "overdevelopment" in soft coal has been a means of national security in times of strikes and abnormal demand. Moreover, the bituminous industry compares favorably with other business in the matter of excess capacity. During the twelve years ended Dec. 31, 1924, production of steel ingots and castings fluctuated between 33.70 and 85.76 per cent of capacity; refined copper, between 18.50 and 77.24 per cent, and bituminous coal, between 50.71 and 88.93 per cent of capacity. In the boot and shoe industry, 14.5 per cent of the existing plants could take care of 95 per cent of the demand; 2.8 per cent of the flour mills supply 62.1 per cent of the output and have reserve capacity to take care of the entire demand.

The American coal miner is better paid and produces more tons per man than his foreign competitors. The United States leads in the use of mining machinery. If the American coal industry is so inefficient, why is there a steady stream of foreign operators coming over to study American methods? American coal is cheaper than foreign coal. The cost of fuel and power for all manufacturing industries is but 2.6 per cent of the value of the finished product and less than 11 per cent of the total railroad operating expenses.

Mr. Gandy thought it hardly fair to criticize the bituminous industry as "unorganized" when the Sherman anti-trust law effectively prevented any agreement on prices or production, although labor was protected under the Clayton act. He contrasted this situation with that prevailing in European coal-producing countries where the cartel, the syndicate and the comptoir are permitted and often directly encouraged. In the United States, on the other hand, the operator is caught between a combination of labor and a community of interests among large consumers. Nevertheless, wherever the operator may legally co-operate he is doing it through membership in local and national organizations, shippers' advisory boards and with government bureaus.

Proposals for compulsory fact-finding, argued Mr. Gandy, contravene the Fourth Amendment. "The inviolability of private business matters is a common law right, protected by constitutional guarantee. The Supreme Court has affirmed this with unswerving consistency. It rests not upon technical legal requirements but upon the broad, comprehensive, solid foundation of public policy, public comfort, liberty and the pursuit of happiness. The protection extends to corporations as well as to individuals: *Silverthorne Lumber Co. vs. United States*, 251 U. S. 385.

Cites Precedent Cases

Continuing his attack upon the constitutionality of fact-finding in his testimony this morning, Mr. Gandy read extracts from the decisions in *Gould vs. United States*, 255 U. S. 298; *Federal Trade Commission vs. Baltimore Grain* Co., 284 Fed. 886, and *Federal Trade Commission vs. American Tobacco Co.*, 264 U. S. 298. He followed these up with citations from *Heisler vs. Thomas Colliery*, 260 U. S. 245; *Oliver Iron Co. vs. Lord*, 262 U. S. 172; *D., L. & W. vs. Yurkonis*, 238 U. S. 439; *Kidd vs. Pearson*, 128 U. S. 1; *Crescent Cotton Oil Co. vs. Mississippi*, 257 U. S. 125; *Coe vs. Errol*, 116 U. S. 517; *Arkadelphia Milling Co. vs. St. Louis Southwestern Ry. Co.*, 249

Digitized by Google

U. S. 134, and *McCluskey vs. Marysville & Northern Ry.*, 243 U. S. 36, to show that neither mining nor manufacture could be construed as interstate commerce.

Wolff Co. vs. Industrial Court, 262 U. S. 522, was drawn upon to prove that coal was not affected with a public interest. Mr. Gandy also gave his interpretation of the decisions in *United Mine Workers vs. Coronado Coal Co.*, 259 U. S. 344; 268 U. S. 963, which have been cited frequently as supporting the view that Congress has the power to enact regulatory legislation for the coal industry. "The court," he explained, "certainly did not mean to suggest, and the language used bears no such interpretation, that the mining of coal in all its phases would become subject to regulation even if there was some practice that might be likely to obstruct, restrain or burden interstate commerce. The federal power extends only to a removal of such obstructions or restraint and does not reach beyond a regulation of the production of coal in other respects.

"The bituminous coal industry," said Mr. Gandy in concluding his direct statement, "asks nothing more than the right to live, a free agent for good among a free people. The bituminous industry does not believe it would be wise to entrust the domination of the fuel supply of the United States to one or even to a few persons."

Mr. Gandy Questioned

Mr. Gandy, who was still on the stand when the committee recessed for the day, was questioned closely by Congressmen Hoch (Kansas), Huddleston (Alabama) and Newton (Minnesota) on the legal phases of coal control. If the government could not compel mediation and fact-finding, they wanted to know upon what basis it could act voluntarily in those matters. The witness was unable to give the legal basis for such voluntary activities. Mr. Huddleston thought the protection of the Fourth Amendment extended only against unreasonable search and seizure. Mr. Newton intimated that the right of Congress to gather facts as the basis for specific legislation might be broadened to continuous fact-finding by an agency of the government.

The power of the Interstate Commerce Commission, explained Mr. Gandy, is over distribution, not production. He did not think it necessary to re-enact a federal fuel distribution bill although the Interstate Commerce Commission had been doubtful of its authority in 1922, because the Supreme Court has since interpreted the emergency powers given the Commission under the Transportation Act. Whether the Commission could divert shipments as well as set up priorities was a question upon which the witness would express no opinion.

Mr. Newton asserted that neither the spokesmen for management nor for labor had offered any solution for the recurring interruptions to production and intermittent employment at high daily rates. Mr. Gandy replied that the Sherman Law barred action by the operators. Repeal or modification of that statute would be helpful when consumption more nearly approaches productive capacity. "When the normal pre-war rate of increase in demand is restored," said Mr. Gandy, "some of the troubles will be lessened."

Harry L. Gandy

"Assuming there is a national strike in both anthracite and bituminous; under those circumstances there would be no interstate commerce because, as we conceive it, you can't have interstate commerce without coal. Do you still feel that the federal government would be powerless?" inquired Congressman Newton.

"In so far as compulsion is concerned, yes," reponded Mr. Gandy.

Congressman W. R. Coyle, Pennsylvania, at the opening of the hearing, on Monday, filed without reading a statement condemning several of the bills referred to the committee and pled for a settlement of the industry's troubles within the industry.

After the bituminous operators have concluded the presentation of their case the committee will hear representatives of other branches of the industry. Daniel T. Pierce, vice-chairman, and Walter Gordon Merritt, general counsel, Anthracite Operators' Conference, probably will be the chief spokesmen for the hard-coal industry. Ira Cochran, commissioner, American Wholesale Coal Association, will appear for the wholesalers.

Morrow in Pittsburgh Coal Co.

John D. Morrow, nationally known in the coal industry, has been appointed vice-president in charge of sales of the Pittsburgh Coal Co., to succeed James H. Woods, resigned. Mr. Morrow was formerly executive secretary of the National Coal Association, which position he resigned to organize the Morrow-Callahan Coal Co., of which he was president. Later he joined the Joy Machine Co., and became its vice-president.

Sealed proposals will be opened by the Supt. of Lighthouses, Charleston, S. C., 12 o'clock noon, May 18, 1926, for approximately 4,000 tons of steam coal (bituminous) and 150 tons of stove coal (anthracite), delivered on board vessels at Contractor's Wharf, Charleston, S. C., in quantities of 10 to 100 tons as ordered during fiscal year 1927. Information upon application.

Baldwin Raises Hopes Of Breaking Deadlock In British Coal Industry

Hope was felt early this week that an agreement ending the three-weeks impasse in negotiations between the British coal miners and operators would be reached before May 1, when the term of the present subsidy expires. This optimism was based on the untiring efforts at mediation by the Premier, Stanley Baldwin, who held conferences on Monday with the industrial committee of the Trades Union Congress' General Council, which is acting in behalf of the miners' executives, and with the representatives of the mine owners.

Reopening of national negotiations on wages was the chief subject of discussion on Monday, according to a joint statement issued that evening by the industrial committee and the miners' federation executives. An attempt by the operators to force a district instead of a national settlement of wages has been the stumbling block to an agreement. After a conference with representatives of the operators Mr. Baldwin told the industrial committee that the colliery owners were studying his suggestions and stated that he proposed to resume the joint conferences the following day, when he expected a reply from the operators.

Although the present subsidy expires on May 1, it is believed in some quarters that continuance of financial assistance by the government may be necessary, perhaps under another name. The mines department of the government is engaged in drafting a scheme embodying the government's idea of a temporary loan to assist in the organization of the industry, the interest on which would be provided by the government, the operators and the miners each paying one-third. Definite reorganization would be made a condition of granting the loan.

Late last week a special delegate conference of the miners' federation was summoned for Wednesday to hear various reports and decide on the miners' policy. On Thursday a conference of executives of trade unions affiliated with the Trade Union Congress was to be held. Should the negotiations break down, it was expected that this conference would decide on the action to be taken to support the miners in their struggle.

Six Weeks' Summer Course At West Virginia University

The annual summer course in coal mining at West Virginia University, Morgantown, W. Va., will be held from June 14 to July 26. This course is intended to fit miners for fireboss and mine certificates and is always followed by a state examination for these certificates. The course will include a study of West Virginia mining laws, explosives, methods of mining, geology of coal, timbering, mine gas, electricity in mines, drainage, pumping, ventilation, hauling, hoisting, mine fires, first aid, mine rescue, safety lamps, pillar drawing, mine management, safety organizations and administration.

Tangible Evidence Lacking Of Government Influence In Jacksonville Agreement

By Paul Wooton
Washington Correspondent of *Coal Age*

Frequent and reiterated denials that the government had any part in the Jacksonville agreement, other than to suggest friendly mediation, apparently have not been accepted by the United Mine Workers. Despite the fact that no one has been able to cite any letter or utterance from a government source to contradict the administration's declaration that nothing ever was said to anyone as to terms, Philip Murray, vice-president of the United Mine Workers, in his testimony before the Interstate and Foreign Commerce Committee of the House last week, baldly stated that it was the desire of Mr. Hoover that the contract be continued three or four years. He also declared that Mr. Hoover had suggested, in a private conference with John L. Lewis, a continuation of the old rates. As to the latter statement the committee will need go no further than to Mr. Lewis to get a denial. Mr. Lewis never has charged that Secretary Hoover ever advocated terms or even discussed terms with him, so far as is known.

Government Connection Not Proved

By way of substantiation for his statement Mr. Murray also cites the position of Messrs. Donaldson and Armstrong, of the Pittburgh Coal Co., in urging a five-year contract because "it was the desire of the government." He failed to bring out that whatever Messrs. Donaldson and Armstrong said at Jacksonville was an expression of their opinion of what the government wanted. Neither Mr. Donaldson nor Mr. Armstrong ever has made any claim of having anything tangible on which their opinion was based. The Pittsburgh Coal Co. never has claimed to have been influenced to go to Jacksonville by anything more than the open correspondence between C. J. Goodyear, of the Pittsburgh Coal Producers' Association, and Secretary Hoover in which Mr. Hoover said: "My advice is that your representatives should attend this conference and, together with the other representatives from the Central fields, should make every proper endeavor to continue an agreement with the United Mine Workers and thus avoid a suspension of coal production."

Mr. Murray, however, in his effort to establish that the government is a party to the Jacksonville agreement and ought to enforce it, brings in a new point He tells of a letter which the President sent Mr. Lewis complimenting him on the arrangement effected at Jacksonville. This letter, it develops, was nothing more than the perfunctory, courteous acknowledgment of Mr. Lewis' telegram telling of the happy outcome of the negotiations. The operators also sent a similar message, and a courteous letter of acknowledgment also was sent to them by the President.

It is going to be difficult to establish that such letters commit the government to the Jacksonville agreement. Frequently a hundred letters of that type leave the White House in a day. In this instance the President hardly could have replied to the enthusiastic telegrams he received from Jacksonville by asking why they entered into an agreement or by stating that his letter was not to be interpreted as an approval of the terms of an agreement of which obviously he knew no details. One friend might write another that he had succeeded in negotiating a loan with a bank. The friend might send a congraulatory reply, but it hardly could be regarded as a pledge to help pay back the money. Incidentally Mr. Lewis seems to have regarded this letter of courtesy as a government document entitling him to call on the federal authority to enforce this particular labor agreement.

Both Sides Welcome Peace

The government could produce from its files evidence that both the miners and the operators were very happy over the Jacksonville agreement for several months after it was put into effect. Some persons in the industry wrote extravagantly of their love for peace and how splendidly it had been consummated. Then came the slump in prices and with it a change of heart, but some expressions of opinion during the first six months of the agreement might prove embarrassing if produced today.

Socony to Burn Coal

The Standard Oil Co. of New York is converting the fireboxes at certain of its refineries to burn coal instead of fuel oil, according to a story in the New York *Times*, April 16. This is being done because the company finds it cheaper to burn coal than oil at present, as the price of the latter has advanced in the open market during recent months. This switching from oil to coal, it was explained, takes place often in the company's plants, as they are constructed in a manner to enable the company to burn either coal or oil, whichever is cheaper.

The latest switch from oil to coal, however, is especially significant because the company can obtain its supply of fuel oil at primary prices. The fuel-oil market along the Atlantic seaboard and at interior points has been strong for several months, due to the decline in crude-oil production in this country and in Mexico as well as to the larger amount of crude oil converted into gasoline. In former years, when the demand for gasoline was smaller, oil companies found it unprofitable to refine heavy crude oil for gasoline. Improved cracking processes, however, have now made the operation more profitable.

Bids will be opened May 5 for supplying the School Department of the City of Boston with 28,000 tons of bituminous coal and 6,000 tons of anthracite or coke.

Live Topics Scheduled for Discussion by Engineers

Plans for the sectional meeting of the Southern West Virginia and Eastern Kentucky Chapter of the American Institute of Mining and Metallurgical Engineers, at the Kanawha Hotel, Clarksburg, W. Va., on May 6 and 7, which were completed last week, reveal that the opening session at 10 a.m. will be devoted to safety. Robert M. Lambie, of Charleston, chief of the state Department of Mines of West Virginia, and Dr. T. T. Read, of New York City, assistant secretary of the American Institute of Mining Engineers and formerly safety director of the U. S. Bureau of Mines, will make the chief addresses.

At the afternoon session, from 2 to 5 o'clock, the following subjects will be discussed: "Construction and Development of Byproduct Ovens," L. D. Malleis, Pittsburgh, Pa., chief chemist of the Koppers Co., who will illustrate his address with lantern slides; "Marketing the Output of Byproduct Ovens with Particular Reference to Coke and Gas." A banquet will be held at 7 p.m. at the Kanawha Hotel, with J. G. Bradley, of Dundon, W. Va., president of the West Virginia Coal Association, as toastmaster. The principal speakers at the banquet will be Samuel A. Taylor, of Pittsburgh, Pa., president of the American Institute of Mining and Metallurgical Engineers; former Governor William A. MacCorkle, Charleston, and W. H. Cunningham, Huntington, W. Va., secretary of the West Virginia Coal Association.

At the morning session of May 7, Ralph Sweetser, Columbus, Ohio, will speak on the "Evaluation of Coal"; Howard N. Eavenson, of Pittsburgh, Pa., consulting engineer, on "The Mechanization of Mines"; representatives of the National Coal Association and the Society of Mechanical Engineers will speak on "The Effect of Mechanization on the Product of the Mine," and W. W. Freeman, of Cincinnati, president of the Union Gas & Electric Co., will speak on "The Relation of Artificial Gas Either from Coke Ovens or Producer Plants to Natural Gas and the Eventual Replacement of Natural Gas by Other Types of Gas and the Proper Location of Plants and Their Equipment."

C. & O. to Buy 13-Mile Line

The Interstate Commerce Commission has entered an order authorizing the Chesapeake & Ohio Ry. to acquire control of the Pond Fork & Bald Knob R.R. by purchase of its common stock for $250,000. The road extends from West Junction to a point near Rock Lick, W. Va., a distance of approximately 13 miles. The C. & O. filed a petition with the Commerce Commission about two months ago asking authority to acquire the Pond Fork & Bald Knob, which is owned by the Cole & Crane interests. The latter road, which is in Boone County, has a junction with the Chesapeake & Ohio at West Fork, which is connected by a branch line to Madison.

Grant Honored for Settling Hard-Coal Strike

Outside interference by governmental and other agencies is the chief cause for the failure of capital and labor to adjust industrial disputes quickly and effectively, said Richard F. Grant, president of the Susquehanna Collieries Co., speaking at the fortieth annual dinner of the Ohio Society, at the Waldorf-Astoria, New York, on April 26. Mr. Grant, whose home is in Cleveland, was the guest of honor, and many tributes were paid to his work in bringing about a settlement of the recent anthracite strike.

"Labor knows its own needs," Mr. Grant said, "and so does capital. Neither wants a strike. Let us assume the time has come to negotiate a contract between them in a given industry. If they could only get together somewhere, away from reporters, away from well-intentioned politicians, interfering under the cloak of public interest, they could quickly make that contract.

"But that isn't what happens. It isn't what happened in the anthracite strike. Some one comes along; usually some one in public office who wants to walk the stage. He offers a plan. It is unsound from every economic standpoint, but it appeals to one side and is seized upon eagerly. That starts a battle and the first step is taken to impede rapid and sane adjustment of the trouble. From then on the difficulties increase. Along comes another well-meaning intervener, and the result is a long-fought contest.

"Labor and management," continued Mr. Grant, "can and must determine rules of their own game."

Mr. Grant dismissed the possibility of government operation of coal mines with the remark that experience with government railroad operation had answered that question with an emphatic negative.

National Retailers Map Out Live Convention Program

A program crammed with topics of practical interest discussed by leaders in the industry has been mapped out for the ninth annual convention of the National Retail Coal Merchants' Association, which meets at Washington, D. C., May 17-19.

Among the subjects listed are: The future of anthracite; importance of retail representation in local and national business and civic associations; trade-marked coals from the standpoint of the producer and the distributor; what part retailers should take in the distribution of coke; how to meet oil competition; the future of screened low-volatile coal; retail advertising; retail salesmanship; how salesmen should be compensated; efficient storage and handling; the future of bituminous coal in anthracite-consuming territory.

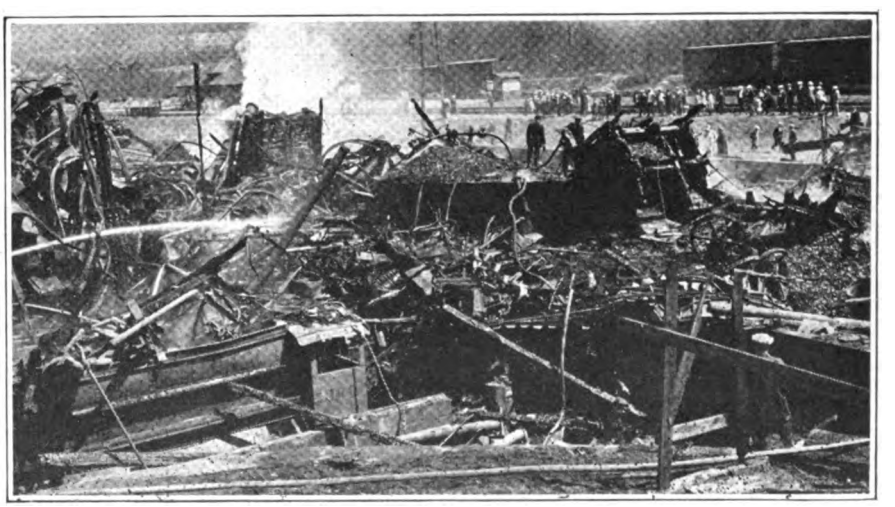
Among the men who have been asked to address the convention are Daniel T. Pierce, vice-chairman, Anthracite Operators' Conference; Martin L. Garvey, president, New River Coal Operators' Association; Ray D. Kelly, president, Mid-West Coal Association; Owen F. Fox, executive vice-president, Chicago Coal Merchants' Association; Walter Barnum, president, Pacific Coast Co.; W. A. Clark, president, New England Coal Dealers' Association.

Other speakers include W. C. Atwater, president, Pocahontas Operators' Association; Hiram Blauvelt, vice-president, Comfort Coal & Lumber Co.; Marshall Keig, vice-president, Consumers Co.; T. F. Farrell, vice-president, Burns Bros.; M. E. Robinson, Jr., president, Milton E. Robinson Coal Co.; Roderick Stephens, vice-president, Stephens Fuel Co.; W. M. Bertolet, secretary, Pennsylvania Retail Coal Merchants' Association; C. Solon Kellogg; J. C. Tattersall, president, Tattersall Co.; G. W. Malcomson, president, Detroit Coal Exchange; W. R. Feuquay, secretary, St. Joseph Coal Service Bureau; C. Benson Ferebee, president, Nottingham & Wren Co., and Harold Almert, chief, Fuel Service Bureau.

Industrial Coal Stocks Ebb To 46,313,000 Tons

Coal stocks in the hands of industrial consumers on April 1 totaled 49,150,000 tons, according to the National Association of Purchasing Agents. Based on the average rate of consumption during March, this was sufficient for 33 days, comparing with stocks on March 1 of 60,014,000 tons, or a 35-day supply. Supplies at steel plants on April 1 were good for 26 days; electric utilities and coal-gas plants, 47 days; byproduct coke plants, 20 days; railroads, 23 days; other industries, 33 days.

Industrial coal consumption during March is estimated at 46,313,000 tons, compared with 43,747,367 tons in the short month of February. Although anthracite output increased to a marked extent during March the consumption of bituminous coal fell off to a greater degree than the use of hard coal gained.



Interesting Talks at Meeting Of Fayette Institute

R. M. Lambie, chief of the state Department of Mines of West Virginia, was the headliner at the Fayette County Mining Institute April meeting held in Mt. Hope, W. Va. Mr. Lambie, who helped organize the association more than six years ago, when he was serving as mine inspector in the local district, spoke on mine explosions and their prevention. After pointing out that coal dust along the passageways, on ribs, roof and floor, is an ever-present danger due to its liability of being thrown in suspense in the mine air, thus serving as an agent to propagate flame or an explosion throughout the mine, Chief Lambie emphasized the value of rock-dusting in limiting the effects of fires and explosions. He stated that the cost of rock-dusting was nominal and urged its use in mines considered dangerous from the standpoint of gas and dust explosions.

W. D. Givan, Charleston, W. Va., described the new match-head detonator. In this device the two wires leading to the detonating charge in the cap are provided with a lead shunt which by short-circuiting the electric current prevents ignition of the explosive charge by accidental cause. A shell of insulating material placed around the detonating charge guards against its discharge in case the copper casing accidentally comes in contact with an electric current.

R. J. Holmes, of Pittsburgh, Pa., gave an interesting talk on the self-rescuer, a device designed as a protection against carbon-monoxide poisoning. Another feature was a two-reel motion picture, "The Story of Sulphur," shown through the courtesy of the Pittsburgh Station of the U. S. Bureau of Mines.

Sealed proposals will be opened by the Supt. of Lighthouses, Custom House, Boston, Mass., at 2 p.m., May 3, 1926, for furnishing 3,500 tons of bituminous coal at New Bedford, Mass. Information upon application.

Alaska Breaker Passes Away in Clouds of Smoke

This breaker of the Philadelphia & Reading Coal & Iron Co., at Mt. Carmel, Pa., was destroyed by fire on April 17. Within two hours $350,000 of damage was done and the breaker had been burned almost level with the ground.

169 Miners Meet Death By Accidents in March; Decline in Fatality Rate

Accidents at coal mines during March, 1926, caused the death of 169 employees, compared with 164 in the preceding month, according to reports furnished by state mine inspectors to the U. S. Bureau of Mines. The total production of coal for the month was 54,927,000 tons, of which 46,137,000 tons was bituminous and 8,790,000 anthracite. There were 132 fatalities in the bituminous mines and 37 in the anthracite mines. Fatality rates per million tons of coal produced were 2.86 and 4.21, respectively, with 3.08 for the industry as a whole, compared with 3.37 in February.

The accident record for the first three months of 1926 showed 658 fatalities while that for the corresponding period of 1925 showed 630. The production of coal for these months was 157,422,000 tons and 150,178,000 tons, respectively, indicating a rate for 1926 of 4.18 and for 1925 of 4.20. The three months' fatality rate in 1926 for bituminous mines alone was 4.17 based on a production of 146,376,000 tons and 4.35 for anthracite, based on an output of 11,046,000 tons. The corresponding rates for the first three months of 1925 were 3.77 for bituminous mines and 6.70 for anthracite mines.

Comparing the figures for all mines for the three-month period, January to March, with those for the same months last year, a reduction is noted in the per-million-ton fatality rates from all of the principal causes except gas and dust explosions, which materially increased due to the major disasters. The comparative rates were as follows:

	Year 1925	Jan.–Mch. 1925	Jan.–Mch. 1926
All causes	3.811	4.195	4.179
Falls of roof and coal	1.842	1.851	1.734
Haulage	0.615	0.732	0.641
Gas or dust explosions	0.590	0.759	1.308
Explosives	0.174	0.246	0.101
Electricity	0.144	0.146	0.101

Oil More Costly Than Coal As Domestic Fuel

The use of oil for domestic heating in the average New England home costs annually about $200 more than the use of bituminous coal and about $150 a year more than the use of anthracite, according to figures given to a representative of the National Coal Association by R. T. Haslam, professor in chemical engineering, Massachusetts Institute of Technology, and a recognized authority on the subject. In arriving at these figures Professor Haslam takes into consideration both the depreciation of an oil burner and interest charges. He also qualifies his statement to the effect that the margin between ultimate oil and coal costs will be slightly reduced if the coal is not consumed smokelessly. His convincing answer to the question as to the most economical fuel is a statement that he burns low-volatile bituminous coal in his home.

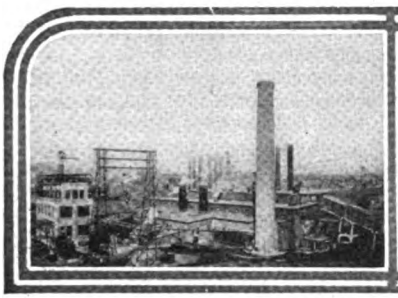
Pittsburgh Terminal Corp. Closes Avella Mine

The Avella mine of the Pittsburgh Terminal Coal Corporation has been closed, due to a falling off in business, the company announces. It was stated, however, that the closing is not permanent.

The closing down of this mine has attracted more than ordinary attention in the Pittsburgh market because the Pittsburgh Terminal Coal Corporation has been running its seven mines in this district on the Jacksonville scale almost full for nearly two years, while other mines working on the same scale were choking from the competition of the non-union operations.

According to officials of the company, it is planned to continue operations at the other six mines.

Railroad Coal Cost Higher



Average cost of coal used in March by Class 1 railroads of the United States in locomotives in transportation train service, according to a report by the Interstate Commerce Commission, was as follows, by districts: Eastern district, $2.69; Southern district, $2.21; Western district, $2.91; United States, $2.63. Compared with the preceding month this was an increase of 4c. in the Eastern district; 1c. increase in the Southern district; 1c. decrease in the Western district; 2c. increase in the country as a whole. Compared with February a year ago there was a decrease of 19c. in the Eastern district; 15c. in the Southern and Western districts, and 18c. for the United States.

Coal-Mine Fatalities During March, 1926, by Causes and States

News Items From Field and Trade

ILLINOIS

The Clarkson Coal & Mining Co., Nashville, installed a new shortwall cutting machine April 1.

The Cripple Creek mine, at Bryant, has closed down for the summer.

The Binzel Coal Co., Farmington, has filed a petition in bankruptcy, listing its liabilities at $115,620, of which $104,113 is in unsecured claims. A payroll of $10,483 also is listed. The assets are stated to be $124,410, including real estate valued at $53,100 and tools and machinery at $70,000.

The Kathleen mine of the Union Colliery Co., at Dowell, was closed down April 17 for repairs and improvements. It probably will reopen early in May.

INDIANA

The Paxton Coal Co., of Sullivan, has filed a certificate of dissolution with the Secretary of State.

Bids for providing coal for Indiana state institutions will be received by the state joint purchasing committee May 1 in Indianapolis. The committee received bids in March, but all bids were rejected because the board felt they were too high. The contracts terminate May 1, but the committee will not consider new bids until about May 19. Coal that will be needed in the interim is to be bought either under the old contract or in the open market.

The coal miners employed at the Carlisle mine completed the withdrawals of their liens recently, and as a consequence work preliminary to reopening the mine has been started. The mine is being operated by the Carlisle Fifth Vein Coal Co., composed of Carlisle men, who hold a one-year lease on the property. The new directors are W. L. Cooper, J. A. Bummere, R. A. Duffer, L. J. Kixmiller, C. M. Ott, S. A. Sproatt and D. O. Schilling. Mr. Duffer is president; Mr. Kixmiller, vice-president, and Mr. Schilling, secretary-treasurer.

The Western Indiana Mining Co., of Terre Haute, has filed a final certificate of dissolution with the Secretary of State.

KANSAS

The Reliance Coal Co. on April 17 sold its steam-shovel mine east of Pittsburgh and near Litchfield to J. J. Stephenson, Harry Miller and James Fennimore, all of Pittsburgh, who are the principal owners of the Litchfield Coal Co., The consideration was $150,000. The plant includes a 225-Bucyrus shovel, loading machinery, trackage and tipple. There is considerable acreage yet to be worked. With this sale the Reliance Coal Co. disposed of its last steam shovel operation but still operates a deep mine six miles northwest of Pittsburgh and has large coal land holdings in that vicinity.

The Kansas Supreme Court in a recent decision on a compensation case held that X-ray photographs are admissible as evidence toward proving injury to lungs in mine explosions. Previously such photographs had been admitted as evidence only on bone fractures or displacements.

KENTUCKY

The Kentucky-Knox Coal Co., of Barbourville, has leased a mine near Artemus, with an output at present of three cars per day, which will be increased.

The South Diamond mine, operated by the West Kentucky Coal Co. in Hopkins County, has been shut down after continuous production for forty years. The company's policy of cutting operation costs was given as the reason for the close-down. Four mines have been closed by the company recently.

Fire of undetermined origin April 17 destroyed the tipple and was burning in the Zion coal mine, six miles from Henderson, causing damage estimated at $20,000 and throwing seventy-five persons out of employment. The flames were under control at 5 p.m. The mine is owned by John and Thomas Baskett, of Henderson, but is leased to C. A. Moss, Jr., and others of Zion. No one was in the mine when the fire started.

MINNESOTA

Two furnaces are being built at the University of Minnesota, Minneapolis, to test the smelting of low-grade iron ore without coke. Should the experiments prove successful it is probable that there will be a new market for vast quantities of fuel.

NEW YORK

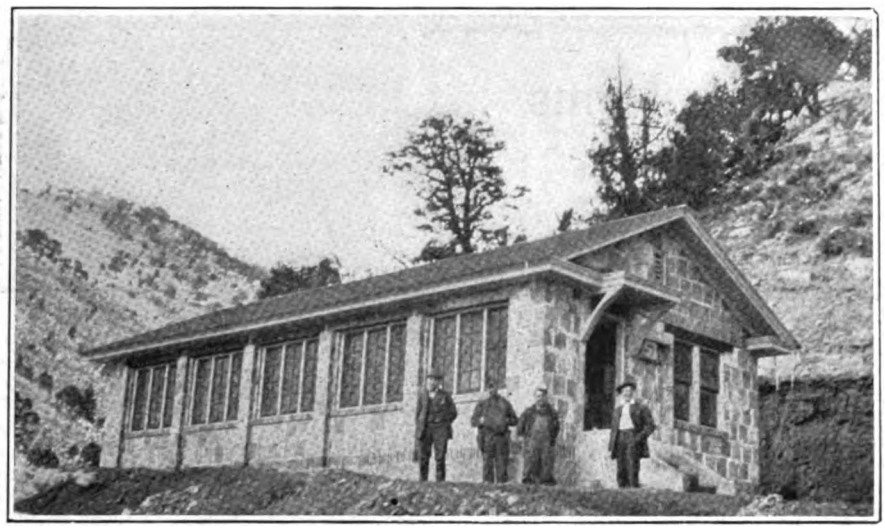
The contract for furnishing 25,000 tons of high-volatile slack coal to the Buffalo schools during the coming school year has been awarded to the firm of E. L. Hedstrom on its bid of $4.34 delivered. The contract for furnishing 20,000 tons of low-volatile mine-run (Diamond smokeless) coal to the schools was awarded to the Weaver Coal Co. on its bid of $5.59 delivered.

OHIO

The Pennsylvania R.R. has entered into a contract for the delivery of ten carloads of smokeless coal a day at Cincinnati, which marks the end of a contest of years' standing with Gordon Rowe, head of the city Smoke Department. Having contended for a half dozen years that the railroads are the largest contributors to the "smoke nuisance" of Cincinnati, Mr. Rowe has urged not alone the installation of smoke-consuming devices but the use of low-volatile coal for engines and roundhouses. According to R. C. Barnard, superintendent of the local division of the Pennsylvania terminal, locomotives, roundhouses and all equipment will use smokeless coal.

OKLAHOMA

Petition for a receivership of the Eastern Coal & Mining Co., owner of the Degnan-McConnell Mine at Wilburton, where more than 90 miners lost their lives in January, was asked in federal court at Okmulgee last week.



PENNSYLVANIA

May Settle Tax Mix Up.—Mayor E. B. Jermyn and City Solicitor C. B. Little, of Scranton, have negotiations under way with coal companies operating in the city for the settlement of litigation resulting from an appeal by the companies from an increased assessment on coal lands. In 1924 the assessors boosted the valuation on coal lands from $320 to $800 per foot acre. The companies appealed and have since been paying taxes on a basis of a $200 assessment, so that the city, whose 1925 and 1926 budgets were based on a $320 figure, has about $220,000 due from the companies on this valuation.

Annual Hard-Coal Output Low.—Output of anthracite in Pennsylvania last year was 61,351,543 net tons as compared with 87,277,440 in 1924. The effect of the strike was to reduce production by at least 25,925,897 tons, according to figures just made public by the State Department of Mines. The figures show that the production for 1925 was in excess of normal for the first eight months of the year. The strike, commencing Sept. 1, 1925, was still in existence at the end of the year, and its effects will be reflected in the figures for this year, as it did not end until Feb. 18.

The Youghiogheny & Ohio Coal Co., it is reported, plans to establish a mine on the 1917 scale in the Pittsburgh district within a short time, probably the first week in May. The mine said

Digitized by Google

Check Cabin of Standard Coal Co., Standardville, Utah

All the buildings at Standardville are well built. This one, though back in the hills, is not an exception. The country is by no means arid. Note the two trees behind the building.

to have been selected is the mine at Wyano, which heretofore has been working on the union scale. The same company has operations in the Pittsburgh district which are working on the Jacksonville scale.

While plans are not yet announced, it is believed that the next mine to be opened by the Pittsburgh Coal Co. will be a river mine. The company has a number of river mines, located principally on the Monongahela River, but of the 11 mines now in operation on the 1917 scale none is shipping by river. The company, it is believed, would find a steady market for its river coal if operations were resumed, but the chief difficulty to date is said to have been that the river mines have not been in auspicious labor territory.

The Union Trust Co. of Pittsburgh and S. A. Taylor, of Bolivar, have been appointed receivers of the Ridgeview Coal Co., of Bolivar, near Blairsville. John M. Raybourn, of Pittsburgh, and W. B. Hammond, of Bolivar, were appointed appraisers of the concern.

Madeira, Hill & Co. recently closed down its breaker at Marion Heights. Hereafter the coal formerly prepared at this plant will be sent through the Greenough breaker which is of concrete and steel construction. Not many years ago the Marion Heights breaker was considered one of the most modern in the lower anthracite field but now it doesn't compare with breakers in which the latest machinery has been installed. The Greenough breaker has a capacity of 3,000 tons of coal each day. The breaker was put to several hard tests several weeks before the old breaker was abandoned.

Will Rebuild Alaska Breaker.—The Philadelphia & Reading Coal & Iron Co. has decided to rebuild the Alaska breaker at Mount Carmel, recently destroyed by fire at a loss of $350,000. The new structure will be of steel construction and modern in all respects. The origin of the fire has not been determined, but the general opinion is that sparks from a passing engine ignited the structure. The Alaska breaker was equipped with sprinklers, but the flames gained such headway that employees could not reach the main valve which regulated the sprinklers. Several hundred men and boys have been thrown into temporary idleness as a result of the breaker's being destroyed.

In order to replace worked-out areas officials of the Lehigh Valley Coal Co., at Centralia, are contemplating sinking the Continental shaft another lift, or 125 ft. deeper than the present level. The work probably will be started within a few weeks. According to H. J. Heffner, superintendent of the coal company, the coal will be taken from this new level and sent underground to the Centralia breaker for preparation. The present shaft at the Continental is 275 ft. deep.

VIRGINIA

Virginia Iron, Coal & Coke Co. reports for the quarter ended March 31, 1926, net loss of $10,017 after interest, etc. This compares with net income of $9,752, or 39c. a share on $2,500,000 preferred stock, in preceding quarter, and $217,306, or $1.75 a share, on common after allowing for preferred dividends in the first quarter of 1925.

WEST VIRGINIA

The Morgantown Coal Co., with general offices at Beckley and operating a mine at Morganette, Fayette County, has filed a voluntary bankruptcy petition at the office of the clerk of the U. S. District Court in Charleston. The inventory gives the company's indebtedness at $94,862.09 and its assets as $57,688.03, of which $15,000 represents real estate, $25,000 its leasehold and improvements and $10,000 the value of the machinery and tools.

Organization Drive Deferred. — Although it had generally been expected that the United Mine Workers would soon launch another effort to organize the non-union workers in northern West Virginia, Van A. Bittner, chief international representative, states that "It is impossible to say at this time when such a call will be issued. We were expecting it early in May, but circumstances may delay it and the present economic situation can hardly be considered a propitious time to issue a strike call. With practically all the union and non-union mines closed down, a strike call would not be productive of any substantial results. Frankly, we would want such a strike to have a certain effect. What could be expect from a strike now, with coal production almost at a standstill without a strike?"

A motion has been heard in the Circuit Court of Fayette County by Judge Early to discharge the receivers for the Tioga Coal Co., of Tioga, Nicholas County. The receivers are R. L. Porter, of Charleston, and a Mr. South, of Philadelphia. They were represented in court by Joseph Kenna and J. Raymond Gordon, of Charleston. T. W. Ayers, of Richwood, represents the creditors.

Formation of a safety club under the supervision of the West Virginia Department of Mines was started recently at the Booth mine of the River Seam Coal Co., at Almina. Three hundred and twenty-five miners were present. Thomas Jarrett, William B. Riggleman and Lazear McGee, of the mine safety department made addresses at the organization meeting.

"Eviction notices issued by the Cleveland-Morgantown Coal Co. at Pursglove, Monongalia County, are without effect, we believe, as this company has a signed agreement with the United Mine Workers, and every legal defense known will be made to protect the rights of the miners and their families," declared Van A. Bittner, head of the union forces in West Virginia, last week.

E. M. Posey, of Charleston, has been awarded the contract to erect a conveyor line 1,200 ft. long for the Webb Coal Mining Co. at Garrison, Boone County.

Stockholders of the Crab Orchard Coal & Land Co. met on April 16, in Charleston, and elected these directors: Isaac Prince, Beckley; W. O. Abeny and E. G. Smith, of Charleston; S. Dixon, Price Hill, and Richard Ellison, Cincinnati. These officers were chosen: President, Isaac Prince; secretary and treasurer, J. M. Clark. The company owns 8,000 acres of coal land in Raleigh County. The Stonega Coke & Coal Co. mines coal on the holding company's acreage.

Stockholders of the Cabin Creek Consolidated Coal Co. re-elected the following directors at the recent annual meeting: James McKay, Malcolm Jackson, B. B. Brown, E. W. Knight, G. H. Caperton, W. A. Ohley, Josiah Keeley, Azel Ford, Ockawaha, Fla., and C. R. Moriarity. Officers were re-elected as follows: President, Josiah Keeley; first vice-president, C. R. Moriarity; second vice-president, Azel Ford; third vice-president, W. A. Ohley; secretary and treasurer, E. B. Needham.

Coal loading along the Norfolk & Western Ry. in March aggregated 3,428,305 tons. Production in the various districts was as follows: Pocahontas, 31,019 cars; Tug River, 12,453 cars;

Digitized by Google

Thacker, 13,513 cars; Clinch Valley, 3,664 cars; Kenova, 4,922 cars. Privately owned cars loaded totaled 1,496. Coal produced by the largest concerns in that month was as follows: Pocahontas Fuel Co., 6,661 cars; United States Coal & Coke Co., 8,109 cars; Fordson Coal Co., 2,844 cars; Consolidation Coal Co., 2,541 cars.

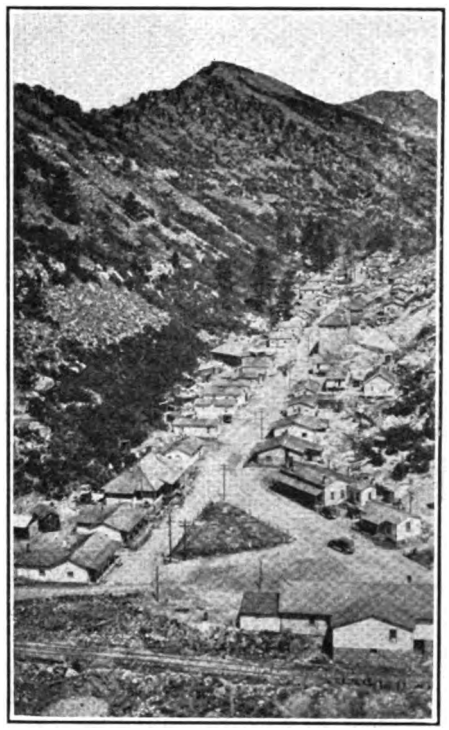
A certificate was filed recently in the office of the secretary of state in Charleston showing that C. M. Moderwell & Co., coal wholesalers, with offices in the First National Bank Building, Huntington, had surrendered its authority to transact business in the state.

The Vester Coal Co., of Morgantown, has been dissolved by a deed of sale, according to papers filed in the office of the Secretary of State on April 13. W. R. Burr has acquired the property, which is located in Monongalia County, according to the deed.

John L. Lewis, president; Philip Murray, vice-president and Thomas Kennedy, secretary-treasurer of the United Mine Workers, filed a petition in the Kanawha Circuit Court, in Charleston, on April 15, asking for authority to sell the oil and gas in certain property at River Side, in the Cabin Creek district, to Godfrey L. Cabit, Inc. Objections must be filed to the sale or persons appear May 22.

The Birch Fork Coal Co., Charleston, has called in the remaining bonds of $29,000 for payment. The company will retire these bonds, it is said by T. E. B. Siler, the president.

The Webb Coal Co., operating at Garrison, in Boone county, has awarded a contract for the installation of a conveyor line, which is to be completed within two months. The Webb company operates in the Winifrede seam on the line of Chesapeake & Ohio Ry.



CANADA

Output of coal in Canada in January was 1,223,648 tons, compared with 1,560,975 tons for December. Coal exports from Canada in January totaled 65,047 tons, against 116,585 in December and the preceding five-year average for January of 138,720 tons. Anthracite imports into Canada for January were 65,848 tons from Great Britain and 9,582 from the United States. Bituminous imports were 891,934 tons from the United States and 1,111 from Great Britain. December imports of bituminous were 1,284,918 tons from the United States, and 2,908 tons from Great Britain.

During March the production of by-product and gas-house coke in Canada was 152,480 tons, a decrease of 8 per cent from the February total but an increase of 13,697 tons, or 10 per cent, over the output for March of last year. Imports of coke into Canada showed an increase in March over February, the figures being 102,485 tons compared with 73,796 tons. The exports were 5,332 tons against 4,449 tons for March.

The Cape Breton strike in 1925 greatly curtailed coal purchases by the Canadian National Rys. in Nova Scotia. In answer to a question by I. D. Macdougall (Conservative, Inverness), Charles Dunning, Minister of Railways, stated that the quantity of coal purchased in Nova Scotia last year was 718,826 tons. In 1924 the purchases in Nova Scotia totaled 1,251,539 tons, and in 1923, 1,573,456 tons. The roads purchases of coal mined in the United States last year totaled 2,917,706 tons, compared with the previous year's total of 3,012,401 tons and of 5,292,556 tons in 1923. Purchases of coal produced in western Canada during 1925 totaled 1,146,667 tons against 818,358 tons in 1924, and 1,622,266 tons in 1923.

Every coal mine in Cape Breton is ready to open full blast, day and night, as soon as ice conditions in Cabot Strait and the Gulf make shipping up the river possible, it was learned at Dominion Coal Co. headquarters, Glace Bay. All the mines are now working, but not steadily, the general average being approximately half time.

Rains, Carbon County, Utah

A cheerful village in a pleasing country. Here the Castle Gate seam is mined, which shows at this point a thickness of 9 ft. Note the village triangle with its grass plot.

Traffic News

Widens Differentials Favoring Birmingham District Mines

Readjustment of the relationship in the rates on coal from southern Illinois, western Kentucky and the Birmingham district of Alabama to destinations in Tennessee, Alabama, Mississippi, Louisiana, Arkansas and Texas has been ordered by the Interstate Commerce Commission in *Alabama Mining Institute vs. Illinois Central R.R. Co., et al.* The general effect of the decision will be to widen the differentials paid by southern Illinois and western Kentucky, although in some cases there will be a reduction.

The basis adopted by the Commission in prescribing the differential adjustment over the Birmingham base rate is an increase of 5c. per net ton for every 25 miles or major fraction thereof in which the average distance from Illinois Central mines in the southern Illinois-western Kentucky districts exceeds the average distance from Frisco group 2 and Southern Ry. groups 4, 11 and 12 in Alabama. From this adjustment, however, the Commission excepts destinations such as Memphis, Tenn., where no line serves the destination at the base rate from the Alabama field, on the one hand, and the western Kentucky and Illinois fields, on the other.

Ten years ago, in *Galloway Coal Co. vs. Alabama Great Southern R.R. Co.*, 40 I. C. C. 311, the Commission approved a differential approximating 30c. per ton to certain points east of the Mississippi River. In this case Alabama sought differentials ranging from 25c.@$1. How these compare with the adjustment authorized by this decision is shown in the following table. To the points covered by this table, complainant had asked a differential of 75c.

To Mississippi	From Ill.-Ky. Distance, Miles	From Ill.-Ky. Rate per Ton, Cts.	From Alabama Distance, Miles	From Alabama Rate per Ton, Cts.	Present Differential in Favor of Alabama, Cts.	Differential Prescribed, Cts.

Alabama						
Mobile	610	255	324	180	75	55
Louisiana						
New Orleans	642	255	416	230	25	45
Baton Rouge	622	267	415	242	25	40
Hammond	589	310	379	270	40	40
Bogalusa	572	310	362	305	5	40

The complainant also attacked the divisions allowed certain short-line delivering carriers in the lower Mississippi River valley by the Illinois Central on Illinois and Kentucky coal on the theory that these divisions were so "liberal" that they unjustly discriminated against the Alabama operators when seeking railroad-fuel contracts from such short-lines. The Illinois Central justified these divisions on the return haul of higher grade traffic it received from those connections. Attention also was called to the fact that Alabama in 1924 captured the fuel business of one of the short lines. The Commission refused to sustain complainant's charge of undue prejudice and discrimination with respect to these divisions.

The question of the cost of the transportation of coal from the Maritime Provinces and Alberta to points in Ontario has been taken up by the Canadian Board of Railway Commissioners, which under orders from the Dominion Government began a comprehensive investigation into the matter on April 16. The hearings are being held in public and experts from the provinces concerned and from the railways will testify.

Among the Coal Men

E. L. Michie, who for the last year has been manager of operations of the Elkins division of the West Virginia Coal & Coke Co., has resigned to enter business for himself. Mr. Michie had been in charge of the Elkins division of the West Virginia Coal & Coke Co. since the company's reorganization about a year ago. Previous to that time he was in charge of mines owned by the Hutchinsons in the Kanawha field.

L. T. Putnam, for several years assistant to General Superintendent George Campbell, of the Old Ben Coal Corp., Chicago, Ill., has been transferred to the Eastern field and will look after the operation of Old Ben properties in the non-union field.

Frank D. Rash, former president of the St. Bernard Mining Co., later vice-president of the West Kentucky Coal Co., now president of the Kentucky Mine Owners Association and Inland Waterways Co., Louisville, Ky., was elected president of the Technology Club of Kentucky at the annual meeting, on March 26, of Massachusetts Tech graduates living in Kentucky and southern Indiana.

Stephen Arkwright, general manager of the Paisley coal operations in Monongalia County, West Virginia, has moved his residence from Fairmont to Morgantown, where he expects to make his permanent home.

Fred Raines, for a score or more years in charge of the Cincinnati office and Western distribution for Castner, Curran & Bullitt, resigned, effective April 1, and has taken charge of the Old Ben Coal Corporation's new offices in the Dixie Terminal Building, Cincinnati. This was to be expected with the acquisition of the Ed White and Glen Rogers properties by the company, but another angle was injected when a large number of Castner, Curran & Bullitt employees went with their old chief to his new post.

Charles Gates has been made superintendent of the Caples mine of the Central Pocahontas Coal Co., of Welch, W. Va. This was formerly known as the Shannon Branch mine.

E. M. Robinson, for four years Norfolk manager for the Eastern Coal & Export Co., has accepted a position as Richmond manager for the Sugar Creek Coal Sales Co., effective immediately. He will succeed W. B. Wooldridge, who has been the company's Richmond manager for a number of years and is now being transferred to New York. Mr. Robinson's successor has not been appointed, but W. R. Evans, from the Richmond office of the Eastern Coal & Export Co., has taken charge of the Norfolk office temporarily.

Georgie J. Mechau, widely-known in the Buffalo trade, has left his position with the Acme Coal Mining Co. to accept the management of the Toronto office of the F. P. Weaver Co., of Canada, with headquarters in Montreal.

Capt. T. V. Peake

Captain T. V. Peake, manager of the Cannock & Rugeley Colliery Co., Ltd., Staffordshire, England, who is making an observation tour of American coal fields. Accompanied by Norman Forrest, agent of the Holly Bank Coal Co., Ltd., in the same British field, he recently inspected a number of mines in southern West Virginia, followed by a trip to the Pittsburgh district.

Fred Carr has been made sales manager of the Lion Coal Co., of Ogden, Utah, succeeding James T. Hill, who resigned recently. The Lion company may consolidate with the Superior Rock Springs Coal Co., the Premier Coal Co. and another company, unnamed, according to Mariner A. Browning, president of the Lion company.

C. H. Mead has been elected secretary of the Winding Gulf Operators Association, succeeding George Wolfe, who resigned shortly after the first of the year. Mr. Mead has had wide experience in the coal business, being interested extensively in coal operations in the Winding Gulf field. He located in Raleigh, W. Va., about ten years ago and has been largely instrumental in the formation of a number of large companies. He is now the president and general manager of the C. H. Mead Coal Co., operating mines at East Gulf, the general offices of the company being in Beckley.

W. D. Givens, of Charleston, W. Va., local manager of the Atlas Powder Co., addressed the Fayette County Mining Institute at Mount Hope, W. Va., on April 1 on the match-head detonator. By displaying a "harmless" model he explained the piece of mechanism in detail.

Frank W. Newhall, of Uniontown, Pa., chief engineer of the Republic Iron & Steel Co.'s coal mines in Pennsylvania, has been re-elected president of the Uniontown Tennis Club, an office which he has filled for several years.

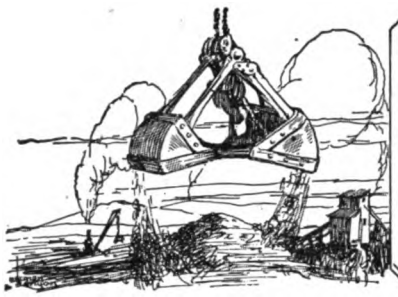
Obituary

John Kimberly Mumford, well known as a war correspondent and special writer for newspapers and magazines, died April 17 at Singapore, British East India, aged 62. At various times he had been connected with the New York *World*, *American* and *Herald Tribune*, *Harper's Weekly* and the *Red Cross Magazine*. He also was the author of books on industrial subjects, among them "Wire," "Bakelite" and "Anthracite." At the time of his death he was collecting material for a book on rubber.

James S. McAnulty, of Scranton, Pa., died April 15 from heart trouble. He was one of the organizers of the Connell Anthracite Mining Co., and served as secretary and treasurer from 1903 to 1923, when he was made president upon the death of W. L. Connell. He also was president of the East Point Coal Co., of White Haven, Pa., and the Scranton Life Insurance Co. He is survived by one daughter.

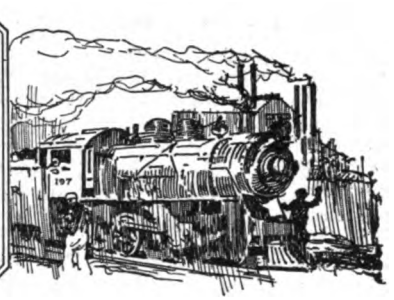
Frank P. Christian, of Scranton, Pa., former president of the Peoples Coal Co., died at Geneseo, near Clifton Springs, N. Y., on April 13. He is survived by his wife, one daughter and a son.

William G. Payne, prominent coal operator, died April 13 at his home in Kingston, Pa., following an attack of appendicitis. He was 82 years old. Born in Minersville, Pa., Mr. Payne moved to Wilkes-Barre early in life and became associated with his uncle in the coal business. At the time of his death he was president of the East Boston Coal Co., Consumers' Coal Co., Dolph Coal Co., and Pierce Coal Co.



Samuel Irwin Sawyer, owner and operator of the mine bearing his name at Punxsutawney, Pa., was killed by a Pennsylvania R.R. train a few days ago. He was standing on the station and as the train started up seemed to become dizzy and fell under the wheels. He was about 58 years old and is survived by a widow and two children.

W. W. Brunson, formerly a steam-shovel coal operator in the Pittsburg (Kan.) district, an associate of Joseph F. Klaner, with whom he went to Pittsburg from Colorado, died April 6 in Idaho Springs, Colo., after a long illness. He was 47 years old. While in the Pittsburg district he was associated with the Ellsworth, Klaner Coal Co., B.R.&H. Coal Co., Liberty Coal Co. and North Cherokee Coal Co. He returned to Colorado three years ago on account of his health.



William Schanzenbacher, manager of one of the Louisville (Ky.) yards of the St. Bernard Mining Co., who was shot by two young bandits, in an attempted robbery, on April 3, as he was entering his home with company money taken home for safe keeping, died on April 9, as a result of the injury, having been shot through the stomach.

Col. Morgan Jones, 86 years old, operator of coal mines and reputed to be one of the wealthiest men in Texas, died at Abilene, April 11 after several months of ill-health.

Production And the Market

Soft Coal Market Has But Few Bright Spots; Anthracite Moving Slowly

Unevenness continues to characterize developments in the bituminous-coal trade, with depressing influences overshadowing those of an encouraging nature. Backwardness of spring temperatures in the Middle West has served to provide a number of small orders for domestic sizes for current needs, but little stocking for winter requirements is being done. Dejection has overspread the mining districts of Illinois and Indiana because of the numerous shutdowns and the knowledge that western Kentucky will take over much of the business.

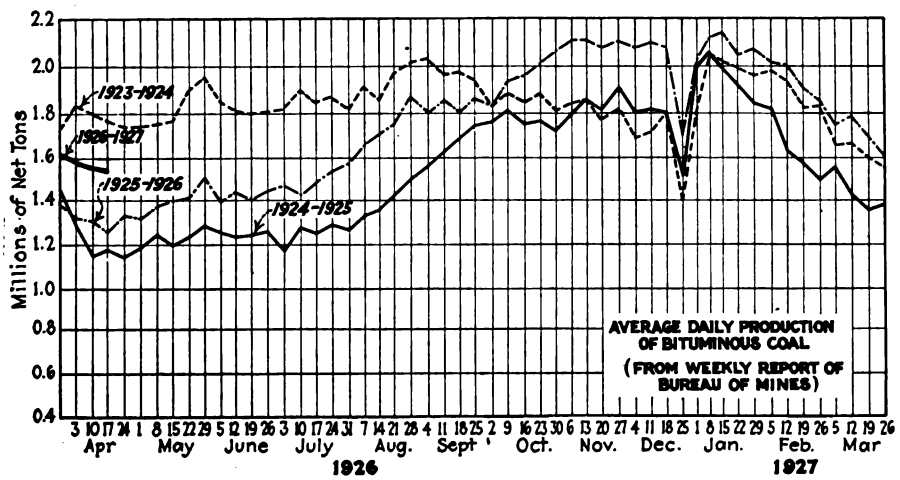
Inability of the lake season to get under way as well as warm weather has caused an easing up in the movement of Kentucky coal, so that dependence must be placed in day-to-day business. As a result operation in western Kentucky is only about one-third of capacity and in eastern Kentucky even less, but comparison with previous years is encouraging. Movement at the Head of the Lakes also is ahead of last year. Typical spring quiet marks the trade in the West and Southwest

Lake Movement Under Permit Control

A firmer tendency pervades the Cincinnati market due to dealer inquiry and signs of interest in the West and Northwest. While the embargoes on lake coal to Toledo and Sandusky have not been lifted, the permit system being used to control such traffic, these infuences have had a steadying effect. The central and eastern Ohio situation, however, is dull and featureless. The trade in western and central Pennsylvania continues to sink into the depths, and in Buffalo, too, no ray of hope pierces the gloom.

Quiet industrial conditions in New England hold out little encouragement against the keen competition for what little business is in sight. Spot trade at New York has improved slightly; distress tonnage has been cut down considerably but prices are still low. At Philadelphia and Baltimore the recent dullness is unrelieved, though export possibilities are seen in the event of a British strike.

Contracting is slow, the railroads in most instances piecing out remaining stocks with open-market purchases at low prices. Most of the large industrial consumers also are following this practice.



A slight further advance in prices has taken place since last week, *Coal Age* Index on April 26 standing at 159 and the corresponding price at $1.93, compared with 158 and $1.92, respectively, on April 19.

Output of bituminous coal during the week ended April 17 is estimated by the Bureau of Mines at 9,295,000 net tons, a decline of 125,000 tons from the preceding week.

Anthracite Demand Lacks Life

Hard-coal demand at both New York and Philadelphia is quiet. Warnings and recommendations that consumers lay in winter supplies early lack the pulling power of spring discount inducements in past years. Company producers are getting most of the business, independents being unable to obtain more than 25c. above company circulars, and not much of their product is moving at that. Pea is an exception, however, this size in some instances bringing as much as $1.25 over company quotation. At Baltimore, on the other hand, domestic consumption has been heavy and many fill-up orders have been forthcoming. Trade in steam sizes is dull. Company output is not moving easily at circular prices and the independents are glad to get business at prices well below bottom company quotations.

The Connellsville coke market shows few signs of life and output continues to decline.

Estimates of Production

(Net Tons)

BITUMINOUS

	1925	1926
April 3	7,547,000	9,040,000
April 10 (a)	7,843,000	9,420,000
April 17 (b)	7,515,000	9,295,000
Daily average	1,253,000	1,549,000
Cal. yr. to date (c)	146,359,000	169,003,000
Daily av. to date	1,612,000	1,860,000

ANTHRACITE

April 3	1,438,000	1,549,000
April 10	1,672,000	1,793,000
April 17	1,522,000	2,086,000
Cal. yr. to date (c)	25,581,000	15,389,000

BEEHIVE COKE

April 10 (a)	212,000	228,000
April 17 (b)	201,000	233,000
Cal. yr. to date (c)	3,749,000	4,518,000

(a) Revised since last report. (b) Subject to revision. (c) Adjusted to equalise number of days in the two years.

Hand-to-Mouth Policy Rules

A hand-to-mouth policy still controls railroad buying in the Middle West. Although bids have been in for some time, most carriers are meeting current requirements with open-market orders at low prices. A number of industrial contracts for 5,000 to 50,000-ton lots of screenings have been placed, but the largest consumers are following the lead of the railroads. On the whole, the spot market in steam coals is good.

Continued cold weather has served to maintain a steady flow of small orders for domestic sizes. Little is being done, however, in the way of stocking for the winter. The price situation for the coming months is an uncertain quantity. In the mining regions of Illinois and Indiana the wholesale closing down of operations and the knowledge that much of the business will go to western Kentucky this season have created an air of gloom. All producing districts have coal on track at the mines.

Shippers of high-volatile coal from the East still comb the Chicago market for business. Prices on prepared sizes range from $1.85 up to $2.75, with an occasional order at $3. The smokeless interests are keeping consignment coal away from this territory. Competition between anthracite and coke at Chicago has been further intensified by reductions of 50c.@$1.75 in oven prices on domestic sizes. Aside from a weather demand, which helps the small-lot movement of the medium and cheaper grades, the local St. Louis market is devoid of notable change.

Spring Takes Toll of Kentucky

The advent of real spring temperatures has slowed up the movement of Kentucky coal. Lake business has not yet got under way, so that the state must depend upon day-to-day current demand for orders. Western Kentucky is running about 33⅓ per cent of capacity, but the eastern part of the field is not equaling that percentage. Nevertheless, compared with previous years the present seasonal volume is encouraging.

Prices show little change. Some shippers in the Jellico and Straight Creek districts are asking $2.50 for choice block, but the general range is $1.75@$2.25. Eastern Kentucky lump, egg and nut are $1.75@$2; mine-run, $1.35@$1.60, and slack, $1@$1.10. Western Kentucky 6-in. block is $1.65@$1.85; lump and egg, $1.40@$1.65; nut, $1.35@$1.60; mine-run, $1@$1.50, and screenings, $1@$1.10.

Despite a falling off in shipments from the docks at the Head of the Lakes during the past fortnight, the movement is well ahead of last year—possibly by as much as 2,000 cars. List prices on the better grades of coal are well maintained but concessions are frequent on slower-moving stock. Prepared sizes of smokeless, which threatened to be a drug, are fairly well cleaned up, and reserves of mine-run and screenings are not burdensome.

Current Quotations—Spot Prices, Bituminous Coal—Net Tons, F.O.B. Mines

Screenings of all grades, in fact, have been in active demand.

Future of Anthracite in Doubt

The future of hard-coal in the Northwest is much in doubt. Many householders, forced to use other fuels last winter, balk at paying the prices asked for anthracite. Moreover, the number of consumers who will use anthracite but who normally laid in supplies early has greatly diminished. Further expansion in the sale of coke for domestic purposes is expected.

No new features developed in the situation at Milwaukee during the last week. Industrial demand is fairly satisfactory, but the call for domestic fuel is fading. Prices are unchanged. Coal movement continues to slow down in the Twin Cities, the weather having turned warm. Contract business is backward and inquiries have been mostly only preliminary. Retail demand is weak, regardless of the inducement of a discount on hard coal.

The trade in Kansas has reverted to its normal spring somnolence after six weeks of activity. Operators report an accumulation of close to 150 cars of coal on Kansas tracks, but as many mines are idle and some working only two or three days a week, this is not causing much concern. Crushers are again in use to help fill the demand for screenings. As stocks in consumers' bins and retail yards are unusually low, the operators are hopeful that summer storage demand will be brisk.

Colorado Market Steady

The third week in April witnessed no material change in the Colorado market. The smaller domestic sizes are scarce, but there is a surplus of lump. Mines are averaging 65 per cent running time, but the surplus labor has migrated to other fields. There has been little demand for coal for storage in spite of the substantial reductions made on fuel for that purpose. Lump, grate and nut from the Kemmerer and Rock Springs districts of Wyoming are selling at $3.50. Quotations on Wyoming steam coals are erratic.

Utah mines are not averaging over two days a week. "No bills" block the mine tracks. Little or no tonnage is moving to the domestic trade. The absence of demand for prepared sizes is keeping up the market in screenings. The principal industrial buyers at the present time are the metal interests, railroads, packing plants and brick producers.

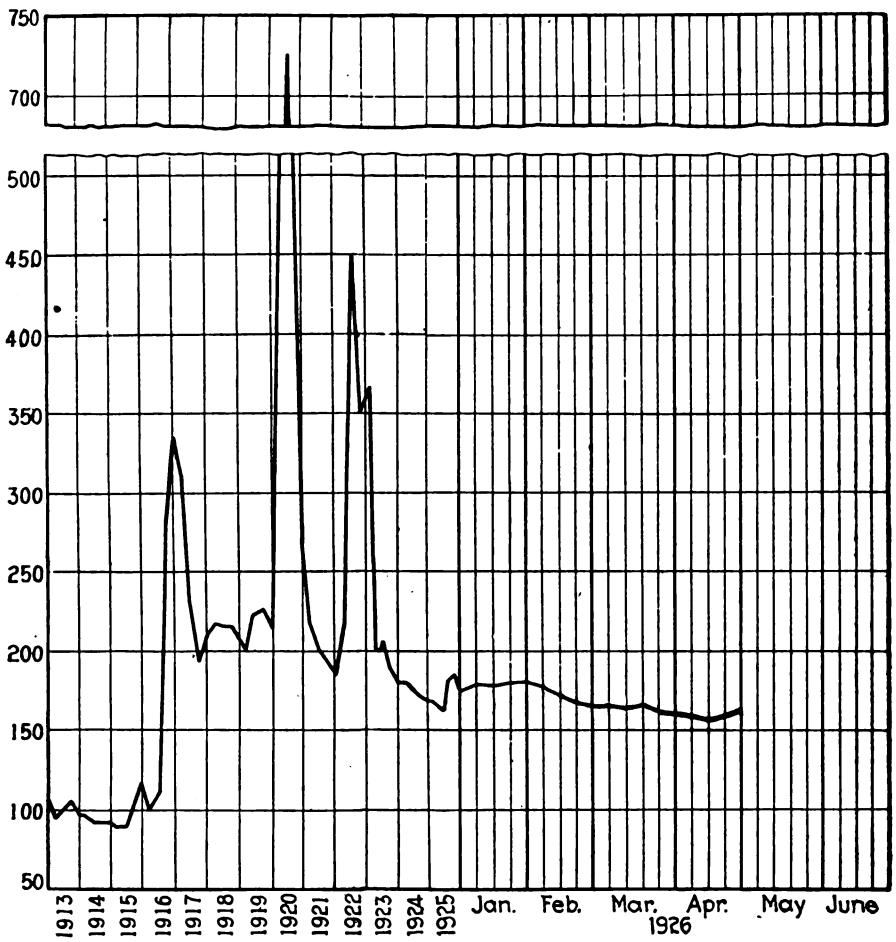
Tone Improves at Cincinnati

At Cincinnati a better tone is in evidence as a result of dealer inquiry, high-volatile slack buying by utilities and industries and a display of interest from the West and Northwest. Embargoes against Toledo and Sandusky are still in force and the permit system is in use to move lake coal, but these have proved steadying influences.

Low-volatile lump has been hard to get at $2.75, some asking $3, which it is believed will be the May circular price. Egg is now $2.50@$2.75; nut, $2 @$2.25. Mine-run is unchanged, but screenings are firm at $1.50, only off-grades being obtainable at $1.25. High-volatile lump from West Virginia is weak, but Hazard, Harlan and Elkhorn offerings are firm at $2. Egg is hard to move. Mine-run and screenings have tightened up about 10c. a ton.

Retail business during the last fortnight has exceeded expectations. May prices will show no change from those now prevailing. River conditions are excellent and the movement is normal.

With lake traffic held back by embargoes at the lower ports and ice in the passages to the upper ports, the coal trade in central Ohio continues dull and featureless. Blocking the lake movement means sharper competition in the Ohio local markets from non-union coal. Steam consumers still play the open market. Domestic trade is quiet and retailers show no inclination to buy ahead for the winter months. As a result, domestic prices are somewhat easier.



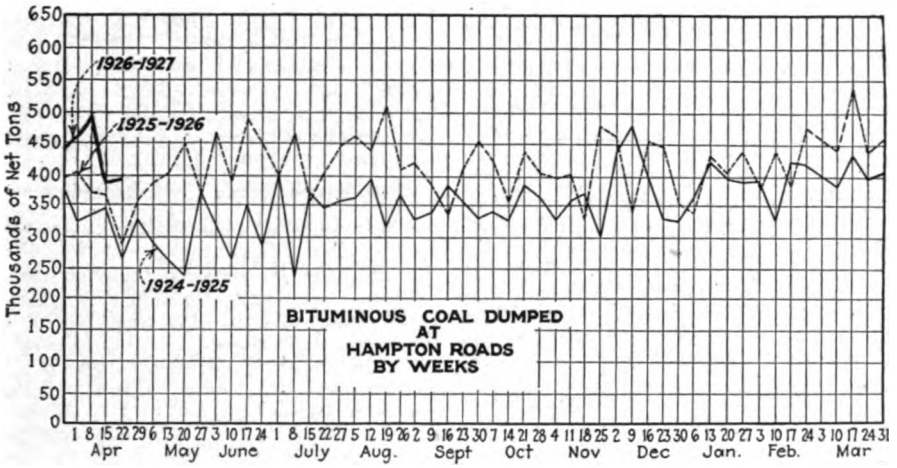
Eastern Ohio Lags in Depths

The tendency to weakness in eastern Ohio is more marked, though spot prices are practically unchanged. It is a long time since both steam and domestic activity was at so low an ebb, "no bills" being more numerous than at any time for a year. Even distress coal which finds its way to market is hard to move at figures under the market. During the week ended April 17 the eastern Ohio No. 8 district produced 212,000 tons, or about 30 per cent of capacity, an increase of 13,000 tons over the preceding week and 19,000 tons over the corresponding week of 1925.

Pittsburgh Trade Still Drooping

Three-quarters coal in the Pittsburgh district has yielded further to the selling pressure induced by moribund demand. Last week gas lump was down to $2.25@$2.40 and three-quarter steam dropped to $2.15@$2.25. Slack, however, holds at $1.40@$1.50 for steam grades and 10c. higher for gas coal. The Pittsburgh Coal Co. started up another mine last week, but the general labor situation in western Pennsylvania is unchanged. In the Bessemer district open-shop operations find current coal prices a losing venture.

Central Pennsylvania production is still on the decline. Up to April 17 loadings had totaled 30,388 cars, as compared with 40,804 cars for the corresponding period in March. Most of the tonnage rolling is on spot orders. Pool 1 is quoted at $2.35@$2.50; pool 9, $2.20 @$2.35; pool 10, $1.90@$2.20; pool 11, $1.70@$1.85, and pool 18, $1.60@$1.70.



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	April 26	April 19	April 12	April 5	April 27	April 28
Index	159	158	158	160	162	171
Weighted average price..	$1.93	$1.92	$1.91	$1.93	$1.96	$2.07

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

Pessimism Enthroned at Buffalo

If there is a ray of light in the Buffalo bituminous market, factors in that trade decline to admit its existence. Slack prices are slightly stronger, but only because there is no demand for screened sizes. Nominal list prices show Fairmont lump at $1.60@$1.75; mine-run, $1.40@$1.50; slack, $1.25@$1.40; Youghiogheny gas lump, $2.15@$2.35; No. 8 and Pittsburgh steam lump, $1.65@$1.85; gas and steam slack, $1.40@$1.55, and Allegheny Valley mine-run, $1.60@$1.85.

In the domestic trade, Buffalo is absorbing a fair amount of coke at $10@$10.50, curb. There is a slight demand for low-volatile coal for house-heating purposes, but sales difficulties are increasing. Retail business at Toronto has eased up with the appearance of milder weather. Stove now leads in anthracite demand and supplies are ample to take care of all orders. Canadian industrial buyers appear interested only in immediate requirements.

Gloom Shrouds New England

In New England there is every indication of continued close competition for contracts to be closed this season. Extremely low prices have been named both wholesale and retail, and even though output in the West Virginia districts is being curtailed by reasonably good co-operation the amount of distress coal at the Virginia terminals is a constant menace to quotations.

On board vessels at Norfolk and Newport News there is ample No. 1 Navy Standard Pocahontas and New River available at not over $4.25, with 15c. less being freely quoted. In that respect the spot market is under more depression than a week ago.

Purchasers everywhere are taking note of current conditions, and there is no disposition to buy in April and May when most consumers have on hand comfortable reserves for the next 60 to 90 days.

Coals from central Pennsylvania are scarcely heard from in the open market. With lowering prices on cars at the tidewater distributing points the range of smokeless coals is spreading and the territory open to all-rail coals is an always narrowing ribbon along the Connecticut River.

The spot bituminous trade at New York registered another slight improvement last week. Considerable reduction was effected in the distress tonnage on cars and in barges, but open-market quotations remain at low levels. Whatever contracting has been done has been done very quietly. For the most part buyers feel themselves well protected—barring a British strike. Should that take place, shippers look for increased export business and some orders already have been closed for South America.

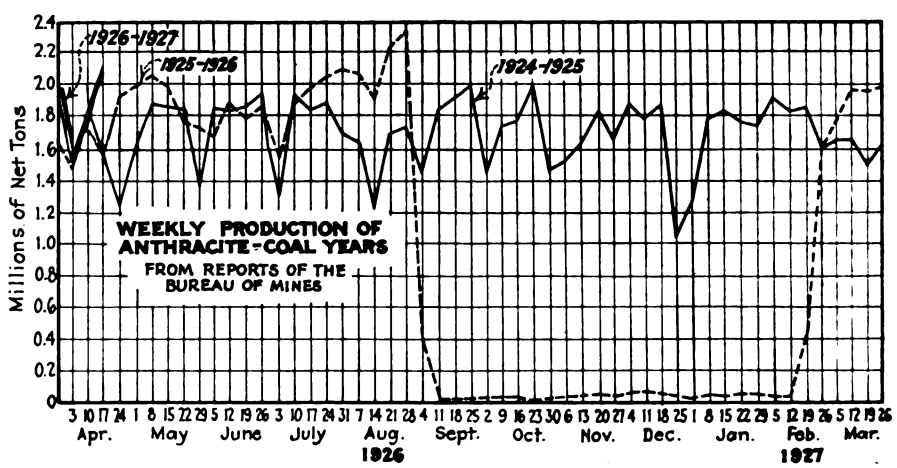
At Philadelphia the psychological depression is as deep as ever. A substantial volume of coal is moving to industrial consumers, but the prices at which the coal is sold bring no joy to the shippers. The railroad attitude toward the situation continues a sore point with the producers. As long as surplus stocks accumulated last winter last and distress tonnage can be snapped up, it is not likely that the railroads will be willing to pay higher figures.

Factors in the Baltimore trade find it more pleasant to contemplate the possibilities of a strong export demand if the British miners go out than to consider the low state of the domestic market. So far, however, there has been little in the way of export inquiry. Spot prices for American consumption are weaker and purchasing agents are stronger in their determination to avoid contracts, except upon their own terms.

Spot steam coals are moving moderately well in the Birmingham market, and with output holding close to trade needs, prices are quotably unchanged. Industrial and railroad consumption is heavy and bunker demand is unusually brisk. Few new contracts are reported, but old ones are readily renewed as they expire. Production, which is close to 400,000 tons weekly, is well ahead of a year ago. Foundry coke is in good demand at $5.50@$6.50, spot or contract; egg and nut are in such light request that some is being stored by producers.

Hard-Coal Demand Soft

Domestic demand for anthracite is easy at both New York and Philadelphia. Campaigns to induce early buying by the householder are not meeting with overwhelming success. Most of the buying favors the low-circular shippers. Independents at New York are unable to obtain over 25c. above company prices and not much coal is changing hands on that basis. Philadelphia is no more kindly disposed to paying premiums. The one size which is the exception is pea. As high as $1.25 over company circular has been obtained. On the other hand, some has been sold at circular in conjunction with orders for egg.



The steam coal market is dull. Company tonnage is not finding a ready market at circular prices and independents are frankly seeking orders at considerably less than the company minimum. The domestic trade, however, is welcoming the domestic buckwheat offered by the D. L. & W. at $3.50 and the collieries shipping that coal are behind on their orders.

Domestic business at Baltimore is on a firmer basis than farther north. April consumption has been heavy and many householders have been giving their orders for spring and summer fill-ups.

Connellsville Coke Market Sinking

The Connellsville coke market is making new records—in stagnation. Spot demand is dead and interest in new contracts moribund. Production of furnace coke, however, is so closely regulated that there is no surplus tonnage to further depress the spot range of $3@$3.15. A slight overproduction of foundry grades, on the other hand, has sent the level for that coke down to $4@$4.50—a net decline of 50c. since February. The odd lots of miscellaneous coke offered as anthracite substitutes are begging in vain for buyers at any price.

Output during the week ended April 17, according to the Connellsville

April 7, 1925	344,258	184,461	.....	.....

Courier, totaled 175,500 tons. Furnace oven production was 102,400 tons, a decrease of 3,900 tons when compared with the preceding week. Merchant oven output dropped to 73,100 tons, a decrease of 330 tons.

The district is shipping very little steam or gas coal and not a great deal of byproduct coal to the commercial market.

March Exports Increase

Exports of coal and coke from the United States during March showed increases in all divisions over February figures. Bituminous exports were 1,143,060 gross tons, as compared with 1,013,158 tons in February; anthracite exports jumped from 37,157 tons to 297,316 tons; coke shipments increased from 67,697 tons to 86,857 tons.

March exports by countries were as follows:

Argentine Imports Decline

Total imports of coal into Argentina during 1925 are reported at 2,973,852 tons, compared with 3,299,392 tons in 1924 and 2,579,466 in 1923, so reports Assistant Trade Commissioner Sherwood H. Avery, Buenos Aires. Of the 1925 imports, 2,610,045 tons, or about 89 per cent, came from Great Britain, 186,933 tons from Germany, 124,950 tons from United States; 47,922 tons from the Netherlands and the remainder from Chile and Brazil.

Daily Average Coke Output Declines in March

Byproduct coke output in March increased over that of the short month of February by 277,000 tons, or 7 per cent, although the daily rate was less, according to the Bureau of Mines. Compared with January, both monthly and daily output decreased, the coke plants operating at about 91 per cent of capacity. In March, the total production was 3,777,000 net tons and the daily, 121,825; in February, 3,500,000 and 125,006 tons, respectively, and in January, 3,804,000 and 122,718 tons. Of the 80 byproduct plants in existence, 74 were active this month.

Beehive coke production, however, continued to decline in March when the output was estimated at 1,158,000 net tons; 244,000 tons, or 17 per cent, lower than in February.

The production of all coke totaled 4,935,000 tons, byproduct plants contributing 77 per cent and beehive plants 23 per cent.

Output of Byproduct and Beehive Coke in the United States by Months*

(In Thousands of Net Tons)

	Byproduct Coke	Beehive Coke	Total
1923, monthly average	3,133	1,615	4,748
1924, monthly average	2,833	806	3,639
1925, monthly average	3,332	893	4,225
December, 1925	3,760	1,307	5,067
January, 1926	3,804	1,381	5,185
February, 1926	3,500	1,402	4,902
March, 1926	3,777	1,158	4,935

* Excludes screenings and breeze.

Coal consumed in beehive and byproduct coke plants in March amounted to 7,252,000 tons, 5,426,000 tons at byproduct plants and 1,826,000 tons at beehive plants. This is 11,000 tons more than was used in February for this purpose at all plants.

Estimated Monthly Consumption of Coal in Manufacture of Coke

(In Thousands of Net Tons)

	Consumed in Byproduct Ovens	Consumed in Beehive Ovens	Total Coal Consumed
1923, monthly average	4,523	2,507	7,030
1924, monthly average	4,060	1,272	5,332
1925, monthly average	4,787	1,371	6,158
December, 1925	5,403	2,062	7,465
January, 1926	5,466	2,178	7,644
February, 1926	5,029	2,212	7,241
March, 1926	5,426	1,826	7,252

Of the total output of byproduct coke during March, 3,120,000 tons, or 82.6 per cent, was made in plants associated with iron furnaces, and 656,000 tons, or 17.4 per cent, was made at merchant or other plants.

Uruguayan Coal Imports Gain

Following an increase of 65 per cent in Uruguay's coal imports during February as compared with the preceding month, a further expansion took place in March, reports Consul G. O. Marsh, Montevideo, in a cable to the Department of Commerce. Shipments received during the first 27 days of the month totaled 33,000 tons as compared with 20,000 for the entire month of February, an increase of about 67 per cent. Of the 33,000 tons received 7,000 came from the United States and the remainder from Great Britain.

Coal Leases in Montana and Utah to Be Sold

Sale by public auction of coal leases on three tracts of public land in Montana and Utah has been authorized at the Interior Department.

One of the tracts in Montana comprises 160 acres in Richland County. Under the terms of the lease, the successful bidder must make an initial investment of $5,000 during the first three years of the lease and must produce 5,000 tons of coal annually commencing with the fourth year of the lease. A royalty of 10c. per ton, mine-run, must be paid the government on all coal produced.

The other tract in Montana authorized to be leased includes 40 acres in Roosevelt County. An initial investment of $500 must be made on this tract and a minimum production of 410 tons of coal annually after the third year. Both of these coal leases will be offered for sale at the local land office at Great Falls, Mont., the exact date of the sale to be announced later from that office.

The third tract is situated in Sevier County, Utah, and comprises 80 acres. The successful bidder for the tract must make an initial investment of $1,000 during the first three years of the lease with a minimum production of 550 tons per year after the third year, at the same time paying the government 15c. per ton, mine-run, on all coal produced. The date of the sale covering this lease will be announced later from the local land office at Salt Lake City, where it will be held.

Coal-Loading Record Shifts To Sewalls Point

The Virginian Ry. coal pier No. 2, at Sewalls Point, Va., the new $3,000,000 electrically operated terminal, set up a new world's record for coal dumpings April 20, when it loaded 11,875 gross tons of coal on the steamer "Lemuel Burrows" in 2 hours and 55 minutes. The pier trims automatically. This achievement surpasses the performance at the Curtis Bay pier of the Baltimore & Ohio Ry., at Baltimore, on April 13, when 11,353 tons was dumped in the "Lemuel Burrows" in 3 hours and 1 minute, which did not include time for trimming. On March 7 the Sewalls Point pier dumped 11,953 tons of coal in an ocean-going vessel in 3 hours flat. Only two conveyor cars were used in each operation.

New South Wales Coal Output High in 1925

New South Wales, Australia, produced 11,396,199 gross tons of coal, valued at the pitmouth at £9,302,515, in 1925. Production in other parts of Australia approximated 2,000,000 tons. The highest output of New South Wales was in 1924, when 11,612,216 tons, valued at £9,589,547, was raised.

Sealed proposals will be opened by the Supt. of Lighthouses, Portland, Me., at 2 p.m., May 17, 1926, for furnishing anthracite chestnut, f.o.b. mines or tidewater Portland, Me. Information upon application.

Foreign Market And Export News

Rising Demand for Coal Reopens Many Welsh Pits; Buyers Increase Reserves

London, England, April 13.—The Welsh steam-coal market is in a very strong position, though business has not yet quite settled down after the Easter holidays. The better arrival of shipping has served to clear off accumulations at the collieries, and ships are now waiting for cargoes. Many of the pits that had been closed down for some months have reopened and in many cases additional men have been taken on at the collieries. Nothwithstanding these facts, the collieries are well booked for the early part of May, and very little coal is going at the ruling prices at present.

Many buyers are accumulating stocks, especially the public utilities, and many of the railroads are increasing their normal three-months' supply of coal. The pressure on the collieries resulting from the tendency of domestic and foreign buyers to stock coal will, of course, be compensated for later when the collieries must slow up on deliveries. In addition to this, some business has been lost owing to heavy contracts placed for American and German coal for delivery over the next six months.

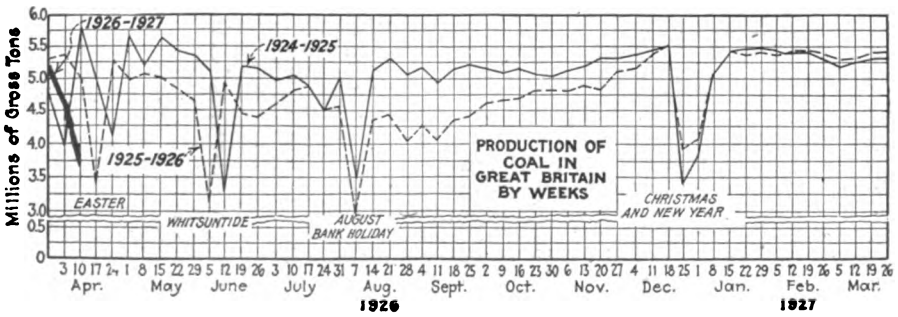
The Newcastle market reflects the Welsh improvement, though to a lesser degree. Most of the collieries have sufficient business on hand for the present, but the outlook for the future is uncertain. The best business is in gas coals, many of the European gas plants still coming to Durham for their fuel, in spite of German competition.

Output by British collieries during the week ended April 10, according to a special cable to *Coal Age*, totaled 3,696,300 gross tons, compared with 4,633,400 tons the preceding week.

Coal exports during March totaled 4,702,536 gross tons, as compared with 4,340,006 tons in February and 4,148,042 in January. The volume of exports for the first three months exceeds that of last year, but the value is nearly £2,000,000 less. The per ton value of exports during the first quarter of last year was 21s. 1d., against 18s. 3d. this year.

Belgian Market Unsettled

Easter holidays and fluctuating exchange rates have further upset the Belgian coal market, reports Brussels under date of April 15. In the domestic trade anthracite alone holds firm. Stocks of other domestic fuels are increasing and prices are wavering. In many cases official quotations have been cut 10 fr. per ton.



Industrial coals maintain their position. Semi-bituminous raw smalls are ordinarily quoted at 75 fr.; semi-washed smalls, 87 fr.; lean smalls, 66 fr.; washed duffs, 76 fr.; lean washed duffs, 55 fr.; lean raw duffs, 38 fr.; semi-bituminous peas, 105 fr.; lean peas, 95 fr.; coking smalls, 85 fr.; briquets, 112.50 fr. Except in the case of briquets, which show an advance of 7.50 fr., these prices are the same as those prevailing on March 1. Special grades of briquets are up as much as 20 fr.

Agreement finally has been reached on prices for fuel supplied to the Belgian State Rys. For the first quarter of 1926 and for April the prices on smalls with an ash content of 12 per cent have been fixed at 84@88 fr., according to classes. Briquets have been fixed at 100 fr. for the first quarter and 110 fr. for April.

Taxes Boost Quotations on French Coal Offerings

Paris, France, April 15.—The end of the Easter holidays finds the French coal market showing no material change. Industrial demand continues on a satisfactory basis. Domestic business reveals a normal seasonal inactivity. Rail transportation from the Nord and Pas-de-Calais fields is more regular and a good tonnage is moving via the canal routes.

To offset increased taxes, French producers have raised prices 0.70 fr. Imported coals are subject to the same advance. In addition, import duties recently were increased 30 per cent. On coal this is equivalent to 0.36 fr. per ton. On top of all this, the French railways have asked permission to increase their rates from 330 to 355 per cent of the prewar basis. If this is granted, rates to Paris from the Pas-de-Calais field and from the Belgian frontier will go up 2.25 fr.

During March the O. H. S. received 509,400 metric tons of coal, 298,900 tons of coke and 32,700 tons of lignite briquets from the Ruhr. Receipts of reparation coke by the O. R. C. A. for the first twelve days of April totaled 98,029 tons.

In February the French mines produced 4,088,172 metric tons of coal and lignite. The country imported 1,064,764 tons and exported 418,776 tons. Consumption for the month, excluding Saar imports and stocks as of Jan. 31, approximated 5,274,160 tons. The French mines also coked enough coal to make 277,967 tons of coke. Imports were 448,251 tons, and exports, 52,905 tons. These coke figures are exclusive of coke produced by the steel industry and merchant ovens not affiliated with the collieries. Patent fuel output by the mines totaled 330,568 tons; imports, 140,102 tons; exports, 29,231 tons.

Coming Meetings

Chamber of Commerce of the United States. United States Chamber of Commerce Bldg., Washington, D. C., May 10-13.

Chemical Equipment and Process Engineering Exposition, under the auspices of the Association of Chemical Equipment Manufacturers, Inc., at the Public Hall, Cleveland, Ohio, May 10-15. Secretary, Roberts Everett, 1328 Broadway, New York City.

Mine Inspectors' Institute of America. Annual meeting, Seventh Avenue Hotel, Pittsburgh, Pa., May 11-13. Secretary, G. B. Butterfield, Hartford, Conn.

International Railway Fuel Association. Hotel Sherman, Chicago, Ill., May 11-14. Secretary, J. B. Hutchinson, Omaha, Neb.

National Retail Coal Merchants' Association. New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, with operating conference. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. Fourteenth congress, Madrid, Spain, May 24, 1926. Secretary, E. Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

Pennsylvania Retail Coal Merchants' Association. Annual meeting, York, Pa., May 27 and 28. Secretary, W. M. Bertolet, Reading, Pa.

Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

West Virginia Coal Mining Institute. Annual meeting, June 1-2, Bluefield, W. Va. (tentative). Secretary, R. E. Sherwood, Charleston, W. Va.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

National Coal Association, June 9-11, at Drake Hotel, Chicago, Ill. Executive secretary, Harry L. Gandy, Southern Bldg., Washington, D. C.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Illinois Mining Institute. Annual summer meeting on steamer "Cape Girardeau," leaving St. Louis, Mo., June 24 and returning June 26. Secretary, Frank F. Tirre, Central National Bank Bldg., St. Louis, Mo.

New Equipment

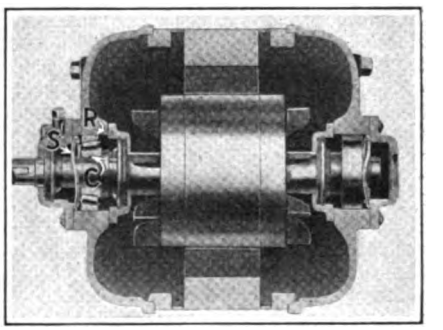
This Pipe Joint Will Tighten As Pressure Rises

A flexible joint for use in connection with steel, wrought-iron, or cast-iron pipe is being manufactured by the Victaulic Co. of America, 26 Broadway, New York, N. Y. The joint is adaptable to plain-end piping that has a small groove near the ends. The groove is about the depth of the ordinary screw thread.

The joint consists of a sectional housing clamped around the intersection of the pipe. Inside of the housing is a hollow inner ring. This ring seals the joint without pressure from the housing. The housing holds the inner ring in place, engaging in grooves in the pipe. An increase in pressure from the inside is said to add to the tightness and to the sealing qualities of the ring. An angle of 5 deg. on either side of the horizontal can be obtained by means of the joint.

It can be used on a vacuum or on a pressure up to 1,000 lb. It is claimed that lines equipped with the joints have been used over a period of five years for carrying oil, gas and water. The joints can be used on pipe lines where the temperature is not greater than 175 deg. F. Piping adapted for the joints is said to be now stocked in pipe mills.

Saws Six Times as Fast as A Man Can Saw by Hand

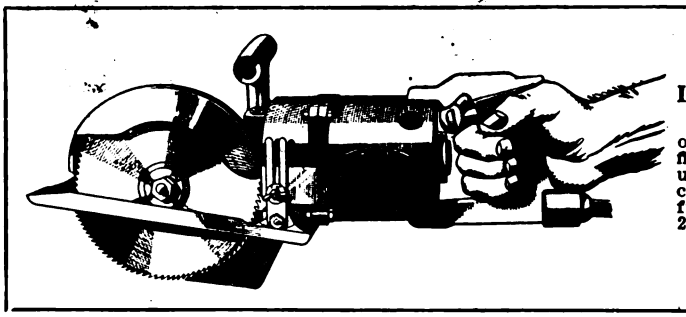


An electrically-driven, hand-guided wood-cutting device known as the Skilsaw has been developed and is now being marketed by the Michel Electric Hand Saw Co., 3814 Ravenswood Ave., Chicago, Ill. This device is a combination in one machine of an 8-in. circular saw and a ½-hp. universal motor, each the product of a well-known manufacturer. The saw may be set to cut to any depth from nothing up to 2⅜ in. The tool complete weighs 19 lb. and consequently is readily portable.

This machine is now being used in no less than forty-three different businesses. About the mines it will prove particularly useful in car building as well as in construction and repair work. It is approximately six times as rapid as fast hand cutting. Unlike a hand saw, however, it can be adjusted to cut to an exact depth. Thus for instance, it can be so set as to just cut through a floor without touching the concrete beneath or nicking the joists.

Day by day we are finding more and more ways of relieving human muscles of the work that it was once thought they alone could perform. The power hand saw is one of the latest steps in this direction. It is doubtless destined to receive wide adoption in many arts and trades. The building and repair of mine cars as well as the performance of other construction and maintenance work about the mines will be among these applications.

These Motor Bearings Keep Themselves in Center



It is said that 95 per cent of all motor troubles may be traced to the bearings. Many of them are the result of the bearings wearing to such a degree as to allow the rotor to rub on the stator. In order to insure a continuous uniform air gap in motors, the Howell Electric Motors Co., Howell, Mich., has brought out a line of motors with anti-friction bearings, in which

Cross-Section of Motor Showing Bearings

Spring ring automatically takes up wear by its pressure on the tapered bearings. Consequently the rotor does not lose center nor rub against the stator.

any looseness in the bearing, caused by wear or otherwise, is automatically adjusted so as to keep the rotor centered and thus maintain a uniform air gap. This is accomplished, as shown in the figure, by the use of a Timken tapered roller bearing, shimmed with a fluted wire spring, which acts as a compression member.

Let Power Do It

This saw, weighs only 19 lb. and is fitted with a ½-hp. universal motor. It cuts to a depth of from nothing up to 2⅜ in.

Digitized by Google

The inner race or cone *C* of the bearing is fitted on the shaft with a light press fit. The outer race *R* is fitted into the bearing housing with a sucking fit that allows creeping of the outer race. The spring *S* is held tightly against this outer race by the grease cap pushing the race against the rollers and keeping the bearings tight at all times. This type of bearing is put in each end of the motor and keeps the rotor automatically centered, and the bearing does not need to be adjusted for wear or any other looseness. The spring allows for any lateral expansion of the shaft that might occur due to heat.

These bearings are arranged for grease lubrication, and effective seals are used to keep the grease in and to keep out foreign matter, such as dust, dirt or abrasives. The motors can be mounted in any position without changing the end bells. They will operate in any vertical position as well as horizontal, as these bearings have a thrust capacity equal to their radial capacity.

General-Purpose Shovel Of Medium Size

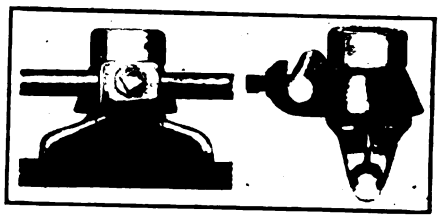
A 3-cu.yd. revolving shovel for general use has been developed by the Bucyrus Company, of South Milwaukee, Wis., recently. It is said to represent a new departure in that it is built along lines never before used in general-utility shovels. In design it follows the basic plan developed by the company in building the 120-B, a 4-cu.yd. mine-and-quarry full-revolving shovel announced last year. In principle it offers a machine that combines the advantages of a small revolving shovel with those of the railroad-type shovel, but has a working range considerably greater than either. The makers claim that it has the speed of action, big dipper capacity, ruggedness, and power of the railroad-type shovel, with the mobility, the full-revolving swing, and the maneuvering ability of the small revolving shovel. It is remarkedly close-coupled, the boom length being only 29 ft. 6 in. and the rear-end radius 16 ft. Throughout, the clearances have been held within close limits.

Shovel Combines Features of Railroad and Smaller Types

The railroad shovel is speedy, has large capacity, is rugged and powerful. The small shovel is readily manoeuvered. This equipment is of intermediate size and lays claim to the advantages of both.

Clamp Holds Both Trolley and Feeder Lines

Simplicity, safety and economy in the support of auxiliary feeder wire in the mines is afforded by the new Sure-Grip combination clamp, shown in the accompanying illustration and made by the Electric Railway Equipment Co., of Cincinnati, Ohio. This improved trolley-feeder clamp was designed in order that both trolley wire and feeder could be supported from one insulated support, thus elminating the need for feeder taps or jumpers. The advantages of combining the trolley and feeder-wire support in one device are many.



In most mines some of the haulage locomotives in use require more current than a 4/0 trolley wire will carry without an excessive drop in voltage. To overcome this difficulty it has been customary to run feeder wire along the "rib" of the main entry connecting it to the trolley at intervals by means of "jumpers." This arrangement entails the purchase of extra insulated supports, the expense of installing a separate feeder together with the necessary jumpers as well as the extra maintenance of a separate line.

The tendency always has been to use entirely too few taps between the feeder and the trolley wire, with a resulting increased voltage on the trolley line. This combination clamp eliminates all need for such taps.

Balanced Voltage Assured

In this new device the lug that supports the feeder wire is made a part of the compression ring of the well-known Sure-Grip trolley clamp. This entirely does away with all supports for the feeder as well as with the maintenance of two separate lines. In addition it insures balanced voltage in both feeder and trolley wires, as each supporting clamp gives a good electrical contact and dispenses with all tap connections. The greatest point of merit in this device, however, is the fact that the trolley wire and feeder are clamped independently of each other making it possible to draw up the "slack" in either without disturbing the other.

A break in the trolley wire does not cut off current beyond the point of rupture. If the current requirements of the mine are such that only the carrying capacity of the trolley wire is required during the first few months of operation, it is necessary only to install this wire in the combination clamp. The feeder wire may then be placed in position at any future date without in any way disturbing the original anchorages of the trolley line.

Holds Both Trolley and Feeder

Any size or shape of trolley wire and any size of feeder up to 4/0 may be installed in this clamp. Slack in either conductor can be taken up without disturbing the other.

Another advantage lies in the fact that the feeder wire is not carried directly over the trolley but either to the right or left of it as conditions may require. Thus "slack" in the feeder wire does not interfere with the operation of the trolley wheel. The set screw in the new clamp provides the means of mechanically fastening the feeder wire in position and also insures good electrical contact between it and the trolley clamp.

Still another advantage is the fact that it is possible to place the feeder wire in position in the supporting lug through its open top. This makes it unnecessary to disturb the clamping arrangement of the original trolley support and also removes the necessity of "threading" the wire through the supporting member.

The design of this clamp is such that the jaws gripping the trolley wire will accommodate all sizes of either figure-eight or grooved trolley wire from 0 to 4/0. The feeder lug will accommodate all capacities of either stranded or solid wire up to the 4/0 size. The complete clamp is only slightly higher in price than the standard type without the feeder support and the compression ring. The feeder lug may be supplied in either malleable iron or bronze.

Installation of this type of clamp will in any mine go far toward reducing the cost of coal haulage. The fact that the line loss is reduced exactly one half, insures much better performance for the haulage locomotive with a consequent saving in armature and controller repairs.

New Companies

The Liddle & Jones Coal Co. has been incorporated in Grand Junction Colo., with a capital stock of $50,000, by William Liddle, R. N. Jones and S. G. McMullin.

The Monroe Coal Co., Greenville, Ky., capital $25,000, has been chartered by Henry B. Lee, George T. Collamore and O. S. Roberts.

Over a thousand of the cars illustrated have been made for a large western Pennsylvania mine. The coal capacity is four tons (water level capacity 120 cubic feet), and the overall length 10 feet five inches.

The car is of the composite type, for use in cross-over dumps. It has cast steel bumpers, and spring draft gear. There is maximum capacity for its height.

Your transportation problem may be properly solved only by designing cars to fit your specific requirements.

Over a thousand types, for as many applications, have been designed and produced by Hockensmith. All this accumulated experience is at your call, to help make your transportation system more effective and economical.

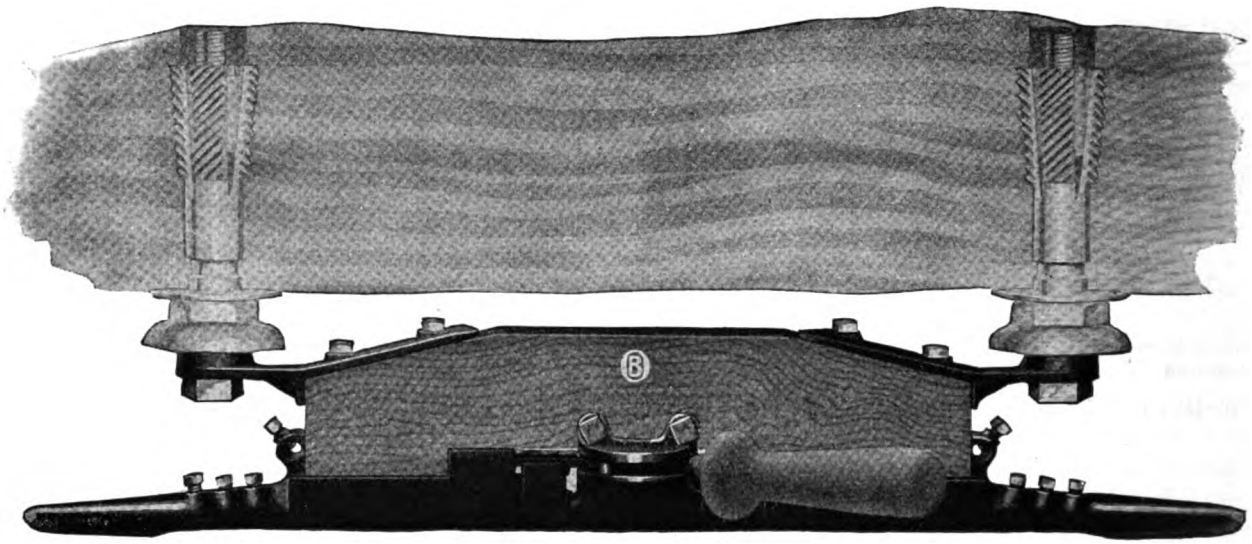
New McGraw-Hill Publication

To complete the service now rendered to the engineering-construction field by *Engineering News-Record*, the McGraw-Hill Publishing Co., Inc., has acquired the magazine *Successful Methods*, which will be published monthly to serve the men who are concerned from the practical operating point of view with construction methods and plant and with certain industrial activities that involve the same methods and equipment. Profuse pictorial treatment of general construction and material-handling plant will be a feature of the publication. The first issue of *Successful Methods* under the new management will appear in June.



Scans Field for Your Advantage

The attention of *Coal Age* readers is directed to a notice appearing on pages 36 and 37 of this issue's advertising section. *Coal Age* is one of a large family of technical and industrial publications from which inspiration and counsel are taken in preparing a paper that meets your needs. Editors are continually coming and going and so getting in touch with developments that concern the progress of our industry. As there are 125 of them with 542 special news correspondents, and as the editors travel some 700,000 miles yearly, prepare 23,000 editorial pages and keep in touch with their 220,000 subscribers, the office of the McGraw-Hill Publishing Co. is a center of advance information, hardly to be excelled anywhere. It is in touch with national and world events. It is responsive to scientific and business progress. It cannot fail to be cognizant of the latest in the immediate present and sense the tracks that lead like high roads to the future.

Vision that is worthy the name is not all inward. It is based on knowledge of the past and the present. Having such contacts with all that passes north, south, east and west, *Coal Age* and its sister publications cannot fail to have the vision that is demanded of leading publications.

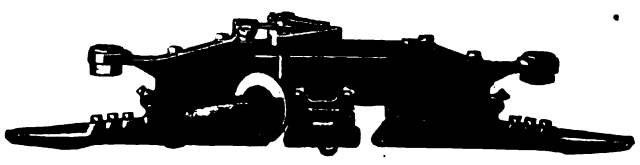
Shut down the Whole Mine —or just a Heading?

What do you do when you want to disconnect power from the trolley near the working face?

Shut down the whole mine—or just a heading or branch line?

It is such a simple matter to sectionalize the trolley circuit—so you can isolate short-circuit trouble without affecting main haulage—so you can isolate sections where repairs or extensions are under way.

Put up O-B Type M Section Insulator Switches at least at butt headings—the cost is insignificant. Time lost in otherwise interrupted production will pay for many switches.



Our engineers will gladly make suggestions for effective trolley sectionalizing.

Ohio Brass Company, Mansfield, Ohio
Dominion Insulator & Mfg. Co., Limited

PORCELAIN INSULATORS · LINE MATERIALS · RAIL BONDS · CAR EQUIPMENT · MINING MATERIALS · VALVES

M-5 With Locking Device

Here is a special insulator with attachment for locking it open. Safety for the man working on the dead side of the switch!

Speed Up Production With This O-B Headlight

YOU know how difficult it is to make good time yet "play safe" when driving your car on a dark, stormy night, with lights dimmed or out. You can more safely put on speed when the night is clear and your lamps are throwing plenty of light on the road ahead.

Underground the result of good lighting is just the same. Put on O-B Type MS Incandescent Headlight, 94 watt lamp, on your mine locomotive if you want to insure safer operation and also speed up the production. It's a good investment from the maintenance standpoint, too, because steel construction makes this lamp indestructible.

Volume 29 NEW YORK, MAY 6, 1926 Number 18

Strike in Great Britain

AT LAST THE PEOPLE of Great Britain face the general strike so long threatened and so much discussed. Sympathy with the miners will doubtless be quite general in the United States. They are not paid any wonderful wages though they are well in line with those paid other wage earners in Great Britain. Compared with our own workmen, they are underpaid, and their wages would be still lower if the owners of the mines had reduced them in a degree necessary to meet competition.

But it is easy to discuss wages in a vacuum. It must be remembered that Great Britain is in Europe and must compete with Europe, that her beds of coal are in many places quite thin and in most places, as she would say, quite "fiery." The roof is bad and the danger of spontaneous combustion, especially in one thick seam, is such that the need for close stowing of rubbish adds greatly to cost. The objection to the use of trolley locomotives has also hampered production.

When men produce less than one ton per man per day, when they have to compete with others having low wages and have to supply coal to industries which, in turn, have to meet the competition of those in other countries which buy their coal from operators paying low wages, what can be done to keep the wage scale up to American levels?

The large mass of workmen who are taking part in the general strike doubtless feel they have a right to combine. The public of Great Britain believes also that it has the right to enter into a combination as against the first group. No one knows what such an action as this might effect. The first group declines to serve the second group, and the second group may refuse to serve the first, and without going into details, it may be surmised that the first group may find the reaction to its attack on the second group extremely disastrous. There is something ominous in the words "Organization for the Maintenance of Supplies." The idea was not intended doubtless to be menacing, but what may not happen if the second group, which has the road transport facilities in its hands, decides to maintain supplies for its own advantage solely.

Growing Old

TOO MUCH HAS BEEN SAID by the critics of the coal industry as to its archaic methods. It is indeed not up to date. No industries are. If they could be, they would be obsolete tomorrow. Progress is a matter of tearing down and building up, rejecting old equipment and buying new. Most industries are none too active in thus cleaning house and wiping out equipment that has ceased to have value. A big mine takes about five years to construct and about twenty, thirty or forty to exhaust.

It would be a slow industry that would not develop in the quinquennium some new method of operation, and in the longer periods many developments may take place. Perhaps the appropriate change in methods can and will be effected, but if the revision is large and requires ruthless scrapping of recently purchased equipment or of recently constructed development the change may not be made.

In all industries the trouble is that we do not recognize "obsolescence." It is not carried on the books like depletion and depreciation. The United States Steel Corporation is quite aggressive in keeping its plants up to the minute. The authorities term this "plowing in profits." Recently it has been questioned whether that is a correct term. Is it not rather correcting obsolescence? Certain it is, that unless the mining man is to spend money steadily to bring equipment to date he is going to fall behind in competing with new plants which have newness and nearness to the shaft to give them the jump on the older developments. At one plant eight-mile hauls are necessary to get coal to the surface. To cope with such a handicap there is no solution other than that afforded by an extreme in efficiency; yet the old mine, built as a leader some decades back, cannot be abandoned. Can it renew its youth after so many years? Unless it does, it cannot hope to be in the running.

Let us be in all things fair. Are there not in Washington inefficiencies and buildings out of date? Is the ancient Patent Office and the furbelowed Treasury Building up to the minute? Is the firetrap Printing Office even permissibly suitable to its purpose? Washington dreams not only for a better coal industry but for itself better departmental conveniences and better organization of its own many establishments. The practice of all of us falls ever measurably below our standards of practice and our dreams of possible performance.

A Word to the Farmers

SUCH DISTRESS has come to the farmers that the National Industrial Conference is appealing to the public to do something wise and constructive to put this large population on its feet. The case the Conference makes is excellent. If the farmers were making more money they would be better buyers and so help industry in general. In particular they might well consume more coal. Many farmers heat their houses only in spots by the use of stoves rather than throughout by the aid of furnaces and as they use little fuel can afford in their idle moments to split wood for their needs and so do without coal altogether. Give them somewhat larger profits, and the stove would give way to the furnace as it has already done in many places.

The farmer has suffered from a shrinkage in land values that has jeopardized all his investments and in some cases broken the banks from which he has borrowed, in which he has invested or by which his loans

Digitized by Google

have been carried. But coal lands have also shrunk in value. In some cases the prices quoted may be little lower than they have been, but the lands have no sale, and if they were sold they would have to be sacrificed. An owner advertised recently a piece of land in the Elkhorn district with virgin timber, four seams of good coking coal with oil and gas. He will sell it for $35 an acre.

Farmers in Iowa, with land at $150 to $275 which used to range about $400 an acre, sell your corn lands and buy for $35 an acre lands underlaid with four far-famed seams of coal! You have heard that the coal barons have fleeced you for generations. Now is your chance to free yourselves from dependence upon them and make an easy fortune. Why hesitate? You have assurances from all quarters that farming is ill-paid and coal mining highly profitable. As coal lands can be bought cheaply why not retrieve your fortunes by a shift in business? Or does the price itself make you wonder if what you have heard has been a tale without substance.

Friendly Counsel

NOBODY CAN ACCUSE the New England retail coal merchants of unfriendliness toward the anthracite industry. When those dealers in convention assembled express regret that the producers made no reduction in prices on April 1 and couple that expression with a plea to the operators to maintain standards of preparation, the opinions thus mildly voiced carry more weight than stern censure from sources less closely allied with the hard-coal industry. The retail distributor is the real contact man between the producers and the public. When he speaks, as in this case, he reflects not only his own feelings, but the reactions of the man who burns the coal.

Certain groups outside the trade have capitalized the failure of the operators to cut prices this spring in a way probably not contemplated or anticipated by the producers. It was a point strongly pressed by Congressional advocates of coal regulation, some of whom endeavored to read into this action a betrayal of the public trust reposed in the industry during the recent strike. That householders, too, resent the denial of their expectations was evident in the discussion which preceded the adoption of the resolution of regret by the New England retail association.

Possibly if the industry could have foreseen how its policy was to be interpreted, a different action, or at least a full explanation of the reasons for the departure from tradition, might have resulted. To retreat now, however, would accomplish nothing but to make a bad situation much worse. Even belated explanation of the reasons back of the change in policy probably would increase instead of diminish criticism and antagonism.

The question of prices is debatable. The same thing cannot be said of preparation. Good faith and sound merchandising alike obligate the producers to maintain as a minimum the standards which they themselves fixed. Any change made should be in the direction of more exacting standards, and a change in that direction should not be postponed too long. Preparation which falls below the existing standards ought not to be countenanced. Nevertheless, since the strike ended some coal which did not measure up to grade and size has entered the channels of interstate commerce. Complaint against quality and sizing is still too common for the good of the industry. The discreet hint in the resolution of the New England Coal Dealers' Association will not be lost upon aggressive producers.

Visualizing the Problem

TO ANALYZE A PROBLEM correctly is a big step toward its solution. To visualize that analysis and to make the major points stand out so that remedies or corrective measures suggest themselves is a short cut to a prompt and effective solution.

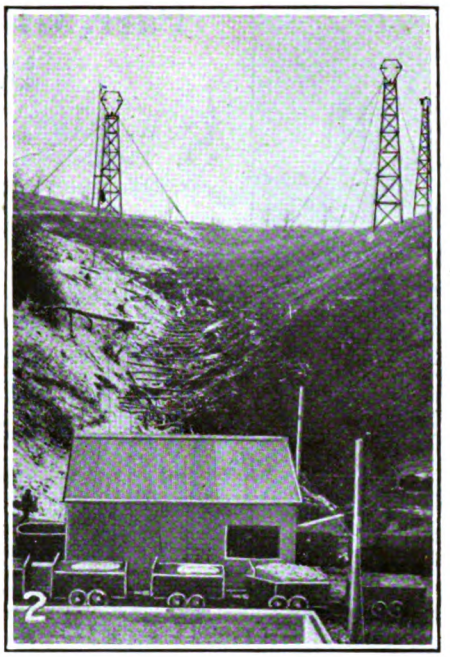
A better aid to effective management than graphic charts would be hard to find. They are easy to construct once the required data are at hand. We are all interested in peak loads and demand charges. If we knew the nature and character of the load, which the demand meter does not show, and the time of the occurrence of peaks we can switch the units around until we approach as near as possible to a straight line which would be 100-per-cent load factor.

Tabulated data are hard to analyze. Take the same data and chart it, and we have a picture of the entire structure, whether it be mining, organization or the power system.

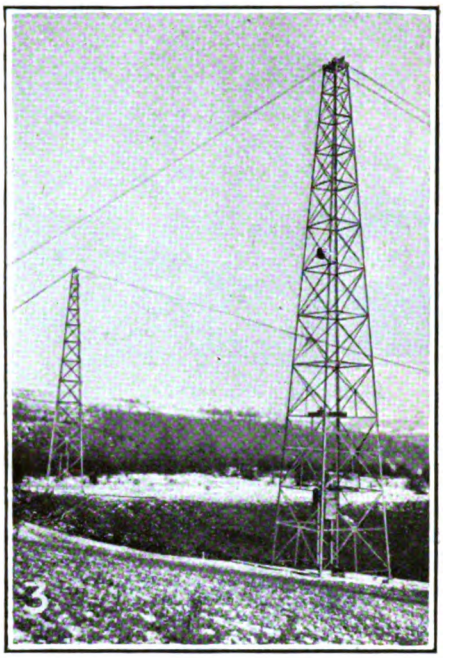
Graphic load-distribution charts are not difficult to construct and they analyze the load and its character which a graphic recording demand meter does not do, the graphic recording meter merely showing the peak demand and the time of its occurrence. One of these completed charts would suggest many switches in loads from the day to the night.

Interest in lowering peaks increases as the changes are effective. Much can be done if further studies are made. For instance, sumpage arrangements may be made to handle sixteen hours' storage and pump only at night. Thus it may be possible to take many horsepower off the day load and switch it to the night load. Using purchased power this would be a large saving, and even under company-generated power it would be well worth while.

Cheaper to Wash Out Refuse Than to Gob It



IT HAS LONG been the practice at coal mines to separate the gob from the coal within the mines and not allow it to reach the light of day. This separation is necessarily made by hand and consumes much time. As a result it was correspondingly expensive.



Where sufficient room is available on the surface for the disposal of gob or where this refuse is flushed back into the mine for roof support, improved methods of washing render it profitable for the coal companies to bring out and treat a far larger percentage of rock than was formerly possible from a commercial standpoint. Thus where binders of such consistency that they may be passed through the rolls are encountered, these impurities may be loaded, brought to the surface, crushed and then washed or floated out of the mine product at less expense than this refuse can be picked from the coal and gobbed within the mine.

Conditions in this regard, however, differ widely. An article this week shows the practice of the Woodward Iron Co., that finds it more profitable to leave the dirt in the mine than to haul it a long way underground, to hoist it, to dump it, to haul it to the washer, to wash it and then to haul the washer reject to the dump for disposal.

Warden Mine Installs Aerial Tramway to Dump Four Hundred Tons of Refuse Daily

Rock and Picking Table Reject Fall Into Steel Bin and Is Loaded Alternately Into One of Two 2-ton Cars Which Carry It Out on a Leg of the Triangular Tramway System

A STRIKING example of the awakening of coal operators to the necessity of modernizing their equipment is afforded by the new Warden mine, of the Pittsburgh Coal Co. located at McAdams, Pa. From first to last, the thought behind this plant has been to obtain a layout that will provide a maximum output at lowest unit cost.

One of the most difficult problems facing the designing engineers was that of handling and disposing of the slate and refuse. The site chosen for the tipple was in a long and comparatively narrow valley with high hills on both sides. The railroad tracks, storage tracks and public highway practically fill the floor of the valley, the tipple structure itself extending from the base of the hill behind it, half way across the flat land adjacent to the stream. To find dumping room for refuse anywhere in the valley would be impractical, yet the coal company's engineers estimated there would be at least 400 tons of refuse produced daily when the mine reached its maximum production. With such a large quantity of material to be disposed of, it was necessary to find dumping area not only sufficient in size to take care of several years' refuse, but also near enough to the tipple to keep down handling costs. Behind the tipple, and at right angles with the valley is a break in the hillside forming a triangular shaped "draw" some 10 acres in extent. This was the only dumping area available. The sides of the "draw" widened as the distance from the tipple increased forming an area shaped like a half funnel with its mouth at the tipple, where it is not more than 50 ft. wide. The length of the funnel is about 800 ft. and the width across the far end about 600 ft.

In the headpiece Fig. 1 shows the tramway with the loading terminal in the foreground. Fig. 2 is a view looking up the "draw" from the tipple. This shows the spread of the tramway legs which is sufficient to enable the dump to cover the entire available spoiling area. Fig. 3 shows the tail towers with the counterweighted guide sheave for the haul rope. The height of the track cables above the ground indicates the possible height of the dump piles.

SLATE HAD TO BE LIFTED OUT OF VALLEY

As all slate brought from the mine as well as all refuse from the picking tables at the tipple were to be dumped into a bin below the level of the mine-car track, the task of raising the refuse to piles of any considerable height so as to obtain maximum advantage of the dumping area available, presented a difficult problem.

The slate-handling equipment was designed and constructed by the Interstate Equipment Corporation of New York. In general it consists of a two-car type of aerial tramway, an unusual feature however, being the placing of the outer terminals, or tail towers, approximately 360 ft. apart measured horizontally, giving, in effect, tramways with a common loading point located below the slate bin at the tipple. This arrangement utilized practically the entire available area for dumping purposes.

In plan, the tramway layout forms a triangle, each leg being approximately 800 ft. long with the base, or distance between tail towers, 360 ft. in length. The angle between the two legs of the tramway at the loading terminal is approximately 24 deg. A single four-wheeled car of 2-ton capacity rides on fixed track cables between the loading terminal and tail tower on each leg of the tramway.

The cars are attached to an endless haul rope which passes over a drive wheel at the loading terminal, then

Digitized by Google

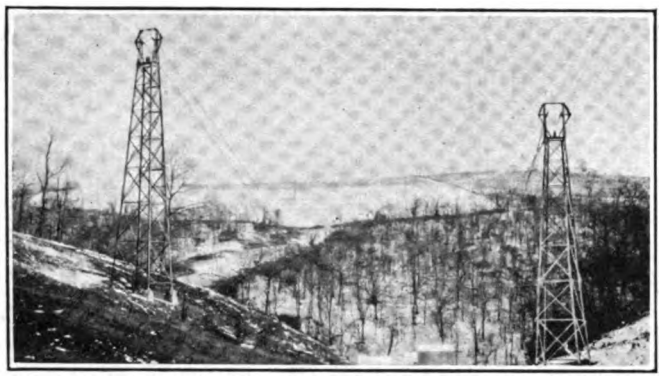

Fig. 4—Looking Down "Draw" from Tail Towers Toward the Warden Tipple

Shows how draw dips toward center line. Refuse piles will probably overlap at the bottom when the piles reach the full contemplated height.

along one leg of the tramway to the tail tower, down the tail tower to a counterweighted sheave, across to the second tail tower and back to the loading terminal. The cars are permanently fastened to the haul rope in such position that when a car is at the loading terminal of one leg, the other car is at the extreme length of travel of the opposing leg.

PILES TO BE ONE HUNDRED FEET HIGH

The ground level at the outer end of the tramway is about 100 ft. higher than at the loading terminal and to provide additional height for dumping the refuse, the tail towers were made 125 ft. high. Each leg of the tramway has one intermediate supporting tower located 300 ft. distant from the loading terminal. These towers are 75 ft. high thus giving a clear dumping space under each leg of the tramway approximately 500 ft. long where slate may be dumped in piles 100 ft. high.

The heights of the two intermediate supporting towers above the loading terminal cause each car to climb a grade of 35 deg. before reaching the dumping span, the incoming car on one leg of the tramway helping to offset the power pull necessary to raise the loaded car on the other. A 40-hp. electric motor located at the loading terminal furnishes the power. It is belt-connected to a countershaft which in turn is geared to the drive-wheel shaft.

ONE MAN HANDLES ENTIRE OPERATION

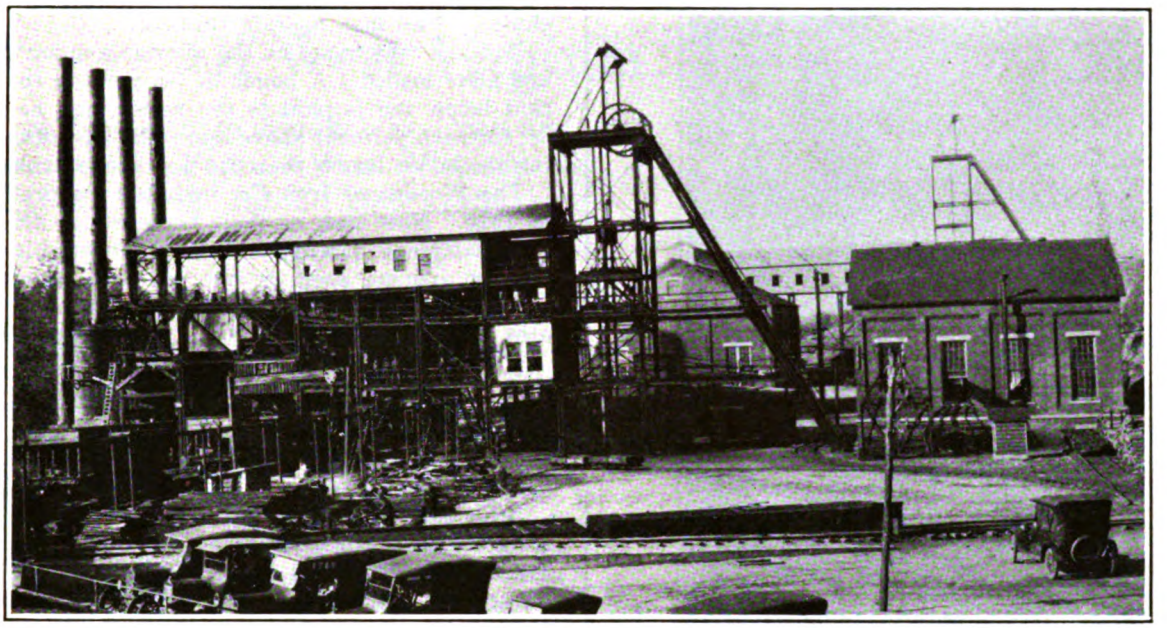
The tramway cars are loaded from a steel bin under the tipple through two undercut gates, each located over one leg of the tramway. The gate-opening mechanism and motor control is brought to a platform control station, so that one man easily controls the whole operation. No tripping device is required in the dumping span as each car has an integral opening mechanism which may be adjusted by the operator in a few seconds so as to cause either car to discharge its load at any desired point along the dumping spans. This solves a difficult problem as the slate dumps will probably catch fire and make it inconvenient or even dangerous for men to work on them.

This tramway was placed in operation early in January and, although the mine is not as yet producing much coal, the operating cost of the tramway evidently will not exceed 2c. per ton of slate handled, including power and labor. A similar installation to handle 1,100 tons of refuse daily is now being installed at the Montour No. 9 mine of the same company.

Parr, Given Chandler Medal, Discusses Coal

S. W. PARR, head of the division of industrial chemistry at the University of Illinois, inventor of a corrosion-resisting alloy known as illium, which serves as a substitute for platinum in the laboratory, and deviser of the Parr calorimeter, delivered on April 23, the Chandler address at Columbia University and was awarded the Chandler medal given by that body in recognition of outstanding achievement in chemical science. The address was entitled "The Constitution of Coal with Special Reference to Problems of Carbonization," the eighth of a series of lectures for which provision was made in 1910 by the establishment of the Charles Frederick Chandler Foundation in honor of that pioneer in the American Chemical industry.

Referring to his own researches Professor Parr declared that when coal was submitted to the extraction process using phenol as the solvent the resinic material was dissolved from the mass leaving the lignite material behind. This lignite residue would not coke but the resinic had the coking quality in high degree.



As a result of studies along this line it is revealed that coals, especially of the mid-continental area, are much more sensitive in their chemical characteristics to alteration than the coking coals of the eastern part of the United States, but by utilizing the information thus attained, it is possible to follow methods of procedure which will conserve these coking constituents, thus forming a coke of excellent density and strength. Studies of this type on the constitution of coal reveal the conditions which must be followed.

EXOTHERMIC HELP IN CARBONIZING

It may be said further that these conditions suggest what is known as the low-temperature type of procedure in preference to the higher temperatures of the standard coking process. It is further of interest to note that by observance of the conditions revealed by these studies it is possible to accomplish a low-temperature carbonization in a cross-sectional area of from 12 to 14 in. instead of the narrower section of 5 or 6 in. ordinarily assumed to be necessary. In this connection Professor Parr described the features of the retort and of the process for the carbonization of Illinois coals which have been developed over a considerable period of years by himself and his associates at the University of Illinois. The coke produced is smokeless and especially adapted to household appliances, and the byproducts are of special interest because of the fact that under the conditions prescribed a large yield of gas is obtained—from 4 to 4½ ft. per pound of coal. The other main by-product, the tar, is of interest because of its type, which has an established commercial value.

Two steps are involved in the process that Professor Parr described; in (1) the coal is given a preliminary heating to a point short of fusion and in (2) it is coked in a vertical shaft retort of narrow cross section heated externally to 1,100 to 1,300 deg. F. Professor Parr said that the exothermic reaction which took place after the preliminary heating would do little to coke the coal if the heat it supplied were available when the moisture was still present but coming as it did when the coal was unable to absorb heat without a rise of temperature it had an immense effect and aided the process of carbonization materially.

Keeps Dirt in the Mine And Only Coal on the Payroll

Woodward Iron Co. Samples Each Mine Car, Saving by Not Paying Coal Price for Rock and by Not Hauling Rock Underground or on Railroad

By J. H. Edwards
Associate Editor
Huntington, W. Va.

IN THESE DAYS of a continuous drive for lower production costs, most mine managements think it a cause for congratulation if they can reduce the number of men above ground or point to the installation of equipment which has separated one or more names from the semi-monthly payrolls. At the Mulga mine of the Woodward Iron Co., in Alabama, however, not only is the regular tipple crew employed but there are eight additional workers who are kept busy sampling the coal to determine the percentage of slate in each car dumped. And the extra service actually saves money.

The Mulga mine is operating in the Pratt seam, which averages 4½ ft. in thickness. Fourteen inches from the bottom is a 6- to 8-in. streak of shaly rock; near the top is another parting 2½ in. thick. The coal is shipped as mine-run to the washery, which is operated in connection with the byproduct ovens.

Before the introduction of the present sampling system the refuse hauled away from the washery averaged 19 per cent of the coal mined. Now the average is 12 per cent. This 7-per cent reduction represents a large saving. The miners are not paid for loading it. Fewer mine cars and other equipment are required to handle the same quantity of usable coal. In consequence, the costs of mine haulage are reduced. Freight charges

Fig. 2—Showing Sampling Car Below Rotary Dump

The samples are taken from holes in the baffle plate below the dump. Because of the restricted headroom gravity chutes from the receiving gates to the samplers could not be installed. This condition necessitates the use of the small drop-bottom car for conveying the samples to the chutes above the respective samplers. Because practically every car is sampled, it requires two men to operate the small car fast enough to keep up with the dumping.

The headpiece shows the top-works of the Mulga mine. On the end next to the shaft the tipple has three decks. The sampling machines are located on the lower deck. Hoisting at this mine is by means of double-deck cages. When the photograph was taken from which the illustration has been prepared, the work of tearing down a large wooden storage bin, which stood at the left, had just been completed, but the old lumber had not been cleared away. Getting rid of this bin eliminated a worrisome fire hazard.

Digitized by Google

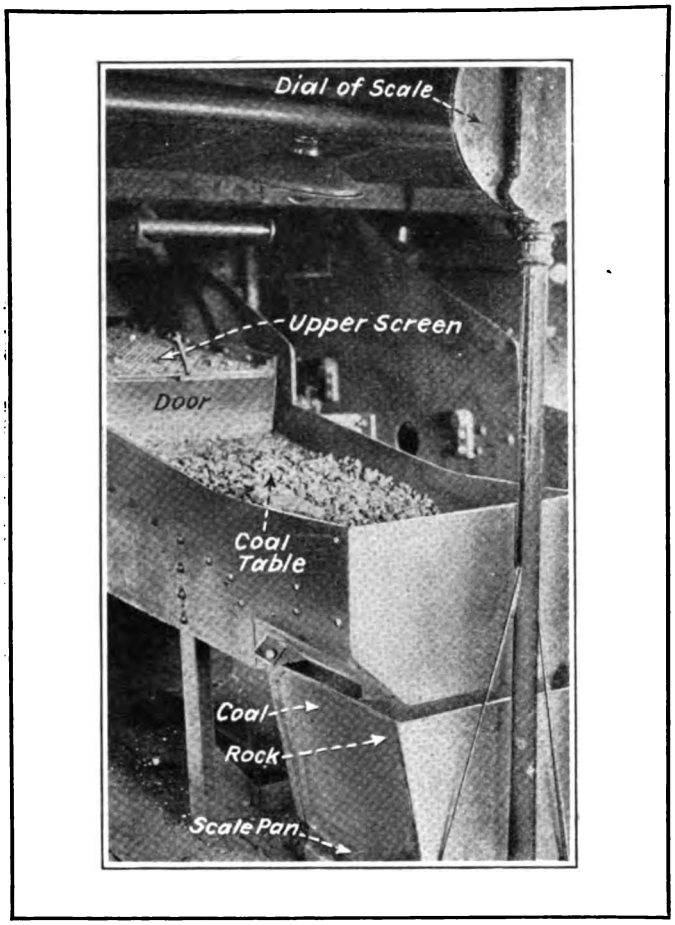

Fig. 1—One of Four Samplers

The samplers are arranged in two pairs back to back. The screens and picking tables are 24 in. wide. Three men do the picking on each pair of samplers. This means that one man must divide his time between two of the machines. The weigh hopper, which is mounted on the scale at the lower right, has two compartments, one for rock and one for coal.

on the transport of coal to the washery and on the refuse from the washery to the dump are also lowered.

Fig. 1 is a close-up of one of the four samplers used. Each consists of a double-deck shaking screen, a picking table and a two-compartment weigh hopper mounted on a dial-equipped platform scale. The screens and picking table are 24 in. wide and only a few feet in length. The upper screen plate has 1-in. diameter perforations and the lower has holes of ⅞-in. diameter. After the lump material which passes over the upper screen has been picked, the gate at the end of the lower deck is opened allowing the second size to pass over the table. The fine material which passes through the lower screen goes directly to the fine-coal chute of the tipple and thence to the railroad car.

The refuse from the picking table is dropped into the smaller compartment of the scale hopper, and the coal drops or is pushed by hand into the larger compartment. The whole weight is recorded opposite a key number which identifies the check number. A second gate is then opened to empty the hopper and the weight of rock is then recorded. From these two figures the percentage of refuse is calculated.

The total weight of sample taken from each mine car is roughly 60 lb. Six men do the picking from the four samplers. The samples are taken from holes in the baffle plate below the rotary dump. Because of the limited headroom in this tipple, a small drop-bottom car or buggy, operating on a 10-in. gage track, is used to convey the coal from the receiving point to the sampler chutes. Two men operate this car.

Ten per cent is set as the allowable quantity of rock and slate loaded. A bonus of 3c. per ton for each per cent below ten is paid to the miner, and he is docked 2c. for each per cent above ten. The advantage of making the bonus larger than the dockage is evident.

The Woodward Iron Co. installed the first samplers in 1920. Now each of their three mines are equipped with samplers, making a total of ten machines in use. The equipment used is the Ramsay patented mine sampler. The principle upon which this sampler operates was described in *Coal Age*, Vol. 11, p. 506.

Missouri Has Seventy-Nine Billions Of Tons of Coal

Information in regard to the analyses, heating values, and general characteristics of numerous Missouri coals are given in Technical Paper 366, entitled "Analyses of Missouri Coals," just issued by the U. S. Bureau of Mines. The coal reserves of the State of Missouri before mining began are estimated at approximately 79,000,000,000 tons. Of this quantity, about one-half of one per cent has been exhausted.

The annual output of the state ranges from three to five million tons, and though perhaps five or six times this quantity of coal annually is used in the State, yet, largely because the coal beds are thin and mining costs high, the mines are restricted to local markets where low freight rates offset the disadvantages of high mining costs.

Missouri has four continuous workable beds, which in downward order are as follows: Lexington, Mulky, Bevier, and Tebo. In addition, there are several beds of small extent. The Tebo bed, though locally thin, is almost everywhere present northwest of its line of outcrop and is at present mined chiefly in Linn, Grundy, Chariton, and Henry Counties. The Bevier, Lower Rich Hill, or Weir-Pittsburg Lower coal, as it is variously called, is extensive and is mined at many places, yielding more than half of the coal produced in Missouri. The Mulky, Summit, and Lexington beds are relatively thin, but are persistent. The Mulky bed is of most importance in Montgomery, Ralls, Audrain, Macon, Randolph, Chariton, Carroll, Lafayette, and Johnson Counties, the Summit in Howard and Boone, and the Lexington in Lafayette, Ray, Putnam and Adair Counties.

Mine Thickest and Shallowest Beds

At present the larger mining operations in Missouri are concentrated in such areas as are underlain by coals that are thicker or more easily mined than those found elsewhere in the area of coal-bearing rocks. In addition to the counties already mentioned, Caldwell, Callaway, Clay, Platte, Schuyler and Vernon Counties contain some thicker coal beds.

"Pocket" coals are worked in a small way in Moniteau and Cole Counties and are at present at a number of points in areas farther south and east. Some lignite is known to be present in the Cretaceous and Tertiary rocks of the southeastern corner of the State, but the beds have not been examined in detail and they can be only of minor importance for a number of years to come.

Smokeless Coals Of West Virginia

What Constitutes Smokeless Coal and Where It Is Found—West Virginia in All Has Thirteen Billion Tons in Reserve

By David B. Reger
Assistant Geologist, West Virginia Geological Survey, Morgantown, W. Va.

David B. Reger

IN 1858 H. D. Rogers,* state geologist, of Pennsylvania, proposed a classification of the coals of high rank. Briefly stated this was based on the diminishing carbon content, there being four ranks known as anthracite, semi-anthracite, semi-bituminous coals, and bituminous coals. Lignites and peats, because of their low rank, appear to have been omitted in his classification.

In 1879 Persifor Frazer,† of the Second Geological Survey of Pennsylvania, elaborated this classification and made it more definite by assigning fuel ratios to the various ranks, the term fuel ratio being defined as the quotient of the fixed carbon divided by the volatile matter. This classification is as in Table I.

Table I—Frazer's Classification of Coals

	Limiting Fuel Ratios
Hard, dry anthracite	99 to 12
Semi-anthracite	12 to 8
Semi-bituminous	8 to 5
Bituminous	5 to 0

In 1925 M. R. Campbell,‡ of the United States Geological Survey, discussed these early classifications at some length and concluded that the limiting fuel ratios should be revised in harmony with modern accepted usage. His classification, which I have reduced to tabular form is as in Table II. Where I have ventured to add to it my initials are appended.

Table II—Campbell's Classification of Coals

	Limiting Fuel Ratios
Anthracite, hard, igniting with difficulty and burning with blue flame	99 to 10
Semi-anthracite, hard, burning with a short yellow flame	10 to 5
Semi-bituminous, hard or soft, burning with thin, yellow smoke when first fired and then with short, yellow flame (the so called "smokeless" coals—D.B.R.)	5 to 2.5
Bituminous, burning with white flame and smoke (definition and lower limit by D.B.R.)	2.5 to 1

In the above classification I have made certain additions to complete the definitions, as Campbell left much to be inferred regarding bituminous coal and assigned no lower limit to its fuel ratio. As a practical matter this limit will seldom fall below one, although some cannels are lower.

In West Virginia, as elaborately described in many detailed reports of the West Virginia Geological Survey, the coals range in rank from semi-anthracite to butuminous there being a progressive increase in volatile matter from southeast to northwest across the state. For purposes of discussion they may be divided as follows:

Berkeley County Field, a deposit of semi-anthracite, not operated and probably of small value.

Potomac Field, semi-bituminous (smokeless) coal.

New River-Pocahontas Field, semi-bituminous (smokeless) coal.

Coals not yet studied, in parts of Randolph, Pocahontas and Greenbrier Counties, partly semi-bituminous and partly bituminous.

All other Coal Fields, entirely bituminous and not herein further discussed.

BERKELEY COUNTY FIELD—In Berkeley County and the edge of Morgan, as indicated in map, is a basin, approximately 13 miles long by one or two miles wide, containing semi-anthracite coal in the Pocono Series of rocks. This is highly folded and partly overturned. This coal has been described by various writers and has been discussed in detail by Grimsley.* The average of four samples of coal collected by him from old dumps is as Table III.

From the above average analysis it is evident that the coal is semi-anthracite. The samples appear to be low in impurities, but in point of fact Dr. Grimsley states that they are only fragments from old dumps and that in all prospects and attempts at mining the good coal was found to be so mixed with slate and so crushed

Article read before West Virginia Coal Mining Institute at its winter meeting in Morgantown, W. Va.

The headpiece shows the No. 3 Pocahontas bed uncovered by Chesapeake & Ohio R.R. just north of Rodes on Piney Creek in Raleigh County.

Where Pittsburgh Bed Is Being Stripped

Coal at the stripping pit of H. P. Brydon & Brother, Inc., Shores Knob, Mineral County. The top of the coal is plainly visible about 4 ft. above the top of the two-foot rule held in the hand of the geologist, who will be recognized as the author of the article. The rock above the coal is known as the Pittsburgh sandstone.

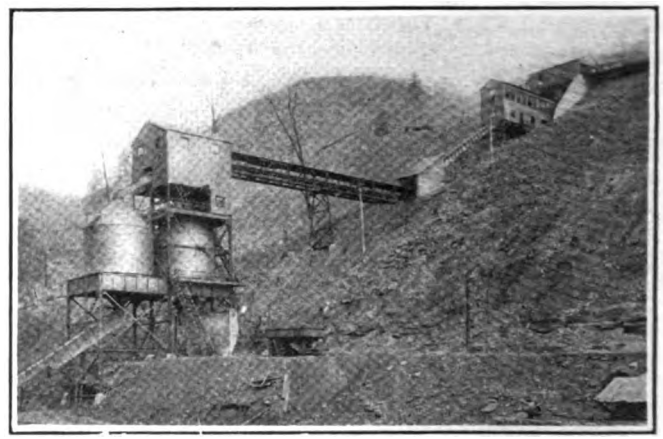
and irregular that failure has resulted from all operations. Others who have examined the territory, including myself, agree as to these facts. In consequence, the

Table III—Pocono Series Coals of Berkeley County Field

	Per Cent
Fixed carbon	81.72
Volatile matter	11.33
Moisture	0.48
Ash	6.47
	100.00
Sulphur	0.83
Phosphorus	0.033
Fuel ratio (Fixed Carbon divided by Volatile Matter)	7.2

field must be dismissed as a present source of smokeless coal.

POTOMAC FIELD—This field, shown in (see state map) embracing parts of Mineral, Grant and Tucker Counties along the Western Maryland Ry. and the Baltimore and Ohio R.R. in northeastern West Virginia, is an area forty miles long and seven or eight miles wide in which there are fourteen minable coals of smokeless or semi-bituminous rank varying in fuel ratio from 2.7 to 4.6. These coals I have fully described in detailed reports of the West Virginia Geological Survey,† and there are additional descriptions of earlier dates by Stevenson, White and others.



These coals have been mined for many years, the product being shipped mainly to eastern markets for smithing, steam, and domestic fuel. The Sewickley ("Tyson") and Pittsburgh ("Big vein") seams are nearing exhaustion but there is still a large tonnage in the Elk Lick ("Four-foot," or "Barton") Bakerstown ("Freeport," or "Thomas") Mahoning ("Six-foot") and Upper Freeport ("Split-six" or "Davis") beds. For several years the field has been much hampered by unfortunate labor troubles and low prices so that the output has been low, but many mines are in operation, the capacities of which could be greatly expanded under favorable conditions.

Table IV shows the average analyses of these coals, and their fuel ratios with estimates of original and present available tonnage. If 80 per cent of the present available 2,150,041,198 tons be recovered it is evident that the field will produce 1,720,032,958 short tons.

SIXTEEN SEAMS IN SOUTHERN FIELD

NEW RIVER-POCAHONTAS FIELD—This is located in southern West Virginia and includes part of Fayette, Raleigh, Wyoming, McDowell, Mercer and Summers Counties. It covers a territory 80 miles long and 25 to 30 miles wide. There are sixteen seams of semi-bituminous or smokeless coal, all of which are in the Pottsville series, two being in the Kanawha group, six in the New River group and the remaining eight in the Pocahontas group. At many localities several of these beds are operated in the same mountain but on account of the regional northwestern dip there is probably no single place where all may be found. These coals have been fully described by Hennen and Krebs* in detailed reports of the West Virginia Geological Survey, and there are earlier reports of a more general nature by Stevenson, White, Campbell and others. Certain additional matter on Mercer and Summers Counties prepared by myself is now on the press.

These coals are low in ash, sulphur and phosphorus, but high in thermal content and fixed carbon, with fuel

ratios that vary from 2.8 to 4.9. They are shipped both east and west for steam and domestic fuel, and are also the principal coals used by the United States Navy and by the merchant marine vessels coaling at Atlantic ports. As metallurgical fuel they are used extensively, but in the manufacture of coke it is often necessary to mix them with coals having a higher ash in order to get the required strength for the blast furnace. In Mineral County the Monongahela Series Has a Few Strippable Areas

Pittsburgh coal at stripping plant of Smith Big Vein Coal Co. This pit is northwest of Sulphur City in the Elk Garden field, an extension of the Georges Creek region of Maryland. Several feet of coal are concealed by the water by which the strip pit has been flooded. Note the brightness of the coal despite light cover.

quality they are the equal of any other smokeless coals in the world, and the mining conditions are so good that no other region can compete with them in the cost of delivered heat units.

The New River-Pocahontas Field is served by the Chesapeake and Ohio, Norfolk and Western, Virginian, and Kanawha and Michigan railways, and it is equipped by hundreds of large and efficient mines so that many millions of tons per year are placed on the market. At the same time the field is capable of carrying a large overload in fuel emergencies and of indefinite expansion in response to a prolonged demand.

Table V shows the average analyes of these coals, together with their fuel ratios and estimates of original and present available tonnage. If 80 per cent of the present available 11,082,856,023 tons be recovered the future output will be 8,866,284,818 short tons. All the analyses in this and other tables were of coal samples taken by members of the West Virginia Geological Survey and analyzed in the laboratory of that organization.

COALS NOT YET STUDIED—In the western edges of Greenbrier and Pocahontas and in the Cheat River valley of central Randolph County are large areas of Kanawha and New River coals, much of which will probably be of semi-bituminous or smokeless rank. These coals have not been studied in sufficient detail, however, to permit an authoritative classification to be made, and for this reason they have been separately designated in the map. A few mines are now in operation in central Randolph and in Greenbrier County.

In the southern halves of Nicholas and Webster and the southwestern corner of Randolph there are further large areas of pure New River coal which do not quite reach the average fuel ratio of 2.5 named by Campbell

Welch

Second largest town in smokeless fields of West Virginia. Once it stood outside the activity it served because the Pocahontas seams under the town laid below water level. Now a number of shafts have been sunk correcting that condition, and all Welch suffers from is a foothold on the hills. The valleys are narrow, the hills are high and not level on top.

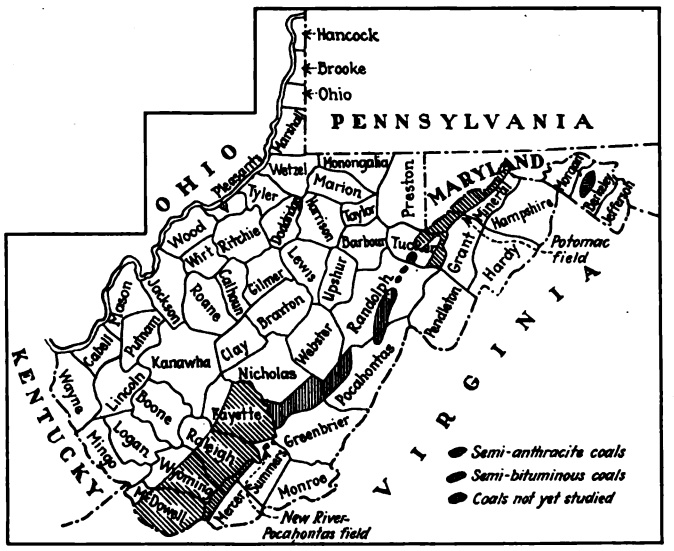
as the lower limit of semi-bituminous coal. I have described these areas in detail in county reports of the West Virginia Geological Survey. Owing to the lack of trunk-line transportation they have been but slightly exploited, but the reserve tonnage is large.

SMOKELESS FIELDS OF OTHER STATES—In the Appalachian region the smokeless coals of West Virginia compete first of all with the anthracite of eastern Pennsylvania, which is more favored as a domestic fuel and which because of its situation is more easily delivered to eastern markets, but which is mined at incomparably higher cost and may therefore be styled a luxury fuel.

Semi-anthracite coal is mined in Sullivan County, Pennsylvania. According to a general analysis published in the *Coal Catalog* the fuel-ratio is 8.2, there being two mines listed from the county in that publication.

In Virginia there are semi-anthracite coals in the Pocono (Price) series in Augusta, Bland, Botetourt, Montgomery, Pulaski, Roanoke, Smyth and Wythe Counties, as described by Campbell in the "Valley Coal Fields of Virginia," previously cited. These coals vary

Seam Its Own Monument



The Norfolk & Western R.R. uses the coal as its level for passing through the hill near Coaldale, Mercer County. As the coal, No. 3 Pocahontas, was 9 ft. 6 in. thick, the contractors made rapid progress and shipped a lot of the "spoil" to market. No more striking advertisement of the excellence of Pocahontas coal, its resistance to weathering, its thickness and its cleanness could be devised.

Smokeless Coal Fields of West Virginia

The smokeless coal lies in almost a continuous belt near, but not at, the eastern borders of the state with Mineral County at one end and McDowell County at the other. The continuity, however, is only geographical. Geologically all measures are represented from the Monongahela series beds to the Pottsville series, showing that fuel ratio is a function rather of the location than of the coal horizon.

generally from 5 to 8 in fuel-ratio and are therefore truly smokeless but the general range of ash is from 14 to 25 per cent, so that there is objection on that account. There are perhaps a dozen commercial mines in Montgomery and Pulaski Counties, some of the product being used as steam fuel and some being sold to the eastern domestic trade as "Virginia anthracite."

In Maryland the semi-bituminous area includes parts of Allegany and Garrett Counties, embracing the Georges Creek Basin and others further west, and being a connecting link between the Potomac Field of West Virginia and the Central Field of Pennsylvania.

In Pennsylvania semi-bituminous coal occurs principally in Clinton, Clearfield, Indiana, Cambria, and Somerset Counties, with scattered deposits in several others. These coals are similar in character to those of the Potomac Field of West Virginia.

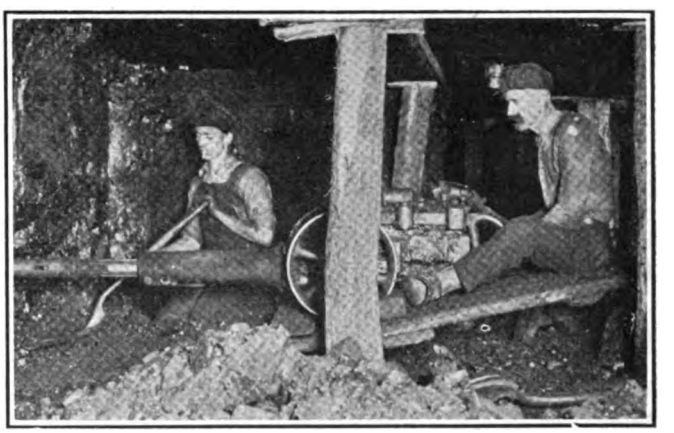
In Virginia semi-bituminous coals are largely confined to the northwestern part of Tazewell County, this area being the type locality of Pocahontas coal.

It is evident from the above statements that the State of West Virginia has in reserve approximately 13,233,000,000 short tons of semi-bituminous or smokeless coal of which approximately 10,586,000,000 short tons can be recovered in mining.

Large Quantities of Water Enter Mines

On the authority of the secretary of the Pennsylvania State Department of Mines, R. D. Leitch, associate chemical engineer of the U. S. Bureau of Mines, Pittsburgh, Pa., says that fifty-four representative mines in the anthracite region average 16 tons of water removed as drainage per ton of coal mined and seventy-five bituminous mines average 36 tons of water per ton of coal. "The figure for bituminous mines," says Mr. Leitch "seems abnormally high; 5 or 6 tons of water per ton of coal would probably be nearer the average for the bituminous mines of this state. Examination of a great number of analyses of mine waters in Pennsylvania indicates that an estimate of 200 grains of sulphuric acid may be assumed. Therefore it would appear that upwards of 9,000,000 tons of sulphuric acid is being dumped annually into the streams of Pennsylvania alone." Drainage from other states on the Ohio River watershed would double this figure. Of more than 300 mines in Pennsylvania, only four showed water which was not acid. C. M. Young states that "there are no fish in the Monongahela River, few in the Allegheny and none in the Ohio until after the Little Kanawha enters at Parkersburg, W. Va., 183 miles below Pittsburgh, Pa."

In Shallow Beds, Effect of Rain Is Devastating



If the water falls into a low area of the coal bed, which is not self draining the water rises till it can flow over the natural dams in the mines. A lake, like that in the Mammoth Cave of Kentucky, is formed and it remains till pumps or underground channels drain off the water.

Tar Is Being Coked in Beehive Ovens

An interesting use is being made of several of the old beehive ovens at the Virginia mine of the Gulf States Steel Co., near Bessemer, Ala. Coal from this mine is shipped to the byproduct plant and the tar shipped back to the mine to be coked in the beehive ovens, thus facing the coking process a second time and this time actually becoming coke.

The difficulty of marketing the tar led to the experiment of attempting to coke the material. A trial in a beehive oven showed that a good grade of coke could be made from this tar which, until that time, had bid fair to find no market large enough to absorb it.

Electric Undercutter's Progenitor

Useful but Rapidly Vanishing

It is quite probable that many coal miners of the younger generation have never seen a pneumatic coal puncher in operation, as this forerunner of the present undercutter is now almost extinct in American coal mines. The accompanying illustration shows a machine of this kind at work in the No. 1 mine of the Gatliff Coal Co., Gatliff, Ky. If the movements of this machine when in operation were not restrained it would go through all the antics of a small rapid-fire cannon. Accordingly the operator sits on an inclined platform, called the puncher board, with his heavily-shod feet, sometimes assisted by wooden blocks, acting as chocks behind the puncher wheels, while he guides the pick point by means of two heavy hand holds on the rear of the cylinder.

Pittsburgh Institute Seeks Light On Two Questions of Safety

How Near Should Trolley Line Approach Face? And What Firefighting Equipment Should Be Provided—A. W. Hesse Reads Paper

THE PITTSBURGH COAL MINING INSTITUTE held its second meeting of the year in the Chamber of Commerce Building auditorium, at which the principal speaker of the evening was A. W. Hesse, chief engineer of the Buckeye Coal Co., Nemacolin, Pa., who read a paper on "Principal Factors in the Development of a Bituminous Coal Mine with Regard to Efficiency and Safety." The meeting, which was held April 17, was well attended and marked by several lively discussions on safety in mines with reference to secondary haulage locomotives, the supplementing of sprinkling at the face with rock dusting in gaseous mines, steps which must be taken to prevent the ignition of gas and the equipment necessary for fighting fires. W. L. McCoy acted as chairman. Secretary Maize announced that the paid membership numbered 1,600.

FAN, LIKE BOY'S SUIT, SOON OUTGROWN

Mr. Hesse's paper dealt with the features which must be incorporated in the design and construction of a new mine plant to obtain the greatest efficiency and safety in mining. He emphasized the need for reserve fan capacity so as to provide sufficient air at all times with ever-changing conditions. He sees no wisdom in striving for peak mechanical efficiency from a mine fan because its attainment requires fixed operating conditions which cannot be maintained. Sprinkling at the face is a necessary adjunct to the practice of rock dusting at least in gaseous mines. A mine, like a factory, is not complete without telephones for direct communication.

In his paper Mr. Hesse mentioned the flameproof cable-reel locomotive used in the Nemacolin mine of his company. Richard Maize, state mine inspector, said this locomotive, as handled at Nemacolin, is safer than flameproof cutting machines. He declared himself confident that it is safer than any type of locomotive not operated by storage batteries. The locomotive is totally inclosed and provided with an interlocking switch, by means of which the electrical circuit to the cable is closed when the trolley harp is lowered to an inoperative position. It is safer than any of the cutting machines because it moves into a place only after the face has been cut and shot and does not go any closer to the face than the length of a mine car.

SEVERED CABLE AS CAUSE OF IGNITION

C. P. Byrne, state mine inspector, asked what would happen if the wheels of this locomotive severed the cable. In reply it was said that a safety fuse would blow, breaking the circuit immediately. Three fuses are provided which are rotated into place as needed, and are protected so that, when they blow out, the flame cannot ignite gas outside the housing. The latter is effectively padlocked. The danger of damage to the cable by the locomotive wheels is minimized by the attention which the motorman gives to the reeling in of the cable from his seat which is located on the outby end of the locomotive. Asked if arcs ever formed between the wheels of this locomotive and the track rails, Mr. Hesse replied that the foreman of the Nemacolin mine reported that he never seen such arcs.

Mr. Hesse added that this locomotive, like other explosion-proof equipment, is safe only so long as it is kept in proper condition. He had heard of instances where explosion-proof equipment had been repaired with parts which were not standard, in which case the repaired machine was no longer explosion-proof.

Several members sought a definition of the term "return air" in the state mine laws, but everyone asked evaded the issue. All as much as admitted that no definite line could be drawn to divide intake from return air within a split. Harvey Nelms laughingly repeated a definition heard in Harrisburg, that air was to be regarded as on the return after it had passed the last working man on the split.

SAFETY AS CONSTRUCTOR'S CONSIDERATION

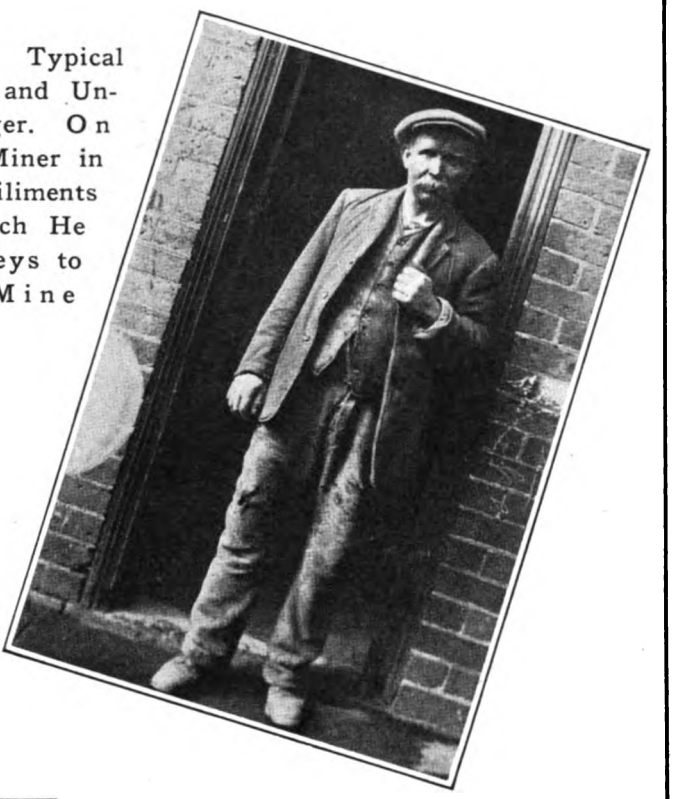
"About nine out of every ten mines," said Mr. Byrne, "are not laid out with safety in view." Locomotive operation in working places is exceedingly dangerous because there is no requirement that the face be examined before a locomotive is allowed to enter a place. State mining laws are more or less specific in the regulation of all equipment other than locomotives.

The question was raised, how far a trolley wire or power line should be carried with respect to the face. Inspector Byrne thinks such conductors should not extend beyond permanent ventilation at any time, by which he meant that they should not be extended as far as any temporary stopping or brattice. Inspector Pratt said he believed that these lines should end at a point a certain distance outby of the last crosscut. What that distance should be he was not ready to say. A committee of five appointed to investigate this problem will report its findings and recommendations at the next meeting.

MORE THAN WATER LINES NEEDED

Francis Feehan of the U. S. Bureau of Mines, asked Mr. Hesse if water lines are adequate for the fighting of mine fires. Mr. Hesse replied that water lines ought to be supplemented with other equipment. A committee of three was appointed by the institute to determine what firefighting equipment should be installed. This committee also will report its findings at the next meeting.

J. J. Forbes, of the U. S. Bureau of Mines, said that after three years' study the Bureau has determined that about 98 per cent of fine coal dust is formed during cutting and loading operations. By laying the fine coal dust at the face, sprinkling increases considerably the effective life of an application of rock dust. In mines not equipped with pipe lines water might well be applied to cutting machine in sprays from a water-tank trailer equipped with pump or compressor.



USING COKE BREEZE—At a conference at Sheffield University, Sheffield, England, on "Solid Smokeless Fuels," it was suggested that a coal with an excess of binding material could be mixed with coke breeze to reduce swelling, to destroy the plastic layer and in general to speed up carbonization.

Practical Pointers For Electrical And Mechanical Men

Straight Socketing with Zinc Proves Efficient but Not Popular

Turn-Back Method Brings Unequal Strain on Wires —How One Mechanic Satisfied His General Superintendent That the Socket Would Outpull the Rope

Despite the recommendations ot wire-rope manufacturers, that socketing be done by leaving the wires straight and filling the space with spelter (pure zinc) after the wires have been thoroughly cleaned with a dilute solution of muriatic acid, many coal companies still persist in the practice of turning the wire ends back into the socket and using babbitt as a filler.

Manufacturers report that repeated tests have proven the straight wire-brush and pure-zinc method of socketing to be the most efficient. When done in this way all wires of the rope are held so as to be under equal tension.

ZINC-FILLED STANDS TEST

Psychology apparently enters into the reason for continued preference of many individuals for the turn-back method. There is a certain comforting security in the thought that the wires are turned back into the the socket and that all break before failure of the rope. The fact is, that as usually applied without careful cleaning of the wires and with a filler of babbitt, the turn-back method will not allow the rope to withstand the ultimate tension for which the rope is rated.

Before the turned-back ends of the wires could resist tension, the wires would have to slip slightly, and as soon as this happens those wires which do not slip must bear an undue proportion of the load. This may cause these wires to break, thus weakening the whole rope and causing it to fail.

Two actual instances where the master mechanics of mines tried to introduce the manufacturers' method of socketing throw an interesting light on the situation. The first case was on a man-and-material incline 1,600 ft. long rising at an angle of 30 to 45 deg. Here the general superintendent learned by chance that the master mechanic had deviated from the "turn-back and babbitt" method of socketing the ¾-in. rope. This superintendent immediately began an investigation and asked the master mechanic to prove that the new socket will have as much strength as the rope.

Accordingly several pieces of new ½-in. rope were socketed by the straight wire brush and zinc method. The wires were carefully cleaned with a weak solution of muriatic acid, rinsed, and dried before the zinc was poured. The 200-ton wheel press in the mine shop was utilized as a pulling machine to test the socketed cables to destruction.

The superintendent predicted that the wires would pull out of the zinc filling, but no such thing happened. He was satisfied after he had seen two ropes break near the center, and the eye of the socket break on another rope. There was no sign of the wires slipping in the zinc.

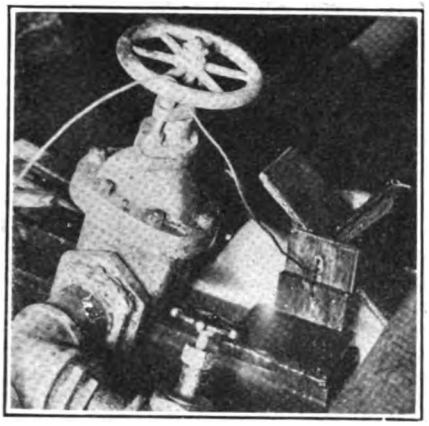
MASTER MECHANIC CONVINCED

At another mine the master mechanic decided to deviate from the past practice in socketing the 1⅛-in. rope of a skip hoist. He ordered some spelter and muriatic acid for the occasion and applied the rope in the socket by the straight wire brush method. He was, however, not satisfied with the appearance of the job so decided to "play safe" by going back to the old method.

He cut into the cone of zinc and imbedded wires to find out if the metal was properly adhering to the wires. He was disappointed to find that the zinc did not appear to have "tinned" the wires to any extent, and concluded that perhaps the filling material sent on his order for spelter was not the "correct mixture." He later learned that by "spelter" the rope manufacturers meant pure zinc and that it was not to be expected that the zinc would "tin" the wires.

These two cases are probably typical of the hesitation with which the old method of rope socketing is abandoned for the new. Another factor which limits the adoption of the recommended method is that zinc and muriatic acid are two materials which few mines keep in stock.

Paddle Wheel Gives Evidence If Pump Is Operating



Pumpers usually have much spare time, and those of an ingenious turn of mind usually utilize their idle moments to contrive ways and means of making the work still easier. This anxiety, however, to lighten toil which is never onerous may result in an improvement to the pumping system. An example is the paddle-wheel flow indicator in use at the main sump of the Exeter mine of the Kingston Pocahontas Coal Co., near Welch, W. Va.

The sump is adjacent to the main pumping station near the shaft bottom. About 1,500 ft. away are located two gathering pumps which discharge through a common line to the main sump. The attendant of the main station looks after these gathering pumps. In case one or both should stop the pumper must immediately investigate the trouble.

PUMPER NOW MORE EFFICIENT

Before he had an indicator of the performance of the pumps he was required to make frequent trips of inspection, which system sometimes resulted in a pump being stopped for a long time before its inactivity became known. The time of the pumper taken up in making these trips to the gathering pumps could

Digitized by Google

Showing Wheel at Time of Contact

The four paddles are made of wood and each has a copper strip on the outer edge, which strip is connected to the signal lamp through the shaft. The distance of the wheel from the discharge opening is adjusted so that the wheel turns slowly.

be better spent in the main pump-room where several large and important pumps are in use.

The discharge from the gathering pumps is within a few steps of the main pump room, but the pumper claims that by looking at the discharge it was difficult to determine if both pumps were operating properly. Accordingly he built and installed the paddle-wheel contactor shown in the illustration.

As the wheel is turned by the water, a 50-watt lamp, mounted in a prominent location in the main pump room, is blinked at a frequency corresponding to the quantity of water discharged. This lamp is on a grounded circuit, and the connection is made through the shaft and metal edges of the paddles to a contact wire fastened to a water pipe. A limited quantity of current flows through the lamp at all times due to the contact with the water, but the lamp brightens each time that a blade of the wheel touches the wire brush.

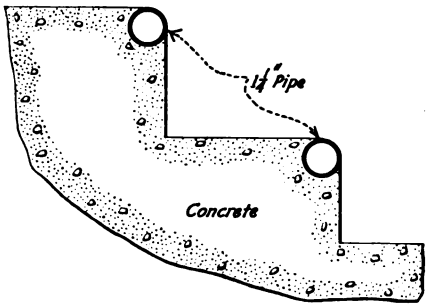
No doubt this type of flow indicator has been used many times, and therefore cannot be classed as a new idea. It, nevertheless, is an interesting application of the toy paddle wheel, and there may be other mines which would profit by installing a similar device.

Grease Wire, Not Wheels

In an article entitled "Shoes Outlast Wheels in Alabama Mine" appearing in the "Practical Pointer" section of the issue of April 1 it is said the "trolley wheels" are greased once a week at the mine of the New Castle Coal Co., New Castle, Ala. This should read, of course, not "trolley wheels" but "trolley wires!"

Hollow-Axle Lubrication On Locomotives

Journal bearings of inside-frame mine locomotives sometimes suffer for the want of lubrication because it is not always easy and convenient to apply the lubricant where needed. With this in mind a hollow-axle system was specified by engineers of the Fordson Coal Co. on certain of their new locomotives.



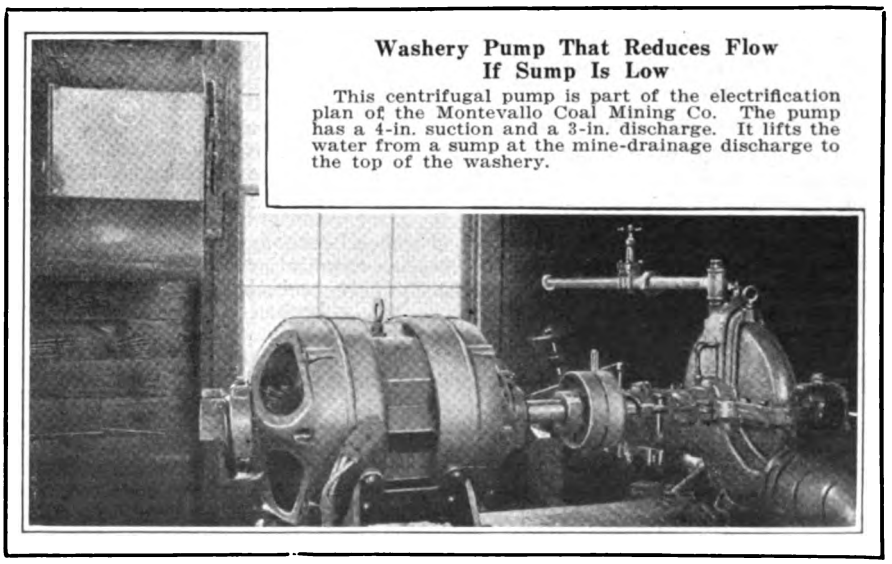
Longitudinal holes have been drilled in the center and end of each axle. These extend to the adjacent bearings where they connect with radial outlet holes. An automatic ball-type grease plug is screwed into a recess in the end of the axle. The lubricant is easily and conveniently forced to the right spot by means of a pump-type grease gun.

Pipe Saves Step Noses From Abrasion and Chipping

The edges of the steps of concrete stairways should be provided with nose pieces, especially if material of any kind is to be moved either up or down over them. Although pieces of this kind are regularly made and sold they are somewhat expensive as compared with some of the scrap material available about most mines.

The accompanying illustration shows how the Kingston Coal Co., of Kingston, Pa., has protected the corners of the treads on a stairway leading into the basement of its office, over which cans of ashes and other material are daily handled. The nose of each step in this instance is protected by a piece 1¼-in. pipe cast into the concrete and extending into the retaining or wing wall upon either side. This takes the excessive wear normally coming on this sharp edge and prevents the concrete from being chipped.

Almost any size of pipe from 1- to 2-in. will serve this purpose. Less, than 1-in. would not be stiff enough



Cross-Section of Stairway

Into the nose of each step is built a piece of pipe. This is set tangentially to both tread and riser and effectively protects the nose of the step from chipping and abrasion.

and more than 2-in. would have too great a radius of curvature and might prove unsafe as the foot would tend to slip off such an easily rounding edge. Smaller pipe might be rendered of sufficient stiffness by welding short pieces onto it at right angles at intervals of a foot or more and building these into the concrete of the step. This would render the edge far less rounding and at the same time afford ample protection.

Float Valve Restricts Flow When Sump Gets Low

At the Aldrich Mine, of the Montevallo Coal Mining Co., in Alabama, a 250-gal. centrifugal pumping station has been installed as part of an extensive electrification program. The squirrel-cage motor, by which the pump is driven is rated at 30 hp., 2,300 volts and 1,750 r.p.m. A balance float valve installed in the discharge line of the pump reduces the flow of water in case the supply of the sump begins to get low.

Washery Pump That Reduces Flow If Sump Is Low

This centrifugal pump is part of the electrification plan of the Montevallo Coal Mining Co. The pump has a 4-in. suction and a 3-in. discharge. It lifts the water from a sump at the mine-drainage discharge to the top of the washery.

News Of the Industry

General Strike On in Great Britain When Coal Negotiations Break Down; Civil Liberties End; Troops Called

A general strike of British industrial workers began at midnight, May 3. All attempts at negotiation of a new agreement between the coal operators and miners having failed, the General Council of the Trades Union Congress ordered a general walkout. Estimates of the number of men affected vary all the way from 2,525,000 to 5,000,000. Of these, 1,120,000 are coal miners.

"The government has found itself challenged by an alternative government," Prime Minister Baldwin told the House of Commons Monday night. "This is a threat to the freedom of our Constitution."

He warned the leaders that their actions would bring the country "nearer to civil war than for centuries." But even as he spoke, orders were being wired to workers throughout Britain to get ready to strike.

Long before midnight thousands of workers had already received their instructions to quit work. These included those employed in transport, the printing trades, the metal and heavy chemicals group of the iron and steel industry, and, to a limited extent, the building, electrical and gas workers.

On Tuesday no newspapers appeared, all race meets were declared off, there was a likelihood that the theaters would close and practically no trains, street cars or busses were running. The government, however, had enrolled thousands of volunteers; had gathered a huge fleet of motor cars; had commandeered tons of foodstuffs and coal and other necessaries and had made far-reaching plans for meeting the defi of the strikers.

Emergency Act Issued

The government propmtly promulgated an "Emergency Powers Regulation, 1926," signed by the King in Council, and the suspension of all civil liberties. In effect, the country is placed under martial law. Last Saturday, four hours after the declaration of the miners' strike, a proclamation calling for citizen volunteers for the O. M. S. (Organization for the Maintenance of Supplies) was posted throughout the country. It is believed that the government can muster 75,000 volunteers, in addition to about 500,000 men in the army, navy, air force and militia.

The breakdown in negotiations between the coal operators and miners came on Friday night, when the miners refused to accept the final offer of the mine owners. The men were asked to agree to an eight-hour working day. In return they would be paid a national minimum wage of 20 per cent above the 1914 standard wage, instead of 33⅓ per cent. The eight-hour day was to be worked until 1929, when a commission of inquiry would ascertain whether the economic position of the industry would justify a return to a seven-hour day or, alternatively, fix the date on which the hours should be shortened.

Mr. Baldwin asked if this plan was the fullest concession the operators were ready to make. They assured him that it was. Thereupon the Premier referred the offer to the miners' delegates in a memorandum.

Miners Reject Offer

The answer of the miners follows:

"In reply to the government memorandum the miners state they are not prepared to accept a reduction in wages as a preliminary to the reorganization of the industry, but they reiterate that they will be prepared to give full consideration to all the difficulties connected with the industry when a scheme for such reorganization shall have been initiated by the government."

The reply also expressed the opinion that the present working hours are long enough to supply all the coal for which a market can be found; that they are as long as any man should be expected to pursue in such a dangerous and arduous calling; that to extend the hours in the present circumstances is simply to swell the ranks of the unemployed and to invite similar measures on the part of Britain's foreign competitors.

Briefly to review the events of the last few days: Friday, April 30, was the last day of the subsidy. Shortly after midnight following that day an official announcement was made that the negotiations between the operators, miners and the government had definitely broken down. On May 1 the representatives of the most powerful British labor unions decided to declare a strike at midnight on Monday, May 2. The text of a royal proclamation bearing the date April 30 was issued May 1. It declared that a state of emergency existed and thus gave the government the special powers conferred on it under the Emergency Power act of 1920. About this time troops were quietly moved into the mining areas of South Wales, Lancashire and Scotland. They have been kept under cover so as not to excite any undue animosity.

The Central League of Transport Workers in Holland on May 3 issued a manifesto declaring that not "one ton of coal may be exported to England." The German Miners' Federation in a manifesto declared May 3 that it would act strictly in accord with the international miners' agreement at Brussels and prevent the transportation of coal from Germany to England during the British coal strike. On the other hand Rinaldo Cappellini stated on the same date at Wilkes-Barre, Pa., that the miners of the anthracite region cannot abrogate their contract with the anthracite operators to direct where the operators shall place their coal.

The railroad men, dock workers and miners of France have called a meeting to decide on the measures to be taken in view of the British strike. Sir Samuel Kelly's mines in the north of Ireland are still working and it seems likely that coal will continue to be produced from this property.

Pittsburgh Open-Shop Output Tops Union for First Time

For the first time in 30 years, or since the organization of the United Mine Workers, the total output of the open-shop coal mines of the former Pittsburgh union district for one week has exceeded that of the union mines of the district for that week. This conclusion was reached after a survey made by the Pittsburgh Coal Co. showed that the total tonnage of open-shop mines of three companies which are operating independent of the United Mine Workers was 77,700 tons for the week ended April 24.

Eleven mines of the Pittsburgh Coal Co. in the Pittsburgh district, working on the November, 1917, wage scale dumped 46,667 tons of coal through their tipples during the week; three mines of the Ellsworth Collieries Co., subsidiary of the Bethlehem Steel Corporation, loaded 25,000 tons, and the mines of the Pittsburgh & Erie Coal Co., at Braznell, in Fayette County, loaded 6,033 tons.

Exact figures as to the union tonnage in the district are not available, since the Pittsburgh Coal Producers Association was dissolved last December. Those who made the survey, however, learned that slack work prevailed at the union mines of the district during that week.

The Ellsworth Collieries Co. is operating one mine each at Marianna, Ellsworth and Bentleyville, in the Pigeon Creek valley of Washington County.

Relief from Legislative Shackles Chief Need of Coal, Say Spokesmen; McAuliffe Favors Full Fact-Finding

Washington, D. C., May 4.—The public interest will best be served by allowing the coal industry to work out its own salvation, unhampered by further legislative enactments. This is the answer spokesmen for the coal trade are making before the House committee on interstate and foreign commerce, which is considering proposals for broadening the scope of federal powers in mediation, emergency distribution and continuous, compulsory fact-finding. Action along the lines suggested, they assert, would either be unconstitutional or impracticable or both. Moreover, government interference in the past, it was charged, has been responsible for national strikes.

The attack begun by Harry L. Gandy, executive secretary, National Coal Association, at the hearings last week and continued by Walter Barnum, president, Pacific Coast Co., was renewed yesterday by Roderick Stephens, chairman, committee on governmental relations, National Retail Coal Merchants' Association; Charles O'Neill, secretary, Central Pennsylvania Coal Producers' Association, and J. G. Bradley, head of the Elk River Coal & Lumber Co. and a former president of the National Coal Association.

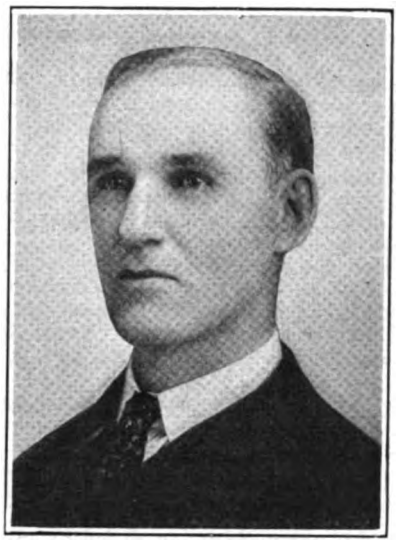
The only voice of dissent so far heard in this chorus of condemnation by representatives of the industry has been that of Eugene McAuliffe, president of the Union Pacific Coal Co., a subsidiary of the Union Pacific R.R. Mr. McAuliffe, who appeared before the committee on April 29, came out flat-footedly for government fact-finding, mediation in labor disputes and full emergency control.

Anthracite Counsel Testifies

This morning the anthracite industry was given its first opportunity to reply to the many charges made against it by some of the earlier witnesses when Walter Gordon Merritt, general counsel for the Anthracite Operators' Conference, took the stand. Mr. Merritt was just summarizing his review of labor relationships, which he characterized as the dominant problem, when the committee adjourned for the day. The witness emphasized the adherence of his clients to the principle of arbitration, but reserved stating the attitude of the industry on the specific legislative proposals being considered by the committee until later in his testimony.

Chairman James S. Parker, who discussed the situation with the President last Friday, has stated both publicly and privately that the committee will report out a bill at this session. He is hopeful that the House will pass the measure before adjournment. No official disclosure as to the scope of the committee bill has been made. Many observers, however, are convinced that it will incorporate compulsory fact-finding in some form in its provisions. Whether it will go beyond that is considered more or less doubtful, although committee members in their examination of witnesses have appeared to be unwilling to accept the contention that the government is powerless to prevent an interruption to the flow of coal.

A subcommittee of the Senate committee on education and labor also is wrestling with a bill, but no hearings have been held on the measure. This Senate bill, framed by Senators Borah (Idaho), Metcalf (Rhode Island) and Copeland (New York), would give the President emergency seizure powers and re-enact the provisions of the Federal Fuel Distributor law for emergency control of distribution. Fact-finding machinery, probably under the supervision of the Bureau of Mines, would be set up. Senator Copeland is quoted as saying he will press for early consideration, but definite action at this session of Congress seems unlikely.



The biggest element of uncertainty which has been injected into the situation is when Congress will adjourn. Originally it was planned to end the sessions on May 15. That date has gone into the discard and June 1 is doubtful because of the insistence of certain members that other legislation, notably farm relief and radio control, be acted upon before Congress winds up its business. If the adjournment is unduly held up, proponents of coal bills will be given an opportunity for urging action on their program.

Calls Retailer Innocent Bystander

The testimony of Mr. Stephens before the House committee yesterday in a measure was an amplification of the position taken by the retailers when called upon recently by Secretary Hoover to state their attitude toward coal legislation. The retailers, he explained, are not directly involved in mine labor disputes and, therefore, can express only the views of the innocent bystander. He did not think, however, that the problem of labor relations could "be solved by legislation." Questioned by Representative Newton (Minnesota), Mr. Stephens said that he did not believe it was the function of Congress to act as a "wet nurse" to the public. At the same time he did not object to granting the President power "to handle a real emergency" if such powers had not already been given.

It was the opinion of the retailers that distribution in times of stress could be worked out more equitably and successfully by the industry itself than by a government agency. Mr. Stephens also questioned the conclusion that "fact information" is a cure-all. "If facts could prevent coal shortages and high prices," he asked, "why is it that strikes have occurred so frequently since the Coal Commission made its report?"

Fact-finding in normal times, he contended, can serve no useful purpose unless the federal government intends to set up machinery to control prices and profits. But no reason has been suggested why coal should be singled out for such treatment and a general excursion into the field of regulation of production, distribution and prices is counter to the American theory of government.

Eugene McAuliffe

Representative Wyant (Pennsylvania), who several times since the hearings opened has stressed the spread between mine quotations and retail prices, examined Mr. Stephens on that subject. It developed that the witness had sold Clearfield mine-run, costing approximately $6, New York, at $7.75 and $8.75 during the strike and West Virginia coal at a maximum of $9.50. The domestic consumer, however, demanded choice screened fuel, for which the New York retailer had charged $14 to $18. This coal had cost as high as $7.50 at the mines and carried a freight rate of $4.19. It was subject to a heavy degradation, leaving slack in the dealers' hands for which there was no market.

Retailers Unjustly Accused

Mr. Stephens sharply challenged charges of profiteering made against Washington retailers at a Senate committee hearing several weeks ago. It was unfair, he said, to take the price on one grade of coal and ignore the costs and realizations on all the other sizes and grades which the retailer must handle. As a matter of fact, Washington dealers had not averaged over 25c. a ton net on their business, some lost as much as 18c. and the highest average profit was under 50c.

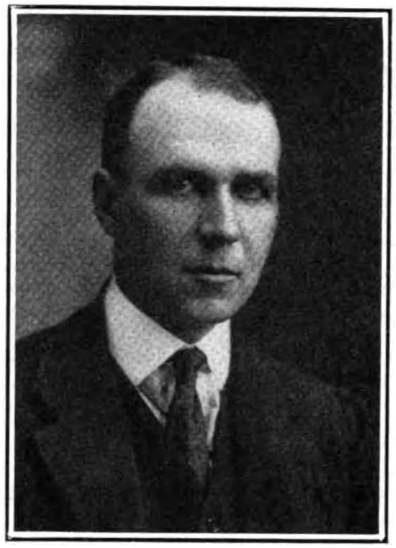
Congressman Newton pointed to the conflict between the witness and Representative Wyant on the question of responsibility for profiteering as evidence of the need for a disinterested fact-finding body. He also brought up the subject of licensing dealers in interstate commerce as a means of regulation. Mr. Stephens thought conditions so changed since 1919-20 in the proportion of union-mined coal and in the attitude of the public toward substitutes as shown in the recent anthracite strike that such control was unnecessary.

Generally speaking, the witness told Congressman Corning (New York),

Digitized by Google

there would be no disinclination upon the part of the retailer to opening his books to an impartial agency, provided that the examination would cover a long enough period to take in both valleys and peaks and so give a true picture. It was Mr. Stephens' belief, however, that more could be accomplished through voluntary co-operation than mandatory legislation.

How the intrusion of the federal government in wage negotiations has made national strikes possible was described to the committee by Mr. O'Neill. Between 1886 and 1919 there had been only one strike of any consequence in the unionized bituminous fields and that had been settled without government interference or public inconvenience. Prior to the time Dr. Garfield, U. S. Fuel Administrator, participated in the negotiations in the fall of 1917, agreements in different parts of the country expired on different dates. The basic Central Competitive Field contract ran out March 31, but agreements in the Southwest, Pacific Coast and Intermountain states, western Kentucky and the Kanawha and New River districts of West Virginia did not.



Deplores Federal Interference

Without government interference the industry itself "had worked out an arrangement which provided for an effective basic wage agreement made by a large and representative group of tonnage upon the economic conditions existing in the country and yet preventing the exercise of the arbitrary power to shut down all the unionized mines in the nation." The Washington agreement provided for the same expiration date in all districts. Thus, "with one stroke of the pen, governmental activity was instrumental in wiping out the system that avoided the emergency of a nation-wide strike which this committee is now talking about and considering."

That the government cannot compel men to work was shown in the injunction proceedings of 1919. "The court ordered the United Mine Workers to withdraw the strike order. A meeting of the miners' officials was called and the strike order was canceled—but the miners remained on strike." In the subsequent negotiations, added the witness, three branches of the government—the Department of Labor, the Fuel Administration and the Bituminous Coal Commission—"made three interpretations of the same state of facts and arrived at three different conclusions!"

Economic conditions, said Mr. O'Neill, are working to restore the pre-war situation. The unsound system maintained by the union is driving more and more tonnage to the non-union fields. Freight rates, too, are helping the Southern districts. The union output is contracting. "Government cannot cure this." Restoration of the pre-war status can and will be brought by the industry itself in a very short time. "The best that Congress can do to help this along is to leave the matter alone."

During the war, Mr. O'Neill testified in answer to a question from Congressman Wyant, the government had encouraged overdevelopment by allowing a 75c. premium to wagon mines. These mines, for the most part loading box cars, had enjoyed a full car supply.

J. G. Bradley

Mr. Bradley, the next witness, caustically criticized Congressmen introducing coal-control bills. His remarks drew a rebuke from the committee and a demand that the speaker confine himself to the subject under discussion. The crises which have provoked Congress to consider legislation, he said, have come from without the industry. In 1916-17 and in 1919-20 it was a failure of transportation that caused prices to skyrocket. In the 1919 and 1922 strikes the industry was the victim of a lawless organization. The transportation situation had changed and the labor problem, he contended, was taking care of itself in the expansion of non-union tonnage. If Congress wants to do something, let it change the appropriations given the Department of Justice by removing the bar against using such money in prosecution of labor combinations.

Charges Juggling of Statistics

Questioned by Congressman Mapes (Michigan) on fact-finding, Mr. Bradley replied that he had suggested to Mr. Hoover the advisability of amending the Census law so that the Census Bureau might have the same authority over mines as over manufacturers. He was opposed, however, to the creation of special bureaus to collect special statistics because such statistics were manipulated to support special theories. The Coal Commission, he declared, could not have reached some of the conclusions it did had it studied the statistics gathered under its direction.

Mr. Mapes wanted to know whether the witness would abolish the Department of Agriculture and the Bureau of Foreign and Domestic Commerce. Another member remarked *sotto voce* that the witness was in favor of abolishing everything. Mr. Bradley's declaration that it was not the function of the government to act as "a smelling committee" led Mr. Mapes to retort that the proper function of the government was to aid industry. Mr. Wyant asked whether the President should have power to protect the public. Mr. Newton repeated the thought in another form. The witness answered that such powers as might lawfully be granted the President already had and that the hope of federal interference in strikes would prolong such contests.

Mr. Gandy, concluding his testimony April 28, answered a barrage of questions from Congressmen Newton, Lea (California), Nelson (Maine), Huddleston (Alabama), Shallenberger (Nebraska) and Dennison (Illinois). He again explained his objections to the proposed legislative program. He could conceive neither of complete unionization as a remedy for coal-trade ills nor the possibility of modification of the Sherman law. Strikes, he pointed out, were not profitable. Prices over the years had been reasonable to the public and were little higher today, despite increases in production costs, than before the war. Emergency wage-fixing by governmental authority would only postpone a settlement of labor disputes.

Mr. Barnum, who followed Mr. Gandy, insisted that both relatively and actually the bituminous industry was efficiently conducted. In support of that position he compared average realizations in the United States with coal prices abroad, percentages of coal mined by machines and output per person employed. In 1921, for example, the average realization in this country was $3.24 per ton, against $5.04 in Great Britain and $6.27 in Belgium; in 1924 the average here was $2.46, as compared with $4.16 in Great Britain and $4.43 in Germany.

Can't Account for Hoover Dictum

Asked how he reconciled his claims on efficiency with Secretary Hoover's famous characterization of the industry, Mr. Barnum replied that he could not account for Mr. Hoover's views. He felt, however, that those directly engaged in the industry have a better opportunity to judge its efficiency. The witness told the committee that the margin of profit was too narrow and that the operators would be overjoyed with an average of 25c. per ton.

"The coal industry," maintained Mr. McAuliffe, the only witness heard last Thursday, "needs a new viewpoint." It has been too much a gambling venture, depending upon strikes and transportation difficulties to create panic demands. No industry of comparable importance has been as backward in labor relations, marketing methods and general production technique. For example, the steel industry, twenty-five years ago as chaotic as the coal industry today, "has displayed a will to compose its business and labor affairs. The coal industry, saturated with coal-mining and sales traditions imported from Great Britain, has failed to make even a substantial start in that direction.'"

Irregularity in coal operations and unbalanced, hysterical buying have compelled the railroads to invest two dollars in transportation facilities to handle coal for every dollar invested in the mines. Most of this railroad investment is non-productive eight months out of the year. This is a burden which indirectly falls upon the coal consumer although it has removed

Digitized by Google

transportation shortage as a cause of high coal prices.

There are signs, too, that labor also must accept the principle of a business relation with the industry or disappear by attrition. The curse of present-day unionism, he said, was the craze for office. If someone could guarantee Mr. Lewis his job, the witness thought the president of the union would express a different viewpoint. Today, however, conservative officers are the victims of the political machinery of their organizations.

The Jacksonville agreement, he stated a little later during a colloquy with Congressman Huddleston, had been the best thing under the circumstances. He though that Mr. Lewis had felt that a three-year contract would give labor a chance to compose itself and lay the ground for a prevention of recurring strikes. The witness was satisfied to go along with the union if given a business administration. If not possible to work with the United Mine Workers, he probably would shift to the company union as the next best thing.

The witness put himself on record as definitely opposed to government ownership and to compulsory arbitration. "All the industry needs is a little intelligent guidance in finding itself." He advocated a law which would provide for a true and complete assembly by the Bureau of Mines of all the facts, including labor costs, cost of materials, hours worked, total costs and realizations. Such data would form a basis for intelligent determination of disputes and pave the way for mediation and conciliation on a sound basis. The cost of collecting such facts would be inconsequential both to the government and to the industry.

"The theory of a fact-finding law and a mediation and conciliation board," explained Mr. McAuliffe, "is based on the principle that neither side to a controversy could afford to defy public opinion when the facts relating to the same were available and of an authoritative and dependable character." Facts now available do not meet these tests.

Arbitration Methods Resented

It was the witness' belief that the method and character of arbitration heretofore employed were "more objectionable to labor than is the principle. Provision should be made by law for placing in the hands of the President the broadest possible power over the industry in the event a cessation of production, in part or whole, takes place and which is of a proportion that prejudices the well-being of the people." Such authority should cover emergency operation and distribution and include power to temporarily fix wages and selling prices. The determination of the exact methods to be employed should rest with the President and the working out of details with the Secretaries of Labor, Commerce and War.

Although urging these broad powers, Mr. McAuliffe voiced the belief that with all the facts available, their exercise probably would not be necessary. "The coal industry today," he concluded, "is in no sense organized, preferring to remain divided along

Walter Barnum

labor, geographical, market and other lines. It has had a generation of opportunity to find itself—and has failed. What it most needs today is to know the truth about itself, and, given such, it will pick its way up to and on to higher ground. Coal is a basic, fundamental necessity, and the welfare of society and government depends on its continuous production and transportation. It is, as managed today, wasting labor, wasting human life, and wasting itself."

Many Illinois Operators Now Handling Non-Union Coal

Invasion of non-union western Kentucky continues by Illinois operators seeking coal tonnage for distribution to replace their own product, made practically unsaleable by the wage scale in union territory. Almost all of the Illinois shippers are now selling western Kentucky coal, having suspended operations at their own mines because of the unsatisfactory price return.

Except for the Peabody Coal Co. and the Old Ben Coal Corporation, shippers handling non-union product maintain silence on the connections they have, regarding the non-union venture as merely an expedient.

In Chicago the move into western Kentucky is accepted as something more than a mere gesture in the attempt to bring about a solution of the wage problem when the union scale expires next spring. The jobbers' move is considered as an expansion of definite permanency aimed at broadening tonnages available for sale and distribution.

Gossip in Chicago on consolidations in Illinois is light. The reported merger at Belleville, in the Standard field, by the Bell & Zoller interests apparently is slumbering. It is declared there will be no development of note in this direction for the present.

Latest estimates are that only 100 mines in the state out of a total of approximately 400 are in operation and that one-third of the 100 mines are "captive" or industrially owned, leaving a scant 60 to 70 commercial mines to provide Illinois coal for the market.

Paisley's Boyd Mine Resumes On Non-Union Basis

Operations were resumed on a non-union basis April 29 at the Boyd mine of the Elm Grove Mining Co., Elm Grove, W. Va. The mine, which is controlled by the J. A. Paisley interests, of Cleveland, had shut down more than a month ago following a strike by union miners who refused to agree to a monthly payday. Three others of the company's mines were closed at the same time.

The Boyd mine had been operating under the Jacksonville agreement previous to the shutdown.

Pickets were on duty near the Boyd mine when the attempt to resume was made, but the picketers remained well away from company property. Ten state troopers were stationed in Triadelphia, but none was at the mine during the first few days. However, they are being held subject to call.

The new wage scale posted at the Boyd mine is: Loading machine coal, net ton, 63c.; cutting, 12½c.; entry yardage, 72c.; entry room yardage, 72c.; room neck yardage, 56c.; track layers (day), $6.50; drivers, $6; motormen, $6; trip drivers, $6; all inside day labor, $5.70, and all outside laborers, $5.44. The reduction is approximately $1.56 per man per day.

John Cinque, president of the sub-District No. 5 of District 6, United Mine Workers, in charge of the local district, stated that the members of the United Mine Workers would not go back to work under the proposed agreement.

Overtures made to the United Mine Workers of eastern Ohio by John S. Snure, manager of the Valley Camp Coal Co., also controlled by the J. A. Paisley interests, in connection with the operation of the Lucy and the Oco mines, located in Belmont County, have been ignored by the miners.

It was proposed by Snure that the two mines resume under the Jacksonville agreement, with the monthly payday, instead of the semi-monthly pay.

Union Firm for Jacksonville Pact

W. T. Roberts, secretary of the district union, said that "Paisley knows the Jacksonville contract and that is what he will have to live up to, to do business with us. We accept nothing short of the complete scale agreement."

Operations were resumed on an open-shop basis at the Mona Mine, at Maidsville, late last week, two cars being loaded during the first day's operation. This Paisley mine under normal conditions has a capacity of about 20 railroad cars. As to whether or not an effort will be made in the immediate future to operate the Connellsville By-Product Coal Co. plant on Scotts Run, the largest single producing mine in that section of West Virginia, no announcement has been made other than that the company has nothing to offer the employees except the 1917 scale.

Union miners continue to picket the plants of the Cleveland-Morgantown Coal Co., owned by the Pursglove interests, as well as the Paisley Connellsville By-Product plant, but so far there has not been any interference with the men going to work.

House Committee Hopes To Report Constitutional Fact-Finding Bill Soon

By Paul Wooton
Washington Correspondent of *Coal Age*

Assurances have been given the President by Chairman Parker of the House committee on interstate and foreign commerce that a coal bill will be reported by his committee and will be pressed for passage at this session of Congress. The President has been advised further that a majority of the committee has come to an understanding as to the principle of the bill that will be recommended, although the details have not been worked out as yet.

It was stated at the White House that this information is very gratifying to the President and that he thinks Congress should enact legislation at this session along the lines indicated.

Any coal bill recommended by the committee is likely to pass. The committee on interstate commerce as now constituted enjoys high prestige in the House. It has the reputation of being conservative and careful. This means that many members who will not have had an opportunity to study the bill will vote with the committee. Moreover, any champions that the coal industry may have among the members of the House seem not to be aggressive.

When Representative Jacobstein made his speech in the House on April 27 a fine opportunity was presented to call to the attention of a large attendance of the membership the arguments against the constitutionality of the proposals made by the New York Congressman. As it was, ten members participated in the debate, but their object was not to disagree with the conclusions of Mr. Jacobstein but to bring out additional points to support his contentions. No champion of the coal industry arose to point out the vulnerable spot in the New York legislator's argument. This tends to confirm the opinion that no great difficulty will be experienced in getting a coal bill through the House.

Action Less Likely in Senate

In the Senate interest centers on other things. The prospects for action are more remote. A sub-committee of the committee on education and labor is considering all of the coal bills in the hope that the Copeland measure can be revamped into such form as will meet the approval of the full committee. Some of the provisions of the Oddie bill probably will be attached to the legislation which may be reported out. The chances all are that any bill that this committee may report will be less acceptable to the Senate than the bill likely to be presented in the House. The Senate, however, is in no humor to take up new business likely to provoke long debate.

The most significant point in the situation, however, is the fact that a bill passed by the House at this session will be before the Senate when Congress meets in December. At that time the rumblings of the storm likely to accompany negotiations for the renewal of the Jacksonville agreement will be heard. It is easy to see that a situation may develop that would cause the Senate to take quick action on pending coal legislation.

In the testimony of Eugene McAuliffe, of the Union Pacific Coal Co., the so-called administration members of the committee heard testimony very much to their liking. It will not be surprising if the legislation recommended by the committee will follow the advice of Mr. McAuliffe to propose a "federal fact-finding law that will provide for a true and complete assembly of all of the facts that surround the operations of the coal and coke industry, including the cost of labor, material, hours worked, hours of work available, total cost and realization, with the margin of profit gained or the loss sustained."

Smoke Nuisance Attacked

City combustion engineers in Chicago began a drive on smoke violators last week. The city Health Commissioner charges wanton air pollution and told a number of the violators haled before an inspection board that every man, woman and child in the city must pay an average of $12 a year because indolent and inefficient janitors and engineers cloud the air with smoke and soot. It was asserted that the aggregate cost is $35,000,000 annually for extra laundering and cleaning and that the annual waste in coal alone amounted to $7,500,000. The Health Commissioner said that 30,000,000 tons of coal literally went up the chimneys last year, as he said that smoke is nothing but unburned fuel.

38 Indiana Miners Jailed or Fined for Rioting

Following a trial lasting many days thirty-eight union miners were found guilty of riot by a jury in circuit court at Boonville, Ind., last week. A total of sixty-two defendants were tried. Three of those found guilty received fines and jail sentences, two fines without jail sentences and thirty-three were fined $25 and costs. William Stinson, of Oakland City, Ind., district board member of District No. 11, United Mine Workers, was find $500 and given ninety days in jail. Ed Spencer was fined $400 and given sixty days, and Alvie Lenn, $350 and thirty days. Steve Evans was fined $350, and Ersie Spencer, $200, with no jail sentence.

When the jury's verdict had been read the judge continued the bonds in force and continued the case until May 4, when the men were to be sentenced. No intimation was given as to what action the United Mine Workers will take toward an appeal. The case grew out of occurrences at the John Bull and Possum Ridge mines on Feb. 16, when organized miners are alleged to have beaten several non-union miners at each of these mines. Of the total of sixty-five miners indicted, three never have been apprehended.

Mining Engineer Hammond Banqueted by His Friends

Dinners were held in South Africa, Japan and in many European and American cities May 3 in honor of John Hayes Hammond on his attainment of the age of 71, but the largest celebration was held in New York City, which "Jack" Hammond himself attended. The President of the United States, the governors of ten states, twenty ambassadors and foreign ministers, railroad presidents, generals and admirals sent felicitations by telegraph, cable and mail.

C. S. Thomas, former U. S. Senator from Colorado, presided, and the speakers were Dr. A. T. Hadley, president, Yale University, who went to school and college with Mr. Hammond and who studied at Berlin when Mr. Hammond was at Freiburg; J. J. Davis, U. S. Secretary of Labor, on whose board of education Mr. Hammond had served; Dr. Alexander C. Humphreys, president of Stevens Institute of Technology, where Mr. Hammond received the doctorate; Key Pittman, U. S. Senator from Nevada, who recorded Mr. Hammond's contribution to mining, which latter he declared to be the determining factor in civilization, without which the upward progress of mankind could, in fact, be scarcely conceived; Colonel Henry D. Lindsay, past national commander, American Legion, who spoke of Mr. Hammond's war services; J. W. Bryan, of the National Press Club, whose club house, now building, finds in Mr. Hammond almost a foster-father, and Rev. J. E. Freeman, Bishop of Washington, who spoke of Mr. Hammond as a cathedral builder and, though eminently successful, not so much a man of wealth and power as one in happy accord with his fellow men. Dr. Humphreys in his address called attention to the fact that Mr. Hammond exemplified the oft-repeated statement that a man trained as an engineer and having an engineer's qualifications and aptitudes made an ideal man for service in public affairs.

Messages were read from Calvin Coolidge, the recently deceased Luther Burbank, Vice-President Dawes, Cardinal Hayes, Mayor Walker of New York and Chief Justice Taft, all of which spoke of Mr. Hammond in the highest of praise.

Coal Consumption by Trains Higher in February

Coal consumption during February by Class 1 railroads of the United States in locomotives in freight and passenger train service totaled 8,351,191 net tons, compared with 7,973,137 tons in the corresponding month of 1925, according to a report by the Interstate Commerce Commission. Consumption by districts was as follows: Eastern, 4,057,632 tons; Southern, 2,048,680 tons; Western, 2,244,879 tons, compared with 3,861,919, 1,879,326 and 2,231,892 tons, respectively, in February of last year. [The average cost of coal used by these railroads, printed in *Coal Age* last week —page 614—was erroneously stated as for March. The figures were for February.]

Cassidy Mine Ordered Closed Because of Blowouts

Owing to a series of "blowouts," the last of which on April 6 caused the death of two miners, George Wilkinson, chief inspector of mines for British Columbia, ordered the closing of the affected section of the Granby Consolidated Mining, Smelting & Power Co.'s Cassidy colliery, in the Nanaimo district of Vancouver Island. Mr. Wilkinson stated that in the area affected, comprising some 20 acres, there had been 39 blowouts, or approximately one for every 150 ft. of driving. These blowouts often project heavy pieces of rock, and add considerably to the hazards of coal mining.

Charles Bocking, general manager; T. Plummer, comptroller for the Granby company, and Robert Henderson, superintendent of the Cassidy colliery, informed William Sloan, Minister of Mines, that the maintenance of the order would mean abandonment of further development in the southern area of the colliery, thereby limiting the life of the colliery to three and a half or possibly four years.

Mr. Sloan said that while he was anxious to assist the company in every way to bring production to the highest possible point, the safety of the miners was of primary importance. He said that careful consideration would be given to the situation by his department and a decision would be reached within two weeks.

Since the Cassidy mine was started, some six years ago, there have been 187 blowouts in different parts of it, and in 1921 there were two fatalities from this cause. The company employed George S. Rice, of the U. S. Bureau of Mines, to make an examination of the property, find the cause of the explosions, and suggest a remedy to safeguard the company's employees. Mr. Rice recommended that holes be drilled well ahead of the driving to relieve the gas pressure, and this practice has worked admirably in thick seams, but in development work, in driving through pinched portions of the seams, as in the instance of the recent fatal blowout, the practice recommended by Mr. Rice does not give the same warning, as the pockets of gas seem sometimes to escape the drillholes.

Chicago Association Expands

The Coal Division of the Chicago Contracting Team Owners' Association has been admitted to membership in the National Retail Coal Merchants' Association. Membership was obtained last week by Paul N. Snyder, manager of sales of the Calumet Coal Co., Frank Carey, of the Carey Coal Co., R. A. Miller, of Miller & Banker, and M. E. Robinson, Jr., of the M. E. Robinson Coal Co., all retailers with yards on the south side. About a year ago several members of the Chicago Coal Merchants' Association withdrew because of disagreements over policies and joined the Coal Division of the Chicago Contracting Team Owners' Association, which had previously been organized as a dual association in opposition to the Chicago Coal Merchants' Association.

Gay Mine Has First Fatality in Its History; In 22 Years Never Had Strike or Shutdown

For the first time in 22 years, the Gay Coal & Coke Co. had a fatality on April 28 at Gay mine, at Mount Gay, Logan County, W. Va. The mine had produced 4,000,000 tons of coal without a death. The Gay Coal & Coke Co. is the pioneer coal company in the Guyan Valley. The record is probably unsurpassed in the annals of the bituminous coal industry.

The fatal accident happened at 1:30 a.m., April 28, when Bud Wheatley, a negro, was caught by a slate fall and instantly killed. One hundred and forty men are employed in the mine, which was opened on Thanksgiving Day, 1904, when it was necessary to haul the coal in wagons to a siding in the town of Logan. Three teams did this work and three of the four teamsters were alive according to last reports, they being Tom Gilpin, Don Ellis and Jack Dempsey, heavyweight boxing champion.

In summing up the history of the mine, Robert M. Lambie, chief of the state Department of Mines of West Virginia, said in part: "Twenty-two years without a fatality; 22 years without a strike; 22 years without a shutdown; 22 years under the same active management."

H. S. Gay, president of the company, attributes much of the success of the low fatality rate to the systematic methods of F. C. Kellerman, foreman of the mine for the first 17 years of operation. Other factors, Mr. Gay said, were observance of the mining laws, good roof conditions, timbering done under the supervision of a company official, employment of native West Virginians with few exceptions and up-to-date transportation equipment and methods.

Ask Concessions on Deadwork To Open Ohio Mines

Several meetings of operators in the southern Ohio field, especially in the Nelsonville-Athens section, have been held recently at Nelsonville in an effort to obtain concessions from the various locals of the miners' union, which it is believed would enable some mines to resume operations. The matter is being worked out by the special scale committee and steps will soon be taken to have a joint meeting with union officials to consider the proposition. The proposal being worked out by the operators has to do with reduction in the cost of yardage, laying of track and setting of props as well as other small jobs. Under the Jacksonville scale miners are not permitted to do this work, but it is planned to get concessions which will permit mines to do such odd jobs and thus decrease the cost of production.

N. D. Monsarrat, head of Monsarrat Bros., operators in the Hocking field, has a plan which he will probably submit to the miners. His proposal is to have 60 per cent of the selling price go to the miners, to be divided equitably, and 40 per cent to the operators, the scale to be adjusted every three months and the miners having permission to audit the company's books. This proposition is not meeting with much favor among miners as a rule.

Southern Ry. Buys Equipment

The Southern Ry. has closed an agreement for equipment to cost $6,900,000. The purchases will include twenty Mikado type locomotives, ten consolidated type locomotives, twelve Pacific type locomotives, seven Mallet locomotives, twelve eight-wheel switching locomotives, four steel postal cars, twenty-five steel passenger coaches, fifteen steel baggage-express cars, 1,000 steel-frame coal cars, six steel mail-baggage cars, 1,000 box cars and 250 ballast cars.

Opening for Coal Economist

The U. S. Civil Service Commission announces an examination for assistant business economist (coal) to fill a vacancy in the Bureau of Mines, Washington, D. C., and vacancies occurring in positions requiring similar qualifications, for duty in Washington, D. C., or in the field. The entrance salary is $2,400 a year. After the probational period required by the civil-service act and rules, advancement in pay, without material change in duties, may be made to higher rates within the pay range for the grade, up to a maximum of $3,000 a year. Promotion to higher grades may be made in accordance with the civil-service rules as vacancies occur, provided the employees possess the qualifications deemed necessary for the corresponding advance in duties and responsibilities. Receipt of applications will close May 11, 1926.

The Commission also announces an examination for associate physicist ($3,000) and assistant physicist ($2,400), receipt of applications for which will close June 6. The examinations are to fill vacancies in the Bureau of Standards and the Bureau of Mines, Department of Commerce, and in positions requiring similar qualifications. At present there is a vacancy in the Bureau of Mines, in the position of assistant physicist, for duty at Pittsburgh, Pa. Advancement in pay may be made to $3,600 a year for associate physicist, and $3,000 for assistant physicist.

For physical chemist, applications will close May 25. The examination is to fill a vacancy in the Pittsburgh station of the Bureau of Mines and vacancies in positions requiring similar qualifications. The entrance salary is $3,800, and advancement may be made without change in assignment up to $5,000.

Information and application blanks may be obtained from the U. S. Civil Service Commission, Washington, D. C., or the board of civil service examiners at the post office or custom house in any city.

Miners Strike Over Wage Cut By Gilbert-Davis Co.

A possible break with the union by the Gilbert-Davis Coal Co., the last remaining company actively operating in the northern West Virginia field under an agreement with the United Mine Workers, was indicated late last week when miners at the company's plant in the Scotts Run district of Monongalia County, West Virginia, went on strike as soon as it became known that they were supposed to have been working on a reduced wage scale since April 1. The reduction amounted to 15 per cent.

At the meeting at which it was decided by union miners to discontinue work, James Rogers, president of the Gilbert-Davis local, admitted that he had been notified some time ago by R. M. Davis, general manager of the company, that a 15-per cent cut would be made April 1, but because no further notice had been forthcoming he had not notified the pit committee. A further conference was scheduled for early this week, it was stated by Sanford Snyder, international representative in charge of Monongalia County union affairs.

Snyder asserted that the union was not taking any backward step and that there could be no deviation from the Jacksonville wage scale.

Reorganization Sought

An attempt is being made to reorganize the Carbonizing Process Corporation, capitalized under Delaware laws at $1,000,000. Two of the stockholders —George W. Disher and George S. Johns—have filed suit for a receiver in the Circuit Court of St. Louis County at Clayton, Mo. The concern was formed to produce a low-temperature process for reducing oil shale and creating a smokeless fuel from coal. The Coal Products Engineering Co., a subsidiary, had the Missouri rights and operated an experimental plant at Affton, Mo., with offices in the Federal Commerce Trust Building, St. Louis.

The receivership petition alleges that the directors of the Carbonizing Process Corporation diverted funds of that company to the use of the Coal Products Engineering Co., which had an identical board of directors. Mismanagement, waste of property, assets and income also are charged.

It was further charged that large blocks of stock were issued without consideration to F. W. Love, George W. Marshall, O. W. Hoopaw and others, and that a reorganization in 1924 was carried through without the approval of a majority of the stockholders of the company.

Walter Barnum, president of the Pacific Coast Co., New York, which has coal operations in the State of Washington, is being urged strongly for the presidency of the National Coal Association. The suggestion seems to be regarded as a happy one by so many of the operators that some are predicting his election at the Chicago meeting, June 9-11.

Forty-Year Service League Of Union Pacific Co.

Those who have been with the Union Pacific Coal Co. twenty or more years are eligible to membership in the company's Old Timers' Association, which will hold its second annual meeting on June 6 at Rock Springs, Wyo. These youngsters of twenty years' service and the officials of the company, who are likewise eligible even though still more recent, have little standing in the organization alongside of the real old timers who have served more than forty years, of whom there are 24, including James Moon, president of the association and a trackman, who has served 52 years, and Thomas H. Butler, the mine superintendent at Hanna, Wyo., who can show only 45 years of service. One man has been with the company 49 years; three, 47 years; three, 46 years; four, 45 years; four, 44 years; two, 43 years; two, 42 years; three, 41 years, and only one 40 years.

Canadian Steamship Lines To Stay in Coal Trade

"There is no foundation for the statement that the Canada Steamship Lines, Ltd., is withdrawing from the coal business," said T. R. Enderby, general manager of the company, in commenting on recent reports current in Montreal to the effect that the company was likely to retire from the coal business.

"During the 1925 season an extensive business in the sale and handling of coal was carried on by its subsidiary, the Century Coal Co.

"Acquisition of the George Hall Coal & Shipping Corporation and the Great Lakes Transportation Co. will add to the equipment formerly used by the Century Coal Co."

Private Enterprise to Exploit Korean Coal Reserves?

Shanghai, China, Feb. 27.—A survey by the government general of Korea of reserve coal deposits in the Daido, Koto, Kosei, Junsen and Kaisen districts, South Heian Province, indicates a total of 600,000,000 tons. Calculating the annual demand in Korea at 1,000,000 tons, the reserves are sufficient for 600 years. It is understood that in exploiting these fields, the government general is in favor of leasing them to private interests for operation rather than developing them under government auspices.

Since improved traffic facilities, such as the Heijo-Gensan and Kan-Kyo railways and the harbors at Sei-shin, Yuki, and Chinnampo, are in a fair way of realization, according to Mr. Kuroki, chief of the mining section in the government general, it is likely that a decision in regard to exploitation of the coal fields will be made soon.

High Safety Records Made In Bronze Trophy Contest

Extraordinary records of production with no loss of time occasioned by accidents were revealed in connection with the announcement made April 29 by Secretary Hoover of the Department of Commerce, of the names of mines and quarries adjudged winners of the national safety competition held under the auspices of the Bureau of Mines for the bronze trophy, "Sentinels of Safety," donated by the *Explosives Engineer* magazine. A Maryland quarry operated 350 days and worked 202,663 man hours during 1925 with no loss of time from accidents. Four other quarries, located in Indiana, Tennessee, New York and California, also operated with no loss of time due to personal injuries.

The winner in the anthracite group is the Upper Lehigh mine, Upper Lehigh, Pa., operated by the Hazle Brook Coal Co. Honorable mention was accorded the Midvalley mine, Wilburton, Pa., operated by the same company.

The winner in the bituminous coal mining group is No. 6 mine of the United States Coal & Coke Co., at Gary, W. Va. Honorable mention was given the No. 3 mine of the same company, also located at Gary, and the Rossiter No. 4 and 5 mine, at Rossiter, Pa., operated by the Clearfield Bituminous Coal Corporation.

Members of the jury of award were H. Foster Bain, James F. Callbreath, W. H. Cameron, H. L. Gandy, A. T. Goldbock, William Green and H. G. Jacobsen.

Gets Life Term for Murder In Insurance Plot

William H. Turner, former superintendent of the Auburn Coal Co. mine at McCarr, Ky., under indictment for the murder of two miners on Jan. 17, 1925, in an alleged framed explosion was sentenced to life imprisonment April 29 by a jury in the Circuit Court at Pikeville, Ky. One of the dead men was identified as Turner and members of his family collected about $85,000 of insurance money. Later Turner, who had fled to Europe, turned up and confessed the plot, apparently as a result of his failure to get part of the money.

Evidence indicated that Turner and some of his relatives conceived the scheme of sending Henry Wilson and another man into the mine to fire a shot when no one else was in the mine. Wires apparently had been connected so that when the men made connections at the other end, the explosion took place. The men were so badly mutilated that it was impossible to identify them positively, as both were decapitated. Turner had left his coat, watch and other personal effects at the scene of the explosion.

The Artemus Jellico Railroad Co., a coal road from Artemus, Ky., to Anchor, formerly the Cumberland Railroad Co., has asked the Interstate Commerce Commission for authority to operate the line and right of extension. It is understood that the company plans connections through the mountains to Knoxville, Tenn.

Germany Resuming Old Place In Export Coal Market

Berlin, Germany, April 15.—Definite figures on the German exports and imports, now available, show 7,680,000 tons of bituminous coal imported in 1925, compared with 13,000,000 tons in 1924 and 10,540,000 tons in 1913. Exports last year were 13,645,000 tons. These figures clearly demonstrate that the foreign coal trade has again become an asset of German business. In 1924 imports of 13,000,000 tons were only in small part balanced by exports of 2,795,000 tons. In 1923, the year of the Ruhr occupation, exports were only 1,200,000 tons as against imports of 25,000,000 tons.

More marked still is the change in coke movement. Imports last year dropped to 69,000 tons, as compared with 338,000 tons in 1924. Exports, on the other hand, rose 3,776,000 tons. Although both imports and exports still remain behind those of 1913, the approach to pre-war conditions is unmistakable, especially when considering that large quantities of coal and coke going to France and Belgium under the Dawes plan are not included in the official statistics.

Of the 7,600,000 tons of coal imported nearly 4,000,000 tons came from former German possessions, the Sarre district, Polish Upper Silesia, and in a minor degree Alsace-Lorraine. Imports from Polish Upper Silesia, however, ceased during the second half of 1925 owing to the fact that the agreement reached after the partition of Upper Silesia, stipulating monthly shipments to Germany of approximately 500,000 tons, has expired and presumably will never be renewed.

Britain Only Exporter to Germany

The present situation leaves Great Britain practically the sole exporter to Germany of coal and in a lesser degree also of coke. As far as British imports are concerned, it is partly based upon the fact that the British market is still able to offer coal in German districts reached by water transportation at or below corresponding German prices. Quality also plays some part. Vigorous endeavors are being made to eliminate British coal from the German market as far as it is bought in consideration of prices, but preliminary figures of business within the first months of the year indicate no success of this movement in spite of special freight rates having been granted for coal shipped to districts in which British competition is most pressing. The increased coal exports of 1925 are a reward of the strenuous efforts made in this direction.

German coal has made progress in nearly all its pre-war markets, with the exception of the Austro-Hungarian successor states, Russia, Belgium and France, which latter two countries still receive considerable quantities on reparation account. Furthermore, a number of new countries are registered as a market of German coal in the definite returns of 1925 which were not listed in those of 1913. Among such may be mentioned Norway, Portugal, British Mediterranean, Dutch India, Turkey and Uruguay. The best coal customer is Holland.

Traffic News

No Cut in Belleville Rates To Missouri River

Equalization of rates from the Belleville district to Kansas City and St. Joseph, Mo., and Atchison and Leavenworth, Kan., with rates in effect from the Springfield district of Illinois via the Alton and Wabash railroads has been denied by the Interstate Commerce Commission in a decision in *Fifth & Ninth Districts Coal Traffic Bureau vs. Chicago, Rock Island & Pacific Ry. Co. et al.* The Commission, in an opinion by Commissioner Meyer, finds the existing rates from the complaining field neither unreasonable nor unduly prejudicial.

The case just decided is another chapter in the fight over rates to Missouri River crossings and related points which started ten years ago when the Chicago & Alton slashed its charges from Springfield to Kansas City and, as a result, built up its fine coal movement from practically nothing to over 500,000 tons per year. The Wabash, not to be outdone, met the cut via its Hannibal route. Other roads, however, have never reduced their rates to the Alton-Wabash levels.

Prior to the summer of 1916, the rates from Belleville, except via the Southern Ry., were 25c. per ton higher than from Springfield and rates from the group of mines immediately north of the Belleville district proper were on a parity with the Springfield district rates to Kansas City. At the present time the Wabash and Alton rates from the Springfield district to Kansas City are $2.49 on fancy lump, $2.37 on commercial lump and $1.98 on fine coal.

Via the Burlington the rates are $2.89 on lump and $2.38 on fine coal; via other routes rates of $2.98 and $2.92 are in effect. Lines charging $2.98 and $2.92 extend those rates to the other destination points involved; via the Wabash and Alton, a differential of 40c. per ton over the Kansas City rates is in effect.

Except via the Burlington, where a $3.28 rate is in effect on lump, complainants' mines are charged $2.98 on lump and $2.92 on fine coal.

The Alton was originally a defendant in this case, but complaint against it was withdrawn by the complainants. This, the Commission, held, narrowed down the question of undue prejudice to the Wabash R.R. This latter line was not responsible for the reductions from the Springfield district, but merely followed the lead of the Alton to protect its traffic. The Commission, therefore, found the charge of undue prejudice was not sustained.

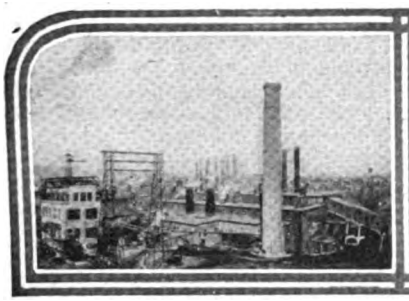
Penna. Rate Makers Reversed

The Pennsylvania Public Service Commission was without authority to reduce freight rates on intrastate shipments of coal within six months of the return of the carriers to private control from federal control under the Transportation Act of 1920, the U. S. Supreme Court held April 26 in a decision by Justice Holmes. The decision reversed the rulings of the state courts, which had ordered the Pennsylvania and New York Central railroads to grant reparations to the New York & Pennsylvania Co., a shipper, for alleged overcharges on intrastate shipments of coal during the period involved.

At Odds on Coke Rates from Alabama to Michigan

A hearing was held before the coal, coke and iron ore committee, representing coal-carrying railroads, in the Chamber of Commerce, Pittsburgh, Pa., on April 29, to consider the continuation of emergency rates on coke from Birmingham, Ala., to points in Michigan, instituted during the anthracite strike. The emergency schedule expired April 30. The Birmingham interests asked continuation of the emergency rates. Byproduct plants in the Connellsville region were willing that through rates be continued, but contended that they should be on a higher level than the rates which expired.

No decision was reached by the committee and the matter probably will get before the Interstate Commerce Commission in an informal way in an effort to find some common ground and fair basis to both the Southern and Northern operators. These rates have already been the cause of considerable litigation before the I. C. C., the Northern interests having opposed their establishment before they were instituted. The rate from Connellsville to Detroit, 372 miles, is $3.65; Birmingham to Detroit, 742 miles, $4.65; Connellsville to Grand Rapids, 490 miles, $4.16; Birmingham to Grand Rapids, 767 miles, $4.91.



Indiana Miners and Operators Ask More Favorable Rates

Representatives of the coal mining industry in Indiana, including both operators and miners, are urging the state Public Service Commission to use its influence in bringing about a change in freight rates so that Indiana coal may compete with coal produced in Kentucky, West Virginia and other states. The complaints against prevailing rates were presented April 23 at the request of the state mining board.

The conference was held behind closed doors and attendants refused to discuss the plans considered. It was suggested that the Interstate Commerce Commission make a change in the rates with a possible view to raising them as they relate to some of the other zones and lowering them as they affect the Indiana field. The particular shipping destination point seemed to be Chicago and surrounding territory.

Members of the mining board, all of whom attended the conference, are: William A. Mitch, secretary-treasurer of District 11, United Mine Workers, and John A. Templeton, operator, both of Terre Haute; Tyler G. Lawton, of Bicknell, president of District 11; Jonas Waffie, of Terre Haute, and Albert Daly, of Knightsville, state mine inspector. Others who attended were Warren Blauvelt, William Zellars, Jet Moorman and B. E. Neal, operators. The commission made no promises, but heard the arguments advanced.

News Items From Field and Trade

ALABAMA

Convict Probe Broadens.—Inquiry into the death under mysterious circumstances of James W. Knox, a convict at the Flat Top camp, has been steadily widening as new witnesses appear before the Grand July. The Grand Jury will investigate conditions at other convict camps, including the Banner Mines, and possibly the entire convict leasing system and some of the high officials. Reports indicate that the Grand Jury's attention had been called to two other deaths at Flat Top under conditions similar to Knox's. A visit to the Banner camp and another to Flat Top are scheduled.

A new steel tipple is being erected and other improvements made to facilitate handling and preparation of output at the Parrish mine of the Railway Fuel Co. This operation, on the Mary Lee seam in Walker County, is one of the largest producers in the district, the output being in excess of 600,000 tons annually. It is a subsidiary of the Southern Ry., the lines of this system taking the entire output for locomotive and other fuel requirements.

The Southeastern Coal Co., formerly the Winona Coal Co., is erecting 50 five-room houses for employees at its mines at Gorgas.

COLORADO

Coal output in Colorado in March was 791,000 tons, an increase of 170,000 tons over the corresponding month of 1925, according to the state coal mine inspector's report. This increase in production was obtained with 12,296 men employed, compared with 13,008 a year ago.

The Colorado Fuel & Iron Co. reports for the first quarter of the year a surplus after all charges of $1,121,115, against $569,752 in the same period a year ago. Gross receipts were $10,557,454, in comparison with $10,866,067, while operating expenses were $8,571,837, in contrast with $9,429,861.

Examinations for deputy state coal mine inspector will be held at the Capitol Building, Denver, June 3, 4 and 5, under supervision of the Civil Service Commission. Applications must be filed by May 25. On the same dates at the same place, examinations will be held for mine officials by the state board of coal mine examiners.

INDIANA

According to an order by Judge Caleb J. Lindsey, L. A. Folsom, receiver, will receive bids for the Pigeon Creek Coal Co. strip mine property at Boonville for thirty-five days. The company has been operating under a receivership for some time. A portion of the property consists of a large acreage of strip coa . In case the receiver shall receive a bid sufficient to discharge all liens against the property, he was ordered to report to the court. If bids are insufficient, the receiver was ordered to sell the property at public sale on the fifteenth day following the expiration of the thirty-five days.

Plans are under way for a third coal mine at Somerville, 25 miles north of Evansville, to be operated by the same company which is now operating mine No. 1 at Somerville. The new mine will be known as mine No. 3 and will give employment to between 100 and 200 men, it is announced.

According to William Mitch, secretary-treasurer of the Indiana miners' union, a rock-dusting bill was passed at the last session of the state Legislature which compelled rock dusting in gassy or dusty mines, but it was lost somewhere between the Legislature and the Governor's office and therefore never was signed and did not become a law. The miners are preparing another similar bill for the next Legislature.

The Possum Ridge Coal Co.'s mine between Evansville and Boonville, has been closed down for several weeks while the company has been constructing a new airshaft at the suggestion of the state mine inspector.

KANSAS

The suggestion that the Kansas state mine-rescue and first-aid meet be held at Pittsburg later this year was definitely rejected at a meeting in Pittsburg on April 26. A couple of weeks before, plans for holding the meet in Pittsburg in May were halted because of lack of money. It is probable that a meet of smaller scope than that originally planned will be held in connection with Labor Day festivities at Arma.

Work Was Resumed April 17 at Jackson-Walker Coal & Mining Co.'s mine No. 16, near Dunkirk. The mine had been closed down six weeks. It is operated under lease by John Fulton.

At the mine examinations in Pittsburg, April 17, seven men sought certificates as shotfirers; three as gasmen, five as engineers and eight as mine foremen.

Fire of Unknown Origin during the night of April 19 destroyed the tipple and top buildings at Hamilton Coal & Mining Co.'s mine No. 7, near Radley. The mine was operated under lease by the Englevale Coal Co. The structures will be rebuilt.

KENTUCKY

An explosion early the morning of April 27 occurred while Burley Fugate and Jeff Wilson, inspectors for the Duvin Coal Co., at Providence, were making an inspection prior to start of the day's work in the mine. Wilson was cut off by a slate fall and was later taken from the mine dead. Fugate was not injured, and was able to get to the surface and call assistance. The mine caught fire, but the blaze was put out and the barricade removed within a few hours.

Orlando Seymour, 18 years of age, self-confessed slayer of William Schanzenbacher, 33 years of age, manager of one of the yards of the St. Bernard division, West Kentucky Coal Co., Louisville, has been sentenced to death for the crime. Seymour and a boy named Huddleston tried to hold up Schanzenbacher and take company money, which the latter was taking to his home for safe keeping. Evidence showed that the boy demanded the cash, and then started shooting. The other boy hasn't been tried as yet.

The West Kentucky Coal Co. discontinued the loading of coal at its South Diamond mine, near Morton's Gap, on May 1. The mine has been operated for 40 years. The company will continue to mine coal from workings of the mine but it will be hauled to the tipple of the Fox Run mine of the company, near St. Charles, where coal from both mines will be loaded into railroad cars. Employees of the mine will be distributed at the Arnold Nos. 9 and 11 mines, near Earlington, and at Fox Run mine.

MINNESOTA

The Carnegie Dock & Fuel Co. has taken over the business of two prominent independent retail concerns, the Crail Coal Co. and the Murray Coal Co. The Carnegie company already had yards in St. Paul and Minneapolis.

OHIO

Bids will be received by the clerk of the Cincinnati Board of Education until May 10 for supplying public schools with coal in the following amounts: 10,445 tons of smokeless mine-run, 5,115 tons of bituminous nut and slack, 1,466 tons of bituminous lump and 541 tons of bituminous mine-run.

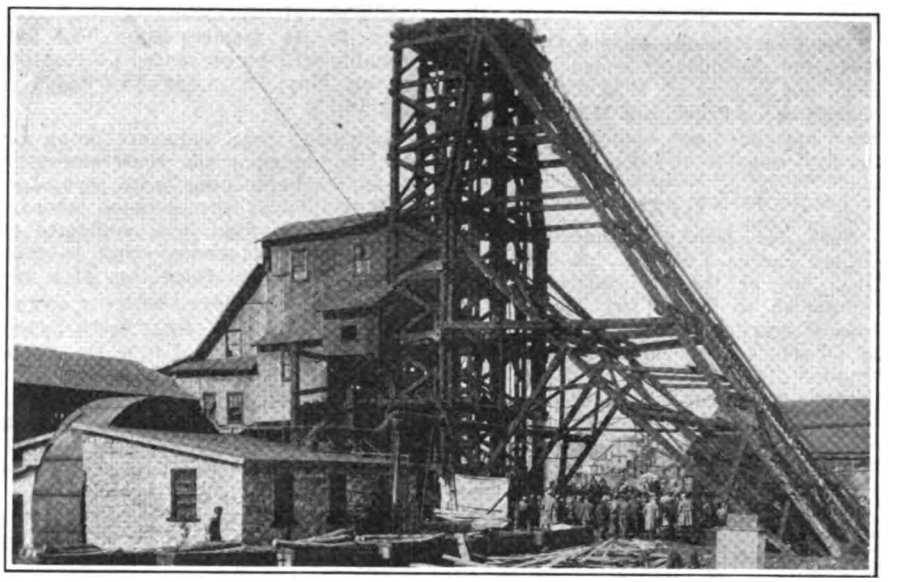
The tipple of the Preston-Morgan Coal Co.'s mine near Nelsonville was burned to the ground recently, entailing a loss of about $18,000. It is doubtful if the tipple will be rebuilt for the time being at least.

Digitized by Google

The Columbus Board of Purchase has rejected all bids for 21,700 tons of Ohio nut, pea and slack which were opened April 14. The board was authorized to purchase coal for the various city departments on the open market for the time being. The W. S. Harman Coal Co., Columbus, was low bidder at $1.24 per ton for 15,000 tons Hocking nut, pea and slack while the Red Jacket Consolidated Coal & Coke Co., Columbus, was low bidder on 6,700 tons of West Virginia nut, pea and slack, at $1.25 per ton for the Water Works Department.

Charles Minich, of Greenville, has been appointed receiver for the Ohio Tennessee Coal Co., which owns 4,700 acres of land in Monroe County. Directors in filing a receivership petition declared the company had assets of $556,763 but was in danger of insolvency because of threatened foreclosures. The company was organized to mine coal in the southeastern Ohio field.

OKLAHOMA



The Cambridge Collieries Co., which has 14 mines in the vicinity of Cambridge, is preparing to operate after a year's shutdown. The company has promulgated an adjusted wage scale based on the 1917 agreement and has announced its intention of opening its mines "with or without the miners' union."

PENNSYLVANIA

Lewis to Boost Pinchot.—John L. Lewis, international president of the United Mine Workers, will campaign in Pennsylvania next week in the interest of the candidacy of Governor Pinchot for the Republican nomination for United States Senator. Mr. Lewis will be accompanied by Thomas Kennedy, international secretary, and Philip Murray, vice-president. May 10 and May 11 will be spent in the soft-coal fields of western and central Pennsylvania, and the remainder of the week in the hard-coal regions. The officers of the five districts of the United Mine Workers in Pennsylvania recently indorsed the candidacy of Mr. Pinchot. The primary will be held on May 18. The other candidates seeking the Republican Senatorial nomination are Senator George Wharton Pepper and Congressman William S. Vare.

The Kuhn Brothers mine at Cokeburg Junction, one of the largest independent mines in the district, has resumed operations under the Jacksonville wage scale. The mine, which had been idle for several months, employs 600 men when operating at capacity.

Osborne Mine Resumes Open-Shop.—The Youghiogheny & Ohio Coal Co. has reopened its Osborne mine, at Wyano, on a non-union basis. The first attempt to operate was made Monday, May 3. The scale is not exactly the 1917 list, in some respects being slightly higher and in others slightly under. Prior to reopening the company posted notices calling on former employees to return to work, saying that a number of them had made overtures for the resumption of the mine. The mine had been shut down since July, 1924.

Crab Orchard Tipple, Eccles W. Va.

Shows surface plant of the Crab Orchard Improvement Co., where nineteen men perished in two explosions on March 8. The first blast occurred in Mine No. 5, where twenty-nine men were working, and spread to No. 6, where thirty-seven others were engaged. Forty-seven were rescued. In April, 1914, an open light caused a coal-gas explosion in No. 5 mine, in which 186 men lost their lives. The Crab Orchard company is a subsidiary of the Stonega Coke & Coal Co., controlled by the Wentz interests.

The Superior Court of Pennsylvania last week sustained the conviction of John A. Bell, former Carnegie banker and coal operator, and refused his appeal for a new trial. He was found guilty of embezzling and misapplying more than $600,000 of the funds of the Carnegie Trust Co., of which he was president.

Net earnings of $93,352, after charges, are reported for the first quarter by the Cosgrove-Meehan Coal Corporation. This is equal to 37c. a share on the 240,462 shares of common stock outstanding. Earnings for that quarter in 1925 were $18,353.

The Cowanshannock Coal & Coke Co. is building at its mine near Yatesboro a modern steel tipple similar to the one built by the Rochester & Pittsburgh Coal & Iron Co. at Ernest.

What has been referred to as a "monkey breaker" has been placed in operation by the Philadelphia & Reading Coal & Iron Co. at its Alaska mine, near Mount Carmel, where the breaker was recently destroyed by fire. This so-called "monkey breaker" was erected in record breaking time and coal is now being prepared in steam sizes for the market. The men laid off by the breaker fire have already returned to their former positions. In the meantime the coal company is pushing work on plans for the new steel breaker at the Alaska mine.

Oscar B. Goodyear and others have purchased from Madeira, Hill & Co. the entire capital stock of the Ashman Coal Co. Mr. Goodyear and his associates have taken over the operation of the Ghem mine, at Munson, including the sale of the coal.

Officials of the Hudson Coal Co. are anxious to purchase outright the cemetery of St. Hedwig's Polish Catholic Church at Larksville. Some time ago the company offered to move all of the bodies to a new cemetery and pay something for the change besides but the offer was rejected. It is the desire of the company to mine all the coal beneath the burial grounds. Most of the members of this congregation are mine employees.

Pinchot Can "Fire" Coal Police.—Whether or not Governor Pinchot is contemplating making wholesale dismissals among the coal and iron police he has just asked for and received an opinion from Attorney General Woodruff which informs him that he can dismiss them "to the extent of elimination." The Governor's grievance seems to be with the coal police, and the Attorney General in his decision on the points raised by the Executive says that during the past sixty years there have been complaints that the special policemen have been used in a way "to harass and oppress the striking miners of certain parts of the Commonwealth." A year ago twenty coal and iron police were dismissed from service in the western part of the state.

The Pennsylvania Coal & Coke Co. and subsidiaries report March deficit of $46,470 after charges, ordinary taxes, depreciation and depletion, but before federal taxes, against a deficit of $39,910 in March, 1925. Deficit for the first three months of 1926 totaled $20,205, comparing with a deficit of $158,684 in the same period of the previous year.

After baffling all efforts of fire fighters for many years a blaze in the old Jersey mine, in Plymouth township, is now beyond control and as a result the Glen Alden Coal Co. has closed operations at the Avondale mine, and the George Lindsay Coal Co., an independent concern, also has been forced to curtail mine production, putting 1,000 men and boys out of work. Several workers of the Avondale and Lindsay mines were overcome by blackdamp while fighting the flames. All modern methods are being used to fight the blaze, but officials admit the situation has become serious.

TEXAS

The Texas Pacific Coal & Oil Co. reports for the quarter ended March 31, 1926, net income of $774,522 after expenses and charges, but before depreciation and depletion, against $493,126 in the first quarter of 1925.

UTAH

Sues for Heavy Damages. — The United States Fuel Co., of Salt Lake City, one of the two largest mining companies in Utah, has filed suit in federal court against the Lion Coal Co., of Ogden, to recover damages in the amount of $173,400.88. The two companies own adjacent properties in Carbon County and the plaintiff company alleges that in underground workings the Lion company has extracted $10,684 worth of coal from the ground belonging to it. It is further charged that the workings of the Ogden company have shut off from the United States Fuel Co.'s mine coal valued at $51,996.78. The plaintiff company charges that defendants have mined the coal entirely away from the adjoining boundary, making it necessary to leave pillars 100 ft. wide. The Industrial Commission of Utah requires that pillars 50 ft. wide shall be left at the exterior borders of a coal mine as a safety precaution.

VIRGINIA

For the first quarter of 1926 the Clinchfield Coal Corporation reports a net income of $126,684, after fixed charges and federal taxes, compared with $158,450 in the same period last year. The 1926 earnings are equal, after preferred dividendes and preferred-stock sinking funds, to 63c. a share on 145,476 shares of common stock, while the 1925 quarterly income equaled 86c. a share.

WASHINGTON

E. L. Brewer, of Satsop, has been elected president of the Morton Coal Co., which owns a valuable property at that place. J. W. Strubel, Elma business man, was chosen vice-president, and J. M. Bell, of La Grande, secretary. John McDonnell, of Morton; Floyd Sherwood, of Ajlune, and H. W. Gibson have been added to the board of directors. Plans have been made to develop a daily output of 300 to 400 tons.

New washing machines are being installed at the Bellingham coal mines.

WEST VIRGINIA

To Hear Coal Men on Taxes.—Taxation in West Virginia as it affects coal will be discussed by prominent coal men during a series of public hearings to be conducted by the tax commission of seven appointed by Governor Gore under legislative resolution to investigate and report on the question of revenue for state purposes. Meetings are to be held at Bluefield, May 10; Huntington, May 12; Charleston, May 14; Martinsburg, May 31; Clarksburg, June 2, and Wheeling, June 4. The West Virginia Coal Association is preparing a brief with particular reference to comparative receipts and expenditures since 1910, together with a résumé of such information as has been heretofore issued through the offices of the association to its membership. The brief probably will be presented at Huntington on May 12 or at Charleston on May 14.

Admitting that plans are going forward to organize the coal miners for collective bargaining with operators, R. M. Williams, former union leader in the Fairmont field, has confirmed reports that he is endeavoring to enlist supporters in the formation of a new labor organization.

The Maryland Coal Co. has reopened its No. 2 mine at Wendell, in the Taylor County field, giving employment to about 300 miners. It is possible, officials state, to operate the mine from three to five days a week, and indications point to steady operations for some time to come. It is possible, according to reports, that the Permid and Morgan mines at Hardman will resume operations soon, after being closed down for several months.

Carl L. Hornor, of Clarksburg, has been named as receiver for the personal property of the Wilbur Fuel Co., operating a mining plant at Lost Creek, Harrison County, on petition of H. D. Talbott Co., Inc., a general insurance and bonding concern. The Talbott company claims that it holds a debt of $7,991.51 against the Wilbur Fuel Co., the Thermal Coal Co., the Vulcan Coal Co. and others, and that there is an indebtedness of $700,000 against the Wilbur company, which is said to be unable to meet the obligation. Back pay of $12,000 also is said to be due miners.

Rock-dusting is nearly completed in the Carolina mine, No. 86, of the Consolidation Coal Co. Limestone has been used in nearly all of the workings and the treatment will be repeated as needed.

Administration offices of the Sycamore Coal Co., operating in the Winifrede seam near Williamson, will be removed to Huntington, quarters in the First Huntington National Bank building having been leased. S. W. Patterson and George Patterson, brothers, owners of the company, are residents of Huntington and are active in the civic and business life of the city. Production of the Sycamore mines is handled through the Old Ben Coal Corporation, Chicago.

One of the largest gatherings of mining men in southern West Virginia will be held in the Look Creek Y. M. C. A. at Mount Hope on Saturday evening, May 8, when the Fayette County and Raleigh County Mining Institutes and the men in the mining extension department of West Virginia University, Morgantown, will hold a banquet.

The West Virginia Eagle Coal Co. Boncar, Fayette County, is erecting a tipple with shaker screens, picking tables and loading booms at a cost of $25,000. The Eagle and No. 2 gas seams are worked there and the plant will have a capacity of 1200 tons.

A wooden tipple of the Davis Creek Land & Coal Co., five miles from Charleston, was burned down on April 24.

According to an announcement made on May 1 by Robert M. Lambie, chief of the state Department of Mines, 115 safety meetings were held in West Virginia during March.

E. W. Tildesley, president, and Sidney S. Stone, secretary and treasurer of the Tildesley Collieries Co., a coal sales agency of Charleston, which went into bankruptcy several months ago, were sentenced on April 30 by Judge McClintock, in federal court in Charleston, to serve two and a half years in the federal penitentiary in Atlanta, Ga. Both men entered a plea of guilty to using the mails to defraud in that they gave false financial ratings and statements. Failure of the concern caused three coal companies to go into bankruptcy, according to reports.

The New River & Pocahontas Consolidated Coal Co. has just completed work on a new steel tipple at its Kaymoor No. 1 mine. It is a four-track structure, capable of handling 250 tons of coal an hour. An output of 900 tons a day is now being handled over it. With better facilities now available for handling output at the No. 1 mine and with a decreased demand for coal, the No. 2, mine, at South Fayette, has been closed indefinitely.

The Ephraim Creek Coal & Coke Co. near Thurmond, Fayette County, has started to rock-dust its mine, according to a report received by the state Department of Mines, in Charleston.

The Camp Branch Coal Co., Greendale, Nicholas County, is planning to install a new tipple at its operation, according to reports.

WISCONSIN

The Stott Briquet Co. is enlarging its briquetting plant at Superior to increase its capacity. A new dryer will be added to the equipment. The present rated capacity of the plant is about 60 tons per hour and the improvements will permit an hourly output of 90 tons of briquets made from anthracite dust.

CANADA

J. S. Woodsworth (Labor, Winnipeg North Centre) called attention in the Dominion House of Commons April 23 to a report appearing in an English newspaper to the effect that 10,000 Welsh miners were coming to Canada in connection with a scheme which would "revolutionize coal mining in Canada." If this report were correct, had these men been informed of conditions in the Dominion? Charles Stewart, acting Minister of Immigration and Colonization, replied that he had no knowledge of the scheme to bring these miners to Canada or the proposed development.

Representatives of 25 municipalities in various parts of Ontario met in Toronto April 27 to consider the coal situation. The meeting was addressed by Premier Ferguson of Ontario and Premier Brownlee of Alberta, and a resolution was adopted calling for the appointment of a special committee to make an effort to obtain a supply of Alberta coal for Ontario. The speakers urged that, if necessary, the traffic be encouraged by a government subsidy.

Among the Coal Men

A. J. Johnson, who recently severed his connection with the Standard Elkhorn Coal Co., Garrett, Ky., as vice-president and general manager, is now president of the Jacks Creek Coal Co., Johnsonia, Ky. His successor with the latter company is **H. H. Davis**, of Huntington, W. Va., formerly general manager of the Kentucky Elkhorn By-Product Coal Co., Dorton, Ky.

A. T. Watson has been appointed director of purchases and stores of the Consolidation Coal Co., with headquarters at Fairmont, W. Va., effective May 1. He has been succeeded as general purchasing agent by F. C. Davis. C. S. Moss, who was in charge of the stores of the Kentucky division, has been appointed general manager of stores with headquarters at Fairmont. The announcement of the changes was made by F. R. Lyon, vice-president in charge of operations of the Consolidation company, the appointments having been approved by C. W. Watson, president of the company.

R. C. ("Jack") Ferrell has resigned as secretary of the Logan Fuel Co., coal wholesalers, with offices in Charleston, W. Va., to accept a position with the Kanawha & Hocking Coal Co., at Longacre. C. A. Pauley, who had been Mr. Ferrell's assistant for some time, has been made secretary of the Logan Fuel Co. The changes were effective April 1.

George Wolfe, former secretary of the Winding Gulf Operators Association, underwent an operation last week which will keep him several weeks in a hospital. Mr. Wolfe was injured while exercising in the Y. M. C. A. gymnasium at Norfolk, Va.

C. W. Watson, president of the Consolidation Coal Co., has been elected to the executive committee of the Elk Horn Coal Corporation, succeeding J. W. M. Stewart, of Ashland, Ky., and to the board of directors, succeeding Harry Clark, of Fairmont, W. Va. The Consolidation Coal Co. stockholders at their annual meeting elected **G. J. Anderson**, executive vice-president, a director to succeed George C. Jenkins, resigned.

G. J. Anderson, executive vice-president of the Consolidation Coal Co., has been elected a director to succeed George C. Jenkins, resigned.

John A. Emslie has been appointed by general sales manager J. E. Westervelt, of Castner, Curran & Billitt, as the company's resident sales manager at Cincinnati. He was vice-president and general manager of the Creech Fuel Co. His place in the latter company has been taken by **Cliff R. Thomas**, long associated with the organization. **Elmer Wierhake**, who was for many years with the Kentenia Coal Co. and who opened the Cincinnati office for the General Coal Co. in 1924, has been appointed assistant to Mr. Emslie and will have charge of distribution for the company in Ohio.

A. B. Thurman, for a number of years property man for the Crowe Coal Co., has been appointed justice of the peace in Arma, Kan., to succeed Henry Forsyth, another former coal company employee, who died recently after having served as justice in Arma for many years.

Paul Shriver, for eight years a member of the Norfolk staff of the Smokeless Fuel Co., has accepted a position in the Norfolk office of the Consolidation Coal Co., which is enlarging its force. His position with the former concern has not been filled.

George S. Brackett

George S. Brackett, head of the Brackett Statistical Service, Fairmont, W. Va., became identified with the Consolidation Coal Co. on May 1. The understanding is that Mr. Brackett's work will be similar to that which he has done for the operators as a whole in the northern West Virginia field. The Brackett Service has been replaced by the Northern West Virginia Coal Bureau, which will operate under a governing committee of five operators, of which J. A. Clark, Jr., is chairman.

Milton Goodman resigned April 1 as sales manager of Richards & Sons, producers of Indiana coal, to manage his own company, the Gibraltar Coal Corp., 1930 Straus Building, Chicago. Mr. Goodman is president of the Gibraltar company, which is newly organized. **E. E. Munger** will be associated with him as vice-president. They will handle all coals, principally southwestern Indiana, southern Illinois and western Kentucky. **H. L. Jump** succeeds Mr. Goodman as sales manager of Richards & Sons. Mr. Jump comes from the eastern department of the company.

R. S. Frazier, for the past five years engineer at the Hiawatha mine of the United States Fuel Co., Hiawatha, Utah, has resigned to take up orange-growing in California.

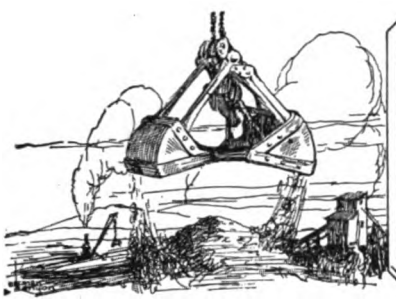
Obituary

S. M. Williams, Former Head Of Burns Bros., Dies

Stephen M. Williams, former vice-president of the Central Railroad of New Jersey and chairman of the board of directors of Burns Brothers' Coal Co., died April 29 at the Hotel Majestic, New York City, in his eighty-seventh year.

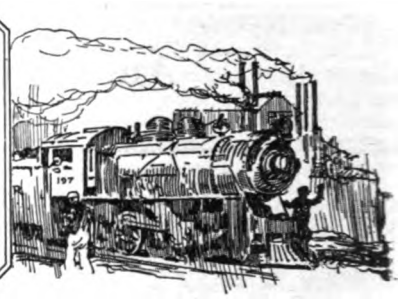
He was born and educated in New York City. While a young man he entered the service of the Central Railroad of New Jersey in a minor capacity. After rising to the vice-presidency he retired about twenty years ago and became interested in several coal companies in New Jersey. When they were merged several years ago with Burns Brothers, he became an official of that corporation. He had not been active in business in recent years.

During the eighties and nineties when he lived in Roselle, N. J., Mr. Williams was active in New Jersey politics, serving several times as chairman of the Democratic State Convention.



W. H. D. Gibson, vice-president in charge of sales of the J. K. Dering Coal Co., Chicago, died from heart disease April 25 at San Antonio, Texas. He was buried April 27 in Oakwood Cemetery, following funeral services at Oakwood Chapel at 3 p. m. Mr. Gibson was 55 years of age and is survived by a brother and two sisters. He began as an office boy with the Chicago & Eastern Illinois R.R. and rose to the general freight agent position from which he stepped into the organization of the J. K. Dering Coal Co.

William Potter, who was appointed by President Wilson during the war as Federal Fuel Administrator for Pennsylvania, died April 29 at the Jefferson Hospital, Philadelphia, Pa., following an operation for appendicitis. Besides being the head of the large oilcloth manufacturing business of Thomas Potter's Sons, he held many positions of importance, being at one time ambassador to Italy, and at his death he was president of Jefferson Medical College, Philadelphia.



Association Activities

The Virginia Coal Operators' Association at its annual meeting, April 17, elected the following officers: President, Lee Long, president, Clinchfield Corp., Dante; Vice-president, Webb J. Willis, president, Norton Coal Co., Norton; Secretary-Treasurer, C. B. Neel, Norton. The directors include the officers and Douglas Terpstra, general manager, Premier Red Ash Coal Co., Red Ash; A. W. Wagner, president, Virginia-Lee Co., St. Charles; J. D. Martin, general superintendent of coal mines, Virginia Iron, Coal & Coke Co., Roanoke; R. E. Taggart, vice-president, Stonega Coke & Coal Co., Big Stone Gap, and R. S. Graham, vice-president, Wise Coal & Coke Co., Norton.

Digitized by Google

Production And the Market

Soft-Coal Trade Suffers from Waiting Policy; Anthracite Demand Quiet but Steady

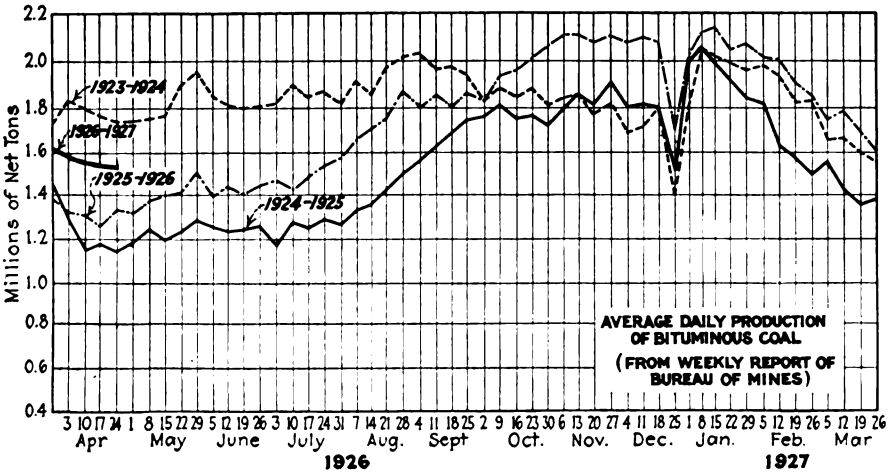
Positive progress toward stability in the bituminous-coal trade is still difficult to discern, developments during the last week having been largely of a negative character. While the British labor tie-up brought about by the collapse of negotiations between the coal miners and operators will inevitably influence the coal trade on this side of the Atlantic, its effect at first will be more of a psychological than a tangible nature. It is too early at this writing to foresee how far-reaching its results may be, which will depend on the extent of the strike and how long it lasts.

Delay in the opening of lake navigation continues to limit the movement of tonnage from eastern Kentucky and West Virginia, which is having a depressing effect on sentiment in those fields. General industrial demand is good—in fact, is increasing in some lines—but open-market buying is keeping producers on the ragged edge. Contracting is backward in all markets, Mr. Micawber's policy being played for all it is worth.

Shift to Non-Union Coal in Midwest Still On

Large Middle Western consumers continue to shift from Illinois and Indiana coals to the cheaper output of non-union mines, the latest development along that line being the recent decision of one of the railroads to close its own Illinois mines and obtain its fuel supply from the docks. Smokeless coals showed renewed strength in the Chicago market last week because of export possibilities, and in Cincinnati an advance is expected within a fortnight. The Hocking Valley Ry. has lifted its embargo on shipments from southern West Virginia to Toledo, but fears are felt that there will be another tie-up unless navigation opens soon. Trade continues quiet at the Head of the Lakes and in the Southwest. The general sluggishness is unrelieved in central and eastern Ohio, western and central Pennsylvania and at Buffalo.

A slightly firmer tone has appeared in New England, due to the possibility of a demand from British shippers. At New York a more cheerful note prevails; surplus tonnages are diminishing and increased activity in contract renewals is expected. The Philadelphia, Baltimore and Birmingham markets are marking time.



Price changes have been so slight as to make scarcely any appreciable difference in the average figure, *Coal Age* Index on May 3 standing at a fraction under 159 and the corresponding price at $1.92, a decline of about 1c. from the preceding week.

Production of bituminous coal also varies but little from recent levels, the total for the week ended April 24 being estimated by the Bureau of Mines at 9,251,000 net tons, a decline of 54,000 tons from the preceding week. Anthracite output continues to advance slightly, as shown by a total for the week ended April 24 of 2,095,000 net tons, an increase of 9,000 tons over the week before.

Domestic Hard Coal Firm; Steam Sizes Weak

Company producers of anthracite are moving domestic sizes without much difficulty, though buyers exhibit no unseemly anxiety to place orders. Independents are able to obtain only small premiums for their product, with pea in best demand. The weather has helped current demand, but buying for spring and summer fill-ups is below normal. May 1 circulars continue the price basis established at the close of the anthracite strike, as forecast in *Coal Age* at that time. Steam sizes are feeble.

The Connellsville coke market is dull, and an increase in spot offerings threatens to depress prices still further.

Estimates of Production
(Net Tons)

		1925	1926
BITUMINOUS			
April 10		7,843,000	9,420,000
April 17 (*a*)		7,515,000	9,306,000
April 24 (*b*)		8,030,000	9,251,000
Daily average		1,338,000	1,542,000
Cal. yr. to date	(c)	154,389,000	178,296,000
Daily av. to date		1,595,000	1,841,000
ANTHRACITE			
April 10		1,672,000	1,793,000
April 17		1,522,000	2,086,000
April 24 (*b*)		1,880,000	2,095,000
Cal. yr. to date	(c)	27,461,000	17,484,000
BEEHIVE COKE			
April 17		201,000	233,000
April 24		189,000	228,000
Cal. yr. to date	(c)	3,938,000	5,746,000

(*a*) Revised since last report. (*b*) Subject to revision. (*c*) Adjusted to equalize number of days in the two years.

Shift to Non-Union Coals Continues

In the Middle West the shift of large consumers from Illinois and Indiana to the cheaper non-union coals continues. Within the past few days one of the important railroads in that section has laid plans to close down its own Illinois mines and to seek its fuel supply from the docks. Many big industrial plants, which have not definitely changed over, keep the producers on tenterhooks by open-market purchases. This policy, however, helps to maintain firmness in spot quotations.

Domestic business is slow. No operation in the southern Illinois field is wholly free from "no bills" of prepared coal and the number of suspensions is steadily growing. Only a few mines are working in the Duquoin district, but railroad storage orders are helping out the Mt. Olive section. The Standard field still suffers from ruinous competition. Central Illinois and Indiana are finding the going hard these days.

In the Chicago market, smokeless coals were stronger last week because of the export possibilities. High-volatile offerings, on the other hand, were weak. There was some small-lot weather business in St. Louis territory, but the volume was not large. Retails schedules effective May 1 show Standard coal at $4.75; Mt. Olive, $5.50; Franklin County, $6.25; gas coke, $10.25; byproduct coke, $10.50@$11; smokeless coal, $8.75@$9; domestic anthracite, except pea, $15.75@$16.50, and pea, $13.50.

Late Lake Start Hurts Kentucky

The delay in opening up the lake shipping season is having a depressing effect upon sentiment in eastern Kentucky. General industrial demand, however, is good and in some lines the volume of tonnage moving is increasing. Spot screenings from both the eastern and the western fields are holding firmly at $1@$1.10. Average prices on eastern Kentucky block are slightly stronger. Western Kentucky nut is a trifle weaker and mine-run is less firm. The changes, however, have been slight.

The most interesting development at the Head of the Lakes has been the appreciation in quotations on prepared smokeless coals, which were marked up 50c. a few days ago. Mine-run and screenings were increased 25c. at the same time. Buying for household consumption was the explanation for the stronger tone. General industrial and retail demand, while fairly satisfactory in volume, is on a hand-to-mouth basis. Anthracite factors are confronted with an unwillingness of the consumer to store during the spring and summer.

Shipping Open to Milwaukee

The opening of the Straits of Mackinac has put Milwaukee coal dock managers in a state of expectancy. The steamer "W. K. Field" is due with a cargo of 10,730 tons of bituminous coal, and will be followed closely by other steamers from lower lake ports. The only other development in the situation

was a sharp cut in the price of coke, the Milwaukee Solvay Coke Co. announcing that beginning May 1 it will deliver coke at $12.90 a ton instead of $15, which had been the price for some time past.

With warm weather prevailing at the Twin Cities there is little buying except for steam use. Some industries using water power, principally public utilities and some flour mills, have had to use steam auxiliary power because of the low stage of water due to the lack of rain. But demand from other industries has not been as active as had been hoped. Little is being done in contracting in any direction.

Spring Price Cuts in Southwest

Southwestern operators swung in line last week with announcements of spring reductions in prices. The top quotation on Kansas shaft lump was cut to $4. Strip-pit lump is quoted at $3.50; nut, $3.25; straight mine-run, $3; crushed mine-run, $2.50. These reductions and colder weather cleaned up an accumulation of "no bills." Prospects of a brisk storage business are bright. Except for those mines with industrial and railroad contracts, however, the current movement is light.

Farther west, milder temperatures slowed down business at the Colorado mines, although shippers still report a fairly steady demand for lump and nut sizes. Industrial demand also is active. In Utah, on the other hand, there is practically no call for domestic sizes and trade in general is more quiet than it has been for several months.

Ciucinnati Market Holds Its Own

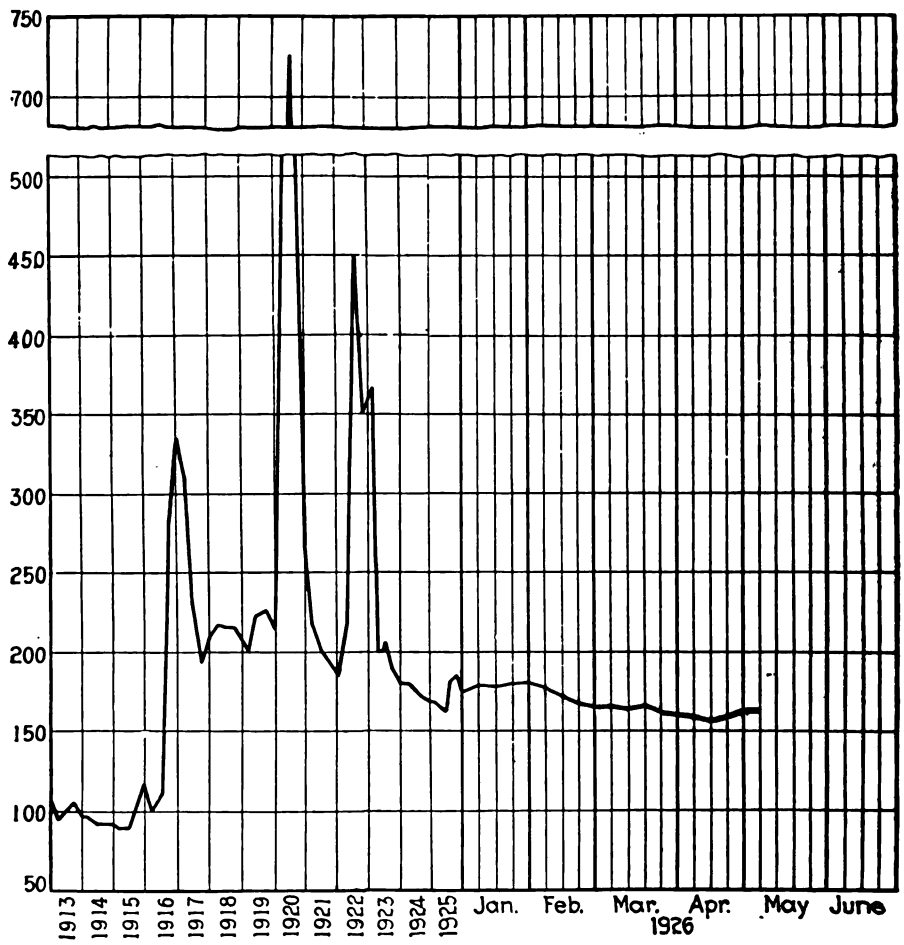
Though winter's hold on the skirts of spring has slowed down lake movement, it has caused Cincinnati retailers to put in more buying orders than for years and to clean up bins and reserves in a way that is gratifying. With the regular stocking season coming, the upper lakes contemplating what must be expected from the Jacksonville agreement's termination next spring, and the British mine trouble the market is holding its own.

The best glimmer of hope has been a $3 circular on standard smokeless with excellent prospect of $3.25 spot within a fortnight. Stove and nut have been raised to $2.50, some naming $1.85 for mine-run, others $1.75. The effort to get $1.50 for byproduct slack still holds, but a scattering of screenings is still obtainable for $1.25. However the market is more $1.35-$1.40 than it is $1.25-$1.50.

The heavy make of 2-in. high-volatile, in anticipation of the opening of the lakes, is pretty well narrowed down and getting it for "mine-run" is a thing of the past. That with a lake designation takes $1.65@$1.95. Block, egg and mine-run are practically where they were a week ago. Screenings and slack still hold firm.

Last month was the best volume April in ten years for local retailers. Prices for May are unchanged. River business is at capacity with nothing untoward retarding it.

Sluggish uncertainty still marks the trade in central Ohio. Activity, it is felt, hinges largely upon the opening of lake navigation, as local steam business is quiet and domestic demand wholly dependent upon the whims of the weather man. Some railroad contracts have been closed, but many more are open. In a number of cases industrial consumers have signed up half-year agreements. For the most part, the price ideas of buyers and sellers are far apart. Southern Ohio production does not average over 17 per cent of capacity.



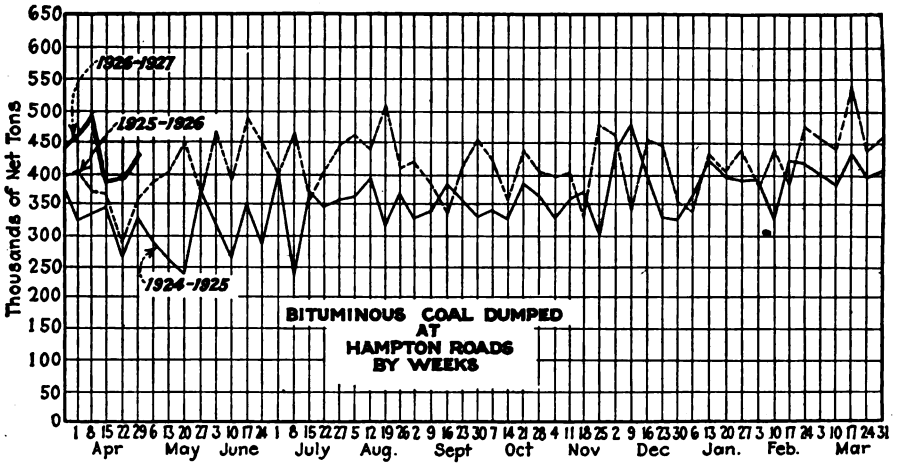
Demand Absent in Eastern Ohio

Eastern Ohio operators and jobbers report that inquiries are practically nil, and the retail business is gone absolutely. Some feelers have been out recently from large consumers for contract quotations, but no sizable agreements have been closed. Prices are unchanged except for distress lots sold at concessions to avoid demurrage. Production is being maintained at around 30 per cent of capacity. During the week ended April 24 the eastern Ohio No. 8 district produced 220,000 tons, which is 8,000 tons over output of the preceding week, and 13,000 tons over the corresponding week a year ago. Several additional mines are said to be on the verge of closing down, however.

Pessimism is the prevailing tone in western and central Pennsylvania. In the Pittsburgh district about half of the present greatly reduced output is coming from mines that have broken with the union. Mine-run prices are weakening. Youghiogheny gas holds to $2@$2.25, but good quality gas coal can be had at $1.90 or less and three-quarter at a shade under $2.25. There is little movement in steam mine-run and prices are off 10 to 15c.

In the central part of the state operators are struggling to keep mines running, but the contest is a disheartening one. "No bills" are accumulating and prices are sinking to lower levels. Pool 1 is $2.15@$2.40; pool 71, $2@$2.25; pool 9, $1.90@$2.15; pool 10, $1.75@$2; pool 11, $1.65@$1.80; pool 18, $1.60@$1.70. Except on pool 11, which is unchanged, these prices represent reductions of 10 to 30c.

Buffalo is as gloomy as ever. Fairmont quotations are off 5 to 10c. In the domestic market, offerings of anthracite and coke leave little room for bituminous and demand for soft-coal for house-heating is extremely light. Buffalo is displaying no interest in premium anthracite. The lake trade is again in operation. Three companies already have taken tonnage and others



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	May 3	April 26	April 19	April 12	May 4	May 5
Index	159	159	158	158	162	169
Weighted average price	$1.92	$1.93	$1.92	$1.91	$1.96	$2.05

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

April 15, 1925	343,048	177,916	.....	.....

will follow. Actual clearances, however, will be delayed several days.

Continued cold weather keeps the retail trade at Toronto busy distributing coal. Added to this are the orders being placed for next winter's supplies. At the present time Pennsylvania anthracite has the call on the market. A small quantity of Welsh coal is moving and quite a demand for coke. Freight rates shut out Alberta coal. Recent reductions in tariffs on manufactured goods may have an adverse demand on the sale of steam sizes.

New England Spot Market Firmer

Owing partly to possible demand from English shippers the spot market for steam coals f.o.b. Hampton Roads last week was slightly firmer. Compared with $4.10@$4.15 as a minimum for No. 1 Navy Standard Pocahontas and New River a week ago there have been sales since at $4.25@$4.35, although the tonnages placed have been by no means heavy. Accumulations are still the rule, but further curtailment has been taking place and more careful supervision exercised than during most of April.

At practically all the discharging ports at this end there has been no relief from the dull market that has prevailed for some weeks. Prices on cars at Providence have been depressed to $5.25 as a minimum per gross ton, with only a reasonable volume of coal being absorbed, while at Boston the range has been about 20 to 25c. higher. Several contracts have been placed for six to nine month periods at barely in excess of $5.50.

Neither all-rail nor by water routes is there any demand for central Pennsylvania output, save in the narrow territory reserved to all-rail shippers. Prices are based on the cost of mining operations, and in no direction is there buying of any moment.

Optimists Reappear at New York

The optimists are showing their faces in the New York bituminous market. Reserve tonnages are diminishing and there is promise of more activity in contract renewals this month. It is no longer easy to buy coal at tidewater on a basis under mine quotations and spot quotations generally are so low that producers consider closing down more profitable than further reductions. Movement over the piers runs between 400 and 500 cars a day.

Slack coal is the most active size in the Philadelphia spot market. With demand for prepared sizes at such a low ebb, the tonnage of free slack naturally is limited and readily commands $1.20@$1.30. In spite of complaints that consumers will not contract, there is, nevertheless, a substantial movement of coal from the mines and no indications that the quantity will be materially reduced. The bunker market is slightly more active as some vessel owners are taking on extra coal because of the British situation. The Baltimore market is marking time.

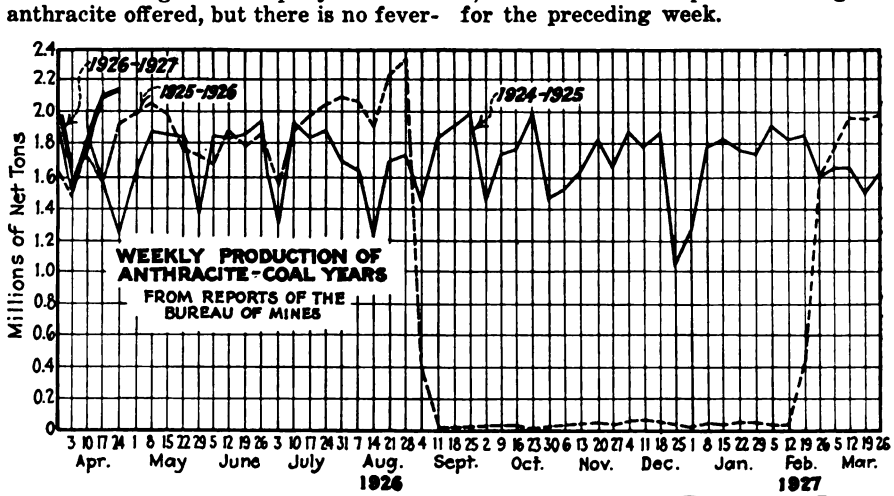
Disposition of low-grade steam coals on the Birmingham spot market is becoming more difficult, but the medium- and high-grade fuels are moving in fair volume. Contract business is confined largely to renewals and the majority of the new agreements carry modest increases over last year's prices. A number of railroad contracts, including that of the Seaboard Air Line, are pending.

Effective May 1, prices on domestic sizes were advanced 15 to 20c. per ton. Big Seam lump is now $1.90@$2.40; Carbon Hill, $2.65; Cahaba, $3.70@$4.20; Black Creek, $3.70@$3.95; Corona, $2.90; Montevallo-Straven, $4.45; Montevallo-Dogwood, $4.70; Montevallo-Aldrich, $4.95. Egg prices are 25c. and nut 75c. under the lump quotations. There has been no change in steam prices. The foundry coke market is firm at $5.50@$6.50, ovens. Domestic egg and nut coke drag at $4.50@$5.

Hard-Coal Demand Unhurried

The New York market is absorbing all the tonnage of company domestic anthracite offered, but there is no feverish buying. Only small premiums are obtainable on independent coal, with pea the most active size. As forecast, the May 1 circulars continued the basis established at the end of the anthracite strike. Steam sizes are weak. Some distress rice was offered last week at $1 and some barley as low as 75c.

At Philadelphia the consumer demand for hard coal has been supported by the weather, but there is less than the normal buying for spring and summer fill-ups. High-premium coals are in eclipse and certain independent shippers are trying to persuade retailers to take monthly allotments at prices only 25c. over company figures. Pea continues to be in unusual demand and some dealers have been trying to satisfy their trade with a mixture of nut and No. 1 buckwheat.



The juniors drag. One of the largest company shippers is openly offering No. 1 buckwheat for spot shipment at $2.50 and has reduced the contract price to the same figure. Barley stands up better than either buckwheat or rice.

Baltimore retailers have been enjoying a good business in deliveries for current consumption. The desire upon the part of the consumers to lay in coal for next winter, however, appears to have been dampened.

Spot Offers Menace Coke Market

Dullness rules in the Connellsville region. Prices are unchanged, but there has been a disquieting increase in the offerings of spot furnace coke. Unless production is more sharply curtailed, it is predicted that prices will suffer. Foundries are working cautiously and most of the larger operations are well covered by contracts.

Coke output in the Connellsville and Lower Connellsville region during the week ended April 24 totaled 169,300 tons, according to the Connellsville *Courier*. Furnace oven output decreased 3,200 tons and merchant oven production, 70,100 tons, showed a decline of 3,000 tons when compared with figures for the preceding week.

Foreign Market And Export News

Buying Pressure Grows In Welsh Coal Field, but Newcastle Market Lags

London, England, April 20.—The Welsh steam coal market is being subjected to pressure from both inland and foreign consumers, who are endeavoring to lay in all the stocks of coal they can before April 30. The operators have sold just about all the coal they can. Only odd lots are obtainable, and these can be obtained only at substantial premiums on recent quotations.

Prices in consequence show wide fluctuations and it is difficult to give a definite price for any class of coal, as operators are getting what they can while the rush lasts. It must be remembered that the present boom is unnatural and that the balance will be restored in a few weeks' time by unusual slackness.

There is greater optimism in Wales now over the outlook and a feeling prevails that some way out will be found which will avoid a national stoppage. One or two knotty points remain to be cleared up, chiefly the questions of national regulation of wages and working hours.

Newcastle provides a striking contrast to Wales. Though the latter field is experiencing a rush, Newcastle is quiet, and the reason probably is to be found in the fact that foreign buyers can get all the coal they want elsewhere at lower prices. There is something akin to a slump in the Newcastle market, with little prospect of a revival.

Output by British collieries during the week ended April 17, according to a special cable to *Coal Age*, totaled 5,610,000 gross tons, compared with 3,696,300 tons the preceding week.

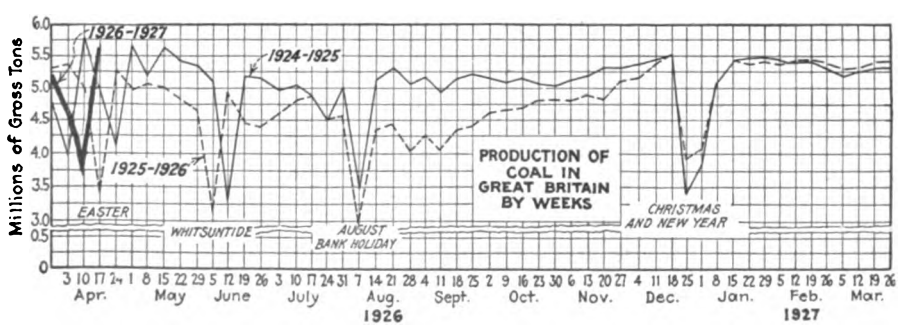
Strike Threat Helps Belgium

Brussels, Belgium, April 17.—Fears of a general tie-up of British coal mines on May 1 have increased inquiries for Belgian fuel. The general situation, however is unsatisfactory. A number of operators are closing down collieries. Domestic stocks are growing and demand is fading.

On the industrial side, coking smalls are finding a ready market at 87@89 fr. and smalls for lime making are up to 72 fr. Lean duffs for cement burning are somewhat scarce at 42@45 fr. Official Syndicate prices on coke continue at 125 fr. for Belgian fuel and 120 fr. for German reparation coke, but open market prices are 117.50@120 fr. Effective May 1, however, the official price on reparation coke will be increased to 137 fr. and coking smalls from 83 to 88.50 fr.

French Trading Marks Time

Paris, France, April 22. — Current trading in the French coal marts jogs along with little material change. Domestic demand is seasonally dull. Industrial orders are well supported by the general commercial activity of the country. With sterling at 145 fr. and a general rush to buy British coals in anticipation of a strike, the purchases made by French buyers are very restricted. This, of course, reacts in favor of the French collieries.



During March France imported 1,352,114 metric tons of coal—principally from Great Britain and Germany—and exported 390,892 tons. Coke imports, chiefly of German origin, totaled 518,084 tons; exports, 49,872 tons. Imports of patent fuel, with Belgium, Luxemburg and Germany the main sources of supply, were 91,294 tons; exports, 21,848 tons.

March Imports of Anthracite Make New Record

Anthracite imports into the United States during March struck a new high level, totaling 305,851 tons, of which 190,000 came from the United Kingdom, 71,000 from Germany and 25,000 from Belgium, according to the Minerals Division of the Department of Commerce. This is the greatest quantity of anthracite ever imported in an equal period of time, and is almost 100,000 tons in excess of February imports, when a record was also established.

Since Sept. 1 of last year up to April 1 this country has imported the unprecedented quantity of 938,000 tons of anthracite.

Imports of coke reached 86,000 tons, which exceeds imports of any month of this or last year. The United Kingdom led among sources of origin with 45,000 tons and was followed by the Netherlands with 34,000. Bituminous imports amounted to 45,000 tons as compared with 36,000 tons in the month preceding.

Heavy Bunkering at Panama

During March, 1926, the coal delivered by the Panama Canal coaling plants amounted to 50,031 tons. This was the largest month in coal disbursements since January, 1921, when a record of 63,420 tons was established.

On March 15, all previous records for a single day's bunkering were broken, when 8,846 tons were delivered to four commercial and three navy vessels. No record for rapid bunkering of any particular ship was established, however.

Coming Meetings

Chamber of Commerce of the United States. United States Chamber of Commerce Bldg., Washington, D. C., May 10-13.

Chemical Equipment and Process Engineering Exposition, under the auspices of the Association of Chemical Equipment Manufacturers, Inc., at the Public Hall, Cleveland, Ohio, May 10-15. Secretary, Roberts Everett, 1328 Broadway, New York City.

Mine Inspectors' Institute of America. Annual meeting, Seventh Avenue Hotel, Pittsburgh, Pa., May 11-13. Secretary, G. B. Butterfield, Hartford, Conn.

International Railway Fuel Association. Hotel Sherman, Chicago, Ill., May 11-14. Secretary, J. B. Hutchinson, Omaha, Neb.

National Retail Coal Merchants' Association. New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, with operating conference. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. Fourteenth congress, Madrid, Spain, May 24, 1926. Secretary, E. Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

Pennsylvania Retail Coal Merchants' Association. Annual meeting, York, Pa., May 27 and 28. Secretary, W. M. Bertolet, Reading, Pa.

Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

West Virginia Coal Mining Institute. Annual meeting, June 1-2, Bluefield, W. Va. (tentative). Secretary, R. E. Sherwood, Charleston, W. Va.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

National Coal Association, June 9-11, at Drake Hotel, Chicago, Ill. Executive secretary, Harry L. Gandy, Southern Bldg., Washington, D. C.

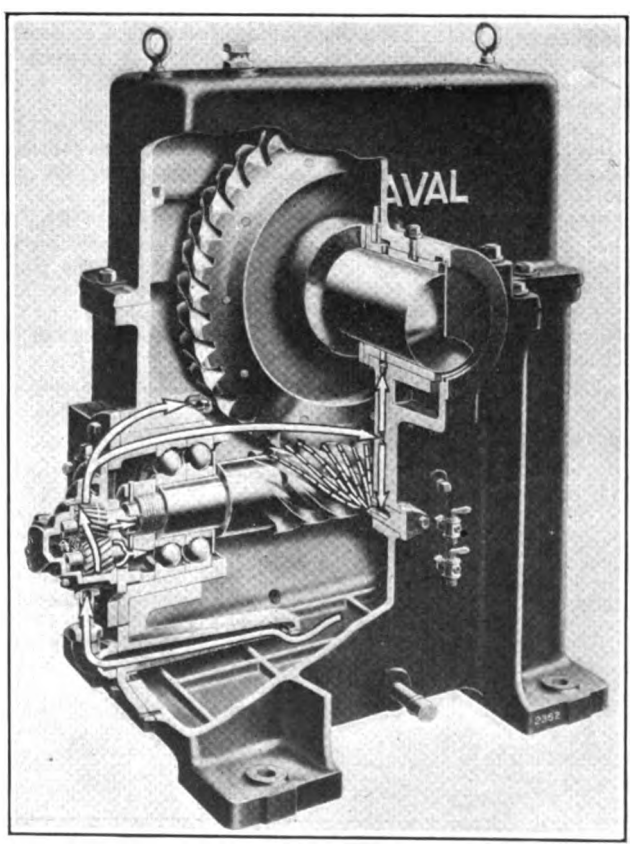
American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Illinois Mining Institute. Annual summer meeting on steamer "Cape Girardeau," leaving St. Louis, Mo., June 24 and returning June 26. Secretary, Frank F. Tirre, Central National Bank Bldg., St. Louis, Mo.

New Equipment

Pressure Assures Positive Lubrication of Worm

Worm speed-reduction gears usually are lubricated by a splash system. Either the worm or the worm wheel dips into the lubricant and the oil thrown off by the moving parts is allowed to find its way down the inside of the casing to the bearings. Special channels or other means may be provided to facilitate this method of lubrication. Splash oiling is not adequate, however, for reductions operating at high speed or those transmitting large quantities of energy.



Gears intended for such speed and for the transmission of heavy mechanical loads as manufactured by the De Laval Steam Turbine Co., of Trenton, N. J., are provided with forced-feed lubrication. Oil is not only forced into the bearings but sprayed under pressure onto the worm threads. This assures a constant circulation of the oil and copious lubrication of contact surfaces at the most advantageous point. By means of a rotary pump the oil is drawn upward through a large bronze strainer, placed some distance above the bottom of the gear case. The pump delivers it through passages in the casing to the bearings and to spray nozzles located upon either side of the worm. The oil passages may be easily and readily cleaned, and the spray nozzles may be removed without disturbing any of the other piping. If desired an oil cooler may be incorporated into this system. The oil pressure is maintained constant, irrespective of the speed of the drive by means of an automatic relief valve.

Forced feed is said to eliminate heating which is so noticeable—and by reason of the excessive churning of the oil by the gears, so inevitable—with the splash system. It also obviates the frothing of the oil which is also a concomitant of the churning action. With the forced-feed system, it is claimed, a positive and continuous feed is provided to all surfaces requiring lubrication.

Alloy Valves Resist Attacks Of Corrosive Waters

A new line of acid- and corrosion-resisting valves and cocks is being placed on the market by the Barber Asphalt Co., of Philadelphia, Pa. The valves are of the gate type made with either screwed or flanged ends built in sizes ranging from ¾ to 6 in. The cocks are built with screwed ends only and in sizes from ¼ to 3 in. They are of the extra heavy, plug, two-way type.

All of these fittings are made of an alloy known as Aterite, the exact composition of which is varied to suit the intended use. This alloy possesses some interesting physical qualities. Thus its elastic limit averages about 18,000 lb. and its ultimate strength about 55,000 lb. per square inch. A

Oil Where Oil Is Needed

This shows, somewhat diagrammatically, the course taken by the oil from the reservoir in the base of the casing, through the rotary pump, then through passages in the casing to the main bearings and spray nozzles. Splash systems of oiling appear to this manufacturer suited only to low speeds or the lighter installations. Frothing and heating of the oil are said to be eliminated by the forced feed because no longer is the oil picked up and churned by the worm in its rotation.

Digitized by Google

pressure of 180,000 lb. on a test piece of this metal decreased its length one half or from 1⅛ in. to ⅛ in. without developing cracks or flaws of any kind. The metal is thus shown to be extremely tough and ductile.

While this metal is not entirely immune to the attack of acid it is capable of resisting its ravages for a surprising length of time. It also possesses great ability to resist electrolytic corrosion when used in conjunction or in contact with the commoner metals such as copper, lead, zinc and iron. It is particularly recommended for use in chemical works but will doubtless find a place in mines where trouble is experienced from acidulous water.

Rotates Pipe and Cuts Thread

The Borden Co., Warren, Ohio, is manufacturing a machine for threading and cutting pipe called the "No. 44 Beaver power drive." This is a portable machine in which the pipe revolves and the tool remains still. Cutters can be bought for it or it can be used with hand tools. It holds pipe from ¼ to 2-in. diameter. By means of a universal-jointed shaft, it will cut 2½ to 6-in. diameter pipe by driving a No. 106 Beaver cutter.

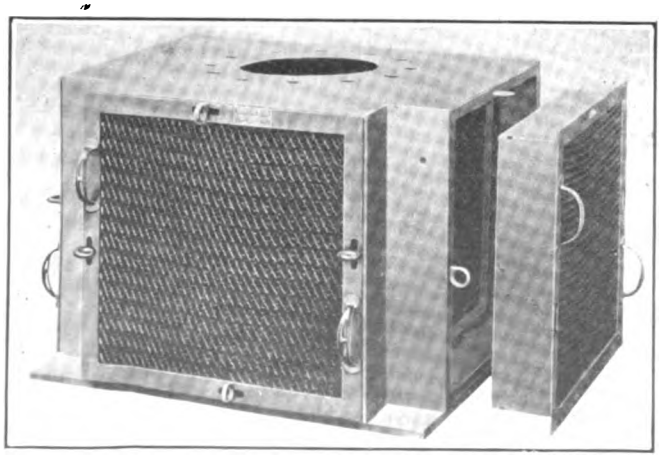
Air Filter for Compressors And Gas Engines

Much trouble in the operation and maintenance of air compressors and internal combustion engines can be avoided by removing dirt, dust, and abrasive materials from the air before it is drawn into the cylinder. An air filter designed for this purpose is manufactured by the Spray Engineering Co., 60 High St., Boston, Mass.

In this make of filter, dust is removed by causing it to impinge on an adhesive surface, which is done by rapidly and repeatedly changing the direction of the air flow. The filter media are arranged from coarse to fine in the direction of air flow, so that where the largest percentage of dust is retained, ample space is provided for its accumulation without materially obstructing the flow of the air. By dipping or charging the cell with a special solution called "Dustix," the surfaces of the filter media are made adhesive. When the filters become dirty they may be cleaned by washing them in a hot solution of water and washing soda, thus removing the clinging dirt.

These filters are built entirely of heavy-gage metal to withstand hard usage. They are made in two types—namely, type "C" and the box type. Type "C" filters are intended for small capacities, and the box type has been designed for larger capacities. The former are small and light and can be bolted to a standard pipe flange, which, in turn, is screwed directly onto the air intake pipe.

Industrial Notes



Leonard Sargeant, former sales manager and assistant general manager of the Fairmont Mining Machinery Co., Fairmont, W. Va., has been promoted to the position of general manager following the resignation of J. E. Johnson, former general manager, who will leave soon for New York City. Mr. Johnson has not announced his plans for the future.

Directors of **E. I. du Pont de Nemours & Co.** recently elected **Lammot du Pont** as president of the company to succeed Irenee du Pont, who desired to be released from the duties of the office so that he might devote more of his time to personal affairs. The retiring president was made vice-chairman of the board of directors and chairman of the finance committee. He retired from the executive committee and the new president was made its chairman.

The Electric Storage Battery Co., Philadelphia, announces the appointment of **H. B. Gay** as vice-president. Mr. Gay will continue in charge of sales. Mr. Gay, who is a graduate of Cornell University, entered the employ of the Electric Storage Battery Co. in June, 1901.

The Goulds Manufacturing Co., Seneca Falls, N. Y., announces a change in corporate name, effective April 1, to **Goulds Pumps.** There is no change in organization, business policy or ownership. The board of directors, officers, managers and personnel remain the same.

The Dodge Manufacturing Corp., of Mishawaka, Ind., has taken over the entire business and personnel of the **Hugh P. Robbins** organization, of Chicago, and has created a new division known as the material handling division, headed by Mr. Robbins.

Air Filter

Made of heavy gage metal and designed for large capacity. Air used in compressors should be free of dirt, dust and abrasive materials. A solution causes dust to adhere to metal surfaces.

New Companies

The Huskery Coal Co., 37 West Van Buren Street, Chicago, was recently incorporated, with capital of $500,000 to engage in coal mining. The incorporators are H. A. Huskery, W. P. Worth, E. C. Scarls, Frank A. Stava and Frank L. Wolf.

Super Coal Co., Inc., New York City, manufacturing coal products and briquets, has been chartered at Albany with a capital of 500 shares preferred stock of $100 par value and 15,000 shares common stock of no par value. Almet R. Latson, Jr., 193 East 17th St.; Ethel M. Jennings, 45½ Pulaski St., and Olga Beiswenger, 28 Palmetto St., Brooklyn, are the directors and subscribers. Latson & Tamblyn, 66 Broadway, New York City, are attorneys for the corporation.

The Southern West Virginia Coal Co., of Ashford, Kanawha County, W. Va., having a capital of $25,000, has been chartered by W. L. Peters, F. M. Stambaugh, D. W. Orth, D. A. Marsh and C. L. Bird, all of Charleston, W. Va.

The Camp Fork Coal Co. recently was organized with a capital of $200,000 to operate near Greendale, in the Nicholas County field of West Virginia. Among those interested in the new company are Ottway Gunmore, of Gauley Bridge; George C. Backus, E. M. Johnson, C. D. Burges and C. E. Krebs, all of Charleston, W. Va.

Bertha Jellico Coal Co., Grays, Ky., capital $10,000, has been chartered by Mattie Gray, J. H. Gray and R. C Gray.

The Kentucky Knox Coal Co., capital $25,000, has been incorporated at Barbourville, Ky., in the eastern Kentucky district, by J. R. Ketcham, J. Q. Redding and R. D. McDade.

Articles of incorporation have been filed by the **Anchor Fuel Co.**, of Trinidad, Colo. The company is incorporated for $100,000 and has as its purpose to mine and sell coal. Incorporators are Enis A. Siegfried, Conway E. Risley and Oliver M. Knecht. Mr. Siegfried said he was not ready to announce the details of the new company's operations but that the Anchor Fuel Co. will take over the operation of some coal mining properties in Las Animas County.

The formation of the **Gifford-Brown Coal Co.**, New York City, has been announced. The members are **James S.** Gifford, who was connected for several years with Williams & Peters; Willis H. Brown, who has been in the coal trade for many years, and J. C. Meyerhoff, Jr., who also is well known to the trade. The new concern will occupy offices on the 6th floor of No. 1 Broadway and will handle anthracite and bituminous coals on the line at tidewater and for bunkering.

Papers have been filed chartering the **Saltillo Mining Co.**, Cleveland, Ohio, with an authorized capital of $100,000 to mine and sell coal among other things. Incorporators are S. Eugene Wood, Henry B. Johnson, Margaret England, V. J. Borth and S. J. Gibbs.

MAY 14 1926

COAL AGE

The World's Accepted Authority on Coal Mining

McGraw-Hill Publishing Company, Inc. **May 13, 1926** Price Twenty Cents per Copy

—now they haul on Hyatts

They noticed that the efforts of three men were required to move a loaded car to the tipple. They saw their lubrication cost piled up as follows:

Their 175 plain bearing cars used 104 gallons of lubricating oil daily at 15c. a gallon. Figuring 220 operating days a year at $5.00 a day for labor they spent a total of $4,532 each year to keep the old fashioned cars running.

So they are investing in Hyatt Roller Bearing equipped cars for which the lubricant averages only $1.16 to $1.30 a year for each car. You can see that these rugged, modern bearings will rapidly pay for themselves in lubrication savings alone.

Now one of their men rolls a loaded Hyatt car to the tipple—a performance which reflects Hyatt economy in power—man, animal or electric—amounting to an average 50% reduction in draw bar pull on level track.

There are many large manufacturers of mine cars, furnishing Hyatt Roller Bearings today. Consult them about plans for modernizing your running gear, or write direct to Hyatt.

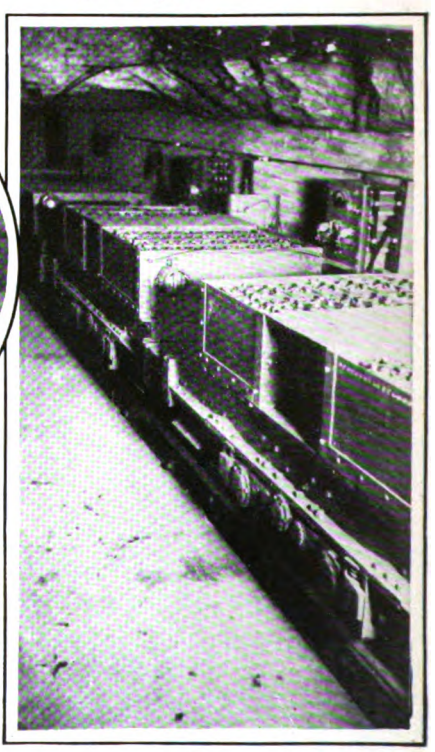
A mine is only as efficient as its haulage system



No matter how up to date a mine is in its layout and equipment, it cannot produce coal faster than its haulage system can bring that coal to the surface. That is why so many leading coal mines today are equipping their haulage motors with Exide-Ironclad Batteries—they know that this speedy, peppy battery gives years of efficient trouble-free service. View shows topworks of Inland Collieries Co., Indianola, Pa.

No matter how long the trip or how steep the grade, an Exide-Ironclad-equipped motor never falters, for it is packed with power, and when extra power is needed, it has the peculiar ability to deliver current at a much faster rate than usual.

This car of coal has reached the end of the trail so far as the mine is concerned. Between here and the working face lies the mine's chance to cut costs. One of the best places to start cutting costs is with the haulage system, and one way to start is to equip your haulage motors with Exide-Ironclad Batteries.

The mule is an economical means of hauling coal under certain conditions, but mules may get sick, whereas an Exide-Ironclad Battery is so ruggedly built that it stays on the job month after month and year after year without losing any time out of service for repairs.

An Exide-Ironclad Battery is not only efficient on the haulageways but also in the charging barn. It takes current in easily, quickly and stores up a high percentage of it as useful energy.

Cincinnati Pre-Convention Issue

Coal Age is preparing to be in Cincinnati in force for the big Convention and Mine Machinery Show of the American Mining Congress. Mine executives will be there in numbers also, ready to learn what the year has brought forth in engineering progress.

In celebration of the event, the issue of *Coal Age* of May 20 will feature many of the biggest developments in the technical realm of coal. It will contain many stories vital to those who have mines to run—stories selected for the helpful suggestions they contain—an unusual issue suited to an out-of-the-ordinary occasion.

To Mark Time Is to Go Backward

The coal fields are sharing in the great mechanical development of the present times. To mark time is relatively to go backward—to mine coal unprofitably in the present and to find later, after all the loss occasioned by inefficient operation, that the expenditure in the end must be made or the mine must be closed. Modernization delayed means impoverishment in the present and a wholesale expenditure in the end. One may believe that "sitting tight" means "sitting pretty," but how will it look when accounts are balanced or the mine is evaluated?

What Washington Is Doing

Sydney A. Hale is in Washington week by week sitting in at the hearing on the desirability and possibility of regulating the coal business. You will appreciate the unbiased reports made by his well-seasoned pen, which records the high lights of the inquiry without regard to any opinions held by correspondent or his paper. You can draw your own conclusions, for you have all the facts.

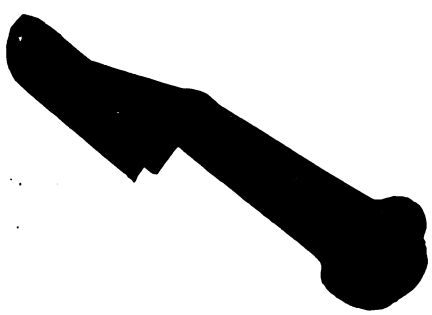
Try a Type D Frog Where Haulage is Heaviest

TRY a Type D Frog where haulage is heaviest—where heavy locomotives, drawing large currents, make frequent passages.

Then you will realize what there is in O-B hot-galvanized Flecto Iron, the treated malleable that does not become embrittled in galvanizing, in the design of the pan, in the cam tip approaches,—that make this frog popular in the mine.



Then you will find satisfactory trolley frog performance that saves on the up-keep cost.
Put up a Type D and see for yourself!

Ohio Brass Co.

PORCELAIN INSULATORS, LINE MATERIALS, RAIL BONDS, CAR EQUIPMENT, MINING MATERIALS, VALVES

The O-B one-piece Cam Tip

Renewable Bronze

These time-saving renewable approaches (put on in 40 seconds each) are provided on all modern O-B Frogs, Cross-overs and Section Insulators. They hold the wire tightly, never become loose or troublesome in service, afford a smooth transition from wire to casting and are easily and quickly renewed when worn. Renew the approaches; save the pan.

Volume 29 | NEW YORK, MAY 13, 1926 | Number 19

Postponed Troubles Draw Interest

THE BRITISH COAL CRISIS has shifted so rapidly from an industrial dispute to a class struggle threatening to merge into a civil war that, for the time being, the issues which precipitated the clash are submerged. This is unfortunate. A class army has been massed with the intention of compelling a nation to coerce the adversaries of a class group. This challenge to orderly government is serious enough to engage the attention of statesmen and citizens throughout the world. The outcome, if the issue is fought to a definite conclusion, necessarily will profoundly affect social and economic life and theories here and abroad.

These large aspects of the situation cannot and should not be minimized. Nevertheless, the coal industry and our government both will be the losers if they permit interest in these more general issues to obscure a clear understanding of the genesis of the trouble. The root of that trouble was economic, but attack upon it was delayed by official palliatives and political compromises. "Peace at any price" was the ruling consideration—until it was finally driven home that steady tribute paying was the price.

Prior to the World War the export trade was not only the key to the prosperity of the British coal industry but coal was the foundation of Great Britain's vast foreign commerce. Wreck that structure, and England ceases to be a first-rate power. The war disorganized and curtailed exports. The problem which faced the British coal industry when peace was restored was the recovery of the foreign markets it had lost. Home consumption has shown little change. The yearly fluctuations in the quantities used in Great Britain, both in tonnages and in percentages, in no wise compare with the fluctuations in this country.

British producers could not meet the demands of labor for higher wages and shorter hours and sell their coal in competition with other contenders for the world trade in fuel. Twice the government forestalled an economic settlement of the problem by subsidies, the last of which expired on April 30. Twice the industry was bribed to forget its internal differences in the hope, apparently, that a turn in the wheel of fortune would somehow eliminate the basic economic difficulties. The withdrawal of this contribution by the taxpayers set the stage for the present strife.

Happily there is no reason to fear that the United States may find itself in a similar predicament. Our non-union output is too large for that. But England's plight shows the dangers of the one-hundred per cent unionization advocated by the United Mine Workers as the cure for American coal evils. The English crisis also is a vindication of the loudly condemned policy of non-interference pursued by the national administration during the last anthracite strike. Interference would have only postponed the issue—and a postponed issue, as England is now learning, exacts a usurious rate of interest when the day of settlement arrives.

And yet the suggestion still is heard in Washington and elsewhere that the government be empowered to take over the mines in times of emergency and fix emergency wages and prices.

Possibilities in Research

FROM A SMALL MINE in southern West Virginia came a story in last week's issue of *Coal Age* on the use of storage batteries to smooth out the load curve of the mine substation and thereby reduce the monthly demand charge. By this means the company saved money. The public utility corporations operating direct-current stations and substations have long recognized the value of storage batteries floating on the line as a help during sudden peaks. Many industrial corporations are following the same plan. But this installation is, so far as we know, the first application at the mines of the principle of storing up current during periods of low demand to be later released upon attainment of a predetermined economical peakload.

Of course, results somewhat similar in principle have been and are obtained wherever locomotives and cutting machines are driven by storage batteries, which can be charged at night or at any time when the demand for power is low.

The fundamental principle of the use of storage batteries for this purpose is sound and possesses worthwhile possibilities as a subject for research, both for manufacturers who desire to widen their markets and for coal-mine operators who seek economies in operation. Battery installations of proper design will enable a mine to be carried over its heaviest peakload, will allow the mine to operate upon the most economical demand rate and will enable it to increase its load factor, the batteries discharging during peakloads and being recharged during periods of lessened power consumption.

The energy in kilowatt-hours put into the batteries at a comparatively low rate over a rather prolonged period will cost little compared with the saving the battery will make by keeping the kilowatt-demand rate within an economical limit. Kilowatt-hours are sold by the power companies at a few cents each whereas the kilowatt demand charge runs over $1 per unit.

Batteries in this class of service if properly inspected and kept in condition should last many years. It would seem that for such service the battery would not need to be so rugged as one used in locomotives of power-trucks. Despite the value of standardization, it might be well to design the batteries for this particular service to suit the needs of the job that the battery has to perform rather than to accord with standards set up for an entirely different class of work. In this way

Digitized by Google

the batteries can be obtained for far less than is necessarily paid for locomotive and power-truck batteries that have to be capable of withstanding frequent shocks.

It Can't Be Done

AMERICA HAS GROWN POWERFUL because it has used power. Ever since about the year 1800 in all phases of this country's industrial activity the utilization of mechanical energy has steadily increased. First came the cumbrous saw- and gristmills driven by ponderous slow-turning overshot waterwheels. Later these gave way to the much smaller and, in most cases, more efficient hydraulic turbines.

With the development of the steamboat and locomotive came a corresponding development of the stationary steam engine. Then, just before the dawn of the present century the steam turbine became a potent factor in power generation. This machine and the electric generator were developed in large measure concomitantly because the one was admirably adapted to driving the other.

Electric distribution of power solved many of the problems in energy transmission that had long vexed industry. Not only was transmission greatly simplified but it was simultaneously rendered more efficient. Lineshafts, belts, ropes, tumbling rods and the like, could not compete, either in cost or utility, with the little, stationary, well-protected electrical conductors with which everyone is familiar today.

Electric transmission, also, has made it possible in many cases to take the machine to the work to be done instead of taking the work to the machine, as before it was necessary to do. This is well exemplified by the electric drill or the more recent electric hand saw that will cut wood from six to ten times as fast as it can be sawn by hand.

And all of this development and utilization of power has taken place because it paid financially. Among the ancients—and not so far back either—a person's prosperity was frequently judged largely by the retinue of servants he maintained. The number of slaves that a man owned and which were constantly at his beck and call, ready at all times to do his bidding, fixed his status in the civilization and community in which he lived.

Today residents of this country have working for them—far more continuously than any bondsmen of former times could possibly endure to work—machinery and mechanical devices of one sort and another equal in power to an average of thirty slaves for every man, woman and child in the land.

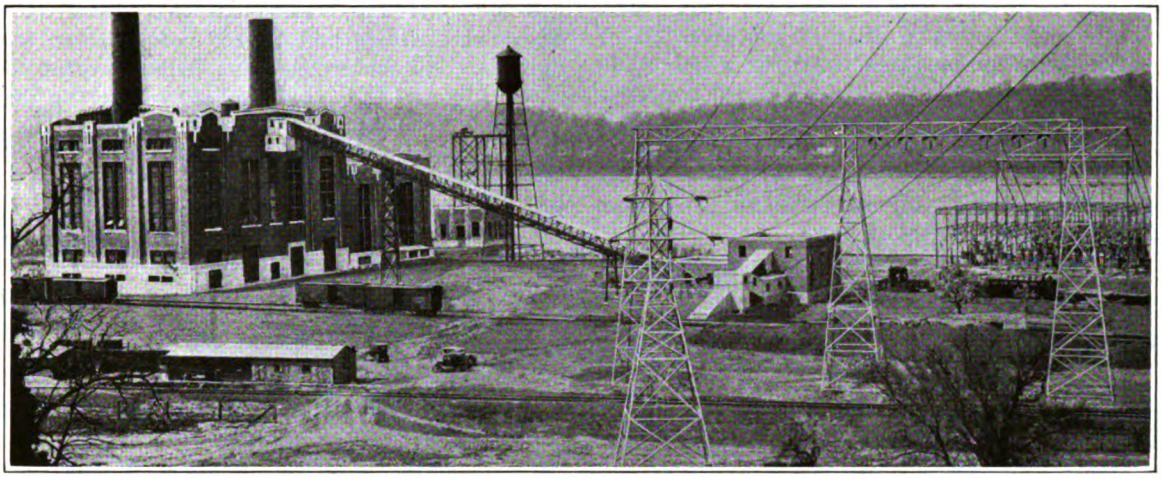
So efficient, so advantageous has the employment of mechanical energy become in the performance of work useful to humanity that it is today recognized as little short of an economic crime to employ human muscles during any appreciable period of time for doing any task that a machine can be made to perform. Unfortunately some people in the past—and plenty of their ilk are still extant—have been inclined "to buck" even to the point of violence, the adoption of labor-saving machines and devices.

They resent interference with the daily routine of their chosen vocations even though this may admittedly further the welfare of humanity, themselves included. Ultimately the economic rearrangement brought about by the adoption of new and better equipment and processes is as much to the workman's advantage as it is to that of the rest of mankind. For in any real democracy where lines of class distinction and caste are non-existent the status of the individual cannot rise without exerting a corresponding influence upon the body politic and vice versa.

When economic advantage lies predominatingly on the side of machinery, it is useless for any man or set or class of men to attempt for long to resist its adoption. Certain it is that many of the processes of coal mining now performed manually are susceptible of mechanization. There are naturally certain problems involved that cannot be worked out immediately or their solutions obtained over night. It is but natural, perhaps, in the light of past experience, that the innovation of mechanical loading should be resisted by the workmen affected by it. In the end however it will redound quite as much to the advantage of the miner himself as to that of the populace that consumes his product.

Concerted effort on the part of the mine workers to stay the advance of mine mechanization may act as a temporary deterrent to the universal adoption of machinery and mechanical processes. Economic laws, however, are as inexorable as are the laws of Nature and the mine workers might about as wisely attempt to prohibit the ebb and flow of the tides as to prevent the adoption of labor-saving machinery in the coal mines of America.

Safety and Sanity



A FAVORITE dictum of C. P. Tolman, at one time president of the National Safety Council, is that "Safety is only good engineering," by which he means that the engineer has not schemed the most profitable way of doing things if he has forgotten safety. He frequently illustrated his thought by showing how a dull band saw was not only a danger to all who had to work around it but wasted power, wrecked itself, cut an undue and irregular kerf and was anathema to a good engineer.

He, in the course of his work, has saved many a life from lead poisoning by conserving the lead of the company with careful methods of handling. A poor place, he thought, was the passing breeze and the bodies of the employees for the good lead dust that the company had been at expense to mine, to ship and to refine. He proved that fact abundantly by the savings resultant on his methods of keeping the dust where it belonged.

In coal mines it is no different. Safety is and always has been good engineering, even though it has become many times as important since the accidents of the mine worker have had to be paid for by his employers. Many an operator who was fully insured has had to deduct from his earnings or from his capital, if he had no earnings, the tremendous cost of an explosion or mine fire. Even the wrecking of a trip, the breaking of a switch, the loss of coal pillars or the injury to a machine is a recognizable charge on profit or on capital invested. The effect of accidents on morale also is bad. No operator is so hedged in by economic difficulties nor is any mine so profitable, that indifference to correct safety principles can be regarded as good engineering.

The Bureau of Mines is showing us in its safety efforts and studies not only the safer way but incidentally the cheaper way to mine coal.

In Southern Illinois Big Central-Station Plants Deliver Reliable Power to Coal Mines

Two Efficient Plants Furnish Mines with Operating Energy — Diversified Load Factor Attained by Serving Industrial Plants and Municipalities Gives Results That Isolated Stations Cannot Attain

By Frank H. Kneeland
Associate Editor, *Coal Age*, New York, N. Y.

AS A RULE the public utilities that devote their energies to the generation and distribution of electric current seek as diversified a load as possible. Power plants can earn only when in operation, and their earnings are roughly proportional to the average percentage of the time during which their generating equipment is utilized. In other words, that plant earns most which operates most continuously day and night at or near its full capacity. The load factor or average percentage of loading on the plant thus plays an extremely important rôle in determining the earnings and profits of the installation.

The load factor afforded by coal mines alone is anything but good, especially in those regions where by union agreement practically all operations except ventilation are performed during the day shift, leaving the night load small and even inconsequential. It is interesting to learn, therefore, that large, reliable, efficient central stations and transmission lines can be built and operated profitably to serve a region whose basic industry is coal production.

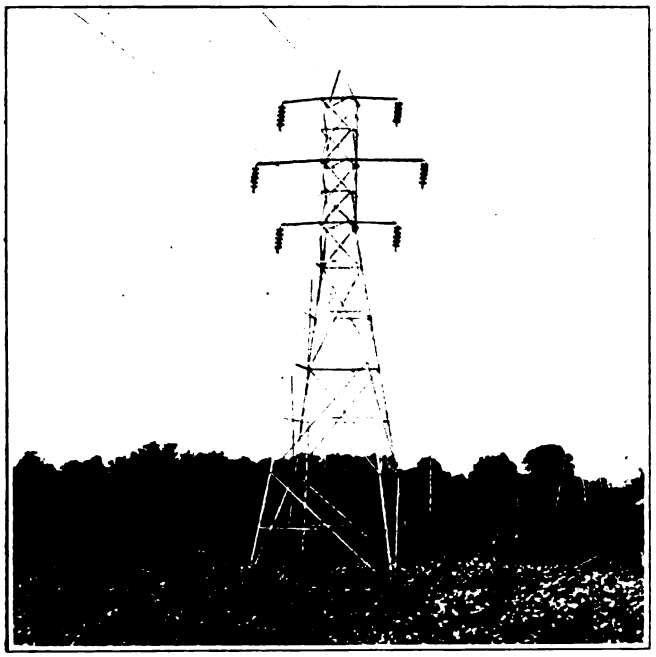
To furnish the southern portion of Illinois, the Central Illinois Public Service Co. has built plants and erected transmission lines so that the counties of Union, Jackson, Williamson, Franklin, Saline and Gallatin, which produce by far the greater bulk of Illinois fuel, are afforded the benefits of central-station power. This is one of six practically complete power transmission systems owned and operated by this public utility in Illinois.

In the headpiece is shown the power plant at Grand Tower, Ill. Here are already installed 50,000 kw., and provision has been made for doubling its capacity twice, making 200,000 kw. in all. The transformer station at the extreme right steps up the generator voltage to that of the transmission line. The hills of Missouri may be seen on the opposite bank of the Mississippi.

In probably no other industry is continuity of service more important than in coal mining. Many, if not most, of the mines in this region are closed-light operations wherein any stoppage of ventilation may prove serious. Furthermore, if haulage is interrupted for any appreciable length of time miners will not long remain idle in their places but will quit for the day. As a result, all reasonable precautions must be taken to make the electrical service rendered thoroughly reliable.

The transmission system is provided with a power plant at each end of the territory served. On the west is the plant at Grand Tower located on the east bank of the Mississippi River. This is provided with six B. & W. boilers of 1,160 hp. each. All these boilers are equipped with chain-grate stokers, those on the east side of the plant being of Coxe and those on the west side of Illinois make. Each stoker is 18 ft. wide and the fuel consumed is 1½-in. Illinois screenings.

Ample Storage Is Provided



Coal is brought to this plant in drop-bottom cars. Ample space is available for storing fuel during the summer for use in winter. It is both stocked out and reclaimed by means of a locomotive crane, which is also available at all times for working over, moving and cooling off the coal should it at any time be threatened with spontaneous combustion or should it actually take fire.

From the railroad cars, coal is delivered to a track hopper from which it is discharged by means of a

Digitized by Google

reciprocating plate feeder and passed through a Bradford breaker that not only breaks down any frozen lumps that may be present but removes any tramp iron or other extraneous material that it contains. It is then delivered to an inclined belt conveyor which leads to the top of the boiler plant. This inclined conveyor delivers to a similar one of the horizontal type that spans the top of the bunkers longitudinally. This latter conveyor is provided with a traveling tripper that can be moved either automatically (that is by the power of the belt passing over it) or by hand.

There are twelve bunkers in all, each of which is capable of holding about a carload of coal so that approximately 600 tons of fuel may be stored in the bunkers. This is roughly one day's supply. The bunkers are arranged in two rows (one to each row of boilers) with doors in the partition between them through which the coal may flow so that a boiler on either side of the plant may be fired with coal from the bunker on the opposite side.

Nervous System of the Territory Known as Egypt

Over sere pastures, waving corn and blooming buckwheat, clear across the southern end of the state from the Mississippi to the Ohio extends this 66,000-volt transmission line, furnishing the power to light the homes and mine the coal that warms the hearths of a prosperous people.

Steam is carried on the boilers at 400-lb. pressure and is superheated approximately 250 deg., giving a final temperature of about 700 deg. F. Each boiler is provided with its own forced-draft and its own induced-draft fan making control of the air passing through the fuel bed and boiler passages easy and certain. These steam-generating units absorb heat with great efficiency, the temperature of the stack gases being only about 270 deg. F. even when the boilers are forced to 250 per cent of their normal rating.

Two main generating units are installed in this plant. These are duplicate turbo-generators each of 25,000-kw. capacity. These machines take steam at full pressure and exhaust to a vacuum which averages approximately 29 in. Naturally these units are highly efficient, a kilowatt-hour of electrical energy being produced from 1½ to 1¾ lb. of coal with an average heat content of 11,500 B.t.u. per pound as delivered.

Abundant water is drawn from the river, but as Mississippi River water is notoriously roily, being exceeded in this respect by few streams in the country, the Missouri alone excepted, this water is carefully screened, strained and filtered before going to the condensers. All water used for boiler feeding is treated chemically and thus purified before entering the boilers. The hot circulating water is returned to the river at a point appreciably below or down stream from the intake, so that by no possibility can it again be drawn into the circulating system.

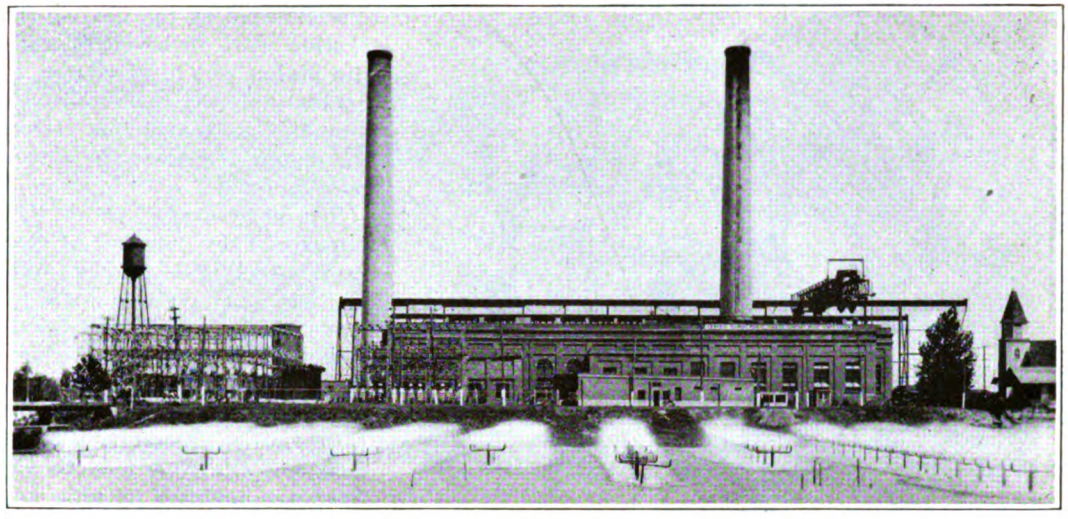
On the eastern end of this transmission system is the Muddy power plant at Harrisburg. This is a much older installation than the one just described although it is still highly efficient. In this plant steam is carried at 250 lb. pressure with 150 deg. of superheat. As this installation is not built beside any large stream able to furnish an abundant condenser supply, water for its operation is impounded, in a reservoir many acres in extent. This furnishes make-up to the spray pond through which the circulating water is passed upon leaving the condensers. In this plant four turbo-generators are installed. These comprise three 5,000-kw. and one 10,000-kw. units, making 25,000 kw. in all. The two power plants operate in parallel with each other in supplying current to the line between them.

MAKING THE LINE ACCIDENT-PROOF

But the most efficient power plant ever built would be at a woeful disadvantage from the standpoint of their value to the public if the line over which current is transmitted to the customer were not efficient. Any public-service company of this kind has two products to sell—kilowatt-hours or energy and service, or continuity of energy supply. It is necessary, therefore, that the transmission line be not only efficient but as nearly accident-proof as possible. If, as in this case, transmission is made by means of a main or trunk line and numerous side, or delivery, branches, reliability is equally important on all of these.

In this power system a double transmission line—that is, two sets of conductors, each set consisting of three cables or one for each phase—is carried on substantial steel towers extending northeast from the plant at Grand Tower to West Frankfort and from thence in a southeasterly direction to the power plant at Muddy. Here a similar line has been built northeast to Eldorado and thence southeast to Shawneetown on the banks of the Ohio River where connection is made to the line of the Kentucky Utilities Co., furnishing electrical energy to western Kentucky. The current is transmitted over this main trunk line at 66,000 volts. The standard towers of this line are about 80 ft. high and under normal conditions are spaced about 700 ft. apart.

WEST FRANKFORT'S TRANSFORMER STATION



Many power lines radiate from the big transformer station at West Frankfort, where the main line potential is stepped down from 66,000 to 33,000 volts for transmission to the various mines and communities served. The biggest industrial consumer in this locality is the Old Ben Coal Corporation. This company takes all its current at one point and transmits over its own lines to each of its twelve mines scattered throughout this region. This arrangement tends to equalize the demand and reduce excessive peaks. The more mines that are connected in this way the more thoroughly and completely are sharp demand peaks avoided.

Other companies served in this region are following

Digitized by Google

Across the Pond

This is a view of the Muddy plant taken from the bank of the spray pond. Make-up water for the operation of this plant is impounded in a reservoir several acres in extent which affords an ample supply for both condensing and boiler-feeding purposes.

a similar practice wherever possible. Thus, the Orient mines, Nos. 1 and 2, of the Chicago, Wilmington & Franklin Coal Co., are connected electrically, and power for their operation flows both ways from a common substation serving both mines.

Again, electric hoisting naturally constitutes an intermittent demand for power and tends to run up the peak requirements which, in turn, affects the price paid per unit of energy consumed. In order to lower, so far as possible, this demand charge, most electric hoists installed throughout this region are operated on the Ilgner, or Ward-Leonard, system. By this system a flywheel motor-generator set is interposed between the line and the hoist. The excessive momentary current requirement of the hoist is thus largely supplied by the momentum of the flywheel which thus irons out, or equalizes, the power demand.

Power Factor Is Ninety per Cent

A higher power factor is preserved throughout this transmission system because of the many synchronous motor-generator sets employed. This power factor averages 90 per cent or more on the entire system.

Throughout this region all or practically all, the mining load comes on in the daytime. About the only operations performed in the mines on the night shift are ventilation (this is common to the day load also), some pumping and some battery charging. In other words, the conditions in this field are such that the night load of the mines is extremely light compared to the demands of the day shift. This results in a bad load factor so far as the mines alone are concerned, their total requirements averaged throughout the entire 24-hr. period being only about 25 per cent of their maximum demand.

By lighting all the communities through which its lines pass and by supplying most of the local industries there located, the Central Illinois Public Service Co. is enabled to increase this load factor to about 45 per cent. This makes possible corresponding economies in power generation and consequently a lower sale price.

Again, the region served by this power system is one that is poorly watered. A glance at any map of Illinois will show that few sizable streams traverse this area, which in this respect differs somewhat from the central and northern portions of the state. Though the actual rainfall over the southern counties probably does not differ materially from that in other portions of the upper Mississippi valley, yet its distribution throughout the year appears to be more erratic. At times no rain has fallen in this region for as much as three months at a time, these being the hottest months of the summer. As a result the procurement of a water supply sufficient for the operation of a sizable power plant may prove to be both difficult and expensive, if not even impossible. Utilization of purchased power relieves the mine of this expense and the management from this source of trouble and worry.

Flat-Rope Hoist Planned For 4,265-Ft. Lift

IN HOISTING from extremely deep mines the great length of round rope that would be necessary on the ordinary drum cannot be accommodated and flat rope must be substituted. The following description of a deep mine hoist built to accommodate this type of rope is abstracted from *The Engineer*, London, England, of Feb. 19 and relates to a recent installation in the Belgian fields where the depth of the coal beds is excessive.

Flat rope used in such deep mines resembles a ribbon woven from steel wires. This is wound upon itself like tape on a bobbin as the cage is raised. Some decided constructional advantages inhere to this system. Thus, the hoist drums are simple and light in weight compared to those of the cylindrical or cylindro-conical type ordinarily used. They consequently impose small gravity and inertia stresses upon the machine.

In the accompanying illustration Fig. 1 shows a flat rope hoist recently installed by the Société Anonyme des Ateliers de Construction de Charleroi in Belgium. It raises coal from the main shaft of the Peiton pit of the Société des Carbonnages de Monceau-Fontaine. It was the original intention at this colliery to employ round ropes because of their greater durability, but the huge size of the drums necessary as well as other considerations caused the abandonment of this idea and the substitution of the flat rope system. The hoist in question is designed for an ultimate working depth of 1,300 m., or 4,265 ft. The present depth is 805 m. (2,640 ft.). Each cage complete weighs 4,000 kg. or 8,816 lb. and will hoist eight mine cars per trip. The weight of an empty car is 300 kg. or 662 lb. while its contents when full of coal will weigh 600 kg. or 1,322 lb. When loaded with rock this weight will be 950 kg. or 2,095 lb. When new the cable is 200x25 mm. (7.9x0.985 in.) in cross-section. It is composed of ten hawsers, each consisting

Digitized by Google

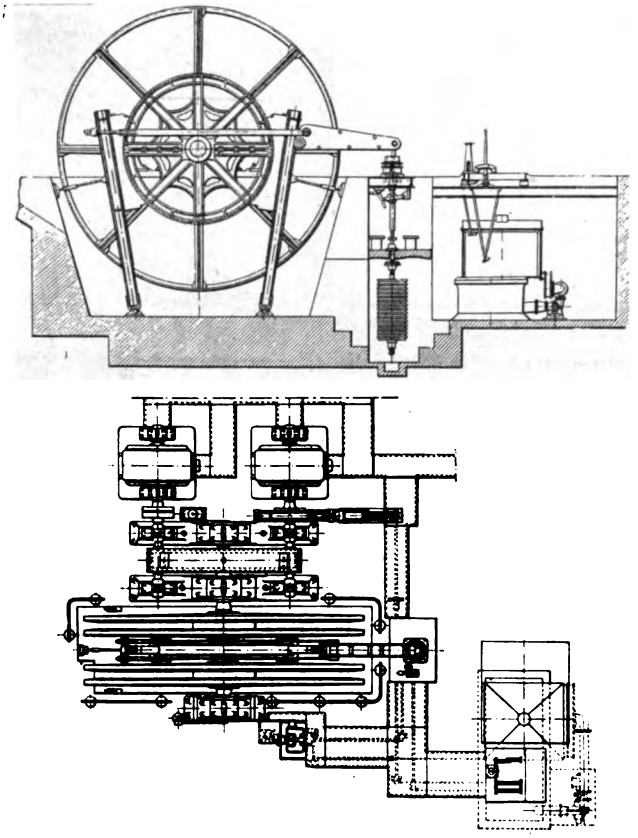


Fig. 1—Plan and Transverse Section of Hoist

This is a typical modern flat-rope hoist. Its distinguishing characteristics are the narrow width and light weight of the drums. Aside from this the machine here shown strongly resembles both in structure and duty cycle a modern American hoist fitted with double conical drum.

of four strands of eleven wires each. Its weight is 11.9 kg. per meter of length (about 8 lb. per foot) and its breaking strength is 212,000 kg. (about 468,000 lb.). This affords a factor of safety of 9 when carrying a maximum load of 23,500 kg. or 50,000 lb.

When hoisting from a depth of 805 m. (2,640 ft.) it was specified that the machine should be able to raise a useful load of 7,600 kg. (16,750 lb.) at the rate of 25 trips per hour. From a depth of 1,000 m. (3,280 ft.) it must be able to raise a useful load of 6,650 kg. (14,650 lb.) at a speed of 23 trips per hour, while from the full depth of 1,300 m. (4,264 ft.) it must be able to lift a useful load of 5,700 kg. (12,580 lb.) at the rate of 20 trips per hour. It was also specified that the machine must be able to raise a load of 500 kg. (1,100 lb.) from a depth of 1,000 m. at a speed not exceeding 75 per cent of normal. A further condition was that the hoist should have a good commercial efficiency when working with cages of half the capacity above mentioned from a depth of 805 meters.

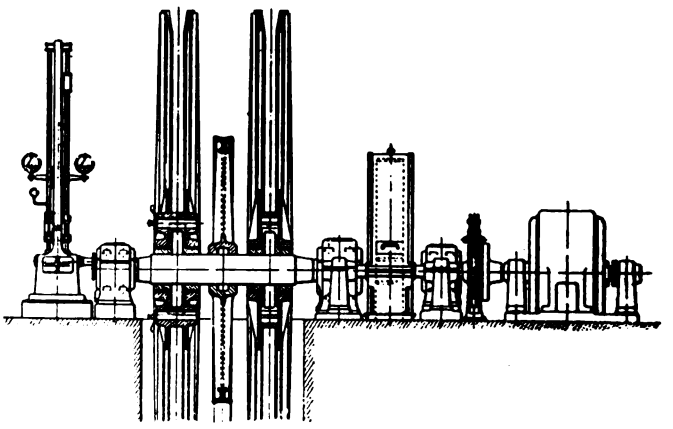
In order to meet the conditions specified it was decided to drive the engine by means of two duplicate electric motors connected to the main shaft by double-helical gears. The arrangement is shown in the accompanying illustrations. The motors are placed side by side with their pinions meshing with opposite sides of the main gear wheel. The speed reduction thus secured amounts to 9.85 to 1. These motors are of the induction type, 3-phase, 50 cycle, 6,300 volts and have a continuous rating of 575 hp. each. Their synchronous speed is 500 r.p.m.

Should it become necessary to operate this hoist for a short period at reduced capacity, one motor may be disconnected at the flexible coupling, while, if such operation were to be continued over an extended period, the pinion would, of course, be removed. It should be noted that the pedestals of the pinion shafts are mounted on continuous transverse sole plates so that the distance between the various shaft centers is rigidly maintained.

The hoist drums are of the type common to Belgian mines. They consist of cast-iron centers carrying radial steel arms of built up T-sections and connected at their outer ends to angle iron rims. Arms and rims serve only as guides to insure an even coiling of the rope upon itself and consequently during normal operation no stress is thrown upon them. Each arm carrries a facing of oak where it comes in contact with the rope. Both drums are movable on the shaft so that adjustments of the rope may be easily and quickly effected. They are mounted on hubs keyed to the shaft and each can be instantly locked to its hub by means of a simple patented device. Provision is thus made for any degree of adjustment required.

DOUBLE WATER RHEOSTAT CONTROLS HOIST

The driving motors are started simultaneously by a double water rheostat, each part of which has three fixed electrodes, composed of numerous sheet iron plates about ⅛ in. thick. Each set of these electrodes is, of course, connected to the slip rings of the motor controlled. The plates are specially shaped to give the required rate of change of resistance as the depth of immersion varies. The liquid employed is a solution of carbonate of soda. This is delivered continuously by a small motor-driven centrifugal pump to the electrode chamber. The tank has a rectangular opening in one side provided with a sluice gate through which the solution can escape into a reinforced concrete tank below. This



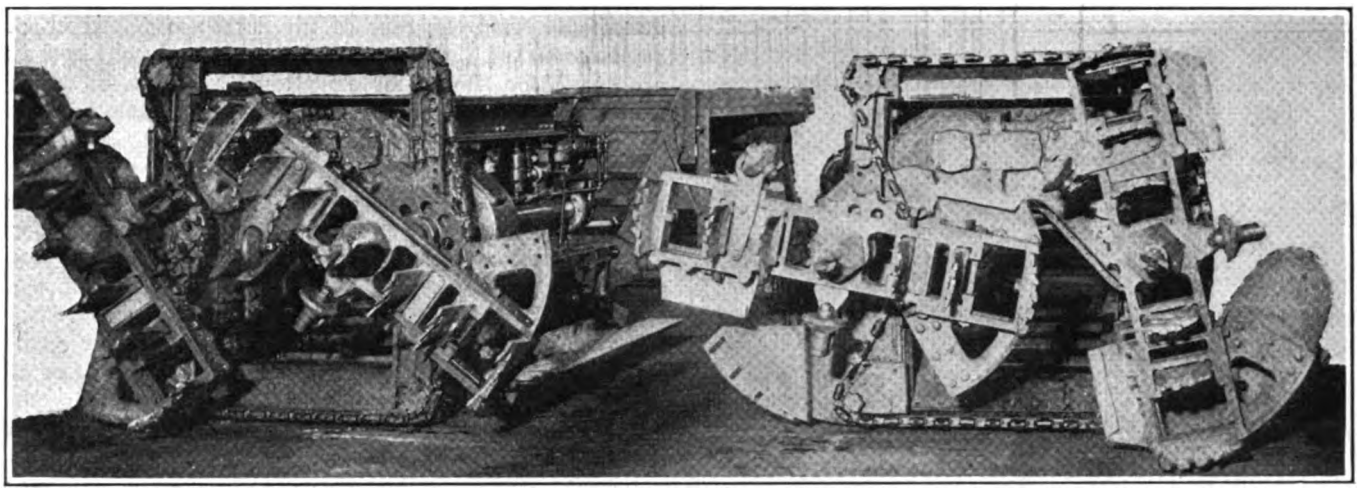


Fig. 2—Vertical Section Through Drums

The narrow width of the drums or spools is worthy of comment. The width of opening of each spool is of course only slightly greater than the width of the rope. Wearing strips of oak protect the drum spokes.

gate is operated by the starting lever and its position will obviously determine the rate at which the electrodes are immersed.

To reverse the direction of rotation of the motors and hoist, a three-pole change-over switch is connected mechanically to the rheostat lever. This switch controls the excitation of sets of solenoids which in turn operate the reversing oil switch. This reverses the connections of the two phases in the stator of each motor and thereby changes the direction of rotation of the magnetic field.

Machine Cuts and Loads with Minimum Breakage And Without Aid of Explosives

Advances One Foot in About Two Minutes—Saves Roof and Ribs by Making Blasting Unnecessary—Shape of Roadway as Driven Is Nearly Oval—Costs Are Less Than Those of Hand Mining

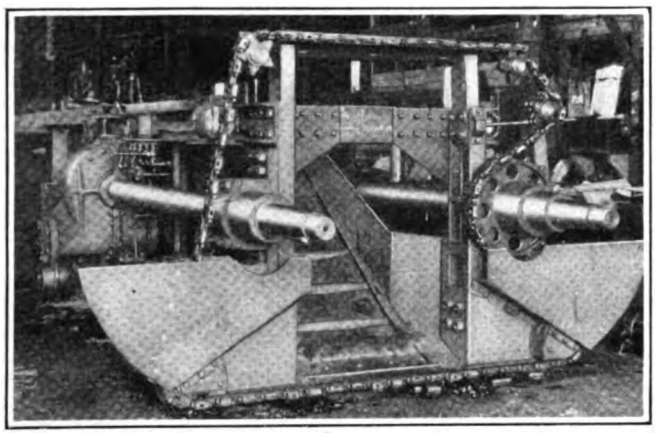
By Oscar Cartlidge
Consulting Mining Engineer
Charleston, W. Va.

TWO large revolving arms fitted with long, thin, protruding blades set with teeth of high-speed tool steel, followed by wedging wheels that break the coal down in large lumps onto a swiftly moving conveyor, the whole device advancing into the solid coal at the rate of an inch every ten seconds—such is the McKinlay automatic coal mining and loading machine, a mechanism that cuts coal out of the solid and delivers it into mine cars or to conveyors without the exercise of manual labor or the use of explosives.

One of these machines has advanced in Pocahontas No. 3 coal at the rate of over 7 in. per minute, cutting an entry approximately 5 ft. high and 10 ft. wide and loading three cars of 3-ton capacity in 10 minutes. In the Illinois No. 6 bed it has advanced an entry 6 ft. 2 in. high and 11 ft. 4 in. wide a distance of 195.5 ft. in 30 hours of consumed working time, with a production of 155 tons of coal. This was accomplished by entirely inexperienced men in the employ of the coal company, with no representative of the machine manufacturer present. None of the men operating it had ever seen a machine of this type before. Later runs in this same mine have averaged 8 ft. of advance per hour, the actual forward movement at times being as much as 4 in. per minute. Places have been driven for 35 ft. in this extremely hard coal without a change of cutting bits.

In a Kentucky mine the first machine of this type actually placed in operation, working under conditions where but one-third of the forward speed was available on account of power shortage, 368.5 ft. of advance was made in 24½ shifts. If full power had been available on the machine to push it into the coal, it is safe to assume that the advance would have been at least twice this distance, if not more. This entry was driven toward the outcrop and was actually advanced to within 4 ft. of daylight before the machine was compelled to halt. During the night the roof caved, and the next morning the machine runners walked outside through the opening. It would have been impossible to approach anywhere nearly as close to the outside if work had been conducted by ordinary methods and the coal brought down with explosives. This entry was 6 ft. high and 11 ft. 6 in. wide.

Actual labor costs for an average day at this mine, in comparison with the standard cycle of machine cutting, shooting and hand loading, is interesting. Such a comparison shows the results recorded in the table.



Cost of Operation of McKinlay Machine Compared with Machine Cutting with Hand Loading

McKinlay Machine		Standard Method	
Daily Expense			
Machine operator			$7.00
Helper			5.60
Car trimmer			5.60
Total labor			$18.20
Tons produced			62.4
Costs per Ton			
Labor	$0.291	Cutting	$0.120
Power (purchased)	0.025	Power	0.025
Depreciation (estimated)	0.100	Explosives	0.040
		Loading	0.620
Total production cost	$0.416	Yardage	0.100
		Total	$0.905
Difference, per ton, in favor of machine			0.489

A test made on this machine covering an entire day's run gave a metered power consumption costing 2½c. per ton of coal produced. Tests on an installation in

The headpiece shows the business ends of two McKinlay machines in different positions. The revolving heads cut out circular openings that slightly overlap each other, leaving triangular segments at top and bottom. These were cut away by means of the cutter chain that follows close behind the revolving heads.

Digitized by Google

With Cutter Arms Removed to Show Conveyor

This shows more clearly the cutter chain and the means employed for driving it and altering its height. As shown the machine will cut a heading about 9 ft. wide and 7 ft. high. The cutter travels at a linear speed of about 100 ft. per minute.

Illinois showed an average demand of 65 hp. when the machine was advancing at the rate of 3 in. per minute.

In the softer Pocahontas coal, during a test run this machine when under full power required 55 amp. of current and three mine cars of 3-ton capacity each were loaded in 10 minutes.

This machine affords a complete process for mechanical coal mining and performs all of the usual functions of undercutting, blasting and loading. The frame is rectangular, built up of heavy structural members upon which the various parts are mounted. Steel castings, nickel-steel castings, steel forgings and nickel-steel forgings intended for extra heavy duty, with bearings of ample surface, are used throughout. Roller and ball bearings are employed where necessary, and the gears are all of hardened steel with cut teeth.

MANY SIMULTANEOUS ACTIONS

The entire unit is mounted on wheels and moves forward without tracks under its own propulsion traveling on the bottom of its own cut. The various operations performed are: (1) The cutting and wedging down of the coal, (2) the pushing or sweeping of the coal onto the conveyor, (3) the transport of the coal through the machine and into cars or onto auxiliary conveyors, and, (4) the movement of the machine forward as it cuts its way into the coal—that is, the feed. These will be considered briefly in the order named.

The cut made usually is about twice as wide as the height of the coal bed in which the machine is operating. In thin coal, however, the cut may be widened by the addition of one or more extra rotating arms. The shape of the cut is almost oval, but with a smooth, flat surface about the vertical axis at both the top and bottom.

The main cut is made by two heavy cast-steel bars, or arms, which revolve in slightly overlapping circles. These arms are driven by the two main shafts and are of nickel steel. Both revolve toward the center at the bottom. The heavy bearings of the drive shafts. with their rigid construction and the balanced motion of the arms, permit the cutting to be done with little vibration. Fitted into these cutter arms are long flat bit holders about 10 in. wide curved to the radius of the circle in which they operate.

These holders are made of nickel steel and are fitted at the ends with removable cutting bits. They are detachable from the rear of the cutter arms for quick replacement of the bits. The distance at which they are spaced on the cutter arms and the depth at which they cut are determined by the size of the product desired and the natural cleavage of the coal. Each bit holder makes a narrow circular kerf about 2 in. wide. When these kerfs are advanced to the proper depth—usually 12 to 18 in.—adjustable wedging wheels also carried on the cutter arms enter them and force the coal apart until it breaks and falls in front of the machine but in the rear of the arms.

The cutter arms, making two perfectly circular openings in the coal, leave two triangular segments, one at the top and the other at the bottom of the cut directly in front of the center of the machine. These segments are overcut and undercut respectively by a chain provided with removable bits driven by cast-steel sprockets on the main shafts. The guides for this chain form wedging plates which break the coal loose.

DRILL GUIDES PROGRESS OF MACHINE

In the center of each cutter arm is a pilot, or guide drill. This bores into the coal slightly in advance of the kerf-making bits and breaks it outward to the first or inner circular kerf. The cutter arms are driven by the main motor of the machine, which is geared to the main shafts. Practically all the power used is absorbed by the cutting tools.

In front of the main frame but behind the cutter arms is a space into which the dislodged coal falls. On the back of each cutter arm is mounted a heavy plate sweep or shovel. This, with a half sweeping, half shoveling action, delivers the coal to the machine conveyor, thoroughly cleaning up all the material that is broken down.

At the bottom of the frame and extending from its forward end to a point beyond its rear extremity, is a sturdily built steel flight or drag conveyor. The coal is pushed onto this conveyor by the sweeps and is delivered by it into mine cars or to an extension conveyor if the mine is using a conveyor system.

The rear ends of the main drive shafts terminate in ball bearings mounted on a steel-casting crosshead. At the center of this crosshead is mounted a hydraulic plunger or ram. This may be jacked to either side of the cut in the solid coal and moves the entire machine forward when pressure is applied through the pump.

CAN REGULATE FEED AT PLEASURE

It can be run at any speed desired by means of a variable-speed electric motor driving a hydraulic pump, employing light oil as the operating liquid. The greater the application of this pressure the faster will the machine move forward. All cutting stresses on the arms are transmitted directly through the main drive shafts to the thrust bearings on this crosshead and do not pass through the frame of the machine. The direction of the cut can be varied by adjusting the jacks extending from the ends of the ram to the sides of the cut. The machine also is kept in alignment by this means.

After the machine has been put in operation and the driver has become familiar with the proper feed to maintain in the coal in which it is working, the jacks can be set and the machine operated with little or no attention until it has moved forward the full stroke of the plunger. The flow of the liquid is then reversed,

Digitized by Google

causing the plunger to move inward; the jacks meanwhile are reset. This operation takes about one minute, after which the machine again may be started.

While cutting is going on the men see to the delivery of the coal into the cars and keep up the mine track back of the machine. An operator soon becomes accustomed to the sound of the machine when it is working properly and needs to give it little attention except to reset the jacks.

The number of men required to operate this machine varies from three for the largest size to two for the smallest. At present three sizes are built, each having extensions on the ends of the cutter arms providing a variation of 8 in. in the diameter of the circular cuts.

The minimum and maximum dimensions of the cuts are: Small size, 4 ft. 6 in. high by 8 ft. wide, extensible to 5 ft. 2 in. high and 10 ft. wide; medium size, 5 ft. 4 in. high by 9 ft. 2 in. wide, which can be increased to 6 ft. 2 in. high and 11 ft. 4 in. wide, and the large size, which is 6 ft. 4 in. high by 11 ft. 6 in. wide, extensible to 7 ft. high and 12 ft. 2 in. wide.

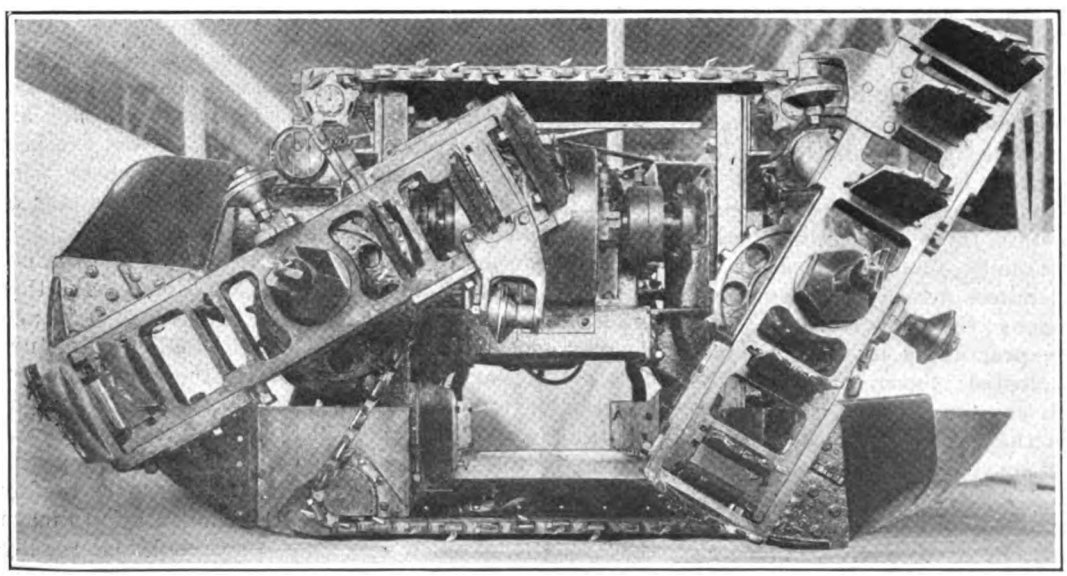
CHAINS CAN BE CHANGED TO SUIT ARMS

When the cutter arms are either lengthened or shortened the cutter chain also must be raised or lowered in accordance. This is quickly done by altering the position of the sliding heads to which the corner sprockets are fastened. The same principle of moving the cutter chain up or down is used to make the machine conform to varying thicknesses and positions of partings when separating them from the coal.

In order to facilitate the handling of cars, the most recently constructed machines are provided with an extension conveyor long enough to permit several cars to be placed under its delivery end, the actual number depending on the size of the place being mined. The ram or pusher advances the cut about 3 ft. at one stroke, after which the oil is reversed and the machine made ready for another start. During the minute or so required for this operation the loaded cars are removed, being replaced with empties. Consequently the conveyor should be long enough to permit the spotting of enough cars to hold all the coal mined at one advance of the plunger.

The most recent machines are fitted with hydraulically operated leveling devices connected directly to the feed cylinder. They are thus enabled to follow any variation of the coal bed by changing the cutting angle.

For thin coal, in order to obtain width more than two circles may be cut or the two circles may be pitched farther apart, with the cutter chain loosening the coal between them. Another alternative would be to have several parallel cutter arms, driven from the main shafts, which would operate on long faces, being propelled by a rope or chain.



The present machines are provided with long axles and removable wheels that may be set to any gage. These are replaced by smaller wheels before the cutters are started into the coal. Dashpots, actuated by hydraulic power, raise and lower the wheels for easy and quick interchange.

Designs are being prepared for other sizes intended for work in coal as thin as 30 in. Still others will provide for the removal of bands of slate and other impurities. This is accomplished by superimposing one set of cutter arms above another, the lower cut extending from the floor to the parting and the upper from the parting to the roof or to the next band of impurity, if there is more than one.

The upper cut will advance slightly ahead of the lower, and the coal from it will be deposited by a short drag upon the main conveyor below. Wedging guide plates, supporting the chain that cuts out the triangular segments, will break up the slate band, and a short side conveyor will carry it to the gob. More than one band can be removed in this way by superimposing cutter arms, all of which will be securely fastened to the lower frame and driven from the main shafts by chain and sprockets. The upper cutter chain is so made that it can be raised and lowered. Thus a parting or band can be followed, should it increase in thickness or change position. It also is necessary to lower this chain when transporting the machine to another working place.

SHARPEN BITS ON EMERY WHEEL

The outer set of bits on the cutter arms, of course, travel much faster than those nearer the center of the cut and are in contact with more coal in any given length of time. As a result they dull more quickly. The number of rotations made by the cutter arms is about eighteen per minute. By experimenting with different grades of high-carbon tool steel and by using blunt-

"Bows On"

With bit holders and bits in place. The center augers, wedging wheels and the means employed for adjusting or changing the length of the cutting heads also are visible. The bits and augers are sharpened on an emery wheel instead of being heated and retempered. As much as 35 ft. of heading has been cut with one set of bits before replacement.

Digitized by Google

nosed or hammer bits it has been possible to make an average advance of 35 ft. in the Illinois No. 6 bed before having to change bits. These bits are not heated and hammered to shape when dull but are simply "touched up" on an emery wheel without retempering.

Successful but experimental work has been done with this machine in fireclay mines. In these tests it was found that by setting the bit holders close together the clay was reduced to small pieces. This is desirable inasmuch as fireclay has to be finely ground before being made into any manufactured product. At present a machine with one crossarm is being built for a Cleveland contractor who intends to drive a tunnel with it in black slate. This passage will be 6 ft. in diameter and 6,000 ft. long. Doubtless the machine can be used to cut not only fireclay but slate and shale.

This machine, which is manufactured by the McKinlay Mining & Loading Machine Co., of Philadelphia, Pa., has a low maintenance cost and promotes safety by dispensing with explosives entirely and by cutting an approximately oval passage that gives more support to the roof than if the ribs were vertical. By making it possible to drive places without the use of explosives the roof, ribs and floor are saved the shattering that invariably accompanies blasting.

Charleston Welcomes Coal And Byproduct Men

Buyers of Coking Coal Call for Evaluation Table and Stabilized Prices—Possibilities of Gas Coals—Loading Problems Discussed

By a Staff Contributor

CONFINED AS IT WAS to coal mining and to the problems involved in producing and disposing of byproducts, the meeting at Charleston, W. Va., May 6 and 7, of the local section of the American Institute of Mining and Metallurgical Engineers proved of special interest to mining men. The attendance of fifty or more was made up for the most part of mine operators and mining engineers. Territory from New York to Illinois, inclusive, was represented.

Appropriately, the subject which to some operators has been a "bitter pill" was placed first on the program. A joint paper by Robert M. Lambie, chief of the West Virginia Department of Mines, and Gordon MacVean, of the Mine Safety Appliances Co., dealt with pertinent facts on the subject, "Rock-Dusting in West Virginia." In the discussion that followed, prominent operators told how "Bob" Lambie had slowly but surely convinced them of the value of rockdusting and how the dose was proving to be sweet rather than bitter.

In May of last year, there were but two completely rock-dusted mines in the state, these being mines Nos. 2 and 12 of the Boone County Coal Corporation at Sharples. Today thirty mines owned by twenty-two companies are listed among those rock-dusted. Although the center of the practice is in the Fairmont district, there are now dusted: Seven mines in the Wheeling-Panhandle district; five in the Pocahontas-Tug River field; four in the New River field; two in Logan County; two in Boone County and one in the Thacker field.

In the paper attention was called to the factors which influence the explosibility of coal dust. Important among these are the volatile content, the fineness and the dryness of the coal. Experiments indicate that with coals of varying volatile content the presence in the dust of the entry of from 54 to 75 per cent of incombustible matter will prevent the propagation of an explosion.

John H. Jones, safety engineer of the Old Ben Coal Corporation, led the discussion of this paper. He described in convincing terms the part that rock dust played in stopping the gas explosion at Orient No. 2 mine. The section of the mine in which it occurred had been dusted five or six months before, and the ratio of rock dust to coal dust was probably 80 to 20. The entries had been driven 250 ft. beyond the end of the dusting and were very wet for this distance. The gas accumulation at the face probably extended only 30 to 40 ft. This condition provided an excellent opportunity for the wet section to stop the explosion, but it failed.

AFTER 25 FT. NO COKE WAS SEEN

At a point 100 ft. from the face the coal dust did not ignite, but at 250 ft. ignition of the dust began. Twenty-five feet beyond the beginning of rock dust no coke was to be found. The inference was that water is of no value in stopping the propagation when such a body of gas is present, whereas rock dust is quite effective in extinguishing the flame.

Mr. Jones disagreed with a statement in the paper regarding the cleaning of the entries before dusting. He thinks it better to rock-dust without waiting to clean the dust from the entry. This gives immediate instead of delayed protection. In his opinion if the coal dust exceeds a certain limit there is no increased danger, for the force of the explosion is limited by the quantity of oxygen the air contains. Any excess of fuel for the flames remains unburned.

He said that in the Illinois mines the rock dusting did not deteriorate 10 per cent per month, as the readers of the paper asserted. Assuming 93 per cent of non-combustible to be present at the start, by the end of the first month the percentage will have dropped to approximately 83. At the end of the following month it will be 81 per cent, and in the succeeding months 80½, 80⅓ and so on. The Old Ben Coal Corporation had found that dusting twice a year would afford protection. The falling of the roof and the spalling of the ribs were the principal causes making redusting necessary.

The material from which the Old Ben Coal Corporation prepares its dust is a shale occurring above the coal. It is ground to an average fineness such that 92 per cent will pass through a 255-mesh screen. Although the dust was of so dark a color that it did not aid much in the illumination of the mine, it was the best that they had found, considering the fineness with which it could be pulverized and the high percentage of incombustible matter it contained.

Asked concerning the practice in the Old Ben mines in regard to rock-dust barriers, Mr. Jones said that the length of the trough has been reduced to 6 ft. and the dust content per trough from 200 to 60 lb. Moisture does not appear to affect the dust in the barriers to an appreciable extent. Certain barriers which were put up nine years ago are still as effective as ever. Although the troughs had been redesigned partly because troughs of smaller capacity were more readily supported, the main reason for the change was to make the troughs of such size that they could be readily

Digitized by Google

lifted and carried, should their contents be needed to extinguish a mine fire.

He described how seven years ago a serious fire was extinguished by rock dust. The chemical extinguishers had failed to control the flame, and seals were in the process of erection, when someone suggested the use of rock dust. A number of troughs were brought to within 150 ft. of the fire, which was as close as they could be transported on account of the heat of the burning coal. A trough of dust was then thrown in the air toward the fire. This dust was carried into the flame by the air current. It cooled the flame to a noticeable extent. This was followed immediately by an advance of about 10 ft., at which point another trough was discharged. The fire fighters proceeded, gaining about 10 ft. with each discharge until at last the men walked right over the fire. Others following plastered dust over the points that were smoking. The extent of the fire is indicated by the fact that, on cleaning up the roadway, a car of coke was loaded. This was shipped to the power plant for boiler fuel.

WATER NOT WITHOUT EFFECT

Carl Scholz, manager of the Raleigh-Wyoming mines, stated that he believed moisture does have a marked effect in arresting or minimizing an explosion. He cited the case of the local gas explosion at Glen Rogers mine, which is very wet. After the explosion no coke could be found. To illustrate the difference in moisture between this mine and a certain Illinois mine he stated that he had to discontinue overcutting in the Illinois mine, whereas in the West Virginia operation he was able to centercut the coal without causing any appreciable dust. He closed his remarks by declaring his belief in the rock-dust remedy, repeating, however, his conviction that the presence of moisture was helpful.

Dr. T. T. Read, formerly of the Bureau of Mines and now assistant secretary of the American Institute of Mining and Metallurgical Engineers, then discussed the relation between the mechanicalization of mines and accidents. Generally speaking, the introduction of machinery in an industry does increase the hazard, but statistics so far show little or no relation between accidents per 1,000 men employed and the degree of mechanicalization of coal mines.

R. W. Sweetser, assistant to the vice-president of the American Rolling Mill Co., read a paper entitled "Evaluation of Coal in Metallurgy." He stated that the necessity for evaluating coal came to mind when he found how closely the quantity of coke required per ton of pig iron varied with the percentage of ash in the coke. The old idea that a certain quantity of ash was necessary in metallurgical coke to give it strength is entirely fallacious, said Mr. Sweetser.

Speaking generally, coke is used in a furnace solely to provide a source of carbon. The higher the carbon content of the coke the better. One per cent of ash in coking coal adds 30c. per ton to the cost of pig iron. Mr. Sweetser advised the coal men to start at the point at which the iron men have already arrived. They had prepared a schedule on which was based the premiums and penalties which determined the relative values of iron ore. He asserted that iron men had just as many variables and difficulties facing them in making a schedule as the coal men have in determining one for their product.

In the discussion Dr. T. T. Read emphasized the fact that a coal table would not have to show the correct relative values of the coke but would need only to provide a scale from which to measure. C. E. Krebs, consulting engineer, of Charleston, related the difficulties which he had encountered in trying to make a table evaluating coals on the basis of their various desirable and undesirable qualities.

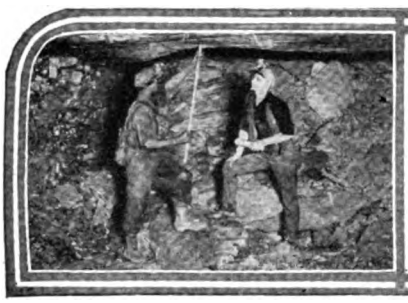
OF MANY ANALYSES, SWORE BY BEST

Josiah Keely, president of the Cabin Creek Consolidated Coal Co., expressed the opinion that to base prices on an analysis would result in an endless squabble as to the fairness of the sampling. Mr. Sweetser replied that the iron men had all of these difficulties and more. Twenty years ago it was not unusual for the seller of ore to engage as many as three different laboratories to sample and analyze his shipments. He based his price on the best analysis. Today the sampling must be done by a method which had been adopted as a standard.

Mr. Kelly, a commercial chemist, stated that 75 per cent of all the coal samples sent to him for analysis are really worthless because of the improper sampling methods. He thinks, however, that a channel mine sample, within the limits of accuracy of the analyzing equipment, can be taken without difficulty.

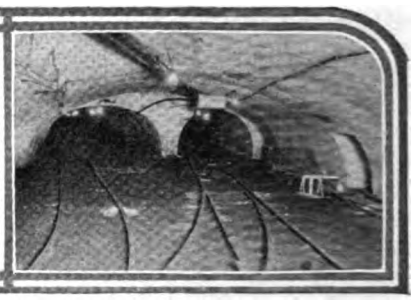
O. O. Malleis, chief chemist of the laboratories of the Koppers Co., which are maintained at the Mellon Institute, delivered an illustrated talk on "Development in Byproduct Coke Ovens." He defined a coking coal as "one which will produce merchantable coke," saying that the limits are now so broad that this is the only safe definition. Most coal is still being pulverized to 70 to 80 per cent through a ⅛-in. hole before coking, but the Carnegie Steel Co. is charging ovens with coal crushed so as to pass a hole of 1½ in. diameter.

Josiah Keeley followed with a paper on "Mechanicalization of Coal Mines and Its Influence on Market Preparation" and Edward Graff, general superintendent of the New River Coal Co., one on "The Effect of Mechanicalization on the Cleaning of Coal."



SMALL CONSUMER WILL BURN SLACK

At a banquet held in the evening after the first day's meeting J. G. Bradley, president of the West Virginia Coal Association, who acted as toastmaster, said that the domestic stoker is a coming development which will widen the demand for coal and lessen the demand for lump sizes. Other speakers at the banquet were S. A. Taylor, of Pittsburgh, president of the A.I.M.E.; W. A. MacCorkle, ex-Governor of the state, and Walter Cunningham, secretary of the West Virginia Coal Association. About 200 were in attendance.



At the morning meeting of the second day J. J. Forest, president of the By-Products Coal Corporation, of Chicago, addressed the assemblage on "Byproduct-Plant Operation and Sale of Product" and later W. W. Freeman, of Cincinnati, president of the Union Gas & Electric Co., spoke on "The Utilization of Artificial Gas and Its Practicability as a Means to Supplement the Available Supply of Natural Gas in Various Industrial Communities."

The Charleston meeting was ended by a short talk by J. K. Taylor, president of the section, in which he deplored the interference of government bureaus in business, referring especially to the Interstate Commerce Commission.

Underground Operation

Why No Mine Can Be Properly Ventilated Unless Roof Is Caved

Air in Open Spaces Should Be Renewed Many Times Each Hour—In Uncaved Mine, Power on Fan Must Be Increased One Thousand-Fold to Achieve That End

By Edward O'Toole
General Superintendent, United States Coal & Coke Co.,
Gary, W. Va.

Failure to extract pillars presents to the ventilation engineer almost insuperable problems. The vacant spaces harbor large quantities of coal dust, no matter how much air is supplied, and that is one reason for providing for such complete extraction that the roof will fall and cover such deposits.

If the air in a gaseous mine is not removed in the extraction areas either by falls of roof or ventilation it will contain dangerous quantities of methane. No really gaseous mine is receiving enough air to bring the atmosphere to a desirable degree of freedom from that gas.

Every Mine Its Own Hazard

In some mines danger is greater and more imminent than in others, but all mines have danger zones. The dangers in some are at the working face, where, as mining proceeds, explosive gas is liberated. Some mines have a danger zone in the second mining, or pillar-drawing, stage, caused by the breaking of the strata overlying the coal and the liberation of explosive gas thereby. This explosive gas, being lighter than air, accumulates in high places, such as the cavities and crevices caused by breaks in the strata or by falls of the mine roof. When the gas is present in sufficient quantities, it floods into the adjacent open workings.

The danger zones in some mines are to be found in the large open spaces resulting from the non-extraction of pillars. Such open spaces, when not properly ventilated, act like the backwater of a stream. In such open areas the fine coal dust that is carried in the mine air settles on the sides, timbering and floor, just as flood water runs into backwater sections, leaving a deposit of fine mud behind.

Where Danger Zone Lies

This dust is raised in the mine atmosphere whenever the passing of cars, the falling of roof, the explosion of gas or of powder, or some other rapid movement causes an inrush of air. In all mines material may fall from the sides or the roof and endanger the workmen.

In our mines we draw a line horizontally along the sides of all hauling, traveling and air ways and along the face of each working place, 3 ft. from the bottom. We consider all space above this line as a danger zone.

The mining laws of most mining states require that all abandoned, or temporarily abandoned, open spaces in the mine shall be made safe by adequate ventilation. This brings up the question: What is proper ventilation?

Table I—Ventilation Required for Certain Rooms

Type of Room	Number of Times Air Should Be Removed per Hour
Public waiting rooms	4
Public toilet rooms	10
Small convention halls	4
General offices	3
Public dining rooms	4
Banquet halls	5
Hotel kitchens	4 to 6
Textile mills	4

According to Allen and Walker's "Heating and Ventilation," page 181, rooms should be ventilated as in Table I.

Do open spaces in mines require as much or more ventilation than these classes of buildings? If they only require as much, the presence of open spaces in mines becomes a serious matter. An estimate has been made of the open space in a mine producing 3,500 tons daily with the result as in Table II.

Table II—Open Space in a Mine of 3,500 Tons Capacity

	Length in Feet	Area of Open Workings, Cu.Ft.
Headings	101,700	6,857,631
Aircourses	94,800	9,297,984
Heading crosscuts	49,285	4,229,638
Rooms	28,300	4,163,496
Machine room	8,900	1,091,140
Room crosscuts	11,280	968,049
Drainage heading	14,800	1,814,480
Total	309,065	28,422,418

From Table II it can be readily calculated that the open space in the mine instanced is about 8,000 cu.ft. for each ton of daily capacity. This ratio of volume of mine space to daily coal output is possibly as low as in any mine operated by the room-and-pillar system with the type of mining machinery now in general use. The average for the country would be about 20,000 cu.ft. of mine space per ton of daily capacity.

Air Required per Ton of Coal

If this mine was ventilated as well as Table I would indicate for general office buildings, 576,000 cu.ft. of air should be circulated through it each 24 hours per ton of coal produced. If this mine was ventilated as well as convention halls should be, it would need 768,000 cu.ft. of air each 24 hours per ton produced. If it was ventilated as well as a banquet hall, it would need 960,000 cu.ft. per 24 hours per ton produced.

Some large mines produce as much as 10,000 tons of coal per day. One ton of coal in the solid seam occupies about 25 cu.ft. of space; therefore, each day's mining produces 250,000 cu.ft. of open space,

Second part of paper on "An Experiment in Combined Cutting, Mining and Loading in Coal Mines," read March 11, in New York City at a meeting to discuss coal loading sponsored by the Materials Handling Division of the American Society of Mechanical Engineers and the National Coal Association. First part, which deals with the action of the mine roof, appeared April 22, pp. 570-571.

Digitized by Google

plus what additional cubic feet of rock and refuse may fall or be taken down and have to be removed.

Allowing 200 days for a year, at the end of the first year there will be 50,000,000 cu.ft. of open space in such a mine; and if in ten years no pillars are drawn and the open spaces are not filled by water or other means, there will be 500,000,000 cu.ft. of open space in such a mine.

I have developed this subject of mine ventilation for the purpose of showing you the magnitude of the problem of properly ventilating large mines by replacing all the air from their vast spaces three, four, or five times per hour, as required in office buildings, assembly rooms and banquet halls, respectively.

Fill Excavations by Falls

One other example, showing the problem from another angle: In June, 1915, two shafts reached the coal seam at a depth of 600 ft. Since that time the mine has been developed, and 1,710,257 tons of coal has been mined and shipped, and, in addition, this mine has hoisted and stored on the mountainside a large quantity of rock and refuse. Therefore the space excavated in the mine is approximately 45,000,000 cu.ft.

As no pillars have been drawn so as to cause the roof to fall and as the space from which the coal and rock has been mined has not been filled, this excavated space is standing full of air. To ventilate this mine, 200,000 cu.ft. of air per minute enters one of these shafts and goes out at the other. The chemical analysis of the exhausted air shows that it contains 0.9 per cent of methane.

Concentration Safer

This methane is transpired from the coal surrounding the spaces from which the coal shipped was mined. When it first issues from the coal it is pure, but when it comes in contact with the mine air it diffuses and mixes with the mine atmosphere and pollutes it to the extent that all the air coming from the mine contains 0.9 per cent of methane. In diffusion it has passed through all percentages of gas and air from pure methane to the mixture of methane and air which is exhausted from the mine.

This mine produces about 2,500,000 cu.ft. of pure methane every 24 hours and at all times about 400,000 cu.ft. of pure methane, mixed with air, occupy the spaces in the mine. This mine has about 130 working places, is equipped with the usual mining machines, and produces about 2,000 tons of coal every 24 hours, or about 15 tons of coal per working place in that same period.

Caves Save Power

Not only does this mine harbor large quantities of methane, but it also stores away part of the gases resulting from the use of about 700 lb. of explosive every 24 hours. It is receiving less than one-tenth of the air required to ventilate general office buildings properly, and for lack of an adequate supply of air is dangerous.

It is possible to increase the air entering this mine 50 per cent, but only at a great expense, as the velocity of the air current in the shafts is now 1,500 ft. per minute, and the power required to produce more air will increase as the cube of the velocity. Therefore, to provide 50 per cent more air will require over three times the power. To meet general-office air requirements over a thousand times the present power would be required.

To safely increase the production from this mine, operations should be concentrated and the extracted areas completely caved. The production from each working place should be from 300 to 400 tons per day instead of 15 tons, as at present. The ventilation would then be a small problem and the mine would be a safer place for the workmen.

Relative Hazard of Electric Circuits in Signaling

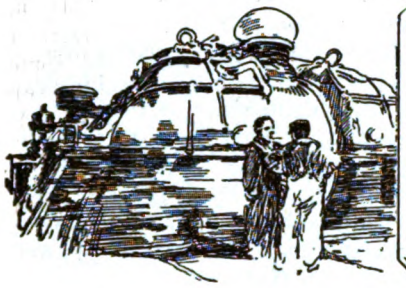
Exhaustive studies, extending over many years, into the ignition of methane by small electric currents such as are used in signals made under the direction of R. V. Wheeler for the Safety in Mines Research Board, of Great Britain, have resulted in the following conclusions: The igniting current for a given mixture of methane and air varies directly with the volatility of the metal at the spark gap, being lower than the boiling point of the metal.

Gold Arc Less Hazardous

Thus if the contact is between cadmium points which boil at 778 deg. C. the igniting current is 0.22 amp. at 120 volts, whereas if the contact is between gold points which boil at 2,530 deg. C. the igniting current is 0.5 amp. at the same voltage. Copper, which boils at 2,310 deg. C., gives a value of 0.49 amp. for the igniting point, the boiling point of copper being lower than that of gold and higher than that of cadmium.

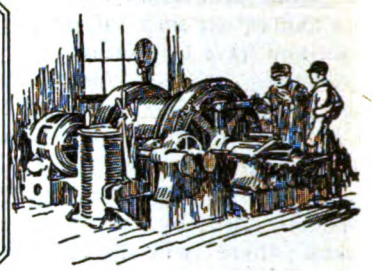
The volatilization of the metal causes a variation in the duration of the flash resulting from a break in the circuit. Thus in the standard mixture of 8.5 per cent methane, the break flash lasted 0.00321 sec. with cadmium and only 0.00070 sec. with gold which volatilizes in a far lower degree. These results were obtained with a potential of 120-volts and with currents of 0.23 and 0.50 amp. respectively.

Other conditions remaining constant the igniting current for a given mixture of methane and air is lower the more rapid the break in the circuit. The smaller the area of contact at the moment of break, the lower is the igniting current required for a given mixture of methane and air under otherwise identical electric circumstances.



No simple universal law connects the value of the igniting current with the inductance of the circuit, but the relationship varies with the mechanical conditions under which the sparks are produced. Under one particular set of conditions, the energy required in the circuit before a break would produce an igniting spark was nearly constant. In general, particularly with highly self-inductive circuits, the igniting power of the flash produced on breaking the circuit is affected far more by the strength of current in the circuit than by the impressed voltage, if the value of the latter is comparatively low. With the higher values of the impressed voltage, however, currents of lower amperage will ignite the gas mixture.

Kind of Current Unimportant



The character of the current supply, whether continuous or alternating, does not materially affect the current strength at which methane mixtures are ignited by breaks in the circuit.

These results are recorded in Bulletin No. 20 entitled "The Electric Ignition of Firedamp: Alternating and Continuous Currents Compared," obtainable from His Majesty's Stationery Office, Adastral House, Kingsway, London, England, price 1/- (25c.).

Practical Pointers For Electrical And Mechanical Men

Hillman Coal & Coke Co. Introduces Automatic Electric Gate

By J. A. Malady
Electrical Engineer,
Hillman Coal & Coke Co.,
Pittsburgh, Pa.

Where cages, instead of skips, are used in the main shaft, and when this shaft is used for handling men and materials, the gate at the surface landing must be opened and closed many times a day. Doing this by hand not only causes delays but is not a safe manner of operation, for the gate may be opened or left open when the cage is not at the surface landing. Furthermore, such practice does not comply with Art. VIII of the Pennsylvania mine law. Automatic, air- or steam-operated gates are rather common, but few installations of successful electrically operated gates are seen about the coal mines.

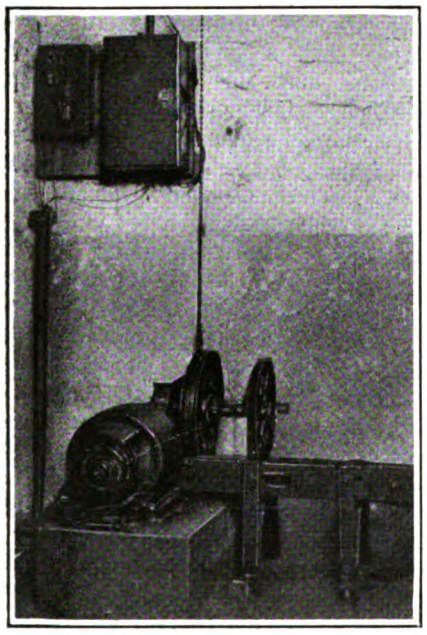

Fig. 1—Worm-Driven Gate Hoist

The relay on the wall near the starting switch is adjusted to a few seconds time delay so that when the cage passes the surface landing at normal, or even at reduced speed, the gate will not open.

At the No. 1 shaft of the Isabella mine of the Hillman Coal & Coke Co., near Brownsville, Pa., an electrical device has been used for about two years to open the gate automatically. The necessity for improvising this equipment arose when the old steam hoist was replaced by one operated by electricity. Formerly, the gate, which was of the rising type, was actuated by a steam cylinder. After the old hoist was removed steam was no longer available, nor was compressed air.

An air compressor might have been installed, however, but this obvious though expensive solution did not suit the purpose because there was a danger that the moisture in the air cylinder would freeze. The company knew of no completely successful automatic electric gate-opening equipment which had been placed on the market, so it built one of its own.

Fig. 1 is an illustration of the gate hoist, starting switch and time-delay relay which is being used at No. 1 shaft. This equipment is installed in one corner of the room in which the main hoist is located. The other end of the rope, one end of which is seen attached to the drum, is connected to the rising gate at the shaft. The small worm-driven hoist is of the type commonly used for dumbwaiter service. The motor is reversible and, at its limits of travel when opening and closing the gate, is stopped by a spring-reset limit switch.

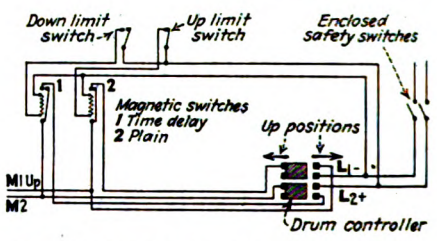

Fig. 3—Wiring and Control Details

The time delay is the brains of the whole arrangement because it decides whether the gate is to be opened at the ground landing for men or left closed for the coal that has to pass to a higher point in the shaft.

Fig. 2 is an illustration of the thread bar and its supporting stand, which is connected to the end of the

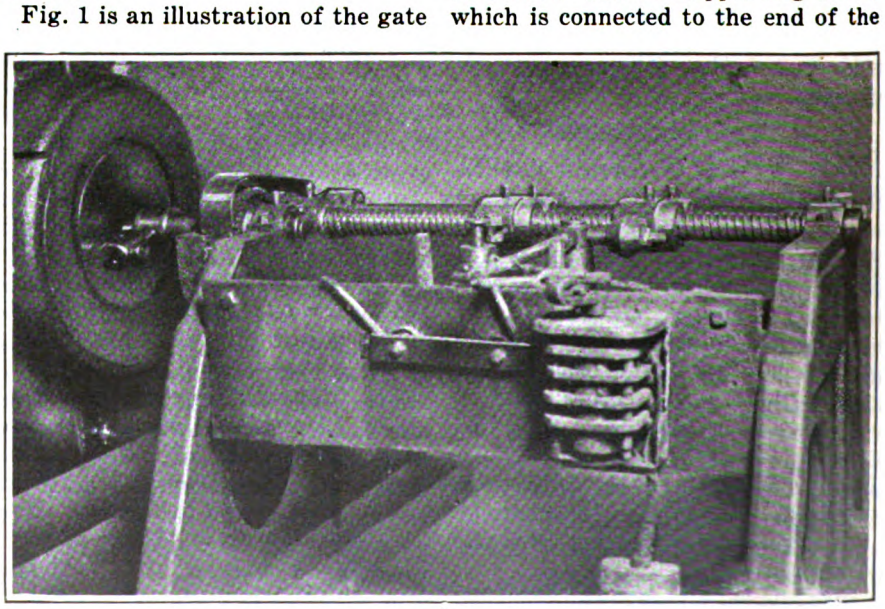

Fig. 2—Thread Bar Which Operates Gate Control

The controller which was added to this device is turned to the gate-opening position whenever the cage passes or stops at the surface landing. This controller is simply a reversing switch and normally remains in the position in which it should be for opening the gate.

Digitized by Google

shaft of the new electric hoist. The controller, with its cover removed, so that this illustration could be made, is mounted on a stand and is essentially a drum-type reversing switch. The cylinder of this controller normally stands in a position which will operate the small motor in the proper direction to lower the gate. When the main hoist is operated the sliding nut on the thread bar moves an arm which turns the

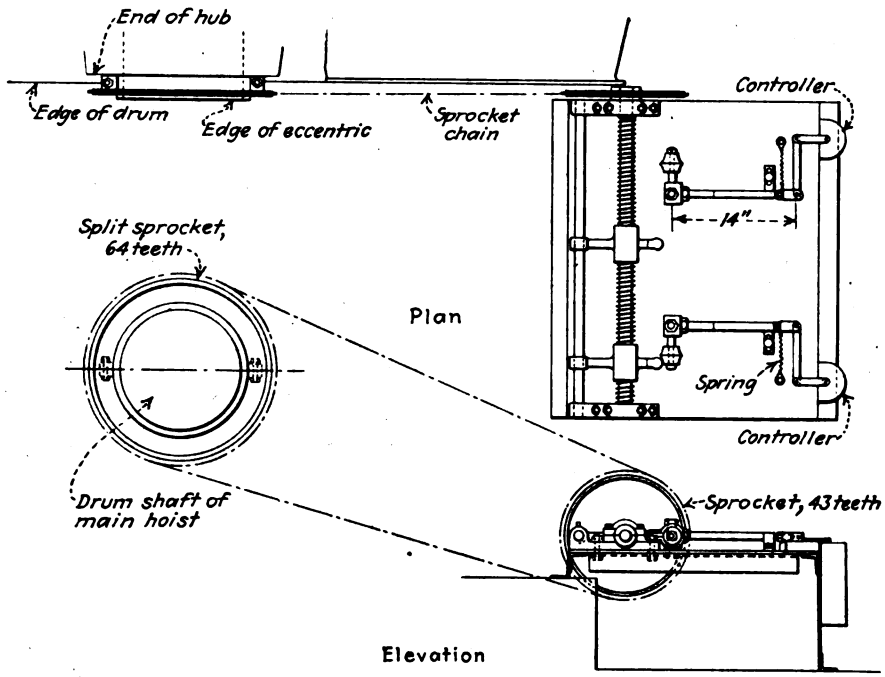

Fig. 4—Mechanism by Which Electrical Control Is Actuated

It gets into action at the proper time to open or close the gates, is governed by the position of the cages in the shaft and is positive in its operation.

controller to the gate-opening position when the cage is at the surface landing.

Here is where the time-delay relay, Fig. 1, which is the brain of the device, plays its important part. If the cages do not stop at the landing, as when hoisting coal, the relay does not have time to close during the short time that the reversing switch has been held in the gate-opening position by the passing nut on the thread bar, and hence the gate does not open. If, however, the cage is stopped at the landing, the relay in about one second closes and the motor quickly raises the gate to the desired height, which is controlled by the setting of the limit switch. When the cage is moved a few inches either way from the landing the motor quickly lowers the gate.

The Hillman Coal & Coke Co. recently installed two additional gates at other mines and has replaced the thread bar and reversing controller by a light contact-making device connected to the dial indicator of the main hoist. These gates operate with entire satisfaction.

Never Confine Transformers In Too Small a Space

In comment on the short article appearing in the "Practical Pointer" section of *Coal Age*, April 22, relative to the placing of transformers in a tank on a steel truck, I would suggest that such an arrangement has the excellent feature that it makes the station portable, but there is danger in too completely inclosing transformers.

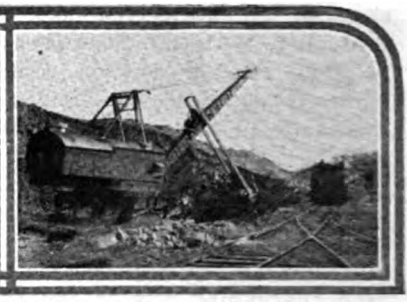
I have in mind a vault in which the transformers reached a high temperature and an explosion resulted. Just what happened is a matter of conjecture. Possibly the oil was vaporized until the coils were exposed and, in consequence, the wire reached a red heat or burned in two, igniting the oil vapor. Perhaps it was one of the lead-in wires that was thus burned. However, it is needless to say that a dense oily vapor and electric flashes are a potent combination from which malignant action may be at any time anticipated. An overheated transformer may give off a large quantity of smoke, yet no flame will be emitted. As a result no fire will sever the safety rope, and the men in the mine may be suffocated by smoke.

At the 1924 summer meeting of the Rocky Mountain Coal Mining Institute we endeavored to overheat a 10 kva. transformer until something happened, but the results were not carried to a conclusion and the crowd left before the climax. However, during the demonstration the transformer gave off a large quantity of smoke for about one hour that would have been serious had the experiment been made in a mine. About one-fourth of the oil was vaporized, and had there been a spark above the oil level, I believe the oil vapor would have been ignited.

I have given serious thought to the system of installing transformers in mines that I am about to describe: Set the transformer between the intake and return airways wherever possible, so that smoke may be diverted to the return if some one is fortunate enough to be present to open the door in the return at the time of the burnout. Place an automatic oil circuit breaker on the primary side of the transformer. Provide a thermal relay to open the oil circuit breaker when the temperature of the transformer reaches 75 deg. C.

NEARLY A CATASTROPHE

The fact that we had placed an electrical installation between the intake and return served us well on one occasion. A synchronous motor that was pretty well filled with coal dust lost its exciting current, gradually overheated and took fire. A dense smoke was emitted that would have passed thirty or forty men but for the presence of mind of some one who opened the door to the return. The motor was still running when this was done. The overload device had failed to work. Wherever possible we eliminate transformers and carry the high voltage (2,200 volts) directly to the motors.



The article by J. H. Edwards on page 561 of the issue of April 22, on the regulation of peak loads by floating storage batteries on the line, shows that W. F. Hossfield, the chief electrician of the By-Products-Pocahontas Co., had every detail in mind when planning the installation. This is the first plant of its kind at a coal mine, at least within my knowledge. The saving is remarkable and should appeal to many mine managers whose contract for power provides for a high demand charge.

D. C. MCKEEHAN,
Electrical Engineer.
Union Pacific Coal Co.,
Rock Springs, Wyo.

News Of the Industry

British Coal Operators and Miners Consider Peace Proposal as Tie-Up Of Industry Enters Second Week

A peace plan for the settlement of the British industrial strike which it was hoped would prove acceptable to both the government and the trades union leaders was under consideration Monday night, though no decision had been reached at 1.30 a.m., Tuesday. The peace proposal was made by Sir Alfred Mond, prominently identified with the coal mining industry, who with Sir Herbert Samuel, chairman of the Royal Coal Commission, presented the plan to the executive committee of the Miners' Federation. Lord Londonderry and David Davis, leading mine owners, took a prominent part in the negotiations, which lasted until Tuesday morning, to be resumed later in the day.

A compromise is said to have been suggested whereby the miners would take a 10-per cent wage cut if guaranteed that the industry would be reorganized at the same time and if some form of government assistance would be forthcoming during the negotiations. A group of large moderate mine owners are reported to have been conferring with Sir Alfred Mond on a scheme to place the industry on a more efficient basis. This would include closing the poorer mines and an arrangement whereby only mines near the sea coast would produce coal for export.

Moderates Want Peace

It is uncertain how much chance these peace moves have of success, but it is becoming increasingly evident that moderates both in the government and the General Council of the Trades Union Congress are anxious to end the struggle. David Lloyd George intimated that a majority of the Baldwin Cabinet do not feel that a sweeping victory over the unions is worth the price of economic collapse and inextinguishable class hatred.

The strike's second week began with neither party to the national conflict showing any disposition to retreat from the positions taken when the national walkout started. The number of volunteers to man transport and other essential services is increasing. More trains are running. On Saturday the government began moving foodstuffs from the London docks under the protection of armed convoys, after refusing the offer of the unions to pass food trains and trucks provided with government permits.

Late last week "the second line of defense" of the strikers was called into action. Workers in the gas and electric plants began to desert their posts. Their places were taken by men from the armed forces of the nation. At Liverpool the millers, butchers and building trades workers were called out. Sporadic disorders have been reported from different parts of Great Britain, but, on the whole, there has been little violence.

Interest in the general situation naturally has overshadowed the controversy between the miners and the coal operators which led to the strike. No attempt apparently has been made to operate the mines, but the temper of the men in some of the districts, particularly in Wales, is said to be ugly.

Coal Issue Comes to Surface

The coal issues, however, were again brought to the fore in a radio address by Premier Stanley Baldwin on Saturday night. In that address the Premier again defined the government's position and reiterated its refusal to be a party to a resumption of negotiations between the operators and the miners until the general strike order had been unconditionally rescinded. The general strike, he declared, was an attempt "to disrupt the life of the nation and to starve it into submission."

The stoppage in the coal industry, said Mr. Baldwin, "followed a nine months' inquiry and negotiations. I did my utmost to secure an agreement upon the basis of the Commission's report, and when the time comes, as I hope it may soon, to discuss the terms upon which the coal industry is to be carried on I shall continue my efforts to see that in any settlement justice is done both to the miners and the owners.

"I wish to make it clear that the government is not fighting to lower the standard of living of the miners or any other class of workers. My whole desire is to maintain the living of every worker and I am ready to press the employers to make any sacrifice to this end consistent with keeping industry in its proper working order.

"There are many people who say: 'I do not hold with the general strike, but I feel a good deal of sympathy with the miners.' So do I, but if Parliament had voted millions to aid the mining industry and had received the report of a very able commission, what else could it do than try to bring about a settlement on a basis on which the industry could be carried on? The government is prepared now, as it has always been, to accept the report and the whole report if the other parties will do so."

Keystone View Co.

Stanley Baldwin

On the shoulders of the Prime Minister rests the chief burden during the general strike. For more than a month he put forth his utmost efforts to bring the coal operators and miners to an agreement in order to prevent a tie-up.

Coal a Sore Spot Since War

The labor situation in the British coal industry has been more or less in the public eye since the close of the World War. The immediate dispute between the miners and the owners is a revival of the controversy which threatened a strike last summer. At that time the operators posted notices that wages would be reduced on Aug. 1. The government intervened and promised a subsidy to reimburse the owners whenever the returns from the industry were insufficient to pay the standard wages and profits. This subsidy, which expired April 30, cost the British government over £20,000,000. Without it, declared the Royal Commission appointed to inquire into the situation, 73 per cent of the coal mined in the last quarter of 1925 was produced at a loss.

This Commission, whose report was expected to determine the future course of the industry, submitted its findings early in March. The Commission rejected the miners' proposal—indorsed by the majority of the Sankey commission appointed during the régime of Lloyd George—that the mines be nationalized. It did, however, recommend national ownership of mineral rights. At the present time approximately 88 per cent of the mining operations work on a royalty basis. These royalties,

Digitized by Google

under the Commission's recommendations, would accrue to the state.

In its consideration of the industry as a whole the Commission recommended amalgamation of existing mines, which could be made compulsory where necessary in the public good. A closer integration of the mining with the larger consuming industries also was proposed. Greater engineering research both in mining and in combustion technique was urged. Government analysis and standards, particularly in the export trade, were suggested. The Commission also favored the adoption of larger railway cars and greater concentration of ownership to replace the present highly scattered private ownership of equipment. Co-operative selling agencies and municipal coal yards received the approval of the Commission.

Labor Aspects Stressed

On the labor aspects of the problem the Commission held:

(1) The principle upon which recent agreements have been based is sound, but amendments should be made in the method of ascertaining the proceeds upon which wages are fixed, particularly in setting prices on coal sold to associated industries or selling agencies.

(2) The standard working day, which averages 7½ hours underground, should not be altered, but the multiple shift system should be extended.

(3) Joint pit committees should be established generally.

(4) Methods of payment of men not employed at the face should be revised where possible to give them a direct interest in output.

(5) The introduction of a family allowance system is desirable.

(6) Profit-sharing schemes, providing for the distribution to the workmen of shares in the operating companies, should be generally adopted and should be made obligatory by statute.

(7) Proper provision for housing should be a condition of the lease for all new collieries.

(8) The general establishment of pithead baths is necessary.

(9) When prosperity returns to the industry, annual holidays with pay should be established.

"We cannot," concluded the Commission, "approve the proposal of the Mining Association that the gap between costs and proceeds should be bridged by an increase of an hour in the working day, reductions in the miners' wages, some economies in other costs, and a large diminution in railway rates to be effected by lowering the wages of railwaymen.

"If the present hours are to be retained, we think a revision of the 'minimum percentage addition to standard rates of wages' fixed in 1924 at a time of temporary prosperity, is indispensable. A disaster is impending over the industry, and the immediate reduction in working costs that can be effected in this way, and in this way alone, is essential to save it. The minimum percentage is not a 'minimum wage' in the usual sense of that term. The wages of the lowest paid men will be safeguarded by a continuation of the system of subsistence allowances. The reductions that we contemplate will still leave the mine owners without adequate profits in any of the wage-agreement districts, and without any profits in most districts. If trade improves and prices rise, a profit will be earned. If prices do not rise, an adequate profit must be sought in the improved methods, which should in any case be adopted.

"We consider it essential that there should be, as there always has been hitherto, considerable variation in the rates of wages in the several districts. But we are strongly of the opinion that national wage agreements should continue. Such agreements are entered into in all the other British industries of importance.

"We recommend that the representatives of the employers and employed should meet together, first nationally, and then in the districts, in order to arrive at a settlement by the procedure we have previously suggested.

"By a revision of the minimum percentage coal mining would be saved from an immediate collapse, but it seems inevitable that a number of collieries would still have to be closed.

"The subsidy should never be repeated."

The report of the Commission was pleasing to neither miners nor operators. The government, however, announced that it would accept it. Attemps to get the miners and owners together, however, failed. When the owners posted notices of wage reductions, the Miners' Federation declared for a strike. Allied labor organizations asserted that the employers were planning a general assault upon wages and made common cause with the miners.

There have been rumors that miners in other countries would refuse to load coal for Great Britain during the strike. Workers in Germany, the second largest exporter of coal, have been cool to this proposal. In France 60 per cent of the production is not under union domination. Belgian workers have expressed sympathy with the British strikers, but the direct issue of shipping coal to Great Britain has not come to a head. Dock workers at Hamburg have attempted to interfere with the movement of coal and the New South Wales unions are endeavoring to prevent British ships from taking on extra bunker supplies. Antwerp longshoremen also are trying to check the clearance of coal cargoes.

While a number of labor organizations in the United States have expressed sympathy with the British strikers the chances of interference with any export movement are remote. The bulk of the coal that would move in export channels from this country would come from the non-union fields. Moreover, neither the United Mine Workers nor the various railway unions have shown any disposition to engage in sympathetic strikes nor to concern themselves with international labor disputes.

Lewis Denies Union Seeks Scale Modification

A report that field agents of the United Mine Workers had been instructed by international union officials to work up sentiment among union miners to demand modification of the Jacksonville agreement is denied by John L. Lewis, international president.

In a letter last week to B. W. Elkins, of West Frankfort, Ill., Mr. Lewis characterized the report that union representatives were agitating for modification as a means of getting a number of idle coal mines in operation and thus giving wider employment as without foundation.

"The officers of the United Mine Workers are opposed to any modification of the existing wage rates set forth in the agreement in the Central Competitive Field or elsewhere in the mining industry," Mr. Lewis said.

Will Settle British Tie-Up Without Disastrous Results, Is Belief in Washington

By Paul Wooton
Washington Correspondent of *Coal Age*

Since the British people have been called upon to meet crises rather frequently for more than 1,000 years, observers in Washington expect this one to be met without most of the dire possibilities that are being emphasized in the newspapers. The investing class, the merchant, the professional group, executives, farmers, small trades people and unorganized wage earners constitute the great bulk of the population even in Great Britain, where the unions include a larger proportion of the people than in any other country.

The general strike will arouse the emotions and the instincts of this majority who recognize that it is a threat at the government which is their representative. Once thoroughly aroused this majority is expected to lend whatever aid the authorities may need to teach the unions that no minority group is as strong as the government.

Even those who hope and expect the British Government to win a 100-per-cent victory think the English authorities have done anything but distinguish themselves in the handling of the situation. It is thought something could have been done to put a real share of the burden on the royalty owners and to require the operators to pool their profits. Certainly a way could have been found to close the high-cost mines. Had the £100,000,000 paid out as a subsidy been used to contract with high-cost producers, 30 per cent of the mines could have been closed and the industry trimmed down to the market. There would have been enough left to pay the dole to the workmen who would have lost employment in the process. Had exports been reduced 40,000,000 tons the industry could have increased prices to the point where higher wages could have been paid to fewer men.

Showdown Thought Inevitable

A very general conclusion is that the whole affair reflects on the ability of both the responsible officials and the labor leaders.

There are some, however, who think this shutdown had to come. While it is unfortunate that it had to come at a time when the British are ill-prepared to meet it, they feel that this ordeal was necessary before the British could regain their industrial position.

In so far as coal is concerned the industry is in an advanced stage of degeneration. It takes 1,100,000 men to produce 300,000,000 tons of coal, whereas in this country 650,000 men produce 500,000,000 tons.

The very low output per man per day—not much over one gross ton per shift—is due partly to natural difficulties and partly to lack of machinery, but an important element is the attitude of the British miner toward the job. It has been brought home to the coal miner through generations of experience that if the piece-rate earnings increase the employer will seek to reduce the piece rate, so that deliberate restriction of output has become one of the means of bargaining. Even when it is not deliberate the established pace has become habitual. A Washington contractor, for instance, has an apartment house under construction in London. He finds the per yard cost of plastering—an operation into which machinery does not enter—is no lower in London, despite the fact that the workmen receive less than half the wage paid in Washington. This applies to most other operations on the building. It is this attitude toward maximum productivity which is at the root of many of Britannia's industrial troubles.

Men Should Gain by Good Work

The principal problem to be worked out in the settlement of this strike and in the reorganization of coal production in the British Isles is to find some way that the men may profit if they do their best.

Mechanization of the mines is one step that must be taken, all agree, but this and other reorganization cannot be done successfully if the men are forced back into the pits in a sullen humor.

Fundamental changes have been going on which have shrunk the market for British coal. Electrification on the Continent, the distribution of reparation coal and the increased use of oil have made for a situation requiring co-operation and intensive effort which cannot be met with sweated and discontented labor. The government is going to put down the general strike with greater ease than is supposed, but a greater task is to devise a plan that will rehabilitate the industries of the United Kingdom so that the losses and the suffering caused by this strike may not go for naught.

To try to get the mine workers to accept a wage of $7.50 per week is just as vicious as labor's plans to increase employment by reduction of hours and by the "Ca'canny" method. There must be less preaching of Bolshevistic doctrines and more preaching of sound economics. While few in Washington think the strike is likely to encompass Great Britain's ruin, there is a widely held opinion that it can be made her salvation if capital, labor and public will grasp the opportunity to put a new fundation under their industrial structure.

Has a Familiar Ring

Conditions in the bituminous coal industry would not be relieved by a modification of the Jacksonville wage scale, William Green, president of the American Federation of Labor, said at Pittsburgh recently.

"The bituminous industry is sick, overdeveloped, overorganized and overmanned," he said, "and the capacity to produce is so far in excess of the normal demand that some of the mines must necessarily be idle. If they were operating they would only need to function on part time to meet the requirements of the trade."

Union Seeks Injunction to Restrain Open-Shop Work

Injunction proceedings have been brought in the Monongalia County (West Virginia) Circuit Court by the United Mine Workers against the Cleveland-Morgantown Coal Co., the Connellsville By-Product Coal Co., the Arkwright Coal Co. and the Pursglove Coal Co., operating eight mines in the county. The hearing has been set for May 20. This is the first time in the history of the union that it has sought to achieve its aims through an appeal to the courts, it is asserted, and the outcome is awaited with more than the usual interest.

In its petition the union seeks to restrain the four companies named from operating under any other wage agreement than that entered into by the Monongahela Coal Association and the United Mine Workers on March 28, 1924, and which does not expire until March 31, 1927. The petition also asks the court to restrain the defendant companies from employing any but union labor, except as provided for in the agreement dated March 28, 1924, and to stop eviction suits brought against former employees of the companies who did not return to work when the mines were recently opened on a non-union basis.

According to Eugene H. Long, Walter R. Haggerty and U. A. Knapp, counsel for the miners, notices of the injunction proceedings were served upon Edgar B. Stewart and Frank P. Weaver, of Morgantown, as attorneys for the coal companies. Both Stewart and Weaver deny that they are retained by the coal companies as attorneys of record, but that they are sometimes called in to act in special cases.

On these grounds the hearing, which was set for May 7, was postponed until May 20, Judge I. Grant Lazelle ruling that improper service had been made.

According to authoritative statements from coal company officials, the injunctions will be opposed on the ground that none of the companies named, all operating in the Scotts Run field, signed the agreement dated March 28, 1924, as individuals, but that it was signed by the Monongahela Coal Association, by Samuel Pursglove, president.

It is pointed out that the agreement, while binding on the Monongahela Coal Association during its existence, is now void because the association is defunct, it having ceased to function soon after the agreement was entered into.

Plan New Outlet from Harlan

Coal men from various sections, with the mining and operating end largely in evidence, attended a meeting of the Interstate Commerce Commission held in Lexington, Ky., May 3-6 to hear testimony as to the necessity of the Louisville & Nashville Ry. constructing a branch line from Haggins, Va., to Chad, Ky., to tap the Harlan field. This line a cut-off, would give the L. & N. an outlet to Charleston and to Hampton Roads for Harlan coals over the Carolina, Clinchfield & Ohio and connecting lines. After hearing all evidence the I. C. C. commissioners took the testimony under advisement.

Attacks on Anthracite Based on Old Prejudices and Misconceptions, Says Merritt; Others to Be Heard

Washington, D. C., May 11.—What the anthracite industry thinks of further legislative action on coal and how that industry proposes to discharge its public obligations will be told to the House committee on interstate and foreign commerce on Thursday. At that time, according to the present plans, Walter Gordon Merritt, counsel for the Anthracite Operators' Conference, will complete the testimony begun a week ago. He had hoped to do that today, but when the anthracite people appeared in the committee rooms this morning they were informed that the hearings would be adjourned until Thursday.

Unless there is another last-minute shift in the committee schedules, however, Dr. George Otis Smith, director, U. S. Geological Survey, and a member of the Hammond Coal Commission, will go on the stand tomorrow. Other government officials familiar with coal also probably will be heard. In addition, the committee has promised to hear Ira Cochran, commissioner, American Wholesale Coal Association, and Edgar Wallace, legislative agent, American Federation of Labor, but no specific time has been set.

Senate Favorable to Copeland Bill

On the Senate side the committee on education and labor has taken favorable action on the revamped Copeland bill. This bill gives the Bureau of Mines the broadest kind of fact-finding powers, including the right "to copy any book, account, record, paper or correspondence relating to any matter the bureau is authorized to investigate."

Title II of the bill authorizes the President to create mediation boards and makes it the duty of employers and employees in the coal industry "to exert every reasonable effort" to make and maintain agreements and to settle all disputes in connection therewith "in order to prevent unreasonable restraints upon or interruptions of interstate commerce." Title III covers emergency distribution and operation. It re-enacts the Federal Fuel Distributor law, but practically makes it obligatory for the Interstate Commerce Commission to follow the recommendations of the Federal Fuel Distributor. The second section of this title empowers the President in times of emergency to take over and operate directly or by lease any and all coal properties which the chief executive deems desirable or necessary.

Ill-advised action by Congress, Mr. Merritt warned the committee in opening his case on May 4, might encourage the development of a situation as serious as that now confronting Great Britain. Most of the attacks made upon the anthracite industry are based upon old prejudices and misunderstanding of the facts. If hard coal has failed to measure up to accepted commercial standards, how is it, he asked, that no one doing business with the industry has appeared to complain?

Ninety per cent of the complaints received by Congress, Representative Wyant (Pennsylvania) interrupted, come from the domestic consumers. Retailers, suggested Congressman Newton (Minnesota), may be silent because they fear complaint would jeopardize their coal supply. This suggestion the witness vigorously repudiated. The householder, he conceded, is objecting because his coal costs more.

The dominant problem in the industry, asserted Mr. Merritt, is labor relationships. Far from being the oppressed toiler intimated by some of the preceding witnesses, the anthracite mine worker enjoys greater protection from oppression, tyranny and abuse than any other toiler. He is a member of the strongest union in the country. Since 1903, when the Board of Conciliation was established, he has had a tribunal to which he could take any grievance, however trivial it might be, arising during the life of a contract.

Says Labor Oppresses Capital

If oppression exists, it is the oppression of capital by labor. The operators, Mr. Merrit pointed out, quoting from the report of the U. S. Coal Commission, are inadequately organized to protect their rights under wage agreements with the United Mine Workers.

"The operators," he said, "have made the mistake of continuous concessions in the face of illegal strikes and the threat to strike instead of insisting that disputes be referred to the conciliation board." These evils the industry must itself cure by promoting better industrial relationships. Progress along that line, however, has not been encouraging. To grant the check-off, he told Congressman Huddleston (Alabama), would afford no permanent solution to the button strike.

Answering the Alabaman's insinuation that the recent strike was a plot upon the part of the operators to destroy the union, Mr. Merritt retorted that "the operators' record for twenty years has been one of sympathy, tolerance and co-operation with the United Mine Workers." Later he emphasized the employers' repeated offers to arbitrate as proof that the "union-busting" accusation was groundless.

Wages, he explained, absorb 75 per cent of the revenue received by the mines from the sale of coal. The annual wage bill of the industry approximates $320,000,000 and the average wage is over $2,000. Contract miners taking full advantage of the opportunities for employment can make $3,000. The average wage for all industries is $1,300. Since 1914 anthracite wages have increased 192 per cent, as compared with an increase of 141 per cent on the railroads, 129 per cent for manufacturing industries and 111 per cent for the building trades.

Sketching the background of the wage disputes since 1920, the witness suggested that the strike habit had grown upon the union, which once proclaimed the virtues of arbitration, because victories in small things had whetted the organization's desire to resort to direct action, and political interference had hampered sound settlements. It was a perversion of terms, however, to say that the operators were insisting upon compulsory arbitration. There may be a six months' strike before an agreement is written under economic pressure, but such an agreement does not mean involuntary servitude for the miners. So, too, a fight to bring about the acceptance of arbitration does not mean compulsory arbitration.

Walter Gordon Merritt

Mr. Merritt did not deny that, if the operators were in the saddle, their attitude toward arbitration might be different—as it was in 1902. But capital is more easily reached by government pressure because property is a hostage to society. Capital yielded to President Roosevelt in 1902—labor declined to yield to President Harding in 1922. The operators now stand committed to arbitration. They are willing to let the public decide. They might even be willing to arbitrate prices if the public would underwrite an agreement to take the coal at the prices fixed.

"It would be a travesty on justice to say you will take the mines away from the operators and strip them of their rights when the operators are ready to submit to the President, and do nothing to the group that refuses. I am not asking or urging the regulation of the union. But why take our mines away to do something which we already are willing to do?"

Mr. Merritt denied that there was any monopoly in anthracite in the legal sense. If there was monopoly it was in the sense that the supply was limited. There might be, he told Congressman Newton, bankers in New York who owned a substantial interest in two or more producing companies, but the operating companies, he declared, were independent in operation, in management and in their price-fixing policies. The largest producer in the region shipped 15 per cent of the anthracite sold, as compared with 20 per cent for the largest copper-producing company, 50 per cent in iron ore and pig iron and 16 per cent in zinc. The anthracite industry enjoys no special privileges, has

Digitized by Google

no tariff to shield it from competition and exercises no powers of eminent domain.

Nor can regulation be supported on the theory that the anthracite industry is a public utility. If the government were to fix mine prices, it would be compelled to double the aggregate profit of the industry to avoid confiscation. Even if the constitutional barriers set out in the *Wolff case*, 262 U. S. 522, could be hurdled, insurmountable legal and practical difficulties would remain. Anthracite is distributed to more than 20,000 communities and the sale to the household consumer in those communities is a purely intrastate transaction which cannot be reached by Congress: *Missouri vs. Kansas Gas Co.*, 265 U. S. 298.

The key to an understanding of the price situation is the percentage of steam sizes produced. Taking the extreme cases, this will vary from 15 to 20 per cent in the northern field to 50 per cent in the southern. These sizes are sold at an average annual loss of $75,000,000. This loss must be absorbed in the prices on domestic sizes. Therefore, a wage increase that the northern field might bear would destroy the market of the southern district. To support this argument, Mr. Merritt submitted the accompanying table, showing the results of the yield from 100 tons of average anthracite sold at the average prices reported for 1924 by the Geological Survey.

In addition, Mr. Merritt submitted exhibits showing how the consumer dollar paid for stove coal in Boston, New York and Philadelphia was divided on the basis of 1924 wholesale and retail prices. The f.o.b. mine price used was $8.75. This was made up of an allocated labor cost of $6.09; supplies, $1.38; general expenses, 76c., and an operator's margin of 52c. In arriving at these figures that portion of the cost of production of the steam sizes not covered in the realizations received was allocated to the profit-paying larger domestic sizes on a percentage and value basis. The exhibits showed retail gross margins per long ton of $4.67 at Boston, $4.21 at New York and $3.80 at Washington.

Valuations Vary Widely

Estimates of the valuation of the anthracite properties, the witness pointed out in his testimony on May 5 and 6, differ widely. Congressman Jacobstein had offered $400,000,000; engineers employed by the Coal Commission had valued the plants and operated lands at $843,500,000 and the reserve acreage at $146,400,000; book values, as determined in co-operation with the Department of the Treasury, approximated $640,000,000. For taxation purposes within the state, Pennsylvania tax authorities had claimed from $700,000,000 to $1,000,000,000. These tax valuations, some of which are in litigation, in many cases represent estimates which are substantially less than the tax authorities maintain is the full value of the properties.

The aggregate net earnings of the industry in 1924, as revealed in the report of the Treasury Department to the Senate under the La Follette resolution (*Coal Age*, Feb. 11, 1926, p. 238), were equivalent to a return of 4.86 per cent on the Jacobstein valuation, 3.65 per cent on the $640,000,000 estimate and 2.25 per cent on the engineers' valuation. Mr. Huddleston questioned the weight of these estimates in the absence of an explanation of what constituted net earnings. The witness referred him to the regulations of the Bureau of Internal Revenue and to the practices of accountants.

Roderick Stephens

Vice-president of the Stephens Fuel Co., New York City, represented the retailers in the House committee hearings.

At another point in the hearing the gentleman from Alabama wanted to know why the operators had failed to reduce prices on April 1. Mr. Merritt replied that they could not afford it, in view of the heavy strike losses, and that in recent years this reduction had been found inadequate to accelerate buying. The total reduction, he continued, would have been only $6,000,000. He thought this a small price for the public to pay for the fight that had been waged in their behalf by the operators.

Mr. Merritt derided the accusation of Congressman Jacobstein that the low-cost mines could drive the high-cost operations out of business by speeding up production. Most of the reserves, he pointed out, were held by the high-cost mines. To develop the mines in the northern field to take care of all the demand would mean doubling breaker capacity and higher development and amortization charges because of the more rapid exhaustion of the coal. These things, it was contended, would so increase costs at the low-cost mines that the differential would vanish and the public would gain nothing.

High-cost mines controlled the price situation, said the witness; not because the low-cost mines "want to hold an umbrella over their competitiors" but because of economic law. That law is that the price of the entire supply of a commodity will be regulated by the cost of producing that portion of the necessary supply which is produced at the greatest expense. But the low-cost mines, continued Mr. Merritt, did not take full advantage of this law, because their prices were less than those of the high-cost mines.

"No government agency," asserted the witness in his discussion of proposals for emergency operation, "played any part in the settlement of the last anthracite strike." The administration's policy of non-interference, however, has been most helpful. The operators, he said, had been willing to have the President intervene, but the President probably feared that he would be rebuffed by the United Mine Workers, as was President Harding in 1922.

Mr. Merritt did not wax enthusiastic over the reputed merits of publicity as a corrective agency. In 1922, for example, it had been agreed that the operators and miners write their next contract in the light of the findings of the Coal Commission, but the recommendations of that body were thrust aside in the framing of the 1923 agreement. The present British situation cannot be charged to a lack of facts. With the action of the committee on the Watson-Parker bill, it seemed inconsistent to seek to impose upon the coal industry a tribunal comparable to that the committee proposed to abolish in the railroad world.

"The government," interrupted Congressman Cooper (Ohio), who presided on May 6 in the absence of Chairman Parker, "always makes a mess of it when it attempts to interfere with the natural processes of capital and labor."

Unlike some of the earlier witnesses, Mr. Merritt in his testimony last week did not emphasize constitutional barriers to compulsory fact-finding. His opposition, he stated, was subject to qualifications. He believed that a way might be found by which Congress could compel the production of all the information it desired. He would not agree, however, that Congress might tie up fact-finding with a licensing scheme. Where there was nothing immoral or deleterious in the commerce itself, Congress, it was his opinion, could not impose restrictions upon the right to engage in interstate commerce.

Average Realizations and Costs on Anthracite

(From Exhibit Submitted to House Committee by Walter Gordon Merritt)

Sizes	Tons	Mine Price	Realization	Average Cost per Ton	Gain or *Loss* per Ton	Total Gain or *Loss*
Lump and broken	2.7	$7.91	$21.36	$6.25	$1.66	$4.38
Egg	14.3	8.45	120.83	6.25	2.20	31.46
Stove	21.8	8.74	190.53	6.25	2.49	54.28
Nut	26.3	8.58	225.65	6.25	2.33	61.28
Pea	8.2	5.59	45.84	6.25	*.66*	*5.41*
Buckwheat	12.3	2.93	36.04	6.25	*3.32*	*40.84*
Rice	6.7	1.93	12.93	6.25	*4.32*	*28.94*
Barley	6.7	1.28	8.58	6.25	*4.97*	*33.30*
Other sizes	1.0	1.45	1.45	6.25	*4.80*	*4.80*
Totals and averages	100.0	6.63	663.21	6.25	.38	38.21

Figures in italics indicate losses.

(The average cost, $6.25, includes approximately $4.62 for direct labor costs, $1.05 for supplies and 58c. for overhead.)

Lewis Refuses to Consider Wage Cut in Southwest, Correspondence Reveals

Failure of an attempt to obtain a readjustment of wages in the coal fields of Kansas, Missouri, Arkansas and Oklahoma is revealed in correspondence between officials of the Southwestern Interstate Coal Operators' Association and John L. Lewis, president of the United Mine Workers, made public May 7 by W. L. A. Johnson, general commissioner of the association, Kansas City, Mo. Mr. Johnson's release of the complete correspondence followed announcement by officials of District 14 (Kansas) of Mr. Lewis' refusal to accede to the operators' request for an investigation to determine the possibility of an early reconsideration of the terms of the present contract, which expires April 30, 1927.

The operators' letter, signed by Mr. Johnson and George J. L. Wulff, of St. Louis, president of the association, declared competition with fields having lower production costs and with mines which, operating open shop, are paying less than the 1924 wage scale, necessitated an immediate reconsideration of the contract. The letter, dated April 23, was addressed to Mr. Lewis, Matt Walters, president of District 14, United Mine Workers; William Dalrymple, president of District 21, and Arch Helm, president of District 25.

The operators' letter reveals that production in the Southwest fell from 20,136,365 tons in 1920 to 10,959,000 tons in 1925. Of the 10,959,000 tons produced in the four southwest states in the latter year, the operators' letter said, "only 5,586,183 tons was produced by association members, employing union men, the remaining 49 per cent being produced by non-association, non-union and so-called co-operative mines, operating mostly under less than the 1924 scale.

Few Union Mines Working

"In Arkansas and Oklahoma, one-half our association territory, less than a half dozen mines are operating with union men, and these only a day now and then, the market having been taken over by open-shop and so-called co-operative mines, working for less than the 1924 scale.

"In the last few months, competition from West Virginia, Kentucky, Alabama, Colorado and New Mexico has made serious inroads in the southwestern markets," the letter continued.

Declining a reconsideration of the contract at this time, Mr. Lewis, wrote in part on May 1:

"The conditions in the coal industry of which you complain largely exist in all other bituminous producing districts, including the non-union territory. Certain factors, more or less local in nature, have operated to the disadvantage of the industry in the Southwest. The demoralizing effect of such influences cannot be properly charged to the wage rates set forth in the Southwestern agreement. It is obvious to the members of your association that the United Mine Workers could not agree to a modification of the existing rates in the Southwest without agreeing to similar modifications in the wage structure throughout the entire United States. It is equally obvious that a general lowering of wage levels throughout the industry would not place the southwestern districts in any more advantageous position than they now occupy."

Lewis Orders Expulsion of Communists from Union

John L. Lewis, international president of the United Mine Workers, has issued a warning, through a letter to district presidents, against members of the organization joining the Communists or any affiliated organizations. The penalty is expulsion from the union. His action is the result of the authorization of such procedure by the international board at its last meeting.

Mr. Lewis's letter in part follows:

"Much evidence has been adduced to indicate that the activities of the officers, agents and members of the various Communist organizations constitute an unwarranted attempt to pervert the policies and change the laws of the United Mine Workers and to set up within the mine workers a dual organization. In view of these facts, the board of directors has authorized the following statement:

"'That it be the ruling of the board that the Communist party and all its affiliated organizations be declared dual to the United Mine Workers, and that membership in such organizations lays a member of the Mine Workers' union liable to expulsion under the laws of the United Mine Workers, Art. 14, Sec. 2.'

"Your district is hereby authoritatively notified of this action in order that the machinery of our union may be utilized for its protection when necessary."

Berwind-White Co. Wins Suit Against Government

A jury in U. S. District Court at Philadelphia on May 3 brought in a verdict of $1,015,560 against the government in favor of the Berwind-White Coal Mining Co. for coal sequestered for Navy use under Presidential order. After the Navy Department had taken thousands of tons of fuel from the company under executive orders of the late President Wilson the government and the company were unable to agree upon a "fair compensation," the Fuel Board fixing the amount of $740,851, while the company claimed $1,591,580.

Under the special war legislation the government paid the Berwind-White company $555,638, or 75 per cent of the $740,851, and the company sued for the difference between the amount paid and the amount claimed. So many complexities were involved in the suit that both sides agreed to submit the matter to E. L. Carpenter, coal expert, on whose testimony the award was made.

Open-Shop Operation Starts At Gilbert-Davis Plant

Open-shop operations have been begun at the large plant of the Gilbert-Davis Coal Co. in the Scotts Run field of West Virginia. This is the last large company with mines active that operated under an agreement with the union in West Virginia. Three cars of coal were loaded under the new conditions by the company on May 5, following the posting of notices at the mine on May 1 to the effect that on that date a 15 per cent wage reduction would become effective.

There was to have been a conference between officials of the Gilbert-Davis company and officials of the United Mine Workers before any definite action was taken. The parley was not held, however, according to an official of the union as the company posted notices of the wage reduction several days before the date set for the conference.

Progress is being made by the two other companies in the Scotts Run field —the Cleveland-Morgantown Coal Co. and the Connellsville By-Product Coal Co., controlled by the Pursglove and Paisley interests, respectively—in loading coal, these companies having recently ceased to operate their mines under an agreement with the union. By the middle of last week the Cleveland-Morgantown company was loading coal at the rate of three cars a day, with the Connellsville By-Product company loading a somewhat smaller tonnage. Union tonnage in the Scotts Run section has now dropped to nothing.

Would Deny Virginian Lease To Norfolk & Western

Examiner Davis, of the Interstate Commerce Commission, has recommended in Finance Docket 4973 that the Commission should deny the application of the Norfolk & Western Ry. for a lease of the Virginian Ry., on the ground, as he explains, that it has not been shown to be in the public interest. The examiner takes the position that under the provisions of paragraph 2, Section 5, of the Interstate Commerce Act, the burden is upon the N. & W. to establish the fact that the proposed lease would be in the public interest. He feels that the N. & W. has failed to sustain this burden and therefore the Commission should enter an order denying the application.

The Chesapeake & Ohio Ry. opposed the application of the N. & W., and while the C. & O. has not yet attempted to lease the Virginian Ry. itself, it made considerable capital out of the fact that in the general consolidation plan set up by Professor Ripley the Virginian is assigned to the C. & O.

Amend Mine Leasing Act

An act amending the General Federal Land Leasing Act of 1920 to limit the extent of leases and permits in states of holdings of coal, phosphate and sodium was signed early last week by President Coolidge. Under it no lease for any of the minerals cited can be held in one state for more than 2,560 acres.

News Items From Field and Trade

ALABAMA

The Stith Coal Co. is putting in a new slope, to cost $250,000, at its mines near Aldridge, which will be completed by September. The output of this company now is 800 tons daily. The new slope will increase the output to 2,000 tons daily.

To Increase Output.—The Alabama By-Product Corp., which recently resumed operations at its Ruby Mine, in Wilker County, is reported to be making preparations to increase the ouput there from around 800 to 2,000 tons per day. This opening is on the Mt. Carmel, or upper bench of the Mary Lee seam and is located on the Southern Ry. near Cordova.

"Teach Others."—During May, the slogan of the Alabama chapters of the Joseph A. Holmes Safety Association is "And Teach Others," adopted from a safety essay written by Alex Mitchell, a negro convict at Aldrich Mines. This essay was the prize winner in a safety essay contest held at Aldrich in March, 1926. The Alabama Mining Institute is distributing copies of the essay to all mining men in Alabama, and it will be discussed at all meetings of the Joseph A. Holmes safety chapters throughout the district.

ALASKA

A coal lease on public lands in the Matanuska field, requiring an investment of $143,000, has been awarded by the Interior Department to the Alaska-Matanuska Coal Co. It covers 1,440 acres. During the first five years of the lease the company will pay the government a royalty of 2c. per ton, mine-run, on coal produced.

ILLINOIS

The St. Clair County Board of Supervisors now has four applications for the office of county mine inspector, which will be filled at the board's reorganization meeting. The four are J. L. Nevener, Harry S. Maitland and Peter Nool, of Belleville, and Fred W. Collins, of East St. Louis. Collins now holds the position.

To Sell Willis Properties.—A decree for the sale of the properties of the Willis Coal & Mining Co. was granted Conrad Raab and C. H. Krause, receivers for the company, by Judge Walter C. Lindley in the federal court at East St. Louis on May 3. The sale will include four large coal mines, 14,000 acres of coal and 3,000 acres of surface lands in Perry and Randolph Counties, Illinois, having a value of about $800,000.

A. B. Lewis, director of the Illinois Department of Mines and Minerals, has announced the following itinerary for the Illinois Miners Examining Board in May: Benton, 13th; Duquoin, 14th; Centralia, 15th; Staunton, 17th; Springfield, 18th; Taylorville, 19th; Danville, 20th; Farmington, 21st, and Peoria, 22d.

Judge Walter C. Lindley, presiding in the U. S. District Court at East St. Louis, on May 3 ordered the sale of the property and assets of the Willis Coal & Mining Co. in Randolph and Franklin counties. The properties are valued at $2,250,000. Conrad Reeb, president of the Southern Illinois National Bank, and C. H. Krause, St. Louis, Mo., receivers for the corporation, asked the order for the sale.

Mine No. 10 of the Indiana & Illinois Coal Corp., at Nokomis, probably will be reopened June 1, when the rebuilding of the tipple is expected to be completed. The structure recently was destroyed by fire, throwing about eight hundred miners out of work.

INDIANA

Articles of dissolution of the Western Indiana Mining Co., as agreed on at a special meeting of the stockholders in Terre Haute, last February, have been filed. G. Ed Talley was president and John C. Templeton secretary of the corporation. The document cites that all debts and obligation of the corporation have been paid and the surplus distributed among the stockholders.

KENTUCKY

The Dudley Coal Co., operating mines at Carbon Glow, on Rockhouse Creek, near Blackey, is building a number of additional miners' homes and making other improvements.

Benjamin Ford, Cincinnati, president of the Ford-Elkhorn Coal Mining Co., Robinson Creek, and president of the Ford-Elkhorn Coal Sales Co., filed a voluntary petition in bankruptcy recently in the U. S. District Court at Cincinnati, listing his liabilities at $130,586 and his assets at $36,348.

The Louisville retail firm of Cummings & Eglan, operating the C. & E. Coal Co., at Brook and Eastern Parkway, has quit business, and the yard has been taken over by the Black Creek Coal & Mining Co., of which Homer Blades is president. The latter company has been operating a yard at Brook and Bloom Streets, which has been abandoned in favor of the better new location.

News that Charles F. Heidrick and his associates has sold their interest in the Cumberland & Manchester R.R. to the Louisville & Nashville and that the line will be operated as a branch is interesting to seven or more large companies operating 44 mines in that section of southeastern Kentucky. The 10c. differential from the line will be done away with and the Jellico rate will apply, it is said. More extensions seem in order, judging from the engineering crews at work. This line would tap some of the large coal properties in the Clay County region owned by Henry Ford.

Operators Expand Retail Outlet.—The Liberty Coal & Coke Co., Louisville, operators with mines in the Pineville section of eastern Kentucky, now operating a retail yard in Louisville, at Eleventh and Maple Streets, has a deal on for leasing the Edward J. Hackett Coal Co. yard, at 2938 Portland Avenue, which would give the company an excellent distributing yard in the western section of the city.

Charles Pitman, of Harlan, has been indicted by the Grand Jury of Harlan County in connection with destruction of a tipple of the Verda Harlan Coal Co. He was released under bond of $5,000.

The Flat Top Mining Co., at Hazard, has taken over and started operation of the Eden Coal Co. mines, at Blackey, on Rockhouse Creek.

MINNESOTA

The Zion Coal Co., Henderson, of which Thomas Baskett is manager, will rebuild its tipple which was recently damaged by fire to extent of $20,000.

The Berwind Fuel Co. has moved its general offices in Minneapolis from the Plymouth Building, where they have been for a number of years, to the new Baker Building, just being completed.

The matter of a license fee for retail fuel dealers in Minneapolis has been up in the Council again. Now it is proposed to reduce the fee from $50, heretofore placed on all dealers, to $25. for the main office and a lesser fee for branches.

Head of Lakes Set for 50 Cargoes.—Fifty cargoes of coal are included in the season's opening movement to Duluth-Superior docks from Lake Erie ports. They were distributed as follows: North Western, 20; Inland, 11; Berwind, 3; Carnegie, 4; Pittsburgh, 2; Zenith, 2; Duluth, Missabe & Northern, 2; Northern, 2; Great Lakes, 2; Reiss, 1, and Philadelphia & Reading, 1.

Digitized by Google

MISSOURI

Large increases in the tax valuation of steam-shovel mines in Barton County brought such vigorous protest from the owners that the board of equalization cut the increase but still left the figures much higher than last year. The Clemens plant, formerly assessed at $75,000, was raised to $106,000 and finally placed at $90,500. The Mulberry Coal Co. operation was raised from $35,000 to $60,000 and finally placed at $47,500. These are typical of the adjustments made on the valuations of the thirteen steam-shovel mines involved.

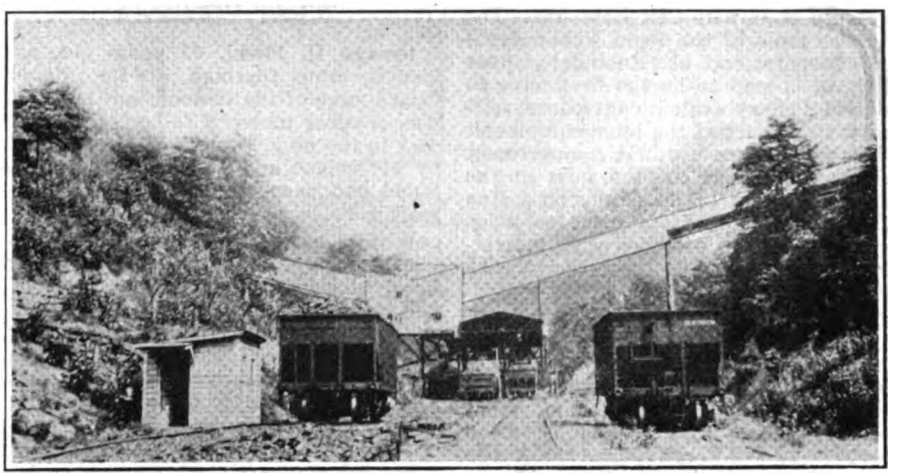
The Howard County Mining Co., which has 1,300 acres of coal land near Higbee underlaid with a bed averaging 3 ft. thick with 25 ft. of overburden, is reported to have closed a contract to put in a plant that will cost about $300,000 and produce the coal at the rate of about 500,000 tons per year. Contracts are said to have been closed with large consumers in Kansas City, Mo., covering a period of years.

The Watson coal mine on the Richmond-Henrietta Road, has been closed for repairs. The shaft at the mine has caved in making it impossible to run the cages in the shaft. The mine will resume operation as soon as the repairs are completed.

The mine of the Trenton Mining Co., at Trenton, has closed down. The company expects to resume operations by July 1 at the latest.

NEW YORK

The Tuttle-Burger Coal Co., Inc., on May 1 moved into new offices at 110 East 42d Street, New York City.



The Pittsburgh Coal Co. announces the removal of the office of its Eastern sales agent to 1 Broadway, New York City; telephone, Whitehall 5144.

The New York office of the Clinchfield Coal Corporation were removed April 29, to the Evening Post Building, 75 West Street.

A coke dry-quenching plant is under construction by the Rochester (N. Y.) Gas & Electric Corporation and it is stated that it will be the first of its kind in America, the system having been perfected by the brothers Sulzer of Switzerland. The cooling of coke is carried on in the new plant by circulating inert gases through it and the heat resulting will be used to generate steam. It is expected that 400 hp. will thus be obtained daily..

NORTH DAKOTA

The Supreme Court of North Dakota has handed down a decision affecting the discretion of the state board of administration in the matter of coal purchases. The Washburn Lignite Coal Co. went into court to compel the award of the entire purchase of coal for state institutions, alleging that as the lowest bidder it was entitled to the contract. The board distributed the business to several concerns, on the ground that heat units and commercial value as well as service of delivery and other factors justified it. The District Court upheld the award as within the discretion of the department of administration. Now the Supreme Court holds that "the board exercised its honest judgment, even though the method followed in determining the lowest bidder was not that contemplated by the statute."

Mine No. 5, Columbus Mining Co., Allais, Ky.

This mine, which is in the Hazard field, is designed for a maximum capacity of 3,500 tons per day. The coal comes to the tipple on button conveyors from the Flag Seam and the 5A Seam, on opposite sides of the valley. The mine is equipped with picking tables, loading booms, etc.

OHIO

A deed for 5,798 acres of Belmont County coal land from the Allen Coal Co. to the Monongahela & Ohio Co. has been filed at St. Clairsville. The consideration is not given other than the nominal sum of $100.

After an absence from the Cincinnati market of over a year the Chesapeake & Virginian Coal Co., of Lynchburg, Va., has reopened a branch office there in the Union Central Building, in charge of Cadwalader Jones.

It is reported that Zanesville and Crooksville capital has purchased the Fleming farm between Crooksville and New Lexington for the purpose of developing the coal deposits. A company will soon be organized to start development work.

The Lewis Hale Coal Co., started some time ago in Huntington, W. Va., now has a Cincinnati outlet, the company having opened an office at 605 Mercantile Library Building. N. A. Lewis, formerly in Cincinnati for the Federal Coal Co. and later with the Hooper Mankin Coal Co., of Huntington, is in charge.

The No. 7 mine of the Neffs Coal Co., located near Neffs, has been closed down for want of orders. The mine had been working at full time for months. The mine is located in the heart of Pittsburgh No. 8 field.

The Lorain Coal & Dock Co., of Columbus, is operating only two of its mines in Pittsburgh No. 8 field, and these are on part time, two having been closed down indefinitely several weeks ago. The mines that are operating are the Crescent and Blaine mines while Stanley and Lincoln mines have been closed.

PENNSYLVANIA

The Shannopin Coal Co., a subsidiary of the Jones & Laughlin Steel Corporation, has started the development of a new coal field consisting of several thousand acres located near Taylortown. The company plans to ship the field's production by water, the first such attempt, on a major scale, in that territory. The company's plans call for the opening of two mines, construction of a narrow-gage railroad from Taylortown to Poland, three miles distant, building of a dock at Poland, from which coal may be shipped on the Monongahela River and erection of 250 houses at Taylortown for miners.

Safe Timbering Explained.—Officials of the Hudson Coal Co. recently staged demonstration of the proper method of standing timber under dangerous roof. The demonstration took place at a dinner at the Eagles' Club, Wilkes-Barre, attended by 650 employees of the company's Pine Ridge mine. A model of a gangway was erected on the stage with one section of timber already in place. Two miners then proceeded to erect a new section of timber in the manner approved by the company, which provides the greatest degree of protection to the workers from falling roof. As the workmen went through the task of timbering the place, John Green and William May, officials of the company, explained how and why the timber was prepared and placed in that manner.

A bill in equity has been filed with the county court in Ebensburg, Cambria County, by W. A. Sheeler and J. D. Keiper against the Rowena Coal Co., asking the appointment of a receiver. The bill sets forth that the company own land and operations in Somerset County and has assets of $192,000 and liabilities of $147,516.92. The petitioners allege that the company has notes and obligations which it is unable to meet and that numerous wage claims have been filed. The petitioners are stockholders and the principal place of business of the Rowena concern is in Johnstown.

In a recent speech delivered at Wilkes-Barre Mayor Dan Hart of that city went after Governor Pinchot of Pennsylvania for the part he played in trying to settle the anthracite strike. Mr. Hart said that he had been told by a prominent anthracite operator the strike would have ended around Christmas but for the governor's intervention.

Digitized by Google

Equip Mine with Self-Rescuers.—The Penelec mine of the Penn Public Service Corporation, at Robindale, near Seward, is said to be the first mine in central Pennsylvania to introduce self-rescuers as part of the mine equipment. The self-rescuers are in a compartment within easy reach of the men in the event of a fire or an explosion. Men who travel about from place to place in the mines are provided with individual rescuers, which they carry with them.

A loss of $75,000 was caused at North Avoca recently when fire destroyed the washery owned by the Hillside Coal & Iron Co. The washery had been in service ten years and gave employment to fifty men. Fire companies from Duryea and Old Forge helped the Avoca companies in fighting the flames, thereby preventing other buildings in the neighborhood from being damaged.

UTAH

A tract of public coal land in Sevier County will be offered for lease at public auction on June 1. The terms call for a 15c. royalty to the government and the expenditure of $1,000 in three years to bring the property to a minimum production of 550 tons. The lease will be awarded to the bidder offering the highest premium over the fixed terms.

The Columbia Steel Co. has plans under way for erecting more homes at its coal operation. It is stated that quite an extensive program will be carried out in order to meet the growing needs of the town.

VIRGINIA

As the result of a conference between Governor Byrd, Lee Moore, Auditor of Public Accounts; John M. Purcell, State Treasurer; members of the purchasing commission and Charles A. Osborne, purchasing agent, on the one hand and a committee of Virginia operators on the other, including C. B. Neel, secretary of the Virginia association; D. Terpstra and Dan Pierson, it has been announced that new specifications for fuel to be used by Virginia state institutions will be issued soon, which will permit Virginia operators to bid on requirements amounting to approximately 70,000 tons a year.

WASHINGTON

Snoqualmie Coke Plant Opens.—The California-Alaska Corp. opened the Snoqualmie coal mine and coke ovens, near Snoqualmie, late in April with ceremonies. Prof. Joseph Daniels, representing the University of Washington and the state development committee of the Seattle Chamber of Commerce, spoke on the significance of producing high grade metallurgical coke as the first step toward steel manufacture in the Northwest. Since taking over the project last July, the corporation has expended $100,000 in developing the mine and installing a coal cleaning plant. The property contains large beds of coking coal. A new 1,500-ft. tunnel makes possible 600 tons daily output. Fifty ovens can handle 100 tons and 100 ovens will be added within two years.

WEST VIRGINIA

George H. Shehl, 44 years old, assistant mine foreman at the Mount Claire mine of the Hutchinson Coal Co., was crushed under a fall of slate and rock in the mine May 7. He is survived by his widow and eight children. Mr. Shehl had been employed by the company for 11 years.

Within a few more weeks all electrical wiring will be removed from the Consolidation Coal Co.'s mines No. 86, at Carolina, and No. 87, at Idamay, if the present plans to equip all cutting machines as well as haulage motors with storage batteries are carried out. The change is partly a safety measure and also is in the nature of an experiment, it is said.

The Island Creek Coal Co., reports for the quarter ended March 31, 1926, net profit of $597,804 after depreciation, depletion and federal taxes, equivalent after allowing for dividend requirements on the $6 preferred stock to $4.40 a share earned on 118,801 outstanding shares of $100 par common stock.

Coal companies in which John Laing, of Charleston, is interested re-elected officers recently as follows: Wyatt Coal Co.—President, John Laing; vice-president, James Martin; secretary-treasurer, T. J. Robson; McAlphin Coal Co.—President, John Laing; vice-president, A. W. Laing; secretary-treasurer, T. J. Robson; Morrison Coal Co.—President, John Laing; vice-president, A. W. Laing; secretary-treasurer, T. J. Robson; Wyatt Coal Sales Co.—President, John Laing; vice-president and treasurer, T. J. Robson; secretary, O. H. Heiserman.

The state Department of Mines has announced that it will hold its annual foremen and firebosses' examinations as follows: Morgantown, Mechanical Hall, West Virginia University, July 26; Elkins, Central School Building, July 29; Welch, High School Building, Aug. 9; Williamson, High School Building, Aug. 12; Beckley, Junior High School Building, Aug. 16; Charleston, Central Junior High School Building, Aug. 19; Logan, High School Building, late in August; Wheeling, High School Building, Sept. 2. It requires two days to take the examinations and the date announced is when each examination begins in the particular town.

The Island Creek Coal Co. has acquired about 12,000 acres of coal land in the vicinity of Elk Creek, a tributary of Pigeon Creek, in Mingo County, and will undertake extensive development. Surveys are now being made for the necessary railroad sidings, town site and plant on which more than $1,000,000 will be expended. It is stated that $350,000 will be expended on a public road nine miles in length to connect the new town with Holden, general operating headquarters of the company. It will be possible to ship the coal out either on the Logan side over the Chesapeake & Ohio Ry. or over the Norfolk & Western Ry. by way of Pigeon Creek branch.

Lesser union officials in West Virginia are showing considerable dissatisfaction over a recent cut in wages, equal to a 50 per cent reduction in some instances, to permit an expansion of union endeavor in this field and the doubling of the organization force while conducting an intensive drive among the non-union miners. Organization work is being directed chiefly toward the negro miners in the Fairmont region now. Union heads announced at a recent mass meeting that practically every effort of the union is now being directed to that end.

The Coal River Collieries Co. is planning to remove its main offices to the Brotherhood of Locomotive Engineers' Building in Cleveland within the next 60 or 90 days, according to reports. The traffic and purchasing departments will be removed to Charleston.

Mines, Long Shut, Reopen.—The Melrose Coal Co.'s plant at Enterprise has resumed operations with a full complement of workers after being shut down two years. A new tipple and new machinery have been installed. The plant of the Winchester Coal Co. at the same place also has resumed operations after a long suspension.

A charter was granted late in April to the Gulf Roan Smokeless Coal Co., with headquarters in Clarksburg, W. Va. The concern, which has an authorized capital of $300,000, was organized to mine coal, manufacture coke and coal briquets. The incorporators are Levi W. Keaster, George G. Lynch, Walter Elliott, Mamie Lee Morris and Dennis S. McIntyre, all of Clarksburg.

CANADA

During the last few weeks there has been a great deal of staking of coal claims on the Mattagami River near Smoky Falls. It is understood that practically 100 square miles have been taken up. While it is commonly reported that there is no prospect of coal in Ontario, it has been known for many years that there were about 11,000,000 tons of low-grade lignite on the Mattagami River. It is stated that drilling operations have located a better grade of coal at a little greater depth, which is the cause of the excitement. The area is about 40 miles from the end of the T. & N. O. branch line north of Cochrane.

Hamilton May Have Big Coal Dock.—A project to establish dock facilities with a capacity of 1,000,000 tons of soft coal each season is under consideration by the harbor board of Hamilton, Ont., which has become an important center for the coke manufacturing industry. The cost is estimated at between $225,000 and $400,000.

Canadian Coal Output Declines.—Output of coal from Canadian mines during February was 13 per cent less than for the preceding month and 14 per cent less than the average for February in the past five years. The production was 1,068,184 in February, compared with 1,225,988 tons in January, and the five-year average of 1,305,367 tons. February imports totaled 825,503 tons, as against 968,475 tons in January and the five-year average for February of 1,169,603 tons. Anthracite was imported to the amount of 29,565 tons, which was 45,865 tons less than the January figure. Exports amounted to 35,517 tons in February as compared with 65,047 tons in January.

Among the Coal Men

Joseph J. Walsh, Secretary of Mines of Pennsylvania, will be the chief speaker at the annual banquet of the Pennsylvania Coal Mining Institute, Johnstown, to be held on May 20. Four hundred mining men of Cambria and contiguous counties are expected to be present. Short addresses are scheduled to be given by Past President Charles Enzian, of Windber, and President-elect Archie Miller, who is expected to outline his schedule of meetings for the ensuing year.

D. A. Stout has been appointed chief engineer of mines of the Colorado Fuel & ron Co., having charge of engineering and exploration in connection with raw materials, with office at Pueblo, Colo. The office of manager of the fuel department has been abolished and **R. L. Hair** appointed general superintendent in charge of production, with headquarters at Pueblo.

Hugh Washburn, formerly with the Louisville office of the Southern Coal Co., of Memphis, until that concern withdrew from Louisville a few weeks ago, has gone with the Southwestern Fuel Co., under resident manager G. H. Sowards.

E. J. McGrew, coal-mine operator of Lexington, Mo., has been elected secretary of the Missouri State Highway Commission to fill the vacancy caused by the resignation of E. S. Austin, of Jefferson City, last May. The post pays $3,000 annually. McGrew has been an active good roads advocate for many years.

Noah H. Swayne, of Philadelphia, formerly president of the American Wholesale Coal Association, has accepted an invitation to act as toastmaster at the banquet in connection with the association's annual meeting, at Toledo, Ohio, June 7, 8 and 9.

The position of general superintendent of the Oliver & Snyder Steel Co. coal and coke plants Nos. 1, 2 and 3, near Uniontown, Pa., made vacant late last January by the death of John H. Lane, is being filled by **Charles H. Hinsey**, of Uniontown, Pa., formerly chief engineer and assistant general superintendent. Mr. Hinsey has been with the company for many years and is an old resident of Uniontown.

Will Huffman, general superintendent of the Fordson Coal Co. (Henry Ford interests) is suffering from a nervous breakdown at his home in Richmond, Va., according to reports. **Joseph Helms** is in charge of the plants in the Pond Creek field at Stone, Peg, Hardy and McVeigh, Ky.

In the statewide primary on May 4, **Oma Hart**, well-known coal operator of Boonville, Ind., was defeated for the Republican nomination for Sheriff of Warrick County.

J. W. Galloway was re-elected president of the Maryland Coal Co. of West Virginia and of the Maryland Coal Co. of Maryland at recent annual meetings of stockholders.

John A. Posey, of Rockport, Ind., who has invented a coal loading machine, received the nomination on May 4 for Prosecuting Attorney of Spencer and Perry Counties, Indiana, on the Republican ticket. Mr. Posey's father, the late Congressman Frank B. Posey, of Evansville, Ind., for many years before operated coal mines at Blackburn, Petersburg, Lincoln City and Yankeetown, Ind.

Alexander Howat

The former president of the Kansas miners' union, Alexander Howat, is in Scotland on his way to Russia to attend the Communist International convention to be held this spring, according to information from Pittsburg, Kan. Howat, accompanied by his wife, sailed from New York April 10. He plans to sit as a delegate in the convention, it was stated in what seemed to be an authoritative source. Howat's personal attorney has denied the report, however, stating that the deposed union official is simply accompanying his wife and father-in-law to the latter's old home in Scotland.

Van A. Bittner, chief international representative of the United Mine Workers in northern West Virginia, returned to the local offices at Fairmont May 3 after an absence due to illness. Bittner, who was suffering from an attack of tonsilitis, went to his home in Pittsburgh more than a week ago.

John Stafford, mining engineer and supervisor of state coal mines in Queensland, Australia, has been appointed Chief Inspector of Coal Mines of that state. Previous to entering the service of the Queensland Government as an inspector of mines, Mr. Stafford was for several years connected with the coal mines of the Ipswich district, Queensland, and occupied every position in a coal mine from trap boy to general manager.

J. W. Littlejohn, formerly superintendent of mines for the Utah Fuel Co. at Sunnyside, Utah, and more recently, with his brother, William Littlejohn, lessee of the company's property at Clear Creek, has disposed of his interests there and moved to California, where he will make his future home.

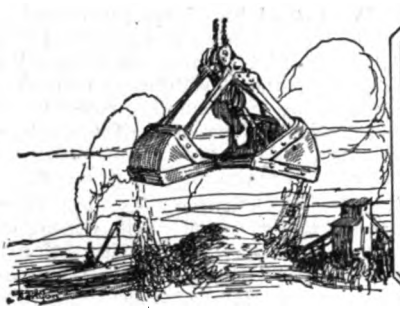
Reports in Scranton, Pa., are that **Frank Benjamin**, owner of the Benjamin Coal Co., of that region, will sell his interests in the Hotel Jermyn and devote his entire time to the coal industry and his banking interests. He also is a member of the Lackawanna County Bar.

John Laing, of Charleston, W. Va., who has been on a tour in the Mediterranean, has gone to Belgium to undergo treatment by a nerve specialist. Mr. Laing is president of the Wyatt, McAlpin and Morridon Coal companies and the Wyatt Coal Sales Co., in Charleston, W. Va.

R. L. Suender, only son of E. H. Suender, general manager of the Madeira, Hill & Co., Frackville, Pa., recently married Miss Elizabeth Beisel, of Pottsville, Pa. The younger Mr. Suender is employed as a mining and mechanical engineer at one of the Madeira, Hill & Co. properties at Pottsville.

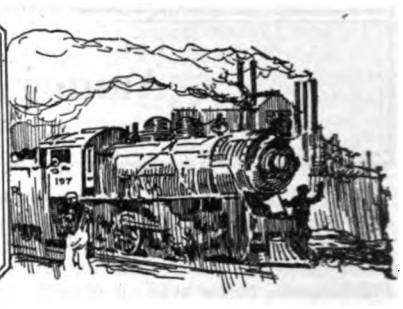
Robert W. Hunter, of the Hunter Coal Co., mine operators of Providence, Ky., and also chairman of the Republican State Central Committee, has announced that he is moving his family to Louisville, where he will make his home. Mr. Hunter is interested in the automobile business and also in oil operations as well as coal.

J. W. Bunting, formerly with the Chesapeake & Ohio Coal & Coke Co. at Norfolk for a number of years and more recently a member of the staff of W. M. Stone & Co., shipping agents, has accepted a position with the General Coal Co., effective April 19. He is one of the best known coal men in tidewater Virginia.



Obituary

Dennison B. Smith, well known in the coal trade of the Twin Cities for more than 40 years, died last week at his home in Minneapolis, after a brief illness. He was born in 1854 in Toledo, Ohio, and went west as a young man, spending most of his life in Minneapolis. He had long been connected with the local dock trade, being with the M. A. Hanna Coal Co. for many years.



William H. Bergenroth, 68, coal-mine operator, died at his home in Troy, Ind., May 3. Early in life Mr. Bergenroth with his brothers operated a coal mine at Hawesville, Ky., going later to Troy to continue their coal operations. Mr. Bergenroth was operating a coal mine near Tell City at the time of his death.

James H. Mays, former Congressman from Utah, died at his Idaho ranch last week. Mr. Mays was stricken while sitting in his chair and died the next day. He held title to about 2,000 acres of coal land in Utah and had devoted considerable attention at times to the development of his holdings, which are located in Emery County. Mr. Mays was born in Tennessee in 1868 and went to Utah in 1902.

Production And the Market

British Strike Indirectly Affects Soft-Coal Trade On This Side; Lake Opening Raises Hope

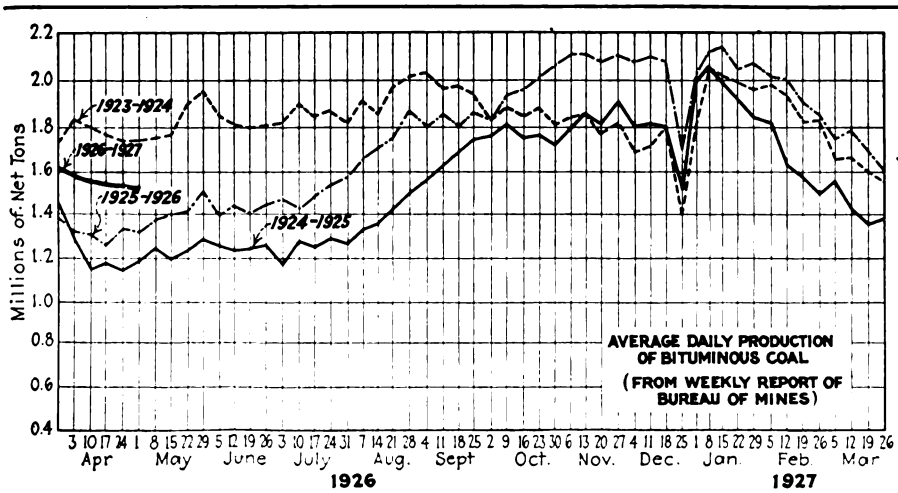
The effects of the British strike upon the bituminous coal markets of the United States during the past week were indirect in character. There was an increase in inquiries from buyers who normally depend upon Great Britain for fuel and a sharp upturn in the asking prices on low-volatile West Virginia coal at Hampton Roads. This was reflected in a strengthening in prices for inland western delivery. But there was no feverish bidding along the Atlantic seaboard.

There has been a slight appreciation in quotations on central Pennsylvania coals, but no broad indications of the secondary reactions which would force up prices on American fuels generally because foreign demand was drawing upon production in this country. As a matter of fact, capacity has been so rapidly developed in the non-union fields in recent years that it probably would take much foreign buying pressure to duplicate—even on a small scale—the runaway market of 1920.

Opening of Lake Trade Welcomed

Another factor of encouragement in the present bituminous situation is the opening of the long-delayed lake shipping season. Several cargoes of bituminous and one of anthracite were discharged at Milwaukee in the past week and over fifty vessels had been loaded for the Head of the Lakes. Railroad facilities at the lower ports, however, are still congested and movement is controlled by the embargo situation. The question of prices continues a sore point with many producers.

During the week ended May 9 there were 343,553 tons of cargo bituminous and 34,714 tons of vessel fuel dumped at the lower ports. The total for the season to that date was 1,598,158 tons, as compared with 2,725,344 tons a year ago and 1,764,525 tons in 1924.



The efforts of the operators to trim output to demand are going steadily forward. During the week ended May 1, production was estimated by the Bureau of Mines at 9,137,000 net tons, as compared with 9,271,000 tons the week preceding. Even with this continued curtailment, the machinery of production is unbalanced because the demand for the different sizes is very uneven. This is particularly true in the Middle West, where "no bills" of domestic coal are the rule. Kentucky also is struggling with this problem and West Virginia is not wholly free.

Spot Prices Move Upward

Coal Age Index of spot bituminous prices has moved upward again. As of May 10 the index figure stood at 161 and the corresponding price was $1.95. The week preceding the figures were 159 and $1.92. The increase in the prices on low-volatile West Virginia coals was the major contributing factor to this advance. In the Middle West the price levels remained constant.

Notwithstanding the general complaint that the hard-coal consumer is backward in storing coal, anthracite production for the week ended May 1 totaled 2,098,000 net tons—a new high record for the year. How much of this production may be credited to a fear that prices would advance cannot, of course, be stated, it is a fact, however, that producers are meeting greater resistance in the sale of their product. Premiums, except on pea, have been shrinking for some time. The slaughter of values in steam sizes by those without facilities for storage goes merrily on.

The spot market in Connellsville coke is dull. Furnace ovens now are reducing their output faster than the merchant operations. Spot furnace coke is weaker.

Estimates of Production

(Net Tons)

	1925	1926
BITUMINOUS		
April 17	7,515,000	9,306,000
April 24 (a)	8,030,000	9,271,000
May 1 (b)	7,987,000	9,137,000
Daily average	1,331,000	1,523,000
Cal. yr. to date (c)	162,376,000	187,453,000
Daily av. to date	1,580,000	1,822,000
ANTHRACITE		
April 17	1,522,000	2,086,000
April 24	1,880,000	2,087,000
May 1	1,926,000	2,098,000
Cal. yr. to date (c)	29,387,000	19,574,000
BEEHIVE COKE		
April 24	189,000	228,000
May 1 (b)	169,000	221,000
Cal. yr. to date (c)	4,108,000	4,968,000

(a) Revised since last report. (b) Subject to revision. (c) Adjusted to equalize number of days in the two years.

Middle Western Markets Calm

A midsummer quiet has settled down upon the markets of the Middle West. Southern Illinois producers decided that May 1 was not a propitious day to advance domestic prices and other Illinois and Indiana operators followed their lead. On the steam side of the market, the undercurrent of strength is increasing. Unless the demand for coarse coal should show early improvement, advances in the prices on screenings are not unlikely. In fact, some mines are crushing mine-run to take care of steam obligations.

The British tie-up induced some high-volatile shippers to Chicago territory to talk higher prices, but buyers declined to be interested. The low-volatile shippers, however, have withdrawn quotations, asserting that they are booked up for the next few days. What little coal is seeping through is offered at $3@$3.25 for lump and egg and $2 for mine-run.

Cool weather has helped small-lot business in the medium grades in the local St. Louis market. There is little activity in the Illinois and Indiana mining districts. Under present conditions the stripping operations have the edge on the shaft mines. Outside of the Duquoin area there is little railroad tonnage moving. All districts report "no bills."

Kentucky Business Backward

The backwardness of the lake season is still embarrassing the Kentucky operators. Mines in both parts of the state have produced faster than the markets would absorb the tonnage. Nevertheless, the shippers seem to have the situation well in hand. Notwithstanding reports that there are hundreds of unbilled loads at the mines, offers of distress lots at terminal points are few and far between.

Spot quotations on western Kentucky screenings are slightly stronger; as high as $1.25 is asked in some quarters and very little tonnage can be had under $1.10. Prices on other sizes show no material change from those prevailing in recent weeks. Western Kentucky mine-run is $1.10@$1.40; lump, egg and nut, $1.35@$1.65; 6-in. block, $1.65@$1.85. Eastern Kentucky slack is $1@$1.10; mine-run, $1.35@$1.65; lump, egg and nut, $1.75@$2; 4-in. block, $1.85@$2.25, with occasional sales of Jellico and Straight Creek at $2.50.

Heavy Movement to Northwest Likely

Heavy movement to the docks this season is forecast by the fact that the vessel sheets a week ago showed 50 cargoes of bituminous had been marked up for the Head of the Lakes. Stocks on hand as of May 1 were estimated at 1,750,000 tons. No loading of hard coal was reported up to last Wednesday, but there are practically no stocks left on the docks and it is estimated that approximately 1,000,000 tons of anthracite will be shipped.

Shipments from the docks to con-

Digitized by Google

sumers over the Northwest are on a seasonable basis. Contracting for the year's supplies by the utilities and larger industrial plants is expected to begin in a substantial way before the end of the month. Further stiffening in the prices on smokeless lump is the only change in dock quotations.

Warm weather has killed any demand for domestic coal in the Twin Cities. Steam-coal buyers persist in their attitude of indifference toward contracting, but producers are not pressing them with offers of concessions. Prices in Illinois and western Kentucky coals are unchanged.

Arrivals of the first fleet from the lower ports kept docks at Milwaukee busy last week. Up to May 6 a total of 135,605 tons of bituminous and 5,000 tons of anthracite was received. Up to Map 6, 1925, bituminous receipts had totaled 227,313 tons, and anthracite, 153,208 tons. There have been some sharp revisions of retail prices. Pocahontas declined $3, and coke, $2.10.

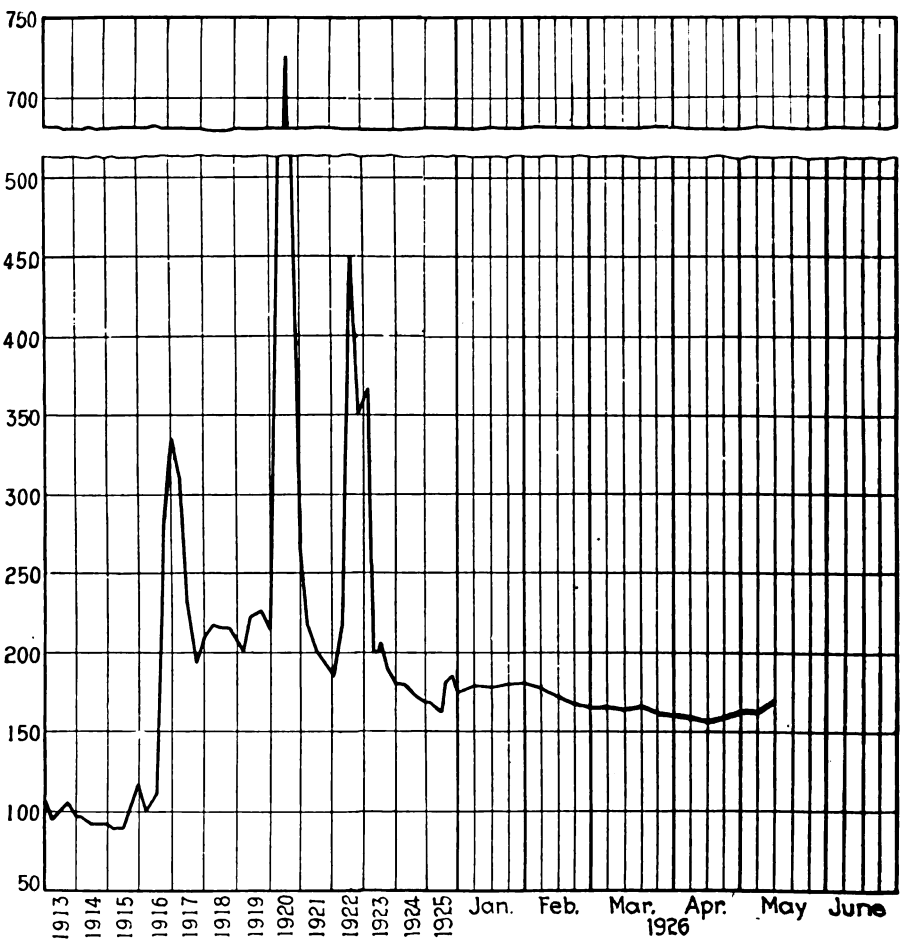
Kansas Fields Mark Time

Little coal is moving in the Southwest. Many mines are down and those working are averaging only a few days a week. This condition prevails not only in Kansas but also in Oklahoma and Arkansas. Paris (Ark.) semi-anthracite lump is quoted at $5.50 for May, $6 for June and $6.50 for July. McAlester lump is $5.60; nut, $4.60, and screenings, $2.50. Lump and nut from the Wilburton mines are 75c. less, with slack $2.50. Henryetta is asking $3.50 for lump, $3.25 for nut, $3 for mine-run and $2.25 for screenings.

Season and temperatures considered, Colorado mines are enjoying a fairly steady demand. Nut is the size most favored by the retailers. Activity in the sugar, steel and copper industries is absorbing all the steam tonnage available. Walsenburg and Canon City domestic lump is quoted at $4.50, mines; washed nut, $4.25, and chestnut. $3; Trinidad domestic lump and nut $2.85; Crested Butte bituminous lump, $4.50; nut, $4.25. Colorado domestic anthracite coals are $6.50@$8.

Dawson district (New Mexico) 6-in. lump and 6x3 egg are $3.20; nut, $3.10; pea, $2.85. Kemmerer and Rock Springs (Wyoming) lump, grate and nut are $3.50. The ruling price on Wyoming steam sizes is $1.25 in the Denver market, but slack is 50c. higher at Salt Lake City. Utah mines are not averaging over two days a week and buying is on a hand-to-mouth basis. Curtailed production is keeping the steam market strong.

Cincinnati More Buoyant



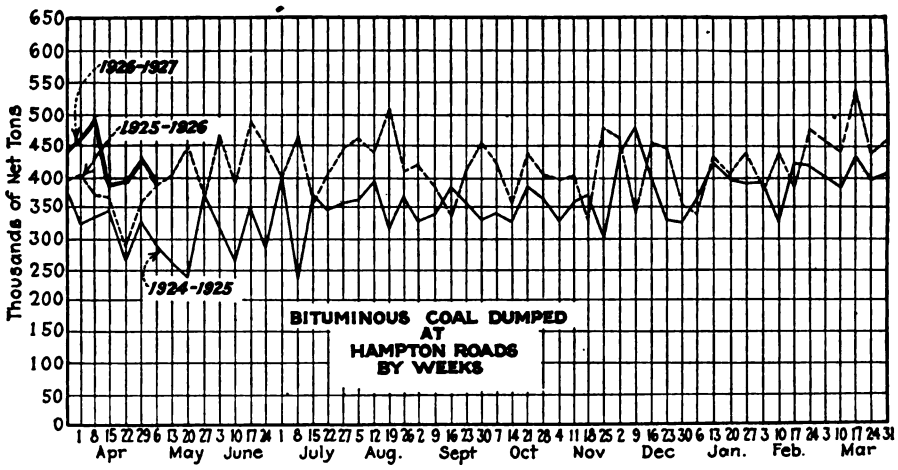
The Cincinnati market wears a livelier aspect. Trade interests now feel that the abbreviated lake season will be a blessing in disguise and they also are counting upon an increased demand as a result of the British strike. Low-volatile coals are stronger, particularly lump and egg, and there is little spot tonnage offering. Slack, however, still lags; quotations are $1.25 @$1.50, but little is going above the minimum figures.

There is a slight improvement in the demand for high-volatile domestic block and lump, but egg is erratic. Better grades of mine-run now command $1.50 and the average is about $1.40. Slack was strong until the B. & O. embargo lake shipments to Toledo. Some of the tonnage caught in the jam sold at 75@ 90c., but most of the coal is held for 90c.@$1.10.

The local retail trade at Cincinnati is unusually active for this season of the year. Coal movement through the Cincinnati gateways, according to the latest figures of the American Railway Association, is increasing, not only because of lake shipments but because general business also is expanding.

No Life in Ohio or Pennsylvania

As for weeks past, sluggishness characterizes the spot-coal markets in Ohio and Pennsylvania. In central and southern Ohio business has been awaiting the opening of the lake season. Lake buyers hold to $1.50, while sellers are hoping that the late start of ship-



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	May 10	May 3	April 26	April 19	May 11	May 12
Index	161	159	159	158	166	169
Weighted average price	$1.95	$1.92	$1.93	$1.92	$2.01	$2.05

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

ping may mean higher prices. The number of loaded cars on the tracks to the Sandusky and Toledo piers runs into the thousands.

Central Ohio steam trade lags. Contracting is backward because spot prices are so depressed. Screenings, however, are firm, but mine-run is a drug on the market. Only a few storage orders have been placed by the retail distributors. Southern Ohio production is running between 15 and 18 per cent of normal.

If there was any change in the northern Ohio situation last week it was a change for the worse. Production is declining and prices are further depressed. Slack coal has dropped 5 to 10c. per ton. Retail trade at Cleveland is light. During the week ended May 1 the No. 8 field produced 189,000 tons, or approximately 27 per cent of capacity. Compared with the preceding week this was a loss of 31,000 tons. Lake Shipments up to May 3 exceeded 1,000,000 tons, but Ohio had a very small share in the business.

Pittsburgh in the Doldrums

There is no cheer in the reports from commercial operations in the Pittsburgh district. The Pittsburgh Coal Co. has sold some tonnage to the lakes. In general, however, mines operating on the 1917 scale find it no easy matter to move coal; the difficulties confronting the union operations are still greater. Prices are unchanged. Stripping mines willing to crush mine-run are holding prices on slack in check.

Central Pennsylvania is living on hopes. April production was only 55,965 cars, as compared with 82,648 in February and 70,245 cars in March. Some tentative inquiries have been received from foreign sources, but at best the central field looks for nothing but a reflected demand. Current quotations are: Pool 1, $2.50; pool 71, $2.20@$2.25; pool 9, $2@$2.15; pool 10, $1.85@$2; pool 11, $1.65@$1.75, and pool 18, $1.60. Compared with the preceding week, the general list is stronger.

No changes worthy of chronicling marked the Buffalo bituminous market last week. Demand, generally speaking, holds up, but prices yield no profit to the sellers. In the domestic trade a quiet struggle is going on between anthracite and coke. Lake movement of anthracite has started, with the clearance of 12,500 tons for Chicago and 10,200 tons for Duluth and Superior.

No Strike Reaction in New England

There has been no real reaction to the British strike in the New England market. Buying is very quiet and the volume of spot tonnage sold shows no appreciable gain. Prices on cars at Boston are somewhat firmer because of diminished receipts, but at other New England distributing points previous levels have been undisturbed.

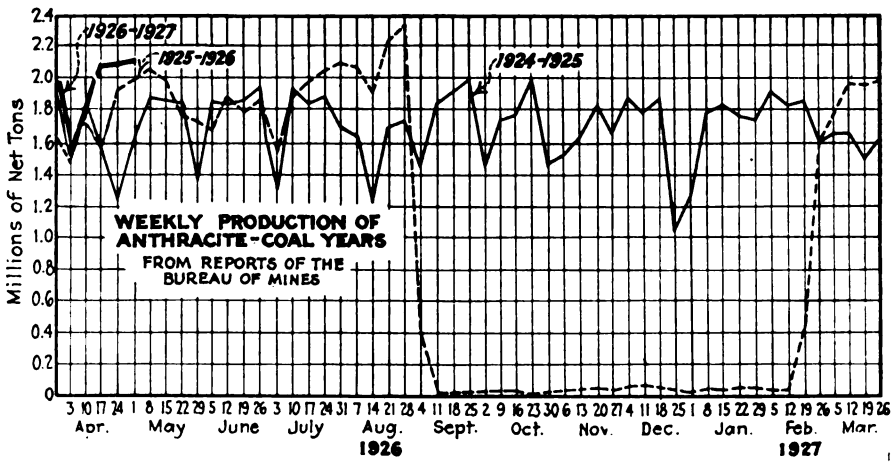
Several of the shippers at Hampton Roads are holding out for $4.75 gross, but there are not many sales for New England delivery at that figure. Practically all the shippers have coal at the terminals and there are occasional reports of placements at prices more nearly approximating the average of a fortnight ago. On cars at Providence and Boston, Navy Standard commands $5.50@$5.75.

No change has developed in the all-rail market for central Pennsylvania coals. Quotations are on a minimum basis, governed by the cost of mining. In no direction is there more than a scattering demand for this fuel and shippers are canvassing the territory assiduously for orders.

British Strike Has Little Effect

The British strike to date has left only a faint impress upon the bituminous markets of the Atlantic seaboard. Pier prices advanced sharply at Hampton Roads last week, but quotations at New York were weaker on the whole and unchanged at Philadelphia. More bunker coal was taken on by vessels clearing from New York, but the number of clearances was less. There also has been an increase in the number of inquiries from foreign sources, but not many actual orders.

New York is still troubled with distress Pennsylvania coal and some lots have been sold as low as $1.75, mines. There has been no change in the nominal quotations on fresh-mined coal. Bargain hunters, however, are able to pick up odd lots at attractive figures.



Philadelphia jogs along at an unhurried pace. Demand is fairly constant and prices show no appreciation. The optimists are hoping that industrial buying will expand as summer approaches. Little store is set by the British trouble. There are rumors that France may look to the United States for fuel, but these tales do not square with late reports from the Continent. Railroads pursue their much-criticized buying policy. At Baltimore, coal men are discussing foreign prospects, but the local situation is unchanged.

The situation at Birmingham is on all fours with that prevailing for several weeks past. Medium- and high-grade steam coals move readily in the contract and spot markets, but only restricted production prevents a surplus of the low-grade fuels. The rapid absorption of the better grades of domestic coal on season contracts has created a slightly stronger market for lower quality white-ash coals. Domestic coke demand is lifeless, but spot foundry is strong at $6@$6.50. Larger users, however, are covered by contracts at $5.50@$6.

More Anthracite Buying at New York

Anthracite consumers at New York are beginning to buy more freely, but activity still is somewhat subnormal. Independents must work hard to get 25 to 50c. above company circulars, but company tonnage is moving readily. Stove now leads in demand and is used to encourage the sale of egg and nut. Pea maintains its strength. There has been a slight improvement in barley, but the steam situation as a whole is sluggish.

The Philadelphia market is more backward and there have been numerous requests to delay shipment on orders already placed. This is credited to consumers' resentment at the failure of the producers to make the usual spring reductions. Nut has become heavy and some independents are using

pea as a bait to move the larger size. Steam coals are dragging. Large producers are putting coal in storage and smaller shippers are offering concessions to buyers. Barley probably is the strongest in demand, but even that is slipping. There is only a moderate demand for hard coal at Baltimore.

Connellsville in Lake Market

The Connellsville district has sold considerable coal for lake shipment on a mine-run basis of $1.50. This coal is screened at the mines and yields slack and lump in about equal proportions. The rate to the lakes is a few cents higher than from the Pittsburgh district.

There is practically no spot demand for furnace coke and very little for foundry. Miscellaneous buying is light. Spot foundry coke is $4@$4.50, but furnace grades have weakened to $3 flat.

Production during the week ended May 1, according to the Connellsville *Courier*, was 169,410 tons, an increase of 110 tons over the output for the preceding week. Merchant-oven production, 72,010 tons, was 1,910 tons greater, offsetting the loss of 1,800 tons in furnace-oven output. The total for the latter ovens was 97,400 tons.

Export Order Rapidly Loaded

The Western Maryland Ry. loaded a 5,000-ton cargo of coal for export on a vessel at Baltimore on May 6, 100 hours after the order had been placed at the mines at Fairmont, W. Va., by a New York broker. The 100 hours included the time required for mining the coal, loading it in cars, moving it approximately 350 miles to tide and reloading on the waiting vessel at the Port Covington pier of the railroad. The coal, destined for Italy, was moved in a train of 100 cars as far as Cumberland, Md., and then to Baltimore in a train of two sections.

New York Anthracite Prices For May, 1926

(Per Gross Ton, f.o.b. Mine)

Open Navy Coal Bids May 20

Bids for supplying 166,000 tons of semi-bituminous steaming coal, for delivery at New York, Philadelphia, Hampton Roads and Charleston, S. C., during the fiscal year beginning July 1 next, will be opened by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., May 20.

On the same date the Bureau will open bids for the supply of 12,650 tons of anthracite for delivery, in varying amounts, to navy yards and stations in the East and on the Great Lakes during the coming fiscal year.

The Bureau also will open bids on May 20 for approximately 374,800 tons of bituminous coal for power-plant purposes, for delivery at the various yards and stations during the fiscal year. These three openings will cover practically all of the Navy's coal needs for the fiscal year 1927.

Railroad Contracts Placed

According to reports the Big Four railroad has let its contract for railroad fuel for the present coal year. It is said that $1.50@$1.60 is being paid for mine-run, and that operators in the Logan field and along the Norfolk & Western Ry. got some of the business. The bulk of the tonnage, according to reports, was placed in eastern Kentucky.

The Chesapeake & Ohio Ry. let its contracts for railroad fuel last week, according to a letter issued to coal operators, which indicates that the company's entire fuel requirements for the coal year will approximate 1,200,000 tons. The price paid was $1.65 and the company has directed the coal to be screened, according to its specifications.

Hard-Coal Stocks Low.—On April 1 Massachusetts coal dealers had 292,427 net tons of domestic anthracite on hand, compared with 725,037 tons on the same date a year ago. Receipts during the last coal year totaled 3,800,218 tons, as against 5,117,176 tons in the preceding year. Total deliveries of domestic anthracite during the year ended March 31 last were 4,233,344 tons, showing a pronounced decline from the preceding year's total of 5,115,717 tons.

Traffic News

Coke Rates from St. Louis to Missouri-Kansas Too High

Freight rates on coke from St. Louis, Mo., to Missouri River cities and to destinations in southwestern Missouri and southeastern Kansas are found unreasonable and unduly prejudicial as compared with the rates from Chicago, Ill., and Birmingham, Ala., to the same destinations, in a decision by the Interstate Commerce Commission dated April 14 issued on April 29.

The rates are held prejudicial to St. Louis to the extent that the difference between St. Louis rates and Chicago rates is less than 72c. and to the extent that the difference between St. Louis and Birmingham rates to the lower Missouri River cities is less than $2.04 per ton, and to the extent that the difference between St. Louis and Birmingham rates to destinations in southwest Missouri and southeast Kansas is less than $1.80.

The roads were ordered to effect new rates on or before July 14. From St. Louis to Missouri River points the new rates must not exceed $3.25 per net ton and to points in southwest Missouri and southeast Kansas not to exceed $3.49 per ton.

Rate Hearing Dates Changed

Further hearings in connection with the Interstate Commerce Commission's investigation of freight rates on anthracite to stations in upper New York, recently set for June 28 and July 14, at Syracuse, N. Y., have been re-assigned for June 14 at Syracuse before Examiner Koch.

Consideration of the establishment of permanent rates on bituminous coal and coke from mines in Virginia, West Virginia, Pennsylvania, Ohio and eastern Kentucky to points in the Middle Atlantic and New England States where no joint through all-rail rates are now in effect, which had been set for June 7 at New York, has been deferred until June 21 at Atlantic City, N. J., before Examiner Koch. The hearing will be devoted particularly to the rates and charges, including tidewater and trans-shipment rates and charges, for the interstate transportation of bituminous coal and coke and semi-anthracite.

The commission also has issued two supplemental orders broadening the scope of the anthracite rate investigation, as reopened, upon petition of the Central Pennsylvania Coal Producers' Association and upon request for joint rates from the upper Potomac fields in Maryland to Eastern destinations.

Orders Investigation Into Intrastate Rates

An investigation into the rates from Illinois mines to East St. Louis has been ordered by the Interstate Commerce Commission. The rates in question were fixed by the Illinois Commerce Commission on Feb. 8 and are lower than those established by the Interstate Commerce Commission on interstate traffic. The inquiry is instituted for the purpose of determining whether the Illinois rates unduly prefer intrastate traffic and unduly prejudice interstate business. No date for a hearing has been set.

Illinois Commission Order on Collinsville Rate Reversed

Judge David M. Brothers, in Circuit Court of Chicago, last week reversed on appeal an order of the Illinois Commerce Commission reducing the rate on coal from Collinsville to Chicago from $1.85 to $1.65 per ton. The Chicago Eastern Illinois Ry. appealed the case. The Lumaghi Coal Co., of Collinsville, located in the Danville district, which pays a rate of $1.85 per ton, obtained consent of the commission in 1923 to fix its technical location in the Springfield zone, which pays a rate of $1.65.

Foreign Market And Export News

Great Rush to Move Coal In Week Preceding Strike; Welsh Docks Hard Pressed

The Welsh steam-coal business during the week preceding the general strike was almost entirely made up of small lots for bunkering or for completing small cargoes for dispatch before April 30, said the report from the London (England) correspondent of *Coal Age* under date of April 27. On paper most of the collieries were booked up until the middle of May and there was very little coal available for sale in small lots. The Welsh docks seldom have been so active and vessels were waiting to get away with their cargoes before any industrial trouble occurred. Sellers were able to obtain much higher prices, but so little coal was available that the prices realized did not affect the average for all sales to any appreciable extent.

Forward business was conspicuous by its absence since neither purchasers nor operators would enter into fresh deals until they had some idea of the outcome of the negotiations between Prime Minister Baldwin, the operators and the miners. Had these negotiations succeeded, May would have been a very slack month, as most home and foreign consumers would be existing on the large stocks already accumulated.

The Newcastle market was at a complete standstill and the operators would not quote for any sorts. The usual customers for North of England coal were getting all they needed from America and Germany.

Industrial Coals Active On French Market

Paris, France, April 27.—Production of industrial coals is moving without difficulty, but there is little demand for domestic sizes, either from the retail distributors or from the consumers.

Coal production is very active because of the conditions existing in the British coal industry and because of a decline in imports following further depreciation of the franc. Buying of industrial fuels is strong in anticipation of a possible shortage in British supplies, although large stocks are being accumulated in the Ruhr.

During the first seventeen days of the month the O. H. S. received 224,000 metric tons of coal, 157,000 tons of coke and 12,500 tons of lignite briquets from the Ruhr. Effective May 1, advances of from 5 to 7 fr. on industrial coals and 6 to 11 fr. on domestic sizes have been announced.

As a result of increased transportation charges and import duties, the price of indemnity coke has been fixed at approximately 171 fr., f.o.b. Sierck. Protests of French metallurgical interests have developed nothing but a notice that from June 1 to Aug. 31 the price will be increased still further.

French imports of coal, coke and briquets during March totaled 1,951,000 metric tons while O.R.C.A. coke receipts from April 1 to 20, inclusive, amounted to 179,000 metric tons, according to a cable to the Department of Commerce from Acting Commercial Attaché R. C. Miller, Paris.

Belgian Market Steady

Brussels, Belgium, April 29.—Aside from a slight improvement, due to threats of a British strike, no important change has taken place in the Belgian market. There was more French inquiry in the Borinage district and a decrease in British imports, but fluctuating exchange rates to a great degree offset these favorable factors. As a matter of fact, some collieries were compelled to further restrict production.

Effective May 1, it is announced that there will be general increases in the prices on German reparation fuels. Bituminous coals will be advanced 3 to 10 fr.; gas and semi-bituminous coals, 5 to 10 fr.; lean coals, 4 to 6 fr.; furnace coke, 17 fr.; lignite briquets, 5 fr. As a result of this announcement quotations on Belgian coals are firmer.

During March Belgium produced 2,132,180 metric tons of coal, 434,810 tons of coke and 190,770 tons of patent fuel. The prewar averages were 1,903,400, 293,580 and 217,220 tons, respectively.

United States Joins Importers Of German Coal

The German coal industry has made strenuous efforts during the last year to extend it radius of sales activity. These efforts have been rewarded in a moderate degree in a number of overseas markets like the Dutch Indies and South and Central America. In the figures on foreign business in January and February, 1926, however, the United States appears for the first time as an importer of German bituminous coal.

These imports amounted in January to 38,128 tons and in February to 48,474 tons. In the case of coke the German shipments to the United States are even more striking. Starting in January with 9,200 tons, shipments in February increased to 42,000 tons out of a total of 406,000 tons. In the February German export returns the United States figures as the third largest consumer of German coke; being surpassed only by Luxemburg and Alsace-Lorraine, which in Germany are not considered as foreign markets having long-standing relations of interchange of coke against steel products with the German interior.

Coal imports by Germany during January and February showed a continued decline.

Japanese Coal Firm at Shanghai

Shanghai, China, April 6.—At Shanghai the market for Japanese coal is firm. There is a strong demand from native dealers, especially for dust coal, due principally to the growing shortage of supplies from the various mines in China owing to the interference with the railways by military authorities.

For Kaiping coal military operations at and around Taku (near Tientsin) have further increased the difficulties of the traffic situation, though shipments continue at irregular intervals from Tongku. The shortage of certain grades has caused the cessation of household deliveries until more regular supplies are again received.

Coming Meetings

National Retail Coal Merchants' Association. New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

Electric Power Club. Convention at The Homestead, Hot Springs, Va., May 24-27. Secretary, S. N. Clarkson, B. F. Keith Bldg., Cleveland, Ohio.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, with operating conference. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. Fourteenth congress, Madrid, Spain, May 24, 1926. Secretary, E. Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

Pennsylvania Retail Coal Merchants' Association. Annual meeting, York, Pa., May 27 and 28. Secretary, W. M. Bertolet, Reading, Pa.

Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

West Virginia Coal Mining Institute. Annual meeting, June 1-2, Bluefield, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

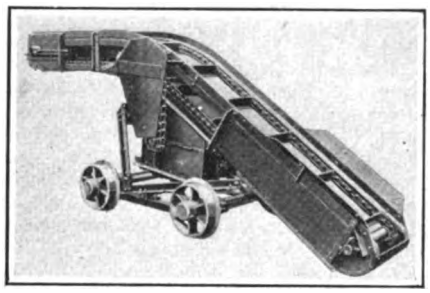
Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

Coal Operators' Association of 5th and 9th Districts of Illinois. Annual meeting, St. Louis, Mo., June 8. Secretary, O. L. Lumaghi, St. Louis, Mo.

Southwestern Interstate Coal Operator's Association. Annual meeting, Kansas City, Mo., June 8. Assistant Secretary, George Manuel, Kansas City, Mo.

National Coal Association, June 9-11, at Drake Hotel, Chicago, Ill. Executive secretary, Harry L. Gandy, Southern Bldg., Washington, D. C.

American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.



American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Illinois Mining Institute. Annual summer meeting on steamer "Cape Girardeau," leaving St. Louis, Mo., June 24 and returning June 26. Secretary, Frank F. Tirre, Central National Bank Bldg., St. Louis, Mo.

New Equipment

Loader Shovels the Coal But the Machine Lifts It

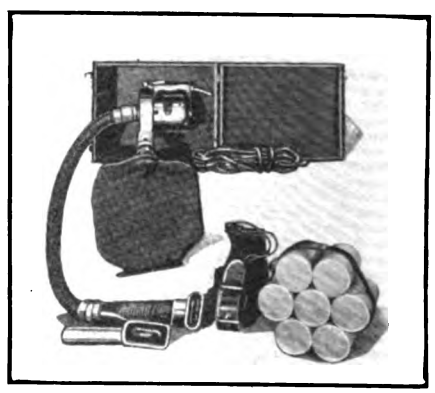
Tests and experience alike have demonstrated that most of the work of loading a mine car is consumed in raising the coal over the side of the car. The accompanying illustration shows the new machine recently developed and placed on the market by the Chicago Automatic Conveyor Co., Old Colony Bldg., Chicago, Ill., for loading coal into cars underground. This machine does not supplant hand shoveling, but it does materially lessen the labor of loading coal by decreasing the height to which the workman must raise his shovel. Several of these machines are already in use and are said to be giving excellent results.

Low Lift Lessens Loading Labor

With one of these machines the loader at the face has to raise coal only a few inches, whereas without it he has to throw it clear over the side of the car.

This machine is built low so that it may be used in comparatively thin beds. It is mounted on a truck and can be readily moved from place to place. It is particularly adapted for use in entries and other narrow work.

Equipped with this new machine a miner is said to be able to handle with ease twice as much coal as he can load without its aid. It has a capacity of approximately 60 tons per hour, which is more than any two ordinary men can shovel even though they have to lift it only a few inches. If desired the machine can be built to move under its own power. This materially decreases the labor necessary to push it from place to place.



Samples Dust On Floor, Roof and Rib by Use of Vacuum

An interesting device for the more efficient collection of samples of coal dust and of mixtures of coal and rock dust has been developed by J. E. Jones, of the Old Ben Coal Corporation. This sampler has been perfected and placed on the market by the Mine Safety Appliances Co., of Pittsburgh, Pa. It is entirely distinct from this firm's rock-dust testing kit, which has been in use for some time.

Too much attention cannot be given to this phase of rock-dusting. It has been recognized that the coal operator has been prone to neglect taking samples properly or with adequate frequency. The method commonly in use at present consists of collecting all the coal and rock dust from a 6-in. strip or zone on the roof and ribs, and separately from the floor, by means of a brush and pan. One can readily appreciate the difficulty experienced in this process in catching or retaining all the dust. This is particularly true on the main intake haulageways, where the velocity of the air current is high. The very fine dust, or that possibly most efficient in the propagation of explosions, and therefore that which it is most desired to sample, is just the material that escapes and defies collection.

With this in mind, the new sampling outfit was designed on the vacuum principle. Instead of brushing, with the inevitable agitation of the mixture and consequent escape of the fine particles, the opposite extreme is attained. The finer particles are those most easily collected because the suction produced naturally picks up these more easily. The particles that will not participate in a coal-dust explosion—those over 20-mesh in size—are totally excluded from the sample by means of a screen placed over the orifice through which the dust is sucked.

The apparatus itself is simple. The suction is produced by a 4-in. fan operated by means of a small 250-volt direct-current motor. As is the nature of fans, a suction is produced in the center and a blowing effect at the tips of the vanes. An aluminum casting surrounding the fan provides for the entrance of the dust at the fan inlet and its collection at an exit on the periphery. The dust is gathered by a nozzle suitable for use upon either rough or smooth mine surfaces and passes through a collection hose into the fan. It then is forced into a small bag which is easily detached and the sample removed. Means are provided for connecting to the trolley wire as

Rock-Dust Sampling Outfit

This kit consists of the sampler proper, which much resembles a little vacuum carpet sweeper; a short length of suction hose, two collecting nozzles, a dust bag, a waist belt, suitable means for connecting the machine to the trolley, a carrying case and a variable number of tin cans for preserving the samples taken.

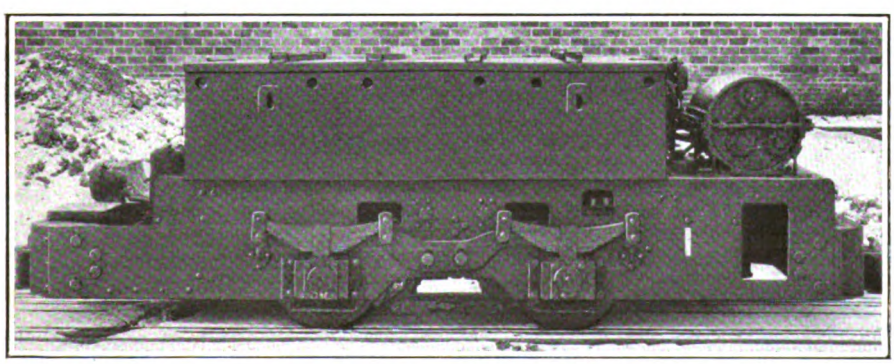
Digitized by Google

Taking a Sample from Rib

This shows the sampler in operation. The black streak on the rib above the collection nozzle illustrates with what effectiveness the air suction removes the dust from the mine surfaces. Pieces larger than 20-mesh are automatically strained out of the sample and left behind.

well as for grounding to the rails. The whole apparatus weighs but 12 lb. and is easily carried on a belt without in any way interfering with the work of the sampler. Naturally this equipment is limited to use where power is available. Extension cable of reasonable length is provided.

The advantages of this new outfit as claimed by the builder are as follows: A more efficient and representative sample is obtained, as the fine particles are all collected. The process of sampling is made far less laborious, as screening of the sample is entirely obviated. Coning and quartering the sample down to a proper quantity (about ¼ lb.) is in most cases not necessary. Samples from the roof are taken with as great facility as from the ribs, something almost impossible by the brush-and-pan method.



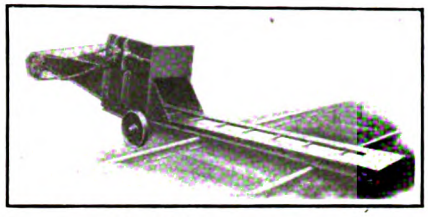
Approved Battery Locomotive For Use On Rough Roads

Government approval No. 1513 recently was granted by the U. S. Bureau of Mines to the General Electric Co., of Schenectady, N. Y., covering a permissible storage-battery locomotive for use in gaseous mines. This machine has a rated weight of 6 tons and is intended for gathering service. It is of outside-frame construction with its weight supported from the journal boxes on heavy semi-elliptical equalized springs. The motors are of the box-frame type, spring-suspended from the locomotive frame. The axles are driven through single reduction spur gearing.

The control equipment is of the progressive series-parallel, magnetic contactor type. It consists of three units; namely, master controller, contactor group and protective relays and a resistor. The master controller—small, compact and easily operated—is of the drum type and handles control current only on the main cylinder and full motor current on the reverse cylinder. Six solenoid-operated contactors are used to make or break connections in all power circuits when current is on.

Overload protection is provided by two relays, one placed in each side of the line. These are reset by a switch contained in the master controller, which also contains another switch for controlling the headlight circuits. The resistor is made up of cast grids inclosed in a permissible compartment.

The type of control on this locomotive is particularly advantageous because it operates reliably with a minimum of inspection, an important consideration with totally inclosed equipment.



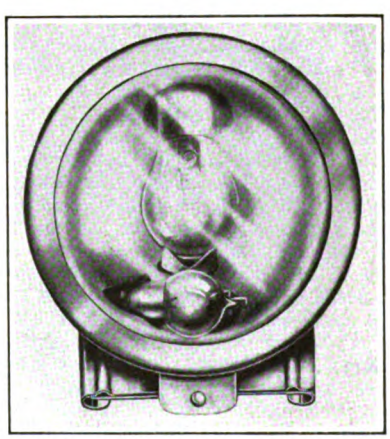
Permissible Storage-Battery Locomotive for Gassy Mines

This locomotive is fitted with outside frames and with equalized, spring-supported journal boxes. It is thus enabled to traverse uneven track with ease. The control is unusual and effective.

Unloads Hopper-Bottom Cars; Feeds Elevating Conveyor

The accompanying illustration shows the new car unloading machine recently developed and placed on the market by the Chicago Automatic Conveyor Co., Old Colony Bldg., Chicago, Ill. This machine is intended for the unloading of sand, gravel, crushed rock, coal or other granular materials from hopper-bottom cars and in such work does away with practically all shoveling. In use it is pushed under the car and across both rails and, with the aid of a second conveyor, if necessary, delivers the material from the opened gates to trucks, bins or to open storage.

Tests of this machine made under exacting conditions show that it will handle the contents of a 50-ton car in less than an hour and there is no reason why it could not be speeded up to handle twice this amount. The receiving end is only 3 in. high above the rails and consequently does not interfere in any way with the drop bottoms. Its sturdy construction will permit it to receive without injury any outrush of material even though the doors are opened wide.



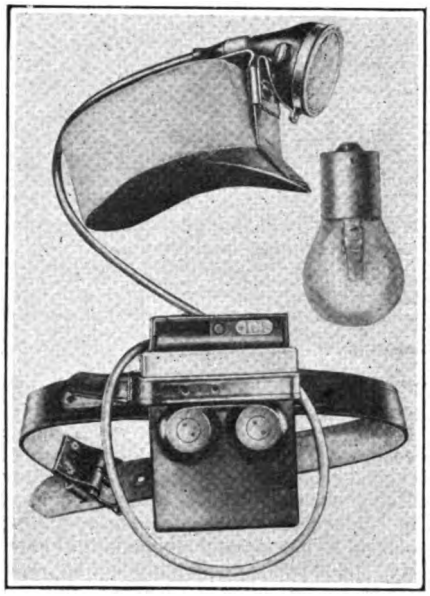
No Pit Necessary

This machine, or rather the receiving end of it, is so low that it can be pushed across the track under a car without in any way interfering with the action of the hopper doors. It delivers to a second conveyor, which can discharge either to a truck or to storage.

No pits and no spotting of cars are necessary. The discharge end is elevated to a height that will allow delivery to a second conveyor without any big lumps rolling backward. The machine is mounted on wheels and may thus be readily transported. The makers assert that it is both economical and flexible in operation and that it will do much to ease the labor and lessen the expense of unloading hopper-bottom railroad cars.

More Light for Dark Mines

It is now possible to obtain the safety inherent in the use of the electric cap lamp with the degree of illumination afforded by the open-flame lamp, for the Super-Wheat electric safety mine lamp made by the Koehler Mfg. Co., of Marlboro, Mass., which gives a beam of 15 candlepower has been approved by the U. S. Bureau of Mines.



Beam Gives 15 Candlepower

Like other lamps made by this manufacture this one is provided with two bulbs. One of these is intended for regular and the other for emergency use.

In size and appearance the bulb of this lamp is practically identical with that of an automobile headlight. It is gas filled, has a tungsten filament and possesses all the other advantages peculiar to this type of electric bulb. The light that the lamp emits is said to be far in excess of that given by former equipment. Lamps have hitherto been considered good if they gave a beam candlepower of 6, but the manufacturer declares that this lamp gives 15, as shown by test.

An emergency bulb is placed within the reflector with the main illuminator. This is of standard size, type and light-

Digitized by Google

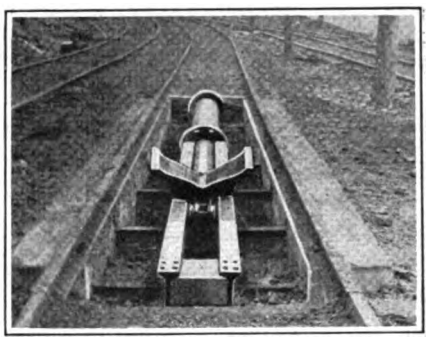
New Lamp Outfit Complete

The battery will supply current to the regular lamp for 13 to 15 hr. or to the emergency bulb for 24 hr. The total weight is normal for an outfit of this kind and repairs have been facilitated by the new design.

giving power. A switch on the headpiece makes it possible for the wearer to use either bulb desired. This is particularly advantageous in case of a bulb burn-out or an accident to the headpiece.

The battery was designed to supply current to the super-bulb for 12 hours. In practice, however, it will furnish current for from 13 to 15 hours. It will energize the emergency bulb, which gives a beam candlepower exceeding 6 for a period of 24 hours either continuously or intermittently.

The increase in illuminating power provided by this lamp has been obtained without any excessive increase in weight. In fact this new lamp is lighter than some now on the market. The average weight of the outfit complete is only 5 lb. 3½ oz. It is well balanced and can be worn for hours with comfort. Like all other lamps of this kind, it can be repaired and made as serviceable as new in the mine lamphouse by the regular mine lampman. Even this individual's work, however, has been lightened, for the filler plug holes are on the outside. All Wheat racks and other charging equipment now in use can be easily adapted to charging the new battery.



Feeds Heavy Trips with Ease

Cars may be fed to dumps that work intermittently by either electrically driven chains or by plungers or pistons working within cylinders. A new device of the latter type recently was placed on the market by the Car-Dumper & Equipment Co., of Chicago, Ill. This feeder is built and shipped as a unit that can be electrically welded or otherwise permanently fastened into a section of the track. The feeder shown in the accompanying illustration is in daily use at a mine in Pennsylvania, handling trips of as many as 100 cars at a time and feeding them to the dump at the rate of 10 to 11 per minute.

By a special construction of the carriage or cross-head embodying a fork that engages the car axles close beside the bearings, the bending stress imposed on these members is negligible. This permits the handling of heavy trips with the same action as is afforded by a double chain feeder, so far as engagement with the car is concerned.

In this feeder the main pushing cylinder works in one direction. The feeder plunger itself is hollow and acts as the return cylinder. This device operates under power in both directions, yet a minimum quantity of air is consumed in returning the device to the starting position. This represents a decided economy over the older types of air-actuated feeders. Another advantage claimed for this feeder is the fact that no finished parts are exposed at any time during the operation of the cylinder.

Naturally a device of this kind can-

Pneumatic Feeder in Place

In this instance the device is built into the concrete slabs supporting the rails instead of being welded to them. The forked crosshead engages the axles near the journal boxes, thus throwing but slight bending stress upon these car members even though heavy trips are moved.

not compete with an electric feeder which affords continuous movement of the trip. Where intermittent movement only is desired, however, as in feeding cars to a rotary or crossover dump or to hoisting cages, this device answers the purpose excellently.. Several installations have been made during the past year and all are reported as giving entire satisfaction.

Graybar Electric Co., New York City, successor to the Supply Dept. of the Western Electric Co., has issued a 1926 **Fan Catalog** covering fans for alternating- and direct-current circuits, including non-oscillating, oscillating, ceiling and ventilating (exhaust) fans. The booklet has 47 pp., 3x6 in.; illustrated.

De Laval Mine Pumps. De Laval Steam Turbine Co., Trenton, N. J. Pp. 20; 8½x11 in.; illustrated. Instructions are given for the design of piping and the calculation of friction head power required.

New Companies

The Wheeler Coal & Coke Co., of 8 East Broad St., Columbus, has been incorporated with a capital of $50,000 to mine coal in the Hocking Valley (Ohio) field and to do a general jobbing business. The incorporators are W. E. Wheeler, C. E. Wheeler, Etta A. Wheeler, Ralph E. Marburger and Edwin B. Pierce.

The Stramer Fuel Co., Charleston, W. Va., having a capitalization of $25,000, was recently chartered. The incorporators are George E. Merryman, H. N. Greenlie and Charles G. Peters, all of Charleston; F. A. Strabley and J. P. Bess, of Seacoal, W. Va. The operations will be at Coal Bloom and Seacoal, in Boone County, W. Va.

The Kanawha Block Coal Co., Wheeling, W. Va., has been organized with 200 shares of no-par value stock, with 20 shares subscribed and $500 paid in. The incorporators are John D. Thomas, Cecil H. Riggs, W. C. Gardner, H. O. Wells and J. Styche, all of Wheeling.

The Harrison Coal Co., Cincinnati, Ohio, has been chartered with an authorized capital of $10,000 to mine and sell coal. Operations will be in the Kentucky field. Incorporators are: Robert E. Harrison, Anna C. Burns, George J. Hagee, Robert K. Main and David V. Attig.

The Coke Oven Co. of Canada, Ltd., of Hamilton, Ont., has been incorporated by Charles H. Leggott, Ernest G. Hathway, and others, with a capital stock of $10,000, to produce coke and gas.

Hope You Will Be There

At Cincinnati will be found all those who have elected to continue in the business of mining coal and who, therefore, are desirous of learning what must be done in order to bring their mines up to date. One cannot waste the time of men, or the power purchased or generated and still continue in the market. We have seen men so busy that they never had time to look at a watch or clock or to consult a timetable, and so they failed to arrive anywhere, at least in time to perform what they had on hand. Others will not take the time to consult maps, the compass or the policeman, and so they spend their time in traveling in the wrong direction. The man who will not attend conventions has nothing on these unwise persons.

In Regard to This Issue

By the way, the convention issue is, we feel, as notable as the convention itself. Mr. Brosky, by whom it was gathered together, labored to make it representative of all phases of mining. Space prevents giving reference to the good things which the issue contains, but when you have read the articles you will realize the depth and breadth of their interest.

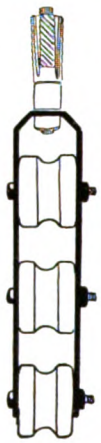
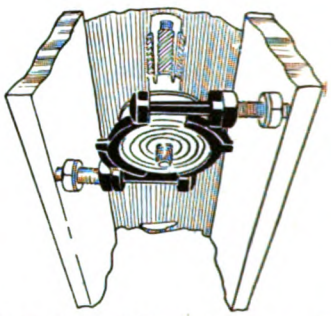
What's New





O-B Bulldog Cable Clamp

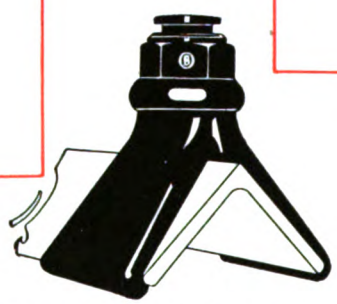
A cable sling with clamping jaw adapted to the old reliable Bulldog clamping principle. Cable gripped tightly, relieving strain on dead-end.

O-B 3-Spool Feeder Insulator

Provides support for three wires from one expansion bolt. Made also with three spools suspended side by side. Only one roof hole to drill!

O-B Guard Board Support

Installed without disturbing trolley hangers or clamps which may have been previously in place. Clamps around skirt of insulated hangers ranging from 3¼ to 3¾ inch in diameter.

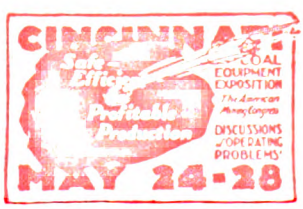


O-B AW-12 Copper Alloy Arc Weld Bond

Welded by copper alloy metallic-arc process. Open terminals catch, retain and support metal deposited by arc. Strands extend into weld, becoming integral part.

O-B Combination Trolley-Feeder Clamps

Combine trolley and feeder wire suspension on one set of insulated hangers. Two styles. "A" supports trolley from feeder as messenger, between hangers. Hangers hold feeder wire or cable in sling. "B" attaches direct to the hanger.



O-B Bulldog Angle Iron Clamp

Suspends inverted 2½ by 2½-inch angle iron used as a trolley. Again the old reliable Bulldog clamping principle.

O-B Cam Grip Splicer

Cam-shaped dogs, with milled teeth, bite into trolley wire. Cam, wedging action increases grip as tension increases. Set screws merely hold dogs in place.

Volume 29 NEW YORK, MAY 20, 1926 Number 20

Cincinnati's Coal-Operating Officials' Convention And Mine Machinery Exposition

IN earlier days, conventions, when they met, discussed "How things are done" and even sometimes "How they used to be done," but today we are more interested to know "How they can and will be done," for we realize that they cannot continue as they are. The old formularies are giving place to new. Change is in the air. Every industry wears a new garb every time we look at it, and the business of getting out coal would be unlike all others if it did not change with the rest. And that it does change everyone will have to acknowledge if he glances back a few brief years.

No longer does the interest in past ways and means hold us back. No one now values experience solely because it is of long standing. A practice is no longer cherished because it is moldy with age. The coal industry realizes that a revolution in methods is on the way. One function of human hands and muscles after another has been taken over by machinery. Haulage, hoisting, and kerf-cutting are almost everywhere and entirely machine-performed operations. A few mules and horses remain and in some mines coal is still, at least nominally, undercut by hand. These are almost the sole reminders—other than loading and drilling—of a bygone age, and they are exceptions to a rule of progress that is almost universal in America, namely to let electricity do the work, more cheaply, more speedily, more cleanly and with less effort on the part of the workmen.

The change that has come to hoisting, haulage and kerf-cutting must come to loading and drilling along with the rest. Hand operations are not more burdensome than they are costly.

* * *

Time was when it was the raw-material industries that made the big engineering advances. It was mining that fostered pumping and ventilation, that gave us the steam engine, the fan, the locomotive, the cross-tie and the metal rail. That was a day when manufactured articles were of no great intricacy. Today mining finds a host of rivals, if they may be so termed—many of them more enterprising than itself. Why does not mining take counsel with these, choosing out men who have had contact with, and perhaps have originally come from, those industries. More outsiders should be absorbed into the staffs of coal companies to devote their peculiar talents to its specialized needs.

Because of these diversities of men and of experience one is sure to find in a big convention what cannot be found at home—peculiar geniuses who have unusual slants on certain problems, slants derived doubtless from their specialized experience and the exceptional circumstances at the manufacturing plants at which they have worked or at the mines which they have directed.

At the American Mining Congress' Annual convention of coal-operating officials in Cincinnati May 24-28 will be presented the opinions of the men who are foremost in promoting the new principles of mining. In the exposition will be seen the newest devices developed for the use of mining men, results of the expert ability that the manufacturers' staffs exhibit.

* * *

And, be it noted, the manufacturer has not been slow to get his men from all quarters and to get ideas from all sections and all industries. He has summoned specialists from every department of engineering that could be helpful to him in his endeavor. The larger manufacturers are interested in nearly all industries. Their products spread the country over, and they would be slow indeed if they did not seek to include in their personnel those skilled in the various industries in which their product enters as well as those who are experienced in the making of that product.

In these days when the mining manager has to cover so many lines of engineering and cannot do it with any degree of satisfaction except by absorbing the predigested knowledged of other men, a trip to a convention like that to be held at Cincinnati is absolutely necessary to keep him in touch with new developments.

In his isolation in the hills of the East and West and in the boundless prairies that lie between, he is liable to fail to realize the progress in other centers and to believe that what problems he is discussing day by day with his associates and cronies and what solutions he is finding in his intercourse with his fellows are all the problems and all the solutions he needs to recognize. But where he meets the full strong current of life among groups of mining men, he learns that there are other problems and other means of solution than those he has at any time considered.

* * *

Most of us believe we have problems enough without traveling anywhere to find more. Unfortunately Nature has a way of working her will with us without our realizing what problems really confront us. There was a coal-dust problem before we knew that coal dust would explode. There is now a loading-machine problem confronting the man who has no machines, but who has a cost-of-coal problem into which he should look carefully. He can do it only by considering what machines and conveyors can accomplish for him. So easy it is, if we live hidden in the hills or isolated by farms,

Digitized by Google

or immured in cities where coal is sold, not mined, to believe that we are doing the best that opportunity affords, making petty decisions when larger ones can alone save the situation, meticulously counting the pennies while letting the double eagles slip by us. Here, in Cincinnati, is a chance to see the industry in a large way and to turn loss into profit.

A word regarding a few of those who will take part in the discussions will be of interest in showing their varied backgrounds and will explain why they have been chosen by the committee to discuss the subject assigned. Some of the outstanding men are omitted as their affiliations and record are well known.

C. W. NELSON, of South Brownsville, Pa., who will discuss cushioned blasting, graduated from Carnegie Institute of Technology in 1923 in mining engineering and was elected to a research fellowship in mining. He spent a year in research on efficiency in blasting coal. At the conclusion of these studies he received the degree of Master of Science in Mining Engineering at Carnegie Institute of Technology and then became explosives engineer for the Hillman Coal & Coke Co.

E. H. JOHNSON, who will discuss machine-loading failures and their reasons, was research fellow of the Carnegie Institute of Technology and joint author with F. E. Cash of the bulletin "Mechanical Loading in Coal Mines." He graduated from the Carnegie Institute of Technology in 1922 and received his master's degree in 1925. He is now engineer and sales manager of the Coloder Co., at Columbus, Ohio.

JOHN T. RYAN, who will speak on "sealing fires in gaseous mines," received the degree of bachelor of science in mining engineering from Pennsylvania State College in 1908. From 1908 to 1910 he did mining engineering work in Huntington, Pa. In the latter year he became superintendent of the Rocky Ridge Coal Mining Co., at Dudley, Pa., and superintendent and engineer of the Langdon Coal Co., at Hopewell, Pa. From 1911 to 1913 Mr. Ryan was successively rescue foreman, junior mining engineer and assistant mining engineer of the U. S. Bureau of Mines at Pittsburgh, Pa. In 1913 he accepted a position as mining engineer in charge of field work for the navy in Alaska. In 1914 he became assistant mining engineer of the Bureau of Mines at Urbana, Ill. In the same year he helped organize the Mine Safety Appliances Co., of Pittsburgh, Pa., of which firm he is now vice-president and general manager.

JAMES O. HANDY, of Pittsburgh, Pa., was the expert retained in 1925 in the water-pollution case of the Mountain Water Supply Co. (Pennsylvania R.R.). He will address the convention on mine-water purification. A graduate of the Massachusetts Institute of Technology, 1886, he aided in the design of the water-softening plant at Winnipeg, Man., Canada. He is director of the chemical and metallurgical investigations of the Pittsburgh Testing Laboratory.

H. L. STEVENSON, who will speak on "Stream Pollution" is a member of the American Society of Civil Engineers and chief engineer of the Pennsylvania Department of Health as well as being chief engineer and secretary of the Sanitary Water Board of Pennsylvania. He was formerly sanitary engineer and assistant director of the Department of Health, Emergency Fleet Corporation, U. S. Shipping Board. He was also at one time assistant engineer in charge, Sewage Disposal Division, City of Philadelphia.

B. L. LUBELSKY, who presents an article in this week's issue and discussion on blasting coal for mechanical loading at the convention, graduated in 1924 at the University of Illinois with the degree of bachelor of science in mining. In 1924 and '25 he was research fellow at Carnegie Institute of Technology and assisted in the preparation of Bulletin 19 on lump-coal production, being given the degree of master of science by Carnegie Institute of Technology. On Jan. 15 of this year he associated himself with the Pittsburgh Coal Co. as explosives engineer supervising safety, economy and efficiency in the use of explosives.

W. J. O'TOOLE, graduated as bachelor of arts at the Catholic University of America, in 1915. From 1915 to 1917 he was secretary and treasurer of three coal companies and from 1919 to 1922 sales manager of the Central Pocahontas Coal Co. From 1922 to 1924, he was American Minister to Paraguay. In the latter year he became general manager of the American Coal Cleaner Corporation.

ROBERT S. WALLACE, who speaks on mechanical loaders, is a native of Scotland, entered the mines as a trapper boy at the age of thirteen years. He came to the United States in 1903 and accepted a position as fireboss with the New River Smokeless Coal Co., where he was made mine foreman and later superintendent. After passing the West Virginia examination for mine inspector, he in 1909 accepted the position of chief mine inspector with the Pocahontas Fuel Co., Inc., with headquarters at Pocahontas. He is still at the same place but now as superintendent.

GLENN B. SOUTHWARD, consulting mining engineer, began his professional experience by inspecting coke in the summer of 1906 for the U. S. Coal and Coke Co., of Gary, W. Va. In 1907 he served as transitman for the Interstate Railroad Co., at Stonega, Va. In 1908 he graduated from the Ohio State University with the degree of engineer of mines. He was employed by the Stonega Coke and Coal Co., Stonega, Va., until 1911 when he went with the Log Mountain Coal Co., at Chenoa, Ky. as mining engineer. In 1912 he returned to the Stonega Coke and Coal Co., as assistant chief engineer with headquarters at Big Stone Gap, Va. From 1917 to 1925 he served as chief engineer with the West Virginia Coal and Coke Co., at Elkins, W. Va. Here he developed the V-system of mining. From 1925 until the present time he has been a consulting mining engineer of Elkins, W. Va.

CHARLES ENZIAN, who will discuss the advantages of rock dusting, has had a varied experience. A graduate of Lehigh University, he was for nine years a mining engineer with the Lehigh Valley Coal Co., with the U. S. Bureau of Mines for six years, and with the Philadelphia & Reading Coal & Iron Co., for five years. He was president and manager of the Liberty Coal Corporation of Kentucky for two years and for the past three and a half years he has been mining engineer for the Berwind-White Coal Mining Co., of Windber, Pa.

JOSIAH KEELY, who will speak on roof control, was born in a cabin near Charleston, W. Va. He was educated for the ministry, graduating from the University of West Virginia in 1896. After teaching for several years he took his master's degree in English at Harvard in 1904. He then engaged in educational work but resigned as principal of the Preparatory Branch of the West Virginia University in 1907 to accept a position in a mine office. After the only fight of his life (wherein he "licked" the local "badman"), he was

Digitized by Google

promoted to the superintendency of the mine, having meanwhile taken a mining course in the International Correspondence Schools. He devoted his attention to the underground, and in a few months was promoted to assistant general superintendent of a company operating 44 mines. In 1913 he took charge of the Cabin Creek Consolidated Coal Co., of which he is now the president.

AMOS A. CULP, a consulting engineer for railway and mine trackage of Birmingham, Ala., who was, from 1919 to 1924, chief engineer of the railroad department of the Woodward Iron Co. and made the standards for that firm's underground trackage will deliver an address on the importance of good track. He has been connected with the Louisville & Nashville, the Southern, and the Pennsylvania railroads as well as the city of Philadelphia.

NIXON W. ELMER, a consulting material-handling engineer of Quincy, Mass., will present discussion on inside mine conveyors. He received a degree from Cornell in 1904. With a long experience in design and construction of conveying systems as a background, Mr. Elmer started, as a pioneer in the profession of a consulting material-handling engineer. In this capacity he has served such organizations as the Berwind-White Coal Mining Co. and the United States Smelting & Refining Co. (The United States Fuel Co.).

C. H. NESBIT who will discuss the volume of the air that should be sealed in with a mine fire, was a mining engineer in Indiana for six years and in Alabama for fifteen. For another fifteen years he has been chief mine inspector for the State of Alabama with headquarters at Birmingham.

WILLIAM J. GERMAN, who will discuss "Mechanical Loaders in Pillar Work," has spent several years in a study of the best methods of shooting down coal for loading out by machine. During the late war Mr. German served as a captain of engineers in France.

Operating Officials Who Will Address Cincinnati Convention And the Subjects They Will Discuss

TUESDAY, May 25, 10 a.m. to 12 noon
CHAIRMAN—SAMUEL A. TAYLOR

SUBJECT: MINE DRAINAGE

1. **"Relation of Mine Drainage to Stream Pollution."**
   By Andrew Crichton, cons. engr., Johnstown, Pa.
   Discussion—Howard N. Eavenson, Pittsburgh, Pa.
2. **"Mine Water Purification."**
   By Jas. O. Handy, director, Pittsburgh Testing Laboratory, Pittsburgh, Pa.
3. **"Restriction of Stream Pollution."**
   By Wm. L. Stevenson, ch. engr., State Health Dept., Harrisburg, Pa.

TUESDAY AFTERNOON, 1:30 to 3:30
CHAIRMAN—WILLIAM L. AFFELDER

SUBJECT: CUTTING AND BLASTING COAL

1. **"Recent Experience in Shearing and Blasting."**
   By L. E. Young, genl. mgr., Union Collieries Co., St. Louis, Mo.
   Discussion—I. N. Bayless, supt., Union Colliery Co., Dowell, Ill.
2. **"Blasting Coal for Mechanical Loading."**
   By B. L. Lubelsky, explosives engr., Pittsburgh Coal Co., Pittsburgh, Pa.
   Discussion—David Ingle, Oakland City, Ind.
3. **"Results from Cushion Blasting."**
   By C. W. Nelson, explosives engr., Hillman Coal and Coke Co., Pittsburgh, Pa.
   Discussion—John G. Bart, Union Collieries Co., Renton, Pa.
4. **"Cutting in Fire Clay Bottoms."**
   By W. J. Freeman, Fayette Realty & Development Co., Terre Haute, Ind.
   Discussion—John L. Clarkson, Clarkson Coal Mng. Co., Nashville, Ill.

WEDNESDAY, May 26, 10 a.m. to 12 noon
CHAIRMAN—EUGENE MCAULIFFE

SUBJECT: MECHANICAL LOADERS

1 **"Mechanical Loaders That Have Operated Successfully at the Face and Their Operating Costs."**
   By A. W. Dickinson, gen. supt., Union Pacific Coal Co., Rock Springs, Wyo.
   Discussion—Wm. J. O'Toole, Welch, W. Va.
2. **"Machine Loading Failures and Reasons Therefor."**
   By H. F. McCullough, engr., H. C. Frick Coke Co., Scottdale, Pa.
   Discussion—Edwin H. Johnson, Columbus, Ohio.
3. **"Best Methods of Adapting Present Mining Systems to Mechanical Loading."**
   By W. L. McCoy, mine inspector, Bertha Consumers Co., Rachel, W. Va.
   Discussion.
4. **"Getting Cars to and from Mechanical Loaders."**
   By Chas. Gottschalk, cons. engr., Evansville, Ind.
   Discussion—F. F. Jorgensen, cons. engr., Superior Coal Co., Gillespie, Ill.

WEDNESDAY AFTERNOON, 1:30 to 3:30
CHAIRMAN—JAMES ELWOOD JONES

SUBJECT: MECHANICAL LOADERS

1. **"Methods for Mining Thin, Flat Seams with Mechanical Equipment."**
   By J. F. K. Brown, chief engr., Hudson Coal Co., Scranton, Pa.
   Discussion—Fred G. Wilcox, West End Coal Co., Scranton, Pa.
2. **"Mechanical Loaders in Pillar Work."**
   By Robt. Wallace, supt., Pocahontas Fuel Co., Pocahontas, Va.
   Discussion—W. J. German, E. I. DuPont de Nemours & Co., Huntington, W. Va.
3. **"Mechanical Loading in Rooms and Entries."**
   By I. N. Bayless, supt., Union Colliery Co., Dowell, Ill.
   Discussion—Jas. Needham, gen. supt., St. Paul Coal Co., Chicago, Ill.
4. **"Mechanical Loading of Top and Bottom Rock in Entries."**
   By A. C. Hohnke, supt., Russell Coal Mng. Co., Clymer, Pa.
   Discussion—F. M. Fritchman, gen. mgr., B. R. & P. Coal Co., Indiana, Pa.

THURSDAY, May 27, 10 a.m. to 12 noon
CHAIRMAN—HOWARD N. EAVENSON

SUBJECT: UNDERGROUND CONVEYORS

1. **"Inside Mine Conveyors."**
   By Nixon W. Elmer, cons. engr., Quincy, Mass.
   Discussion—Glenn Southward, Coal Service Corp., 2 Rector St., New York City.
2. **"Room and Pillar Mining with Conveyors."**
   By R. A. Suppes, gen. supt., Knickerbocker Smokeless Coal Co., Johnstown, Pa.
   Discussion—S. W. Blakeslee, supt., Penn Coal & Coke Corp., Ehrenfeld, Pa.
3. **"Mining Plans for Different Types of Conveyors."**
   By Heber Denman, pres., Paris Purity Coal Co., Clarksville, Ark.
   Discussion—Clarence R. Claghorn, 715 Continental Bldg., Baltimore, Md.

THURSDAY AFTERNOON, 1:30 to 3:45
CHAIRMAN—J. J. RUTLEDGE

SUBJECT: ACCIDENT PREVENTION

1. **"Proven Advantages of Rock Dusting."**
   By Geo. B. Harrington, pres., C. W. & F. Coal Co., Chicago, Ill.
   Comments—J. E. Jones, safety engr., Old Ben Coal Corp., West Frankfort, Ill.; Chas. Enzian, chief engr., Berwind-White Coal Mng. Co., Windber, Pa.; T. E. Jenkins, v.-p., West Kentucky Coal Co., Sturgis, Ky.; George F. Osler, v.-p., Pittsburgh, Terminal Coal Co., Pittsburgh.
2. **"Sealing Fires in Gaseous Mines."**
   a. "Current Practice," by John T. Ryan, Pittsburgh, Pa.
   b. "Territory Required," by Chas. H. Nesbitt, Chief Inspector of Mines, Birmingham, Ala.
3. **"Fire Protection Underground."**
   By Wm. Z. Price, asst. supt., Buckeye Coal Co., Nemacolin, Pa.

FRIDAY, May 28, 10 a.m. to 12 noon
CHAIRMAN—L. E. YOUNG

SUBJECT: ROOF CONTROL AND MINING METHODS

1. **"Elements of Roof Control."**
   By H. F. McCullough, engr., H. C. Frick Coke Co., Scottdale, Pa.
   Discussion—R. Y. Williams, cons. engr., Bethlehem, Pa.
2. **"Roof Control on Long Faces."**
   By E. F. Woodson, gen. supt., Crowe Coal Co., Henrietta, Okla.
   Discussion—W. D. Brennan, gen. mgr., Phelps-Dodge Corp., Dawson, N. Mex.
3. **"Control of Roof in the Eagle Seam."**
   By Josiah Keely, pres., Cabin Creek Cons. Coal Co., Kayford, W. Va.
   Discussion—A. A. Gallagher, gen. mgr., Milburn By-Products Coal Co., Milburn, W. Va.
4. **"Recent Developments in Roof Control."**
   By Wm. C. Stratton, chief engr., U. S. Coal & Coke Co., Gary, W. Va.
   Discussion—Thos. H. Clagett, Bluefield, W. Va.

FRIDAY AFTERNOON, 1:30 to 3:30
CHAIRMAN—R. L. KINGSLAND

SUBJECT: UNDERGROUND TRANSPORTATION

1 **"Importance of Good Track for Safe, Efficient and Low Cost Haulage."**
   By A. A. Culp, cons. engr., Birmingham, Ala.
   Discussion—T. B. Dryer, asst. genl. supt., Sloss-Sheffield Steel & Iron Co., Birmingham, Ala.
2. **"Track Work, Details and Maintenance."**
   By Fred C. Hohn, cons. engr., 1429 Wyoming Ave., Scranton, Pa.
   Discussion—Thomas DeVenny, Portsmouth By-Product Coke Co., Edgarton, W. Va.
3. **"Selecting a Mine Car Design."**
   By Clarence E. Watts, mech. engr., Berwind-White Coal Mining Co., Windber, Pa.
   Discussion—W. D. Hockensmith, Penn, Pa.
4. **"Dispatching for Long Haulage."**
   By J. B. Hicks, Elec. Engr., Consolidation Coal Co., Fairmont, W. Va.
   Discussion—Thos. G. Fear, genl. mgr., Inland Collieries Co., Indianola, Pa.

Mine in Scotts Run District Removes Pittsburgh Coal By Aid of Conveyors

Long-Face Operation—Seven Men Daily Take One Cut Which Yields 100 to 120 Tons—No Difficulty Yet Experienced in Controlling the Roof and Holding Typical Drawslate

By Alphonse F. Brosky
Assistant Editor, *Coal Age*,
Pittsburgh, Pa.

LONG FACES AND CONVEYORS have been in the foreground of discussion and experiment in recent months as means for reducing the expenditure of labor in the mining of coal, but doubt has been expressed as to the possibility of extracting the Pittsburgh seam in such a manner and with such assistance. The drawslate is so thick and so heavy and in places the sandstone above is so little disposed to break that experts are puzzled. Between the rock that breaks too easily and that which resists breakage too resolutely, the operator is perplexed. The former rock makes trouble by breaking as soon as the coal is removed even over a small span; the latter rock refuses to break even when the spans are large, and brings terrific pressures on the face, cribs and posts. Can these difficulties be met successfully?

The Connellsville By-Product Coal Co., which operates its No. 1 mine on Scotts Run, about three miles north of Morgantown, W. Va., hopes it has solved the problem but hesitates to declare that it has been successful till it has had more experience. It has extracted the coal over a large area with a substantial decrease in the labor force and it has obtained a large proportion of minable coal in the seam—practically all of it—but there is still the problem of its control of the roof. Is it solved? The company officials admit that they are not sure.

This, however, is certain: Every day seven men take one cut from a long face and thereby produce 100 to 120 tons, one-third of which is shot down onto the face conveyor.

As shown by Fig. 1, the 85-ft. faces are laid out in 300-ft. blocks, which are separated by pairs of 10-ft. rooms on 25-ft. centers. Faces are developed on the inby end of these blocks by a crosscut which is driven from one pair of rooms to the next. The face pillars and intervening room pillars thus developed may be said to be mined advancing; but in respect to the butt entries from which they are developed they may be said to be recovered retreating. The small pillars between pairs of rooms are recovered by pick work and the coal is loaded into mine cars by hand. A cutting machine is used wherever conditions favor.

The Pittsburgh seam, which is that worked in this mine, has in this section an average thickness of about 8 ft., of which only 6 ft. is taken. A bed of impure coal 6 in. thick is left in the bottom and that coal which lies above the 6-ft. breast of clean coal is left in the roof. The roof coal, high in ash and sulphur, is separated from the clean breast coal by a parting of bony shale. Above the seam are the customary drawslate and a cover 300 to 400 ft. thick. This roof coal, assisted by props and cribs, keeps in place the drawslate, which otherwise would require handling and gobbing, thus making it possible to mine the coal with economy on a long face, provided, as said before, the overlying cover can be controlled.

TWO MEN BY NIGHT AND FIVE BY DAY

A night crew of two men and a day crew of five men jointly complete the mining of one cut a day, performing all operations between and including those of cutting and loading. The only additional labor required is that employed at intervals in moving the conveyors from one face block to another. A plan is contemplated which, if adopted, would reduce by more than one-half the labor involved in moving the conveyors. In the proposed layout two rows of blocks would be developed end to end between double-heading butt entries. These rows would be separated by a single-heading butt entry which would serve as a haulage road while the first of the pair of end-to-end blocks would be mined.

When the two night men arrive at the place at the beginning of their shift they find the face cleaned up. Between the face and a row of cribs is a 7-ft. span of unsupported roof. The face conveyor, which is 28 in. wide, lies 1 to 1½ ft. in the clear of the line of cribs and about 3 ft. clear of the face.

The chief duties of the night crew are those of cutting and drilling. Whatever time remains after the face is cut is spent by these men in preparing the cut by loading out bugdust and moving the conveyor to a position abreast of the face. Whenever the face shows

The longface illustrated in the headpiece is snubbed so as to accommodate a conveyor which is placed under the cut. A single row of cribs is erected 7 ft. from the prepared face and 13 ft. from the back of the cut. Four men and a conveyor runner comprise the day shift. The night shift is composed of two men. These seven men produce as much as 120 tons a day from one 85-ft. cut.

Digitized by Google

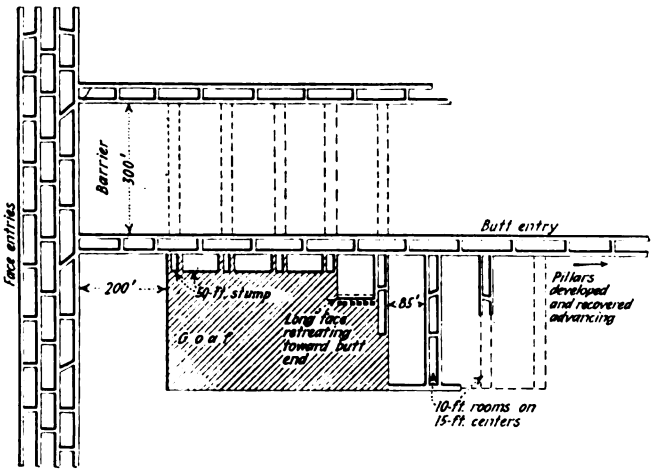

Fig. 1—Long-Face Layout Connellsville By-Product Coal Co.'s Mine

The faces are developed 85 ft. long on blocks which are 300 ft. long. These blocks are separated by pairs of 10-ft. rooms on 25-ft. centers. Panels thus constituted are mined advancing.

signs of taking more than ordinary weight, the shot-holes are drilled before the face is undercut. Generally the drilling is left until the end of the night shift or, if sufficient time is not available, until the beginning of the day shift. More will be said about the drilling later.

The face is undercut to a depth of 6 ft. by a longwall machine. A shortwall cutter of course, would require more clearance between the conveyor and the face than conditions would allow. The cut is started at the goaf end of the face so as to finish at the open end, outby of which point it is stored between cutting cycles. As shown in Fig. 3, a small rib, about 12 in. wide, is left on the goaf end of the face to hold back the loose material in the goaf, which otherwise would roll out beyond this end of the face. The cutting cycle of the 84-ft. kerf on the 85-ft. face requires 4 to 6 hours, of which only about 1 hour is consumed in actual cutting. As the coal is hard, bits must be changed frequently and the machine must as many times be pulled out and sumped in, which accounts for much of the lost time. Some time also is lost in moving the machine to the goaf end of the cut so that cutting may commence. The time required for this operation no doubt will be much reduced after the crew becomes more accustomed to longwall cutting.

BUGDUST LOADED BEFORE SHOOTING

Having completed the cut the men then load the bugdust onto the conveyor, which is kept running during this operation. The cut yields about 9 tons of dust, which is loaded in about 24 minutes. Next the conveyor is moved forward to a position about 1 ft. from the face. This operation requires about 1½ hours

Of the men who comprise the day shift, four work at the face and one works on the entry attending the conveyors and spotting the mine cars. The first job of the face men is that of snubbing the coal and loading what is loosened thereby onto the conveyor. This task is completed in 1 to 1½ hours. The appearance of the coal after snubbing is illustrated in the headpiece, and the face after the coal has been snubbed is shown in Fig. 2.

The snub cut is started from a point on the face 2 to 3 ft. above the floor and is slanted downward to the back of the kerf. It must be of such proportions as to accommodate the face conveyor, which is moved under it to a position shown in Fig. 6. The snubbing of this face is a simple operation, the roof pressure tending to loosen the coal along slips in the lower region of the cut. In fact the bar of the cutting machine sometimes is caught by the settlement of the roof. Snubbing, therefore, consists of little more than shoveling out that coal which lies below the most pronounced slips in the seam and which is released after the bugdust is loaded out.

Should the night men have difficulty in making their cut and therefore not find time to move the conveyor ahead to an advance position near the face, the day men leave the conveyor in the position shown in Fig. 2 while loading out the snub coal and afterward move it in one step from this position to that under the cut as shown in Fig. 6. In Fig. 4 are shown two daymen in the act of moving the conveyor forward and two other daymen drilling the coal.

The conveyor used on the face is the Jeffrey 44-B conveyor loader, and that laid to the entry is a 47-A portable conveyor, also of Jeffrey manufacture. The former is provided with hinged flights which turn up on end in the return run of the conveyor chain. This run is covered by hoods which in section are shaped like an inverted V. The conveyor bar is flexible so that any section may be made to assume a vertical or horizontal inclination with respect to an adjoining section.

UNEVEN FLOOR IS NO OBSTACLE

This flexibility in a vertical plane allows the conveyor to adapt itself to an uneven floor and permits the free use of lifting jacks in raising a portion of the conveyor at a time over any offset in the floor which may have been made by the cutting machine. The flexibility of the conveyor in the horizontal plane, of course, enables one or two men to move segments of the conveyor forward progressively without disconnecting any part. Some of these details also are shown in Fig. 4. The drive head of the conveyor is moved forward by means of the feed chain of the cutting machine, which for this purpose is held rigid by a jack as indicated in Fig. 7.

By means of a rope which is drawn by a ratchet

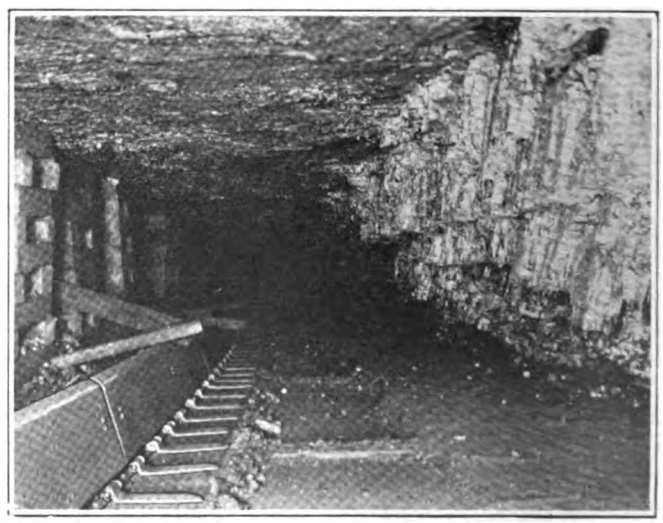

Fig. 2—Long Face After Face Has Been Snubbed

Before this snubbed face is shot, the conveyor is advanced to a position under the cut, after which the line of cribs is re-erected as close to the face as possible. Note the offsets in the floor due to the operation of the cutter.

Digitized by Google

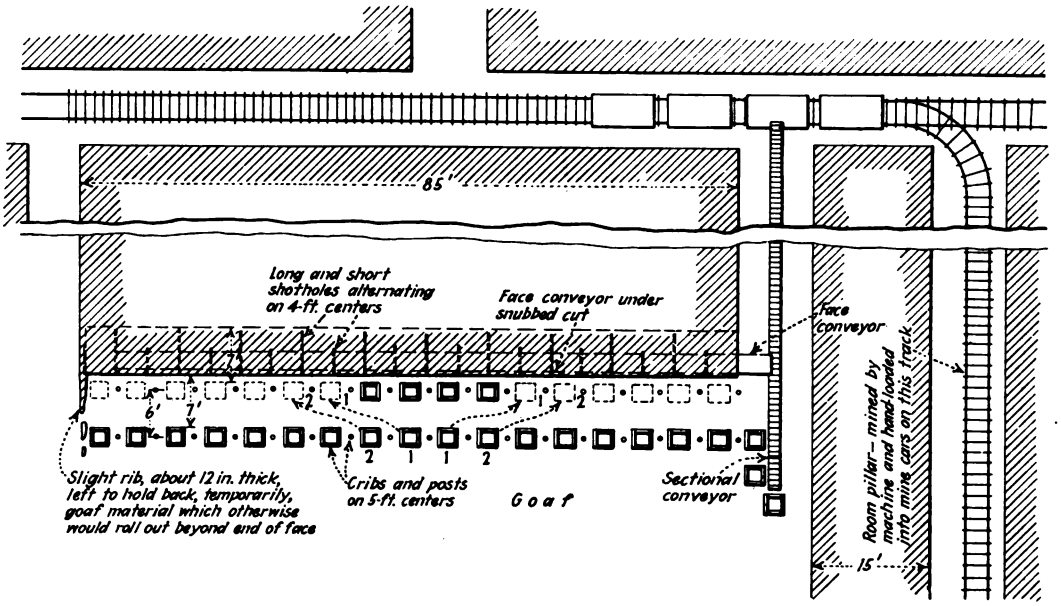

FIG. 3

Face Layout

The moving of cribs starts at the middle of the cut, where four cribs are erected near the face, after which those behind them are removed. This operation is extended to either side of these four cribs until the face limits are reached, only one crib at a time being erected, however.

device the segments of the conveyor are pulled progressively forward on skids. In Fig. 6 can be seen the end of a skid plate inserted under the conveyor and a block which when tightened by a ratchet winds up a wire rope attached to the front end of the skid. As the rope is wound the block and conveyor are drawn toward the front end of the skid, which is held in position by placing a small wedge of wood or a lump of coal under its rear end. Before the conveyor is moved it is lifted by a jack, so that the skids can be extended in front of it.

CONVEYOR IS LAID UNDER THE CUT

The conveyor is placed under the snub cut before the coal is shot chiefly because this arrangement allows the cribs to be moved to an advance position close to the face before the coal is shot. During the earlier work attempts were made to shoot the coal while the conveyor was still clear of the cut. When this was the practice the conveyor was gradually fed into the coal pile. This scheme did not give entire satisfaction at this mine. The steps in the bottom made by the cutting machine made it difficult to move the conveyor and the latter also tended to climb over, instead of working under, the smaller lumps of coal. Though these were all good reasons for moving the conveyor close to the face before shooting so that the coal could be shot down onto it they were none of them so important as the need to obtain space for the erection of cribs, thus shortening the time during which the span of insufficiently supported roof is allowed to stand. With the conveyor moved forward the cribs could be advanced before the coal was shot.

The shoveling of coal onto this conveyor is no great task, for the conveyor flights, and the pan under them, lie practically on the bottom. The face men in shoveling lift the coal but little. The kerf is easily cut; it saves explosive and produces more lumpy coal than could be obtained by solid shooting. At the same time it provides a means by which about one-third of the coal is shot onto and moved by the conveyor. What coal remains after shooting, again about one-third, is cleaned up in about 1 hour, including the time required for picking whatever coal, if any, has not been dislodged by the shots. Altogether, these men spend much less than half their time in actual shoveling and in that time is included the entire operation of snubbing, which, as has been stated, chiefly consists of removing with shovels any coal that the pressure of the roof has brought down.

As indicated in Fig. 3, the roof is supported by 30-in. square cribs set on 5-ft. centers in a single row and so located that they stand before the face is cut about 7 ft. clear of the solid coal. This distance is increased to about 13 ft. after the face is cut to a depth of 6 ft. The span of unsupported roof is maintained at 13 ft. only during the time required to prepare a cut for shooting. After the face is undercut, drilled and snubbed and the conveyor moved to an advance position under the cut, the cribs are moved to within 1 ft. of the face. Between adjacent cribs 6-in. round safety props are placed. These help to hold up the roof coal

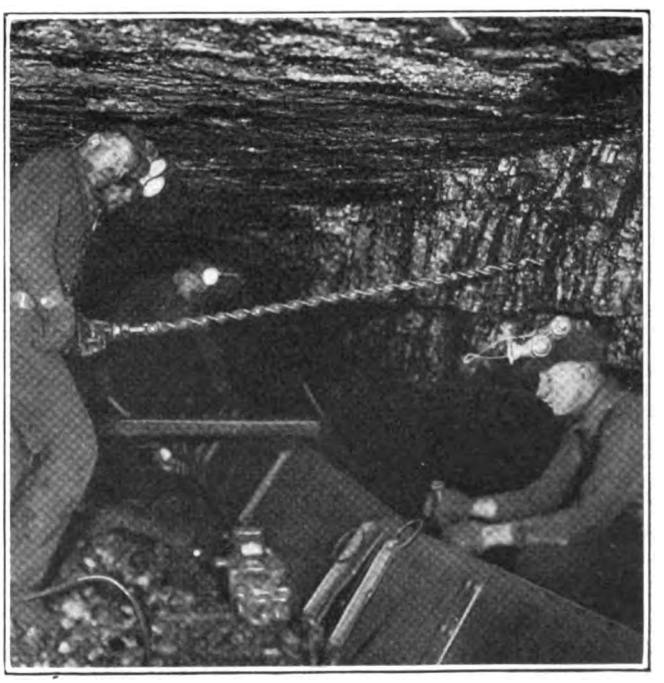

Fig. 4—Moving Conveyor and Drilling Face

Though the night shift of two men usually drill the shotholes, occasionally they are unable to do so, in which case two of the face men drill while the two other face men of the day shift move the conveyor as shown. The coal is drilled by electricity.

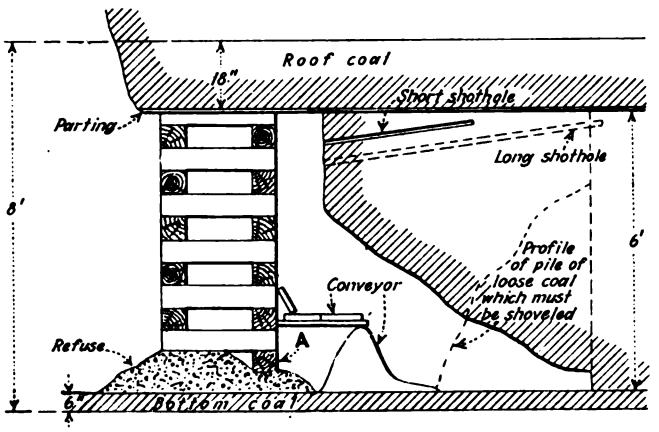

Fig. 5—Cross-Sectional View of Face

The locations of the conveyor, of the line of cribs prior to the shooting and of the shotholes are noted on the drawing. Boards resting on crosspieces between the hood of the conveyor and the cribs prevent coal from falling behind the conveyor when shooting.

and to hold back gob rock which otherwise would creep out between, and in front of, the cribs. They also facilitate the removal of the cribbing.

The crib line is advanced in stages—that is, before each crib is torn down another is erected between it and the face. Before the old line of cribs is dismantled a row of safety props on 5-ft. centers is set at a distance of about 27 in. from the face and between these are built the advance cribs. The re-building of cribs is started from the midpoint of the face and progresses toward the two ends. This job is accomplished by four men who work in pairs, one building and one tearing down cribs. As indicated in Fig. 3, four cribs are erected close to and in the middle of the face before the rear row is touched. Thereafter, crib after crib is torn down and re-erected in the sequence indicated in Fig. 3. By following this schedule the work is accomplished more speedily than it could be otherwise. The cribs are pulled down and re-erected in about 1½ hour.

They are built of 6x6x30-in. oak blocks on a bed of waste material and in the manner illustrated in Fig. 5. One man will build such a crib in about 9 minutes. By loosening with a shovel the refuse bed under the crib the trigger block *A* can be pulled out, after which the crib falls forward. The majority of the crib blocks are recovered, but when the safety props on either side do not support the roof sufficiently a few are lost. Occasionally the men find it expedient to set an extra post or two where the roof shows weakness, so as to enable them the more readily to recover the cribs. The safety props, of course, are not recovered. They crack and fall soon after the cribs on either side of them are removed, as shown in Fig. 9.

This company has found by actual experience that one row of cribs along the face is better than two. When two rows were used, more material and labor were involved and and the roof manifested a greater tendency to bend over the face and to bring an undue pressure on the coal. A single row of cribs, together with the top coal which is left, adequately holds the roof measures, and little or no gobbing of waste material is required. With each advance of one cut the laminated slates and coals in the roof are sheared over the rear ends of the cribs.

As already mentioned, the time chosen for putting in the drillholes depends entirely upon the condition of the face. When the face coal is more or less crushed the night men drill the coal before they cut it. When the face coal shows no signs of crushing, the night men cut the coal first. If, after the cut is cleaned out time yet remains, they also move the conveyor to within about 1 ft. of the face and lastly put in the drillholes. Otherwise they leave one or both these two duties to the day shift. It must be understood that the all-important job of the men on the night shift is that of cutting. Only occasionally do they meet with such difficulties as to preclude them from moving the conveyor or drilling the face.

In any event, whether the drilling is performed at

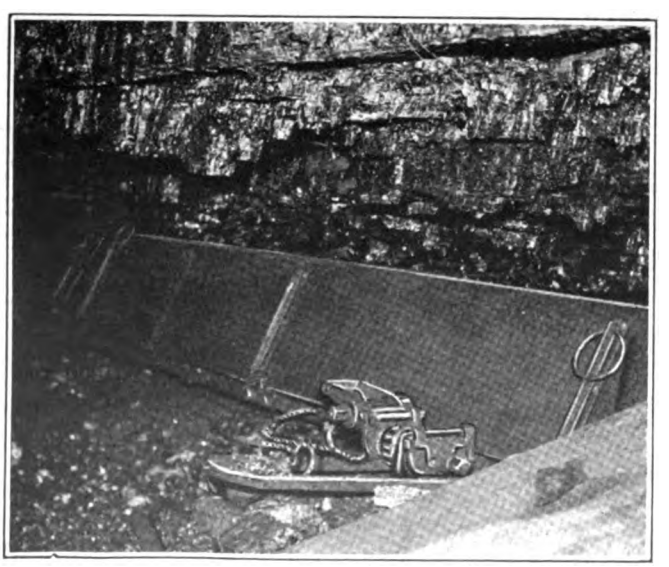

Fig. 6—Conveyor Under Cut Receives Falling Coal

The conveyor has hinged flights which turn up on end under the hood in the return run of the conveyor chain. The conveyor bar is flexible and is moved over skids through the agency of a wire rope wound on a ratchet device.

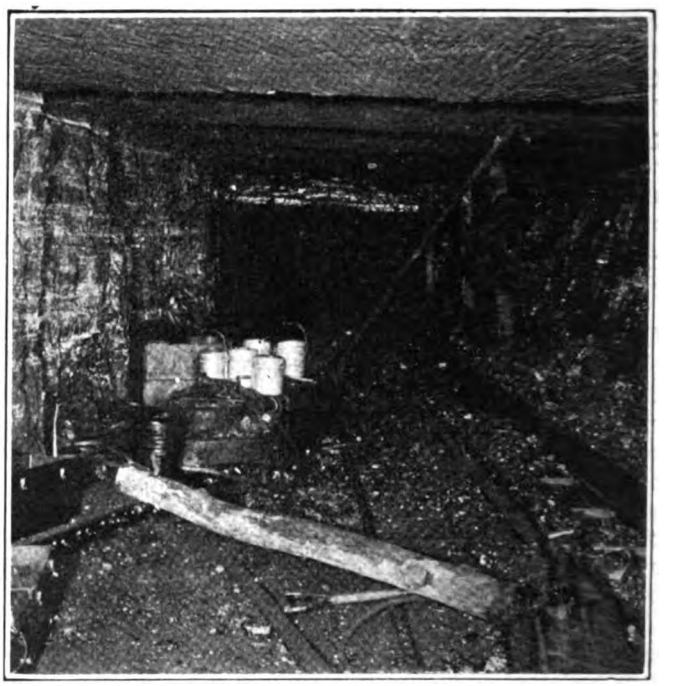

Fig. 7—Sectional Conveyor Into Which Coal Is Discharged by Face Conveyor

This sectional conveyor carries coal from the face to a trip of mine cars on the entry. When not in use the longwall cutter is stored clear of the face in the position shown on the left of the illustration. A pipe jack has been erected to hold the machine in place while its feed chain is being utilized to pull the drive section of the face conveyor toward the face.

Digitized by Google

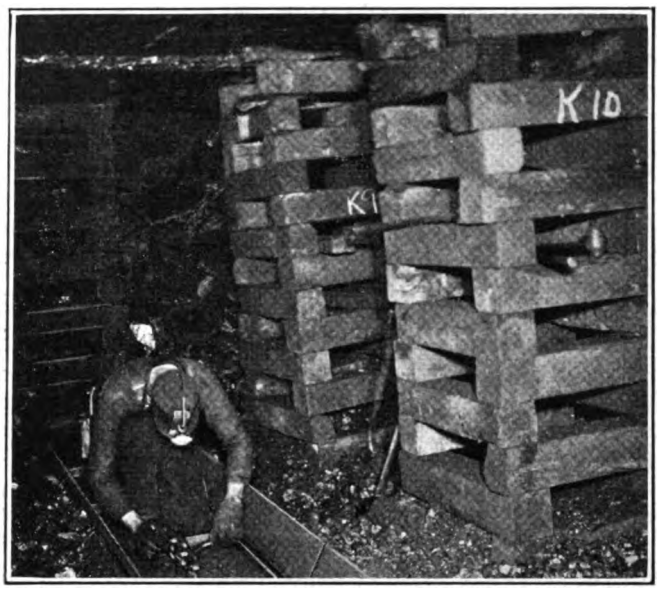

Fig. 8—Shortening Sectional Conveyor

This man is engaged in shortening the sectional conveyor which carries coal from the face to mine cars on the entry. This is done as often as two cuts are completed. The end of this conveyor meanwhile extends as much as 12 ft. into the goaf and is protected by cribs as shown.

the beginning or at the end of the night shift or at the beginning of the day shift, the holes are spaced at intervals of 4 ft., alternately 2½ and 6 ft. long, being put in electrically by two drills of the aforesaid lengths. The short holes are started about 8 in. and the long holes about 14 in. from the roof, both being slanted upward so as barely to reach the roof coal, which, as has been stated, is not removed. Although the long holes are each drilled in about 1 minute and the short holes in about 30 seconds, the drilling cycle sometimes requires about 2 hours, most of which time is consumed in sharpening the drills.

SHORT HOLES SHOT WITH ONE STICK

The short holes are charged with one stick of permissible powder and the long with two. This is done by the conveyor attendant while the face men are moving the conveyor. The shots are fired by a battery, one at a time, beginning from the open end of the face. Of the coal brought down by each shot, that which falls onto the conveyor is transported away from the face before the following shot is fired. As illustrated in Fig. 5, boards are placed under each shot, supported by crosspieces between the cribs and the top of the conveyor hood, so as to catch any coal which otherwise would fall over the conveyor. What coal lodges on this cover is easily shoveled onto the conveyor before the boards are advanced to a position under the next shot. The coal that remains is pulled forward by picks onto the conveyor. There is still a little coal that has to be shoveled. As this coal is easily loaded by hand and requires practically no lifting, no attempt is made to feed the conveyor forward under it. Were this done, the conveyor would have to be moved back again inasmuch as a clearance of at least 30 in. between the conveyor and the face is required for the longwall cutter.

The management of the mine feels satisfied that it has succeeded in producing a major fall extending for a considerable distance above the seam. Other falls of large proportions have occurred at intervals. Whether these falls have penetrated a bed of limestone 30 to 40 ft. thick which lies about 150 ft. above the Pittsburgh seam, being worked, and between it and the Sewickley seam above it, is not definitely known, but it seems likely that this stratum has been broken.

Though the company has not yet demonstrated the merits of this system to its entire satisfaction, because it questions whether the roof has been properly controlled, yet the degree of success thus far attained demonstrates that the system is based on principles which give promise. Already four 85-ft. faces on as many pillars of that width have been drawn for a distance of 250 ft. without loss of equipment of a minable coal. At times the faces have shown signs of heavy pressure, but never such as would compel the abandonment of a place. In most cases the face has been under more or less weight, but in this system this is considered a help rather than a deterrent to mining, as the coal thereby is recovered with greater facility and with less labor and explosive.

The success thus far attained is due to the efforts made to keep the length of the unsupported span of roof in front of the face at a minimum. The aid which the roof coal lends the cribs in holding the roof immediately over the seam no doubt is of considerable importance. The removal or breaking of practically

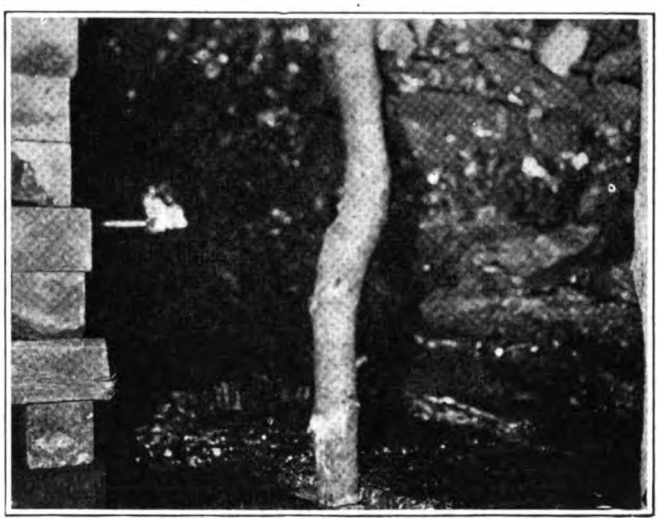

Fig. 9—Safety Prop After Removal of Cribs

These props, which are of about 6-in. diameter, are erected between adjacent cribs. They hold the roof long enough for the men to remove the cribs, but collapse soon afterward. The one in the center, being behind the crib line, is about ready to collapse.

all supports in the goaf, whether of coal or of timber, assists the operation by allowing roof breaks to occur frequently. There is reason to expect that a layout of this kind, in which a new break must be established in every panel, will work at least as well as the present typical room-and-pillar layout and at the same time bring about such economies as will reduce the cost of mining. By increasing the retreating distance of the long faces in a panel or by working simultaneously two or more adjoining panels, a longface layout similar to that described should hold greater possibilities than layouts of rooms and pillars, at least in the thinner seams.

I wish to acknowledge the assistance rendered me by Stephen Arkwright, general manager, and Wallace Dartnell, mining engineer, of the Connellsville By-Product Coal Co. in the preparation of this article.

Adapting Loading Machines To Mine Conditions

Cars of Three-Ton Capacity or Over Should Be Supplied—More Cars Are Needed Because Locomotives and Loaders Do Not Co-ordinate

By Edward Bottomley

General Superintendent, Sheridan-Wyoming Coal Co., Sheridan, Wyo.

OF THE MANY TYPES of loaders now on the market several are proving successful in mining districts suited to their operation. Some of these five or six years ago seemed to be miserable failures from every standpoint, mechanically and otherwise. If it had been my misfortune to have used, or tried to use, one of these at that time, I should do it a great injustice if I were to discuss its shortcomings in that experimental stage. It would be just as unfair as to condemn the present-day automobile because we had experienced trouble in the operation of the same make of machine ten or twelve years ago.

Some loading machines will do good work in almost any seam of coal that is reasonably level, if the bed is 6 ft. or more thick, with a good roof and hard floor, or if the seam is pitching not over 5 or 6 per cent. But almost all the loading machines that have been built are only able to give good results where conditions are favorable. Because of the great variations in mining conditions, many different types of mechanical loaders will be needed. A machine that will do its work well in a bed 8 to 12 ft. will be of no use in one 5 or 6 ft. thick. A machine that will work in a level bed, or one having a pitch not exceeding 5 or 6 per cent, will be useless if the bed pitches 15 to 18 deg.

Most of the machines thus far built are too heavy, too bulky, too expensive, and they require too much room. Unless there is an unusually hard floor, these heavy machines will bury themselves in the clay unless sufficient bottom coal is left to provide a solid floor. This cannot always be done.

WILL NOT RUN WITHOUT FORETHOUGHT

Many operators think that all that is necessary is to buy loading machines, to pay for them and send them into the mine. Nothing could be further from the fact. Much preparatory work is required. If the mine cars do not hold 3 tons of coal or more, without chunking, the cars must be enlarged, if possible, to hold this weight when loaded with the machine, for the cars are merely rounded up and will hold no more than could be thrown on with a shovel without chunking. If the cars cannot have their capacity increased, then it is best to buy entire new bodies.

In panel entries, where one or two machines are operated, a parting that will hold not less than twenty-five cars should be made. This, of course, depends on many local factors, such as the size of the pit cars, the length of the panels and the number of rooms that are worked on a panel, etc. It is not advisable and hardly possible to work more than two machines in one panel entry, regardless of its length. It is well to concentrate machine work to a certain extent, but there is a limit to this and one can go too far with concentration.

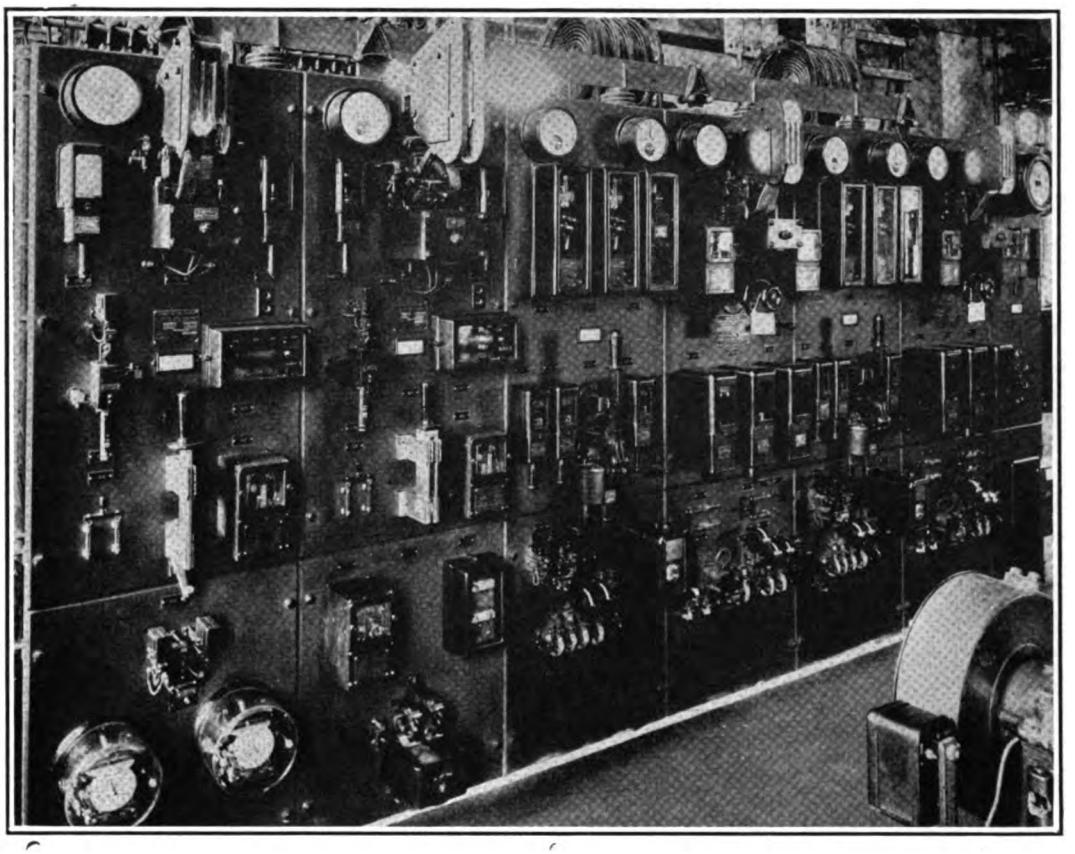
Brief abstract of paper read before the Rocky Mountain Coal Mining Institute, at Denver, Colo.

When machines are loading coal they load fast, and if there are too many in one district, the coal cannot be taken away from them.

After the type of loading machine best suited for a mine has been decided, it must not be forgotten for a moment, that, no matter how much expenditure is put into a loader, no machine is a substitute for intelligence any more than intelligence is a substitute for a machine. A higher degree of intelligence is required to make a success of a mechanically operated mine, than of one which is operated by hand. Skilled men are not only required to operate the machine itself, but each man of the crew must be skilled in his particular part of the work and be ever ready and on the alert to do his part at the right time.

Shooting the coal for mechanical loading calls for the best skill available. Coal, like that in northern Wyoming, is difficult to shoot, if a fair percentage of lump is to be obtained and if at the same time the coal is to be brought down in good condition for machine loading. We found it necessary to drill twice as many holes in a room as were needed for hand loading.

MORE HOLES AND SLOWER POWDER



After some experimenting, we also found we could get better results by using a slower grade of powder and by drilling eight holes in a room, not using any more powder than when four holes were used to shoot a room for hand loading. With such shooting methods the coal as shot down is of more uniform size. The lumps are not too large for machines to handle and the coal is not badly shattered in the immediate vicinity of the shots as when fewer holes and larger quantities of powder are used in each hole. To expedite this work, all hand drills have been replaced with the electric drills, each crew having one.

As the work in a mechanically operated mine is naturally more concentrated than in a mine with hand loading, the haulage system sometimes, especially in a large and well extended mine, has to be entirely revised. More standing cars on the partings are required than for hand work, because when the machine is loading, it loads fast, and more cars must be provided to keep it supplied until the place in which the machine is working is cleaned up. With a good supply of standing cars on the partings, a machine is insured of steady loading when the loading is good, and the haulage locomotive is also insured of having trips at scheduled intervals.

PARTING CORRECTS LACK OF CO-ORDINATION

To illustrate this more clearly, if two loading machines are working in one entry, which is usually the custom at the Sheridan-Wyoming mines, the haulage locomotive that serves this section, will haul a trip of, say, twenty-five cars. It visits this parting every hour. Thus it will haul 200 cars daily, which is a maximum day's loading for both machines. When the machines are working under good conditions, they will each load at the rate of 20 cars an hour, and sometimes more. It is easy to see that without extra cars on the parting, when a machine was loading to full capacity, it would be compelled frequently to wait for cars. On the other hand, when the machines stop loading to move from room to room or are delayed from other causes, which occur frequently, the haulage locomotive will not have its 25-car trip when it makes its regular call.

Pennsylvania Co. Puts Ten Substations And Five Fans Under Automatic Control, Making Striking Advances in Practice

Special Protective Features Added to Standard Equipment— Single-Phase Operation Slows Fan Instead of Stopping It— Large Savings and Protection Are Afforded by Automatic Control

By F. Fraser Williams
Power Department, Pennsylvania Coal & Coke Corporation, Cresson, Pa.

TO STREET-RAILWAY COMPANIES we owe the introduction of automatic substations. As soon, however, as this class of equipment had proved reliable, coal-mining companies became interested. Most of the mine installations have been made only when new substation units were needed to provide for the advance of the mine workings. There have been, however, a number of scattered instances in which existing hand-controlled units have been converted to full-automatic, but comparatively few cases of companies changing practically all their substations at one time.

The Pennsylvania Coal & Coke Corporation recently replaced the ordinary control with the full-automatic type in seven of their substations. These convert the 2,300-volt alternating-current purchased power into the 275-volt direct current used in the mines. This installation presents several new and interesting features.

Probably no one mining company has as much fully automatic controlled equipment as will be found at these mines. The switchboards are of two different makes, and each type has been supplemented by special equipment to provide more complete protection or to decrease the operating cost.

SUBSTATIONS IN MOSS CREEK DIVISION

In the three substations of the Moss Creek division the type of control installed is as shown in the headpiece of this article which illustrates the automatic control and metering equipment of a station which is set in operation by a push button and which contains two 150-kw. motor-generator sets. The panel at the

Headpiece shows the new control board in the Moss Creek substation. This handles two 150-kw. synchronous motor-generator sets and the metering and distribution to a neighboring substation. The two relays which balance the load between machines and which are standard with this make of equipment are to be seen in the lower section of the second panel from the left. Although the motor-generator sets in this substation had to be moved 50 ft., the change was made in 36 hours.

Digitized by Google

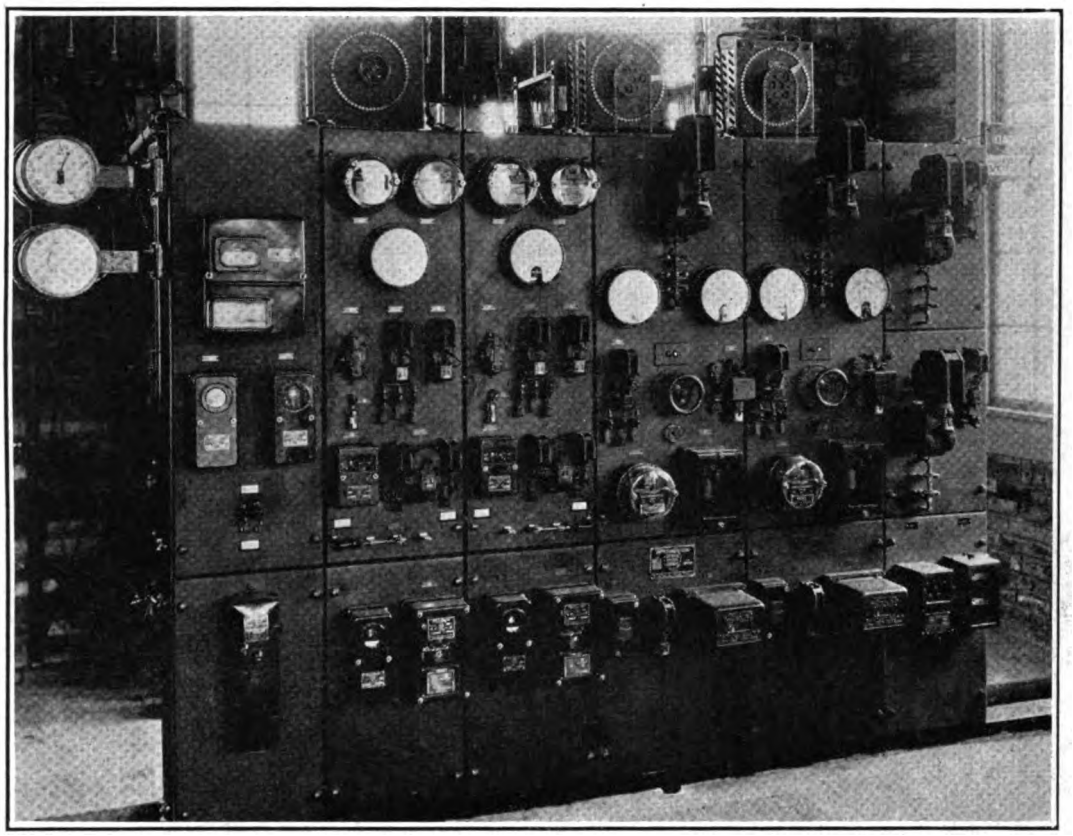

FIG. 1

Two-Unit Board, Arcadia Substation

One reason for the trim and neat appearance of this board is that the starting panels with their heavy contactors were placed in this instance to the rear of the main board (see Fig. 4). The local balance relays, which are not standard for this make of automatic two-unit control, are on the lowest section of the panel on the extreme right. A general view of this substation with its motor-generator sets is shown in Fig. 5.

extreme right controls, through a motor-driven oil switch, the 2,300-volt line feeding one of the other substations.

The substation so fed has its control set for continuous operation, so that it starts up whenever this oil switch is closed. The watthour and demand meters on this panel register the total power used by the installation. The two direct-current meters on the lower part of the panel at the left end of the board register the distribution of power by the two feeders which carry the current furnished by the two 150-kw. sets. Other meters handle the house service and other outside power distribution. Thus an accurate account is kept of the purposes to which the power is applied.

Though the standard protective devices are unusually complete in this control, it was still possible that the machines might overheat if operated single-phase. The thermal relays and the open-phase relay, it is true, tend to prevent this. The open-phase relay is of the voltage type, which, though it prevents any attempt to start in single-phase, will not operate if a phase should open while the machine is running, for the reason that generator action will produce a nearly constant three-phase voltage at the board.

LINE CURRENT 1¾ TIMES THAT IN COILS

Through current transformers the thermal relays are connected in the line and therefore these relays must be set to operate on the line current which is 1.732 times the current in the motor coils. Thus, if one phase should be opened while the load was of such value and constant enough that the line current of the motor did not exceed the value for which the overload relays were set but did exceed 58 per cent of this, the motor could dangerously overheat without any protective device coming into action.

The obvious remedy for this would have been to install a current phase-balance relay but, after due consideration, it was decided to use type C.T. temperature relays with this make of control. These relays which provide protection against overheating from any cause whatsoever, will be described as a part of the fan-motor control. They may be used, however, to protect any electrical apparatus on which a search coil can be placed.

The two feeder panels used in this installation are to be seen at the left of the headpiece of this article. They are of a standard type, designed so as to prevent the breaker closing on excessive overload. They are planned for either stub-end or multiple-feed service and are arranged so that an overload on the machine will drop out one feeder rather than open the machine breaker itself.

As this is an important substation, the work of changing over was speeded up so that it was accomplished in 36 hours. This also included moving the two motor-generator sets a distance of 50 ft. to their new positions.

In all of these installations everything possible is done before starting to make the change so that the power supply to the mine will be interrupted as little as possible. To begin with, the switchboards are, of course, set up and connected together in a suitable place. Bearing thermostats are installed on idle days or Sundays, and in one case the motor and generator field rheostats were moved to their new locations before the actual change was made. All this saves much time in changing over and in two unit stations, can be done, without any interruption, as one machine can usually be shut down in idle hours.

TAP TRANSFORMERS AHEAD OF SWITCHES

In all our installations the operating-control transformers are tapped ahead of the disconnecting switches of the machine. This permits making a thorough se-

Digitized by Google

quence test of the apparatus without the annoyance and danger which might be caused either by starting the machine with each test or by opening the machine leads to prevent starting.

The type of operating equipment used for motor-generator set control at the Arcadia and Ehrenfeld mines is that shown in Figs. 1 and 2, and in the four panels at the left in Fig. 3. At Arcadia the starting panels with their oil switches were installed at the rear of the main board. These are shown in Fig. 4. This arrangement allows the other panels to be aligned in a neater and more satisfactory manner, as indicated by Fig. 1. A general view of the substation is given in Fig. 5. At Ehrenfeld sufficient space was lacking to place the panels in this manner, so the starting panel was placed in line with the others. Disconnecting switches are provided for each machine. In addition to the standard instrument equipment, an alternating-current voltmeter and field ammeters are installed at each place.

Full Protection Against Single Phase

This make of control, for single unit substations, gives full protection against single-phase operation. It includes both a voltage relay, which prevents any attempt to start with single or reverse phase, and also a current phase-balance relay which shuts down the station if a phase opens during operation and which locks out if the open circuit should occur between the machine and the line or in the machine itself. The only special features are overspeed protection and an arrangement whereby the motor field is connected to a discharge resistance while starting. This portion of the equipment is not standard with the maker for this class of control.

In Fig. 3 a combined recording-demand and watt-hour meter is to be seen on the third panel from the left and below it are the time controls, one of which starts and stops the motor-generator and the other controls the fan speed. The clock is arranged so as to shut the set down on Saturday evening as is usual at the end of each day but to delay the starting of it until Monday morning. Also. the clock setting can be changed to leave the station idle on any other day if desired. In the two-unit substations the time control is connected in series with the emergency starting relay, thus allowing the second machine to be set for action at a given time.

This make of equipment, as stated before, is entirely satisfactory in our single-unit sets but did not provide in the most economical manner for paralleling two machines. The general operating scheme in two-unit stations is for one machine to run during the idle hours and the other to come on when the load demands it. However, after starting, the shunt field will take some time to rise to its operating temperature, and the two machines will not divide the load correctly until this temperaure is reached.

To obviate this difficulty, the manufacturer of this equipment allows current to flow through the shunt field of the idle machine when only one unit is running. It is, of course, obvious that this consumes energy and therefore some loss. To prevent this the same type of paralleling equipment was installed here as at Moss Creek. The two relays which do the work can be seen mounted at the top of the lower panel next to the glass-covered meters, shown in the headpiece, and on the lower sections of the right-hand panels shown in Figs. 1 and 2. These relays are so arranged that if one machine takes more than its share of the load a portion of the shunt-field rheostat of the other machine is short-circuited causing it to pick up load until an equal division is attained.

Fans Are Automatically Controlled

In addition to the motor-generator sets there are, at five of the substations, mine ventilating fans which had to be automatically controlled if these substations were

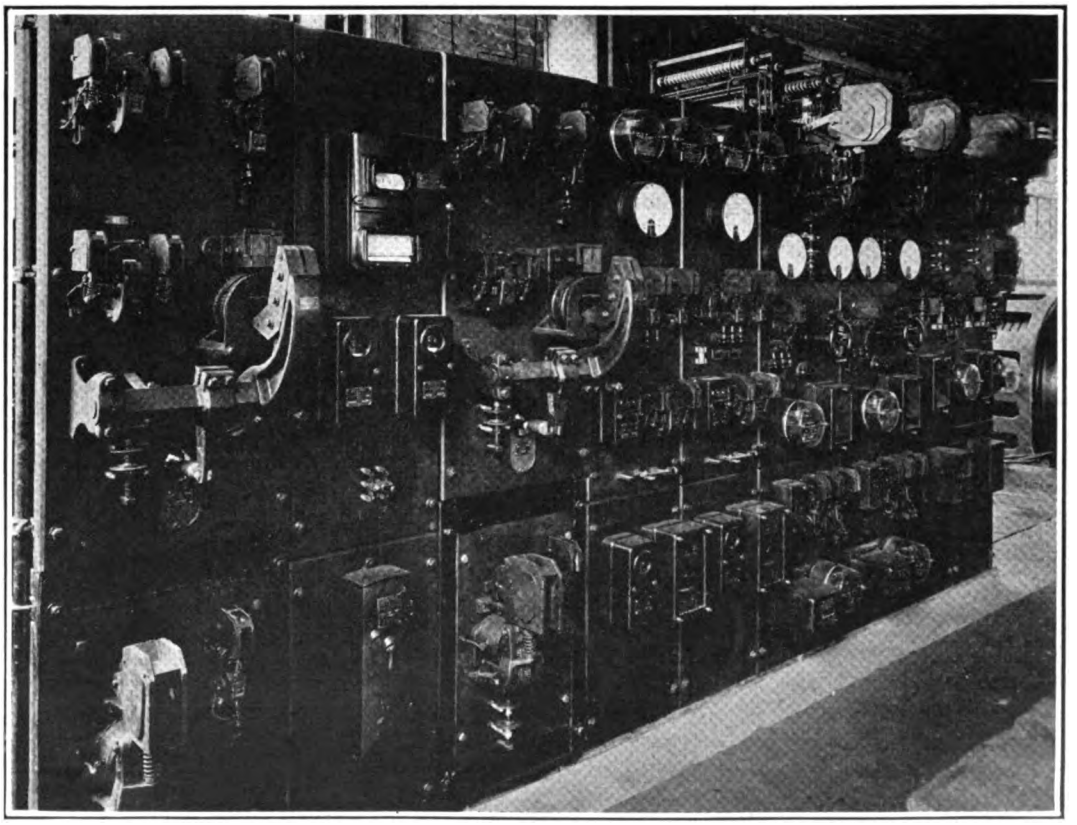

FIG. 2

Two-Unit Board, Ehrenfeld No. 4 Substation

Here, due to lack of floor space the starting panels had to be placed in line with the main board. The time control which regulates the starting and stopping of the substation units is mounted at the bottom on the second panel from the left. In addition to the standard instrument equipment, the boards are fitted with ammeters in the synchronous field circuits. As in the illustration of the Arcadia substation, the local balance relays are on the lowest section of the panel on the extreme right.

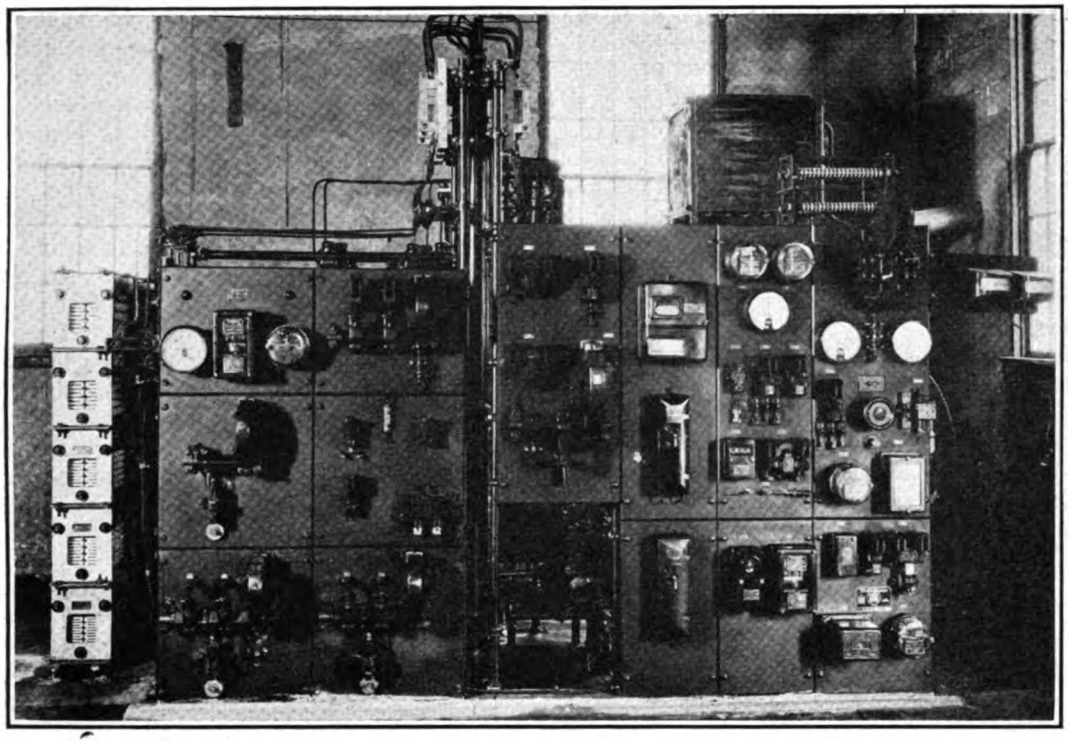

FIG. 3

Control for Fan and Motor-Generator, Ehrenfeld No. 1 Substation

The resistance and the two panels at the left belong to the fan, and the rest of the board to the substation unit. The fan motor is a 100-hp. unit and the motor-generator has a capacity of 300 kw. A contactor provides for the slowing of the fan to a point 42 per cent below the capacity of the motor regularly by a time control during idle periods and occasionally in emergencies by a relay in case the line "goes single-phase."

to operate without attendants. A typical automatic control board for these fans is shown at the left in Fig. 3. The resistance and the two 3-section panels belong to this equipment.

This controller differs in several ways from any that previously have been installed on mine fans in this country. It insures complete protection while providing the extreme in continuity of service. The motor starts by push-button or time control, resistance being cut out in the usual manner until the rotor is short-circuited and the motor attains full speed. During idle hours the time control causes resistance to be cut into the rotor circuit making the motor run at reduced speed. As the fan load varies approximately as the cube of the speed the power saving is large. The usual bearing, low-voltage, and overload protection is provided, and in addition the phase-balance relay, shown in the center of Fig. 6, is also connected in the motor circuit.

This latter, however, does not shut down the motor if a phase should open during operation. Instead it causes a resistance to be inserted in the rotor circuit sufficient to cause the speed to decrease to 70 per cent of normal. This drop in speed will reduce the load to a value less than the 58 per cent which a three-phase motor should safely carry when operating single-phase. The motor is allowed to continue at this speed unless it becomes overheated, in which case the type C. T. relay shown at the right in Fig. 6 stops the motor and locks it off the circuit.

Relay Based on Wheatstone Bridge

This type of relay, which is an interesting application of the principle of the Wheatstone bridge, was developed by the Westinghouse Electric & Manufacturing Co. as an indicating instrument but the electrical engineer of the Pennsylvania Coal & Coke Corporation, J. F. MacWilliams, was able to induce that company to develop it as a protective relay, the work being done with the assistance of W. J. Brennen of the Westinghouse company. Two search coils composed of wire having a high-temperature coefficient of resistance are wound around the motor stator and leads brought out as shown in Fig. 7. These coils are connected with two fixed resistances mounted in the relay case, in the same manner as the resistances of a Wheatstone bridge.

The actuating current is furnished by two current transformers connected in the motor lines, the secondaries of which are paralleled so that current will flow

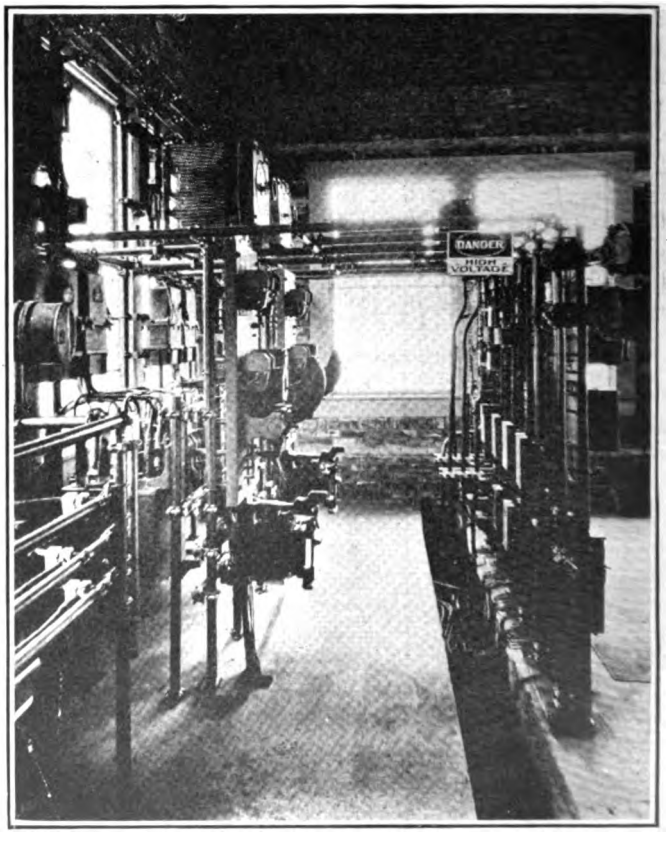

Fig. 4—Back of Main Board, Arcadia Substation

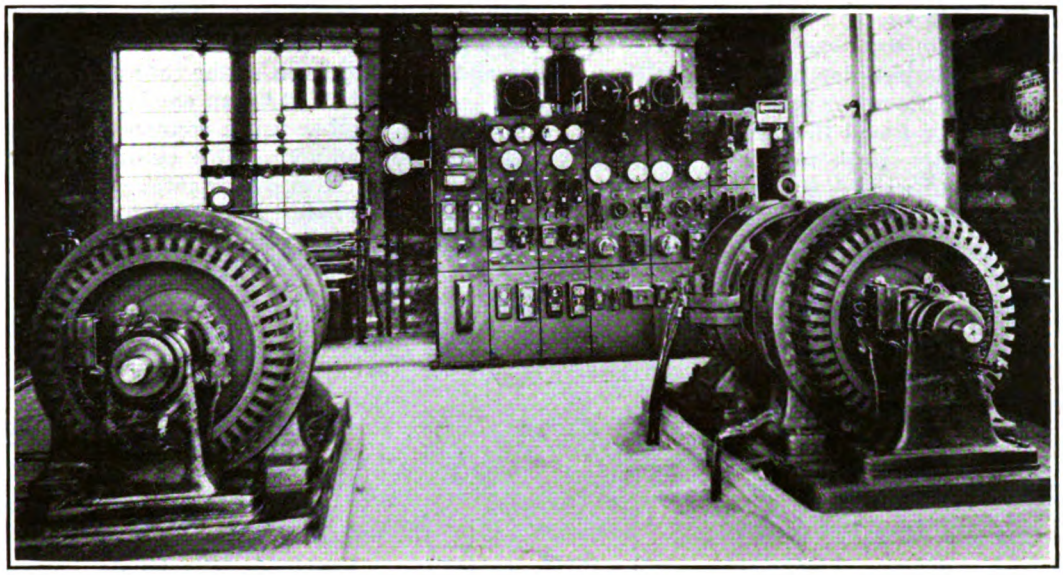

The starting panels are about midway between the board and walls. The auto-transformers are mounted on the wall almost above the oil switches. Wiring installation cost is greater in old buildings because ducts have to be cut in the floors and sometimes through foundations.

Digitized by Google

FIG. 5

Arcadia Substation

When making a change from manual to automatic control everything possible was done before the switch-over, in order to reduce the period of shutdown. Even the field rheostats were moved to their new locations beforehand. Ventilation of the motor-generator sets is by means of ducts from the outside to the centers of the machine foundations.

regardless of what motor phase is opened. The relay coil is connected across the resistances just as is the galvanometer of a Wheatstone bridge. As the resistance of the search coils increases rapidly with temperature, current will be forced through the relay coil should the motor become overheated. Increased load will cause more current to flow from the transformers and, proportionally, through the relay, its closing being dependent on both current and temperature, thus affording complete protection.

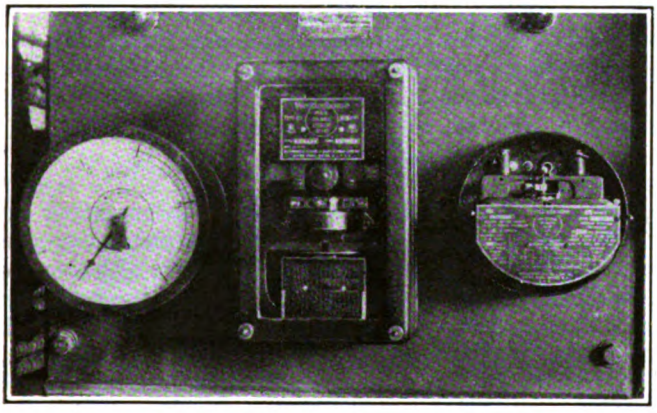

Fig. 6—Protective Relays, Fan Control Panels

The current-balance relay in the center will cause a contactor of the board to insert resistance in the motor circuit in case of an open circuit in one wire of the three-phase line. The type C.T. temperature overload relay, with the cover off to show the contact, is at the right. These fan installations represent a new application of the relay.

The problem of proper ventilation of automatic substations is one which, in many installations, seems to have received little attention. Where there is no attendant, windows or doors cannot be left open to cool the building. In these substations a ventilating duct is built through the floor from the machine foundation to the outside. This duct is slanted at an angle which prevents the entrance or accumulation of moisture. A ventilator in the roof allows the heated air to escape.

Equipment such as this affords a large saving, much of which cannot be shown in dollars and cents. The intangible advantages are: The absolute protection of the apparatus controlled, the greatest possible assurance of continuity of service, and a dependability which enables one at all times to predict with certainty the action of the equipment.

The money saved by automatic installations depends, of course, to some extent on local conditions, but is dependent chiefly on the number of operatives which the new equipment releases for other work. The cost of new equipment, for changing a single-unit substation to automatic control is about $4,000, and for a two-unit plant, $9,000. In order to find the investment represented by the change the erection cost must be added. This installation cost is about $750 for the single unit and twice this where two-unit equipment is installed, but this expenditure will, of course, vary greatly.

A lower cost would naturally be found in a new installation where no trenches or ducts have to be cut for the wires and where a suitable place could be easily prepared for the switchboard. As many of the older substation buildings are limited in size, it often requires much labor to set up a new board in a suitable place, old foundations and other obstructions frequently having to be removed or cut through for the wiring.

DRILLING FOR BEARING THERMOSTATS

The installation of the bearing thermostats causes a further variation in costs. In new machines the babbitt is usually made of a depth sufficient that the thermostats can be enabled to enter by a hole drilled in the babbitt and some even have the hole already provided, but in many of the older bearings it was found that the hole came partly in babbitt and partly in the iron outer section. This, of course, makes it almost

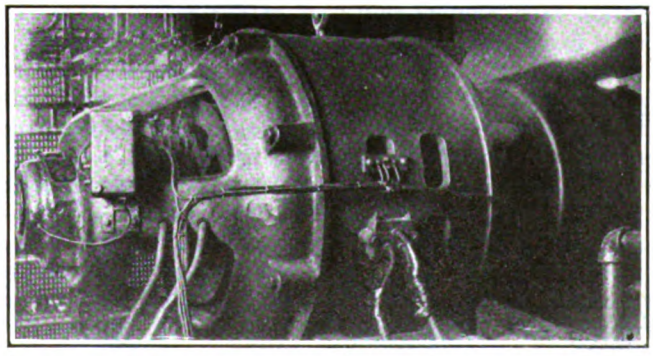

Fig. 7—100-Hp. Fan Motor, Ehrenfeld No. 1 Substation

Above the main terminal block is the 4-wire connection leading to the search coils which have been added to the motor in connection with the type C.T. relay. The search-coil group is wrapped around the outside of the stator coil ends, close to the end of the lamination. At the left end is a bearing-temperature relay.

Digitized by Google

impossible to drill the holes with the ordinary drill press, so in some cases it was necessary to cut a groove of the required depth and size with a shaper and then rebabbitt the upper section.

We have found that the cost of maintenance, including weekly inspection and cleaning is about $250 monthly, for which sum twelve substations can be maintained, as one man should inspect two each day. In normal operation the use of automatic control does not make necessary any replacements that would not have to be made before its introduction. Brushes, breaker contacts, and so on would have to be renewed at least as often with manual operation. There is, of course, a charge for power taken by the relay coils, but this is small and is more than offset by the added reliability.

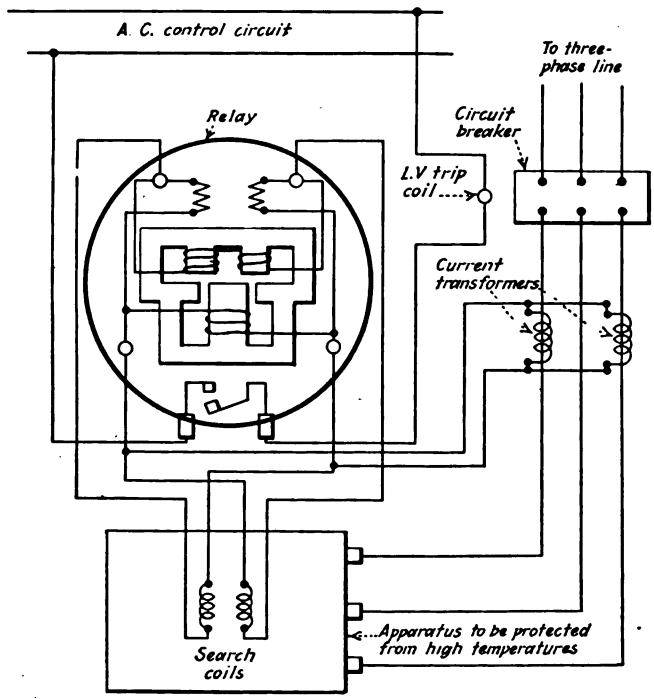

Fig. 8—Connections of Temperature Relay

The relay itself operates on the principle of the Wheatstone bridge. Its power supply comes from current transformers in the motor leads. By using two transformers in parallel the relay is not rendered inoperative if the line "goes single-phase."

To give an approximation of the total savings made by automatic operation, we will consider an installation of six single-unit stations and six of the double-unit type. These, as previously stated, can be cared for by one man. For fewer stations the savings would be in proportion, for the maintenance and weekly inspections would then require only part of one man's time. The total investment for the twelve stations considered would be about $91,500. The annual interest and depreciation on this sum at 12 per cent is $10,980 and the maintenance cost $3,000. Thus the total yearly charge against the automatic operation is $13,980.

The saving to be made is directly dependent on the number of operatives released. In this locality mine-substation operatives are paid approximately $150 per month. At this rate, if only one operative was released per substation by the automatic control, the net saving would be $7,620 per year or $635 per substation. At continuous operations where three shifts are required, the yearly saving becomes $50,720 or $4,220 per substation, because the cost of automatic operation is practically the same whether the plant runs continuously or only part of the time. There seems no question therefore but what a great saving may be made by converting manual substations to automatic.

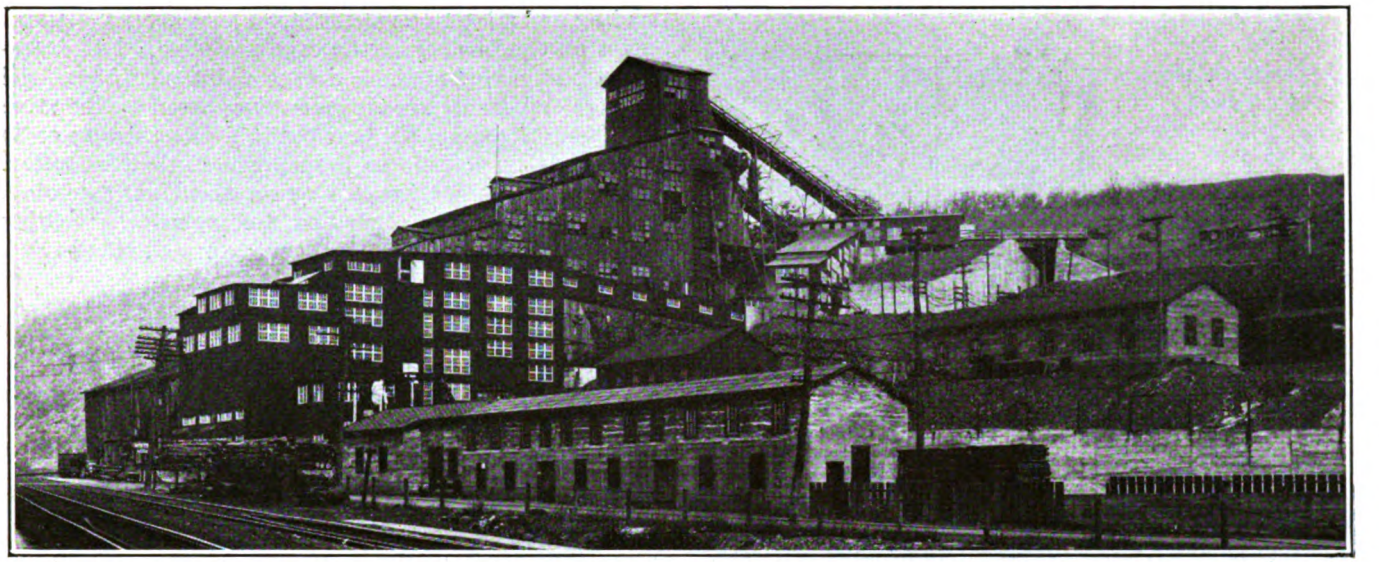
Even in the case of a manual substation which is attended by an employee who spends most of his time at other work, conversion to automatic control may show an appreciable saving. In such cases, however, the saving is rather intangible but may be found in increased production per man and per unit of equipment. Even though it may not be proposed to convert any given manual station to full-automatic, it may be profitable to introduce several of the protective features of such stations because they furnish many valuable advantages and can be applied at small cost.

Main and By Products Exchange Places In Business of Coke Production

First ammonia was the sweetener of the byproduct coke-oven industry; now it is gas. Will toluol come next? A drug on the market after the war, it shows today renewed activity not as the basis of an explosive to propel shells but as a means of making paint.

J. D. Forrest, vice-president of the By-Products Coal Corporation, of Chicago, addressing the local section of the American Institute of Mining and Metallurgical Engineers at Charleston, showed how changed conditions since 1913 had caused rapid shifts in byproduct oven practice, making what were formerly considered main products change places with what at one time had been regarded as a byproduct. The first byproduct ovens were built chiefly to obtain ammonia, but now the chief product is gas. At one time it was not uncommon for one-half of the gas to be wasted, and that which was sold brought only 10c. per thousand cubic feet. Now little gas is wasted, and the plant must get 20c. or more for it in order to continue in operation.

COAL IS DOMESTIC-COKE BAROMETER



Before the war $1 per ton paid the operating and maintenance costs of carbonizing coal, but under present conditions the costs are $2 or more. The sale of coke usually pays for the coal; therefore the byproduct operator is not greatly concerned as to its cost. He is, however, troubled by its price fluctuations. He would not object to the coal operators getting together to stabilize the price, even if he had to pay a little more.

Mr. Forrest explained that the rapid and certain demise of the scattered merchant furnaces of the country is due to the fact that they have no byproduct ovens. It would not pay them to build ovens because they have no city or steel mill to serve as an outlet for the gas. Usually a byproduct plant must be situated so that it can sell the coke within a radius of 150 miles.

Toluol, one of the byproducts of a coke plant, recently jumped in price from nothing to 10c. and up to 50c. per gallon, because of its extensive use in the new lacquers such as "duco" which many of the paint companies are now marketing. The use of these lacquers promises to extend materially in the next few years. Exterior paint of houses is likely to furnish a new field for toluol.

As to the quality of the coals adapted to byproduct coking, Mr. Forrest said that, broadly speaking, the higher the thermal value of the coal, the lower the percentage of ash, oxygen and moisture. For making cupola coke, the higher the fusing point the better, but for furnace coke the opposite statement is true.

Preparing Coal for Sale in a Finical Market

Alloys Lengthen Screen Life—Lime Saves Exposed Metal from Corrosion—Some Devices Economize Water—Others Improve Quality of Coal—Shaking Telegraph Prevents Degradation

By Frank H. Kneeland
Associate Editor, *Coal Age*
New York City

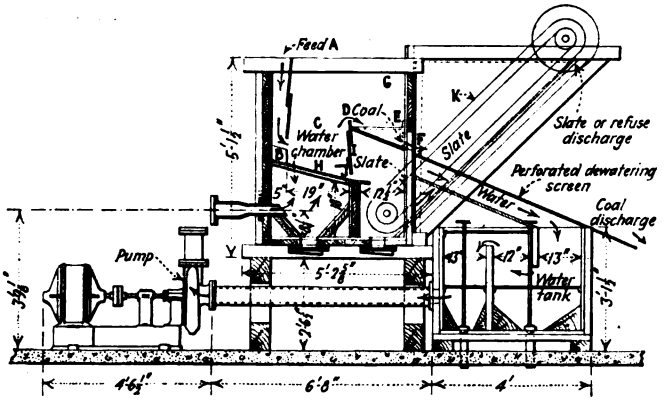
PERHAPS never before in its history has the coal industry as a whole been confronted with a sterner necessity for preparing the best quality of fuel that it is commercially possible to produce. The reasons for this are not far to seek, for the industry is face to face with the fiercest kind of competition both from within and without.

During the recent strike in the hard-coal region a large proportion of the country's population that heretofore had relied almost exclusively upon anthracite for domestic fuel learned the use of substitutes—coke, oil and smokeless coal. These people will not now blithely revert to hard coal unless both its quality and price are reasonable. In order to recover their natural but invaded markets, therefore, it behooves the anthracite producers to look more carefully than ever before to their preparation. For the public is in no mood to tolerate any unnecessary ash.

In the soft-coal fields the conditions are not greatly dissimilar. With mines overdeveloped in comparison to the country's needs, with three-fourths of the nation's bituminous production coming from non-union fields, with protective freight rates that no longer protect, and with inter-field and inter-operation competition of the keenest kind prevailing, the way of the bituminous producer is indeed hard. He who even hopes to survive must needs look well to the quality of his product, and be sure that when he offers coal for sale it is indeed coal and nothing else.

Many producers have already discerned and heeded the handwriting on the wall. Others have not yet seen fit to change their preparation equipment in any way, believing doubtless, and in many instances probably not without good reason, that their methods of preparation and final products are well above the average of their fields. As a rule, however, most mining companies are not satisfied with "things as they are" but are striving for the best attainable.

Radical changes in methods or equipment seldom come at once but usually are the product of a growth that is more or less slow. This is the case at present. Although some new machines and devices have recently made their appearance, most progress is being made through a wider adoption and utilization of machines and equipment already available. In not a few of these, however, recent improvements have done much to render them applicable to present needs and more effective than ever before.



Improvements in Screen Materials

One of the first processes through which coal is passed after being brought from the mine, in most cases, is that of sizing over shaker screens. Although in the anthracite region the type of shaker employed has undergone little alteration in many years, the material of which the screen plates or jackets are composed has changed and is still changing. When the shaker supplanted the revolving screen the first jackets were of ordinary blue annealed-iron or steel plate. Because of the highly corrosive action of the water used these were soon destroyed.

The next step was to substitute bronze jackets, which gave a much longer life as the result of their immunity from acid attack. Because of the comparative softness of this metal, however, it was susceptible to the abrasive action of the material handled. Monel metal was introduced to overcome this difficulty, being harder than bronze and at least equally resistant to acid action.

The headpiece accompanying this article shows the new plant of the St. Clair Coal Co., near Pottsville, Pa. The new breaker may be seen in the foreground with the old breaker behind it. Note the difference in the relative sizes of the two structures. The new installation gives a better preparation than could be attained with the older one and does it more cheaply.

Vertical Section of Hydro-Separator

The floor space occupied by this machine has been reduced by placing the tank under the elevator. Feed enters the machine at *A* and passes through the gate *B* into the chamber *C*, where the rising current of water from the screen *H* buoys the coal up over the dam *D* and into the space *E*, from which it escapes through the gate *F* to the dewatering screen and thence passes by chute to the pocket. Meanwhile the slate and rock collects on the unperforated portion of the screen *J*, passes through the adjustable gate *I* and settles into the conveyor *K* by which it is removed from the machine. The action is gentle and continuous and degradation is negligible.

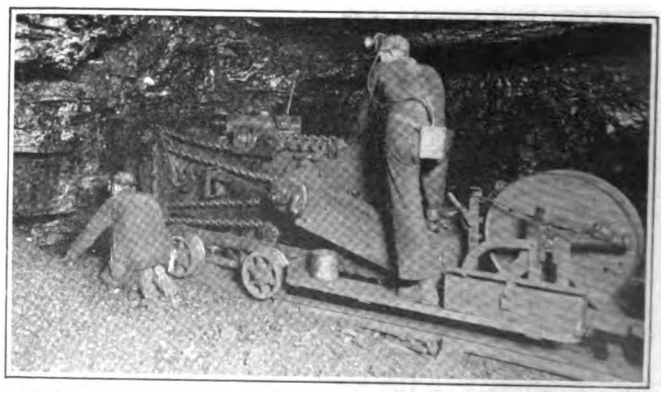
Many copper alloys later made their appearance and were successively employed for this purpose. Possibly the material most recently used for this purpose is what is generally known as "stainless steel" or, what is practically the same thing, "rustless iron." This in reality is merely an alloy of iron and chromium, or a high chromium steel. It is a comparatively hard metal and consequently resists abrasion well. Its acid-resisting qualities equal those of bronze and its tensile strength is slightly greater than that of steel. These desirable qualities render it possible to make jackets of this material from two to four gages thinner than bronze or iron plates intended for the same purpose. This not only decreases the cost but affords a better preparation.

High-chromium steel when used in screen jackets becomes polished under the action of the coal treated. When the recent strike was called and the breakers and washeries ceased operation it was a source of some solicitude on the part of coal operators as to how these jackets would stand the long shutdown. When work was resumed after months of idleness it was found that these jackets were covered with a thin gray powdery deposit that could be easily rubbed off, leaving the plate with almost as high a polish as when the shutdown started. After coal had been run for an hour or so these plates were in practically the same condition as when the shakers stopped operation at the beginning of the strike.

Has High Scrap Value When Discarded

Like bronze this material possesses a substantial scrap value when a jacket has become so worn that it is no longer fitted for screening coal. Taking its first cost, length of life and all other things such as labor, scrap value, etc., into consideration, it is estimated that on the average the standard jacket—37½ x 69½ in.—shows a saving of nearly $5 over bronze and nearly $3.50 over ordinary blue annealed steel. These are savings that are well worth considering.

We turn now to a consideration of preparation treatment proper. In its broadest sense preparation includes not only mining but all subsequent operations through which the coal is passed on its way to the railroad car or other vehicle of shipment. For the plan of operation, method of undercutting, snubbing, shearing, shooting, loading and mine transportation all have their inevitable effect on the quality of the coal marketed. Not infrequently improved methods that would result in material savings or benefits are strenuously opposed by the mine workers. Sometimes this opposition is so strong as to greatly delay, impede or even preclude their adoption.



In the bituminous region center shearing, snubbing, improved methods of charging the explosive, including air cushioning, and conveyor loading are all being tried. In some beds, such as the Illinois No. 6 measure, center shearing in conjunction with careful methods of shooting have yielded highly encouraging results or some that would amply justify the adoption of these practices.

Conveyor loading also is exerting its influence upon the quality of the mine product. Where a long face is continuously undercut throughout its entire length it naturally takes less explosive to bring it down than if the coal were produced from several short faces, with their inevitable tight ends. Long-face coal is thus broken up less than that produced from short faces. Shoveling or rolling the coal into low conveyors also breaks it less than shoveling it into a car which stands much higher above the bottom, although this is offset to some extent by the drop given the coal at the loading point.

Mine Large Lumps and Load Them

At least two combined mining-and-loading machines, where used, are said to produce bituminous coal of large size. These are the McKinlay and the O'Toole machines. The McKinlay machine cuts circular kerfs in the coal face into which wedging rollers are forced, breaking the coal out in chunks. By the O'Toole machine the entire face is undercut continuously and the coal brought down by the action of the roof assisted, if necessary, by light "pop shots." By this means even the friable Pocahontas coal comes down in slabs so large that they have to be broken with picks before the conveyor will move and load them. Both of these machines appear to be giving excellent results in coal production. The McKinlay machine seems to be particularly adapted to entry driving; the O'Toole machine to the robbing of wide, long pillars.

Although not exactly new in point of years, several Miller shaking screens have been installed and used in the West Virginia field during the past few months. The details and action of this device were described by A. F. Brosky in *Coal Age* of Feb. 23, 1922; Vol. 21,

Center Shearing in Illinois Reduces Breakage

This particular coal face is located in the No. 6 bed of Southern Illinois. By dropping the cutter bar onto the bottom of the cut just before it is finished a slab of coal may be broken out upon either side of the shear, thus producing an appreciable snubbing effect. Center shearing, at least in some places, gives a loose end that reduces the quantity of explosive that is necessary to bring down the coal.

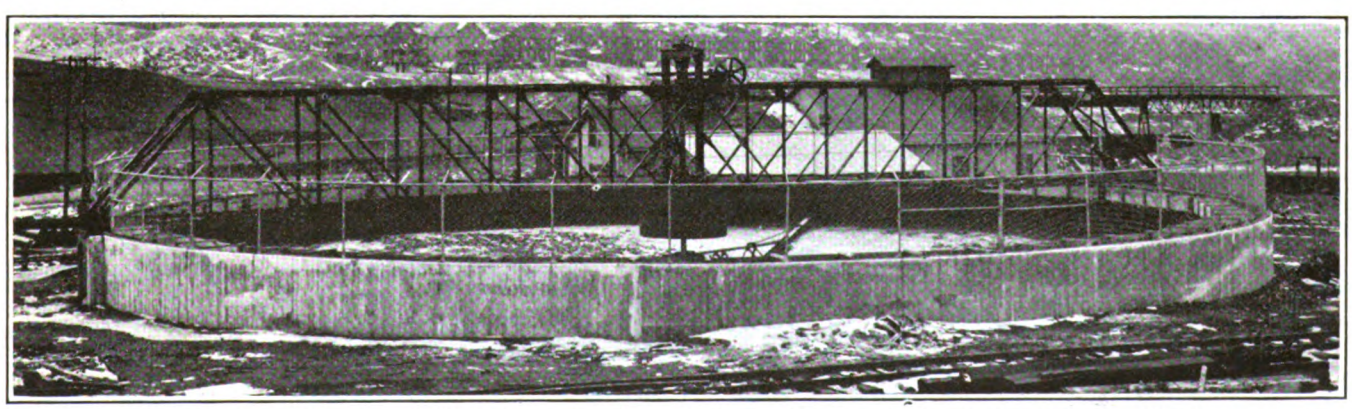
Concentrating Tables

Table room of modern breaker in anthracite field. Here buckwheat, rice and barley are separated from their impurities. The twelve tables can treat 300 to 350 tons of fine material per 8-hr. shift.

page 324. A screen of this type has been in use for several months in one of the tipples of the Lake Superior Coal Co., near Welch, W. Va. It is 6 ft. wide and about 45 ft. long. This screen is supported independently of the tipple and actuated from an inclosed driving head which is belt-driven from a 20-hp. motor located on the ground. The head, which is totally inclosed and lubricated by a splash system, is mounted on springboards or wooden columns which are rigidly attached at both top and bottom. The screen proper is supported by A-frames built up of structural shapes and hinged at either extremity. The entire screen is thus free to oscillate back and forth, being restrained only by the spring of the posts supporting the driving head.

Oscillatory motion is obtained by the whirling of unbalanced weights in the driving head. This oscillation is differential in character; that is, it is a slow forward movement and a quick return, its amplitude when operating at full speed being about 6 in. One peculiarity of this type of screen is the fact that the amplitude of vibration is greatest during starting and stopping; that is, when the driving head is revolving at less than normal speed.

This screen is used both for sizing the coal and as a picking table. One of its noticeable characteristics when in operation is the fact that there is no appreciable retrograde movement of the coal, the material upon it appearing to move forward with the screen and then to stand stationary as the screen is jerked backward beneath it. The power consumption of this screen is extremely small. Starting from rest with the screen fully loaded takes no more power than starting with the screen empty. Both of these statements may appear almost preposterous at first blush, but it should be remembered that the energy required to drive this machine is consumed in whirling weights in vertical planes. Only a small quantity is lost in friction, and the whirling weights shake the screen.

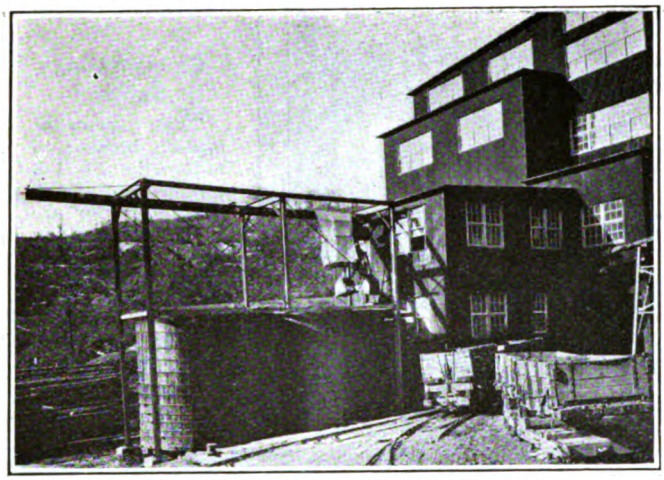


In preparation proper much advance has been made in the recent past. This has not been so much in the development of new methods and appliances as in a further adoption and utilization of those already in use. A Menzie hydro-separator of an improved design (see accompanying drawing) has been installed in the breaker of the East Boston Coal Co., at Kingston, Pa. Commercial tests show that it has a large capacity, much larger than its size would indicate. It is now used in cleaning pea coal coming to this breaker from several different sources and which consequently has a greatly varying specific gravity, which naturally renders it hard to clean. The feed to this washer is irregular, sometimes running as high as 40 tons per hour.

Little Impurity in Pea Coal

Inspection of the top of a carload of pea that has been treated in this machine reveals only here and there a piece of slate or rock. This machine's diminutive size, however, as well as the small quantity of power that it consumes and its low cost are strongly in its favor.

Few pieces of equipment introduced into this country for cleaning coal have attracted wider attention than the Rheolaveur coal washer. This device, which was described in *Coal Age* of Dec. 6, 1923, and Mar. 27, 1924, reached this country from Belgium. It has been successfully employed in Europe for some years.



One of the larger anthracite companies has been ex-

Big Thickener Clarifies 4,000 Gal. of Breaker Slush per Minute; Water Is Available for Re-Use

This 100-ft. thickener has a natural clay bottom. The makeup water is treated with hydrated lime before it is delivered to this tank, and the overflow is re-used in the breaker. Neutralizing the acid does much to preserve the spray and other water lines and to decrease general upkeep. The cost of the water treatment is many times returned by the longer life of the equipment.

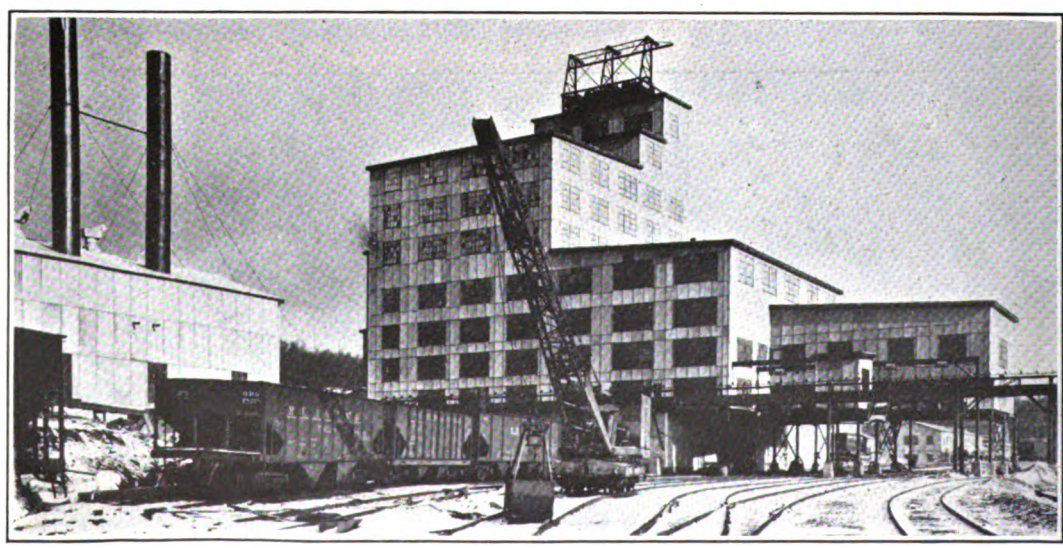
Part of Silt-Recovery Plant at St. Clair

In the modern breaker as in a packing house everything is utilized. In the present-day anthracite preparator even the fine material, down to 65-mesh or less is reclaimed. If this silt cannot be utilized immediately it is carefully stored for use at some future date

perimenting with the "Rheo" for some time, and the results obtained are said to have been highly satisfactory. This method of washing entails the installation of an entire process requiring the building or rehabilitation of a whole breaker or washery or a substantial portion thereof. One large anthracite company is now installing equipment of this kind to treat 3,000 tons per shift. This will form the first half of a 6,000-ton unit which will completely rejuvenate a breaker built only a comparatively few years ago and which has always been considered modern in all particulars. Another big anthracite producer is building a plant of similar eventual capacity and is doing it in the same way—namely, a half at a time. Seven other installations of this equipment, ranging in capacity from 1,000 to 1,600 tons of coal per shift, are either being made or are in immediate prospect. One of these is for the American Smelting & Refining Co., at Cokedale, Colo.

Treats Sizes From 3½ In. To 48-Mesh

This process treats all sizes of coal from 3½ in. down to 48-mesh on the same machine and in a single operation. This is an important advantage, particularly with bituminous coal. Between 4 and 5 tons of water is employed to treat one ton of mine product. That is, about 2½ gallons per minute is in circulation per ton of daily output. The makeup water needed will be from 5 to 10 per cent of the water in circulation. Thus the treatment of 1,000 tons per day will require a makeup of from 150 to 200 gallons per minute.



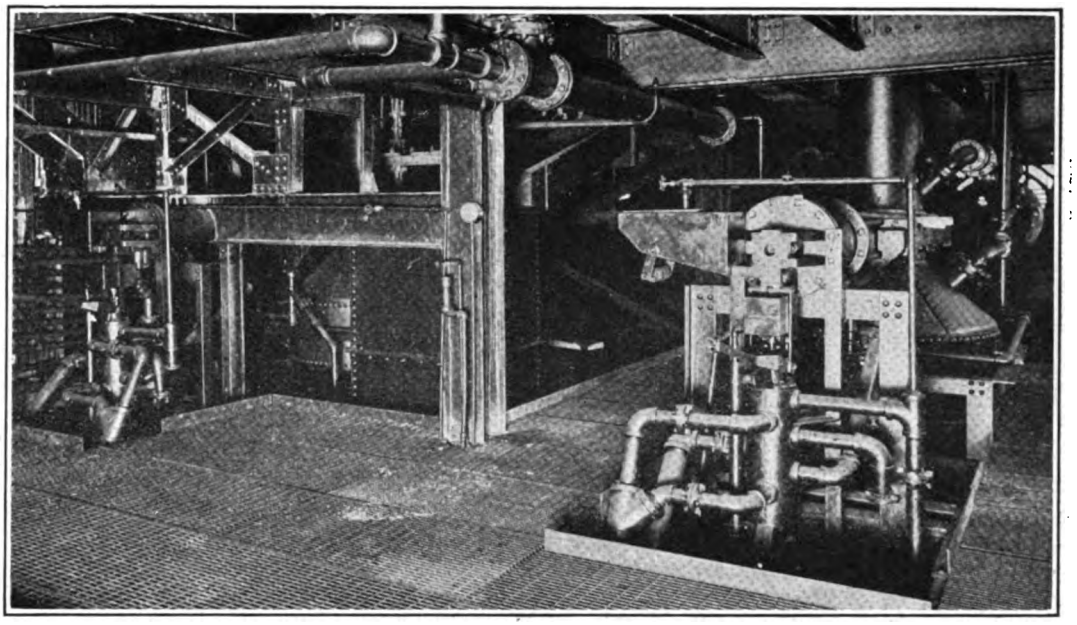
For treating the smaller sizes of coal, tables, classifiers and thickeners are receiving extensive application. Thus one new installation of this kind consists of a Dorr bowl classifier which recovers coal down to 65-mesh, two Deister-Overstrom tables that clean the No. 4 buckwheat down to an ash content of about 16 per cent, a Dorr classifier that dewaters the washed coal and a small Symplex classifier that dewaters the refuse, also a 64-ft. thickener to clarify all waste water from the breaker with the exception of that from the lip screens and track drainage. This machine handles about 2,100 gallons of water per minute and overflows 1,900 to 2,000 gallons per minute.

In this installation makeup water from the mine amounting to about 500 gallons per minute is delivered to a 30,000-gallon tank at the foot of the breaker into which the overflow from the thickener is also introduced. Slaked lime is added to the 500 gallons per minute of makeup water at the rate of about 200 lb. per hour. This is at the rate of slightly over 1/10 oz. of lime per gallon of makeup. The lime neutralizes the acidity of the water going to the breaker and renders it acid free. The expense involved is about $10 per day for lime, but whereas with untreated water the spray lines in the breaker lasted only about a week, with the treated water they last indefinitely. Purifying and using the mine water also obviated the installation of a pumping station on the bank of a creek 2,000 ft. away as well as an expensive pipe line connecting it with the breaker.

Eighteen Concentrating Tables

Another recent installation of equipment for treating the smaller sizes embodies eighteen concentrating tables treating the buckwheat Nos. 1, 2 and 3 with two classifiers dewatering the slate from these machines. A thickener in this plant 24 ft. in diameter recovers the No. 4 buckwheat down to 65-mesh. This product is raised to the top of the breaker and cleaned on seven tables. The washed coal is then dewatered in 6 model C-20 classifiers and the slate in two machines of similar type.

All waste water from this plant goes to a 100-ft. thickener being treated on its way with lime to neu-



Flotation Breaker

This breaker has been built around the Chance process of coal flotation. Naturally it differs radically both in construction and appearance from the older types of anthracite coal preparators. This building well exemplifies the simple straight lines and the stability of construction to which modern processes of preparation are particularly conducive. Steel concrete and glass are freely employed.

Refuse Removal

Equipment for removing slate and refuse from flotation cones in Chance breaker. Many think of a breaker or tipple as a dark, dingy sort of place where dust, dirt and grime are everywhere and eternally present. But note the absence of dirt in this picture.

tralize its acidity. This installation is designed to handle 4,000 gallons of water per minute. About 900 gallons per minute escapes with the sludge which will be used for slushing underground workings.

Particularly in the southern anthracite field where the coal measures are badly distorted, the proportion of fine sizes has always been large and their treatment in the past has been a problem. Modern means and methods, however, are here doing much to alleviate the former difficulties. The St. Clair Coal Co. operating in this field near Pottsville has recently constructed a new breaker utilizing the Chance flotation process of coal preparation. The new breaker is much smaller than the old one which it replaces, and the results obtained are suggestive of what may be expected in other installations.

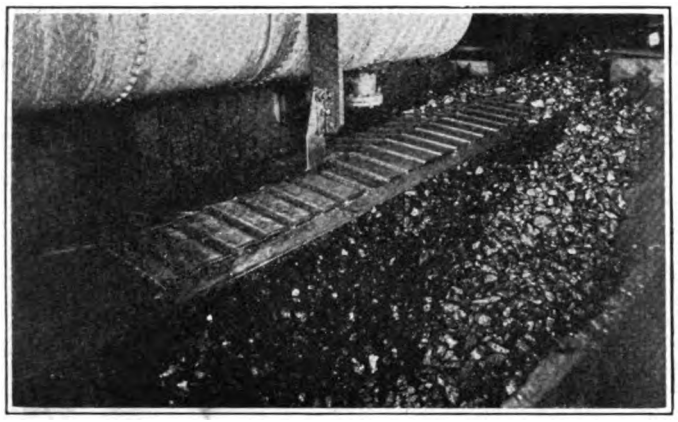
Naturally some mechanical difficulties have been experienced in this plant as the mechanism employed requires a manipulation wholly at variance with that accorded the former equipment. Ridding the final product of the sand used in the flotation mixture has always been considered one of the difficulties to be anticipated with this method of preparation. After the men became familiar with the process, however, no trouble has been experienced from this source. Thus barley now leaves this breaker with only from 14 to 15 per cent of inert content and the silt carries only 18 to 19 per cent of ash.

Somewhat of an innovation in anthracite preparation has been adopted at this plant in that the small sizes are briquetted. The briquets thus made are guaranteed to contain not more than 15 per cent of ash. The inherent ash of the coal mined at this plant will average about 9 per cent.

Three Flotation Cones

Three flotation cones are installed in this breaker. The first treats coal of buckwheat and smaller size; the second takes the product of the mine of pea and larger size and the third retreats the reject from the other two after it has been crushed down slightly. The reject material from the second cone is first screened into chestnut and smaller and into stove and larger, these two products passing to separate rolls. The stove and larger is crushed to chestnut and smaller and the other size is reduced to pea and smaller. These products are then combined and passed through the third cone.

In this third cone the liquid is maintained at as high a specific gravity as possible, that is, between 1.7 and 1.75. In the other cones the smaller sizes are treated with a liquid of 1.6 to 1.65 sp. gr. and the larger sizes with a liquid of 1.65 to 1.7 sp. gr. Refuse from the No. 3 cone ordinarily is sent to a waste bank, but if the quality of this material is deemed to be unsatisfactory it is again crushed and retreated.



At this operation mining is being conducted in three beds, namely, the Buck Mountain, Skidmore and Mammoth. Some coal comes from strippings in worked-out areas and as a result contains much rock. The effectiveness of the preparation process employed, however, may be judged from the rock-and-bone content of the final products. Frequent tests on the coal as loaded for shipment show the following results: Egg, slate 1 per cent, bone, 2½ per cent; stove, slate 1½ to 2 per cent, bone 3 to 3½ per cent; nut, slate 3 per cent, bone 3 to 3½ per cent; pea, slate 4½ to 5 per cent, bone less than 5 per cent. Buckwheat, rice and barely run less than 15 per cent in ash and the silt under 20 per cent. All sizes except the silt are briquetted and the briquets sold under guarantee as to ash content, as has been stated.

Low Percentage of Coal Goes to Bank

The proportion of coal going to the refuse bank at this plant will average 4 or 5 per cent. This figure, however, includes all sizes. The proportion of the larger or domestic grades is, of course, slight, most of the coal thus rejected being the small sizes. The silt at present is pumped to a dam from which it will eventually be reclaimed.

Fine coal is brought to the briquetting plant from storage and passed first through driers, after which it is crushed in hammer mills, mixed with the binder and passed through the presses. The briquets are then baked in an oven in a temperature that gradually increases from 300 to 600 deg. F. After leaving the oven they are passed through a cooler before being deposited in the shipping bin. The capacity of this briquetting plant is approximately 450 tons per 24-hour day. A force of twenty-six men is employed—ten on the day shift and eight on each of the other two.

Egg Coal Eased Into Pocket with Negligible Degradation with Parish Shaking Telegraph

These pictures show telegraph lowering coal into a pocket that is nearly empty and one that is almost full. When the coal has built up around the sides of the curved plate extending across the top of the pocket the material already deposited forms a trough through which the incoming coal flows until it slides off the sides of the plate. The coal may thus slide or it may roll, but it can never fall more than a few inches. In this way degradation is greatly lessened.

Preparation in a true sense does not end at the discharge of the jig or the cone or other washing appliance. In order to assure delivery of the best possible product to the consumer the cleaned and sized coal must be deposited within the pocket and transferred thence to the car with a minimum of degradation. A recent invention for easing prepared sizes into the pocket with a minimum of breakage is what is known as the Parrish shaking telegraph, taking its name from its inventor, A. L. Parrish, superintendent of construction for the Kingston Coal Co., Kingston, Pa.

This device has been installed at the No. 2 colliery of this company at Edwardsville, Pa., and is shown in two of the accompanying illustrations. It consists of a trough or telegraph, slightly inclined, suspended by spring boards or other means and oscillated longitudinally by means of an eccentric in a manner exactly similar to that employed for shaking a screen. The inclination given this trough or chute is slight or far below the critical angle of coal on steel, so that the material moves only by virtue of the oscillation of the trough.

At the edge of the pocket the sides of the trough disappear and the bottom, which extends on entirely or almost entirely across the bin is humped or gabled in the middle. As shown in the illustration, also, it is provided with corrugations or riffles to assist in moving the coal forward. It is somewhat questionable, however, if these are really needed.

Suppose that the bin or pocket is empty. Coal from the jigs or other preparation equipment passes down the conveying portion of this telegraph by a series of short glides or slides. When the edge of the pocket, and consequently the delivery portion of the telegraph, is reached the coal promptly slides off on either side, drops a few inches to the slanting floor of the pocket down which it rolls or slides until it comes to rest at the bottom. Gradually the coal piles up until the delivery section of the telegraph is reached. The coal now builds up along the edges of the telegraph forming a channel the sides of which are loose coal and the bottom of which is the shaking gabled plate.

Coal coming to the pocket will not leave the delivery section of the telegraph until the edge of the pile in the pocket is reached. In other words the coal sides of the channel already referred to are effective in restraining the side movement of the material traveling on the plate and the incoming coal does not, therefore, leave the plate until the edge of the pile is reached. By this means the coal can slide or it can roll either along the bottom of the chute, the bottom of the pocket or down the sides of the pile, but it cannot fall more than a few inches. It thus reaches the gate or chute delivering to the car with far less degradation than if it were spouted or telegraphed into the pocket in the ordinary manner.

And now for a short look into the future. The trend toward better preparation is the logical outcome of economic conditions—the consumer wants clean coal and if it is not forthcoming he is inclined to turn to other fuels. The movement to supply this need has just gotten fairly under way. Barring some unusual contingency, not discernible at the present time, it can hardly stop in its present status. The future, therefore, should witness more efficient and cheaper methods of mining, better and cheaper preparation and less degradation in the processes of handling and delivery to the common carrier. The consuming public, also, should receive a product capable of satisfying all reasonable exactions as to quality.

Should We Neutralize Mine Waters?

"That neutralization of acid mine waters will require an expenditure of large sums of money, but that it does not seem to be prohibitive in most cases to treat these wastes in order to overcome in a large measure present objection to their entrance into streams," is the conclusion of R. D. Leitch, assistant chemical engineer, U. S. Bureau of Mines, Pittsburgh, Pa. "Whether" he adds "this will be an economically sound policy will depend upon the collection of more definite data than is available at present.

Except to satisfy aesthetic demands, there is no reason for spending more money and effort annually to purify natural waters than the damage caused in losses and difficulties experienced by users of water so polluted. The question is, or should be, to decide how much pure waters are worth from all possible viewpoints and then to determine the cost of purification in the same manner. If the one is cheaper than the other, common sense will demand the more favorable." "G. S. Rice has suggested," he asserts, "that the use of limestone for rock dusting to prevent coal-dust explosions will also have a considerable effect on neutralizing acid waters within the mine, and this seems to be a logical conclusion."

Quantity of Explosive Employed One Factor Only Of a Number in Successful Blasting

Rib Gouging to Be Avoided—Kerf Should Be Clean—Shearing Affords Additional Free Face—Resistance to the Explosive Should Be Made Equal in All Directions

By C. W. Nelson
Explosives Engineer, Hillman Coal & Coke Co., Pittsburgh, Pa.

THOSE who would blast coal successfully must recognize from the start that the problem involves a multitude of factors, neglect of any one of which may spell failure even though the others be properly performed. Different beds, and even the same measure, in different localities, may not possess the same characteristics. These peculiarities of seam or locality must be studied by the explosives engineer or blasting expert as special problems. Only those considerations that are more or less common to all coal mines regardless of the characteristics of the particular bed will be considered in this article.

The first operation that has a direct bearing upon

Figs. 1 and 2—Incorrect and Correct Way of Sumping

Serrated ribs are a sign of incorrect sumping. Whatever may be the position of the machine when cutting is begun, the sumping cut should be made in a direction parallel to the line of sights. This will assure a straight rib and avoid a wedging action in blasting. Fig. 1 shows a badly cut face and Fig. 2 one that is properly cut.

blasting efficiency, of course, is the cutting of the coal, whether this be undercutting, topcutting, shearing, or a combination of the last with either of the first two. If the coal is undercut, the side of the kerf should be parallel to the line of sights of the entry or room. One of the most common faults found where the coal is undercut is the practice of gouging the ribs. This is caused by the machine runners failing to square the machine with the sight line before sumping in, thus allowing the cutter bar to gouge or cut into the pillar beyond the normal rib line. Fig. 1 shows a working place in which the ribs have been gouged. It also shows how the machine is improperly placed for the sumping operation. Fig. 2 shows correct practice in these respects.

This gouging of the ribs has two bad effects on subsequent mining. First, it tends to throw the place off the sights and causes it to be mined beyond its normal width. Second, it encourages the drill runners or miners, unless they are closely supervised, to drill shotholes parallel to the edge of the undercut. When the ribs within the limit of a cut are gouged to any extent and the shotholes are drilled parallel to the sides of the undercut, the inside end of the drillholes lie outside of the normal rib lines of the room as shown in Fig. 3.

POCKETING THE SHOT BY RIB OFFSETS

The dot-and-dash lines *AA* and *A'A'* represent the normal ribs of the advancing place and the dotted lines show the edge of the cut to be blasted. That portion of the hole from *X* to *Y* lies beyond or outside the normal rib line *AA*. Under the circumstances practically the entire explosive charge placed in this hole will be located between *X* and *Y*. When this is detonated the force of the explosion will exert its energy in three general directions—downward and in the directions indicated by the arrows *B* and *C*.

With the hole placed as shown in Fig. 3, that component of the force indicated by *C* will act against a solid block of coal and consequently will cause more or less shearing along the edge of the undercut from *E* to *D*. Moreover, because a wedging action is set up, the explosive charge will not loosen the coal nor allow it to move forward. Consequently the major force of the explosive will act toward the undercut and along the general direction shown by arrow *B*, causing the coal to be shattered at the back of the cut and "set down" on the undercut, without allowing it to be lifted toward the front.

Such a shot shatters the coal badly at the back of the cut and fractures it but little at the front. Under these conditions, the miner must do much digging to loosen the coal for loading. He thus produces an undue percentage of small sizes. The practice of gouging by machine, therefore, should not be tolerated for it is entirely unnecessary.

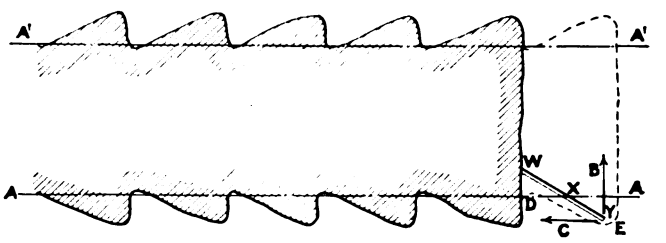

Fig. 3—Effect of Blasting on a Saw-Tooth Rib

Most or all of the explosive charge in the shothole shown lies within or behind the normal rib line. Detonation of such a charge not only results in much shattering of the coal but wedges the material to be brought down between the new face and the sloping rib. Such a shot signally fails to produce the best possible results.

Digitized by Google

Fig. 4—A Shot Productive of Large Lumpy Coal

This place may not appear to have been shot but it has. The illustration shows a tight shot in the Pittsburgh bed. Note how the coal has separated from the roof and also the shearing cracks along the right-hand rib. These are what the miners call powder cracks. A vertical channel will be dug along this rib toward the back of the cut which will permit slabs of the coal to separate at the face cleats and to fall forward with little or no inducement from the miner's pick.

The use of a shearing machine without some type of horizontal cutter, of course, is not regarded favorably. Shearing should supplement undercutting or top-cutting if a large quantity of lump coal is desired. The advisability of shearing in conjunction with horizontal cutting is purely a matter of dollars and cents, and resolves itself into the question: Will the increased percentage of lump coal realized from this process warrant the purchase of the necessary machine and the additional cost of cutting? This question can be answered only after the natural conditions prevailing in any locality and the differential between the market price of lump and of run-of-mine coals have been given due consideration. The additional free face which shearing provides undoubtedly renders blasting much less difficult.

TOPCUTTERS SAVE ROOF BUT NOT COAL

Topcutting machines have had varied success. The greatest advantage obtained from their use, in a mine or section of a mine where the top is tender, lies in the protection afforded the roof from the shock and vibrations from the explosion. This protection in most cases, however, will be obtained at the expense of the production of lump coal. In the Pittsburgh bed difficulty has been experienced, with the arcwall type of machine, in obtaining a top cut of uniform depth where the room or entry in which the cut is made is more than 12 ft. wide. In practically all cases the depth of the cut is greater in the center than at either rib. As a result of this variation in the depth of topcut, the holes cannot be placed in positions that will enable them to break down the coal without undue shattering. Great difficulty is experienced in successfully blasting after this type of machine, as the shots under a topcut will not "roll" the front of the cut as will those over an undercut.

If topcut places could also be sheared, one would then have two well-balanced shoulders which would increase the size of the coal considerably. Here again the added investment, cost of operation and prospective financial return would be the factors that would determine whether it is wise to introduce this method.

The relation existing between the cut and the blasting of the coal has been briefly outlined. Closely allied with the cutting operation and of vital importance in obtaining good blasting conditions with the use of a minimum quantity of explosive per cut, is the removal of the bugdust from the kerf before blasting. The only reason for machine-cutting coal is to provide an additional plane of weakness or free face against which the explosive charge can act. The height of the kerf made by a machine when free from cuttings is about 6 in. With a 6-ft. cut in a 12-ft. entry this void amounts to 36 cu.ft. When all the bugdust is removed from the cut, the coal when shot can expand into this space in addition to being rolled forward into the working place. If only half the cuttings are removed, the coal can expand only a proportionate amount in this direction and consequently must be pushed forward into the room.

WHY CUT COAL IF BUGDUST IS LEFT?

To move the coal through this additional distance more explosive is required, which necessarily results in greater shattering. Under these conditions if enough explosive to heave the coal forward into the room is not used, the coal will be wedged in place and it will be necessary for the miner to dig out the shot. This will produce a maximum of fines, to say nothing of lowering the output of the miner. Probably no single factor upon which efficient blasting depends is more important than the proper cleaning of cuts.

To assure the removal of all bugdust one or both of two things must be done. The helper, or scraper, on the machine crew must shovel away from the machine all the cuttings thrown back by the bits. This will allow the cutters to clear themselves, thus minimizing the quantity of cuttings carried back into the kerf. With proper attention 70 per cent of the cuttings can be removed in this manner. In mines where blasting is done during the loading shift each miner should provide himself with either a hoe-shaped scraper or a long-handled shovel, with which he can remove all the loose material from the cut before shooting. By observing these two precautions full advantage of the cut will be obtained.

To compel the machine men to keep the cuts clean the inside officials must make frequent inspections of

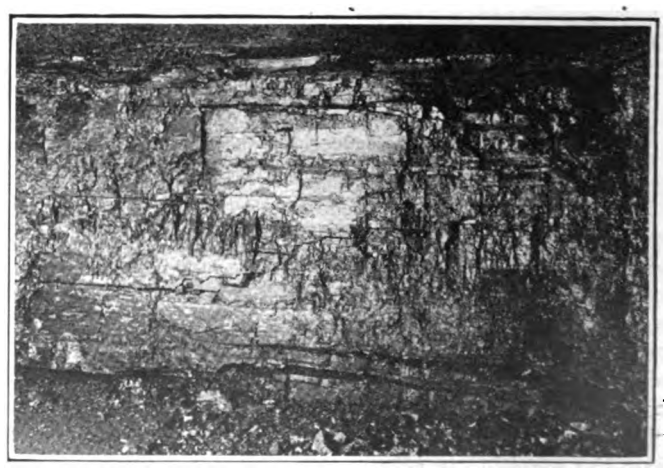

Fig. 5—Coal Well Fractured, but Not Shattered

In many cases explosives, no matter how used, will not throw the coal from the face. In such instances the best result that can be expected is the development of fractures which indicate a loosening of the material. The miner's pick or some other mechanical device must complete the job.

Digitized by Google

the fresh cuts. When one that has not been cleaned is found they should call it to the attention of the machine men. In making these inspections, it is well to use a flashlight so that the back of the cut may be clearly seen. Clean cuts are essential, even when the production of lump coal is not the primary object sought. Coal cannot be efficiently blasted if the machine cuts are not clean.

Where shotfirers blast the coal during the loading shift and lump coal is desired, they should be instructed

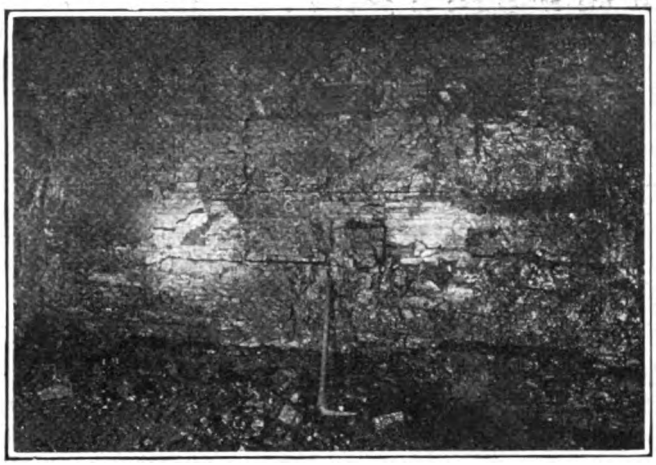

Fig. 6—Too Much Explosives Used in a Tight Shot

In the thick coal of the Pittsburgh bed no successful scheme has yet been developed to roll forward the coal from a tight shot. Although this shot has been overcharged, as shown by the shattering effect on the face, the coal has not been thrown outward into the room.

not to charge or shoot cuts from which the bugdust has not been removed.

Proper placement of holes for blasting depends primarily upon a number of factors, chief of which are the thickness of the coal, the depth of the cut, the direction and character of the cleavage, the hardness and brittleness of the coal, the natural weakness planes, the character of the roof and the bottom and the nature of the binders or other impurities.

MAY HAVE TO SHOOT IN BENCHES

The thickness of the coal will largely determine whether all the material between roof and bottom can be brought down at once or whether it should be removed in two or more benches. Wherever the coal is of such thickness and nature as to permit the practice, it is advisable to bring it all down in one lift. This reduces the number of holes and consequently the quantity of explosive necessary and the degree of shattering.

The depth of the cut naturally should be dependent upon the thickness of the coal and upon its relative resistance in different directions. This latter factor cannot be considered in the abstract. Coal cannot be successfully blasted in a 3½-ft. bed by means of a 9-ft. cut—at least not with the present conventional method of tamping. The distance from the end of the explosive charge to the face would be so much greater than that from the charge to the kerf that the force of the explosive would be expended toward the undercut, leaving the face practically unaffected.

Holes for blasting should be of such depth and location as to place a well-balanced load on the explosive charge. The cut should therefore be of such depth as to offer in all directions the least possible resistance to the explosive force generated.

The direction and character of the cleavage of the coal, if any, should be studied and the holes should be so placed as to derive the greatest possible advantages from these planes of weakness. Disregard of this consideration may result in unnecessary holes and in a material increase in the percentage of slack coal brought down.

In deciding on the number of holes to be drilled it is of prime importance to study the character of the coal itself. If it is of a woody structure, the holes should not be placed in the same manner as they would be if the coal were hard and brittle. Most coals have certain horizontal planes of weakness which may aid greatly in bringing down the material if the holes are so placed as to take advantage of these natural weaknesses.

Where the roof must be protected from the shock of the explosion, care should be taken to keep the holes as far away from it as possible, without losing sight of the fact, however, that the coal near the roof must be either loosened by the blast, or it must be dug or wedged down by hand.

BINDER DETERMINES SHOT PLACING

Probably the number and the resistance of the binders and bands play a greater part in determining the number and location of the holes than any of the above-mentioned factors. The holes must be so placed and the charges so proportioned that the explosive will effectively break these bands or binders and loosen the coal properly and yet at the same time prevent an undue

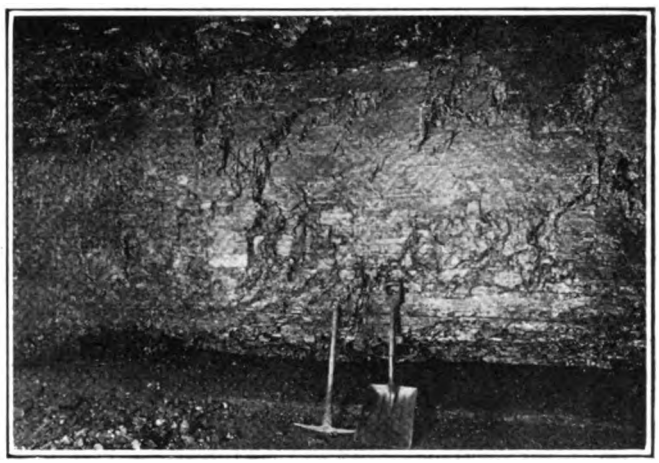

Fig. 7—Hand-Snubbing in the Pittsburgh Bed

This snub cut is started at a point 10 in. above the kerf at the front and extended downward and backward until it meets the kerf at a point 3 ft. in the rear of the face. An attempt was made in this instance to roll the coal forward. A number of similar tests in high coal in the Pittsburgh bed failed in their purpose. The coal being mined is about 7 ft. thick.

shattering or pulverization of these impurities. It is not possible in a general discussion to give the number and direction of holes needed to meet all conditions. Experiments must be made to solve this problem for each mine.

Much discussion during the past three years has centered about the proper sizes of cartridges to be employed and their relative advantages and disadvantages. Many experiments have been made by explosives engineers and technical representatives of the various powder companies with cartridges of small size. As a rule powder companies have objected more or less strenuously to the use of explosives of less than 1¼-in. diameter when these explosives have an ammonium-

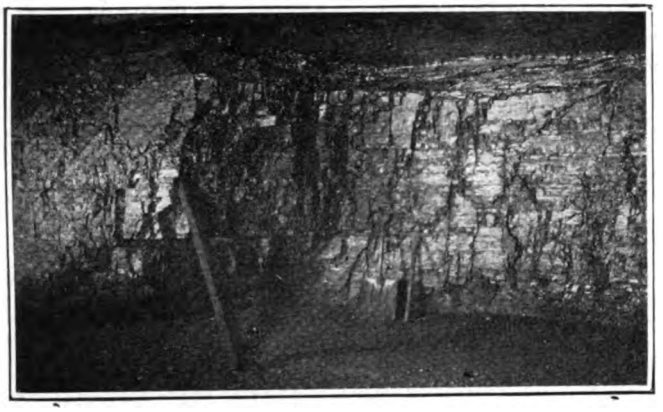

Fig. 8—Face Properly Prepared for a Butt Shot

In the Pittsburgh bed the common practice is to blast the coal with two shots. The place shown in the illustration is 22 ft. wide. The first or tight shot breaks the coal in the cut across about two-thirds of this width. After this initial shot is fired the miner props up what coal remains in place. The butt shot is fired after the coal dislodged by the tight shot has been loaded out.

nitrate base. Their objections have been founded upon the rate of deterioration of an explosive in relation to the diameter of the cartridge. The powder companies have justly claimed that as the diameter is lessened the rate of deterioration is increased. Naturally an explosive cartridge of 1½-in. diameter would lose its strength from deterioration more rapidly than one of 1¼-in. diameter. The manufacturers, therefore, have objected to making cartridges of small caliber, knowing that they would be held responsible for powder that becomes insensitive to detonation.

As will be shown later, the viewpoint of the explosive engineers has been diametrically opposed to that of the powder companies. Various tests have been made to determine the relative advantages and disadvantages of different lengths of explosive charge. The means employed to increase the charge length are known by numerous terms—air-spacing, and cushioned-blasting being the most common.

SPREADING THE CHARGE OVER HOLE

Results have proved that the relation of the length of explosive charge to the length of the hole is an important factor in the blasting of machine-cut coal. It has been found that most coals do not offer the same resistance to breakage in all directions because certain natural planes of weakness are present in them.

In many instances well-defined cleavage planes or slips are found which run more or less perpendicular to the bedding planes. These, and other irregularities, cause the resistance to vary in different directions. It also is true that the thickness of the coal and the depth of the undercut usually hold no fixed relation to one another. One must therefore take all these factors into consideration when trying to determine the length of charge best adapted to blast the coal economically and efficiently.

Satisfactory results from blasting cannot be obtained unless the shots are well-balanced. To provide this balance, the charge should be placed in the holes in such a manner as to assure equal resistances of the coal to the expanding gases in all directions. Should the resistance be unequal, the gases evolved, following the laws of physics, will act toward the line of least resistance. This gives inefficient blasting and entails the use of an excessive quantity of explosive. To remedy it, the depth of undercut and its relation to the thickness of the bed, as well as to the physical characteristics of the coal itself, must be known.

When these factors are ascertained, a theoretical determination of the proper length of charge can be made. For example, if the coal is undercut to a depth equivalent to its thickness, and its resistance is the same toward both free faces, the explosive charge should be placed as near to the back of the hole as possible in order that the expanding gases may not have an easier escape in one direction than in another. If the resistance is greater toward the front of the cut than toward the top of the kerf (in an undercut) tests must be made to determine the relative resistances in these two directions.

This relative resistance being determined, the explosive should be so placed as to put the front of the charge proportionately nearer the face than the top of the kerf in order that the burden on the explosive may be well-balanced. In connection with this problem the diameter of the cartridge plays an important part.

SMALL CARTRIDGES WOULD BE BETTER

With 1¼-in. cartridges one may find that a long charge cannot be used without overloading the holes. Under such conditions it would be advisable to use smaller cartridges so as to distribute the charge over this greater length. This procedure is necessary in districts where air spacing is prohibited. Where such spacing is allowed, the explosives charge can be lengthened so as to obtain a blasting balance by the use of compressible dummies, in conjunction with cartridges of large diameter.

In a bed in which the resistance toward the kerf is greater than toward the face, well-balanced shots cannot be produced with one row of holes. Under these conditions the coal must be blasted in two or more benches. That portion which is brought down in the first bench should be loaded out before the upper bench or benches are blasted in order to provide room for the expansion of the remaining coal. The material from the upper benches should not be allowed too great a fall, for the coal may be unduly shattered.

The foregoing discussion shows that no cure-all is known for the troubles encountered in blasting coal. Each bed and often each mine is a problem within itself and must be treated as such.

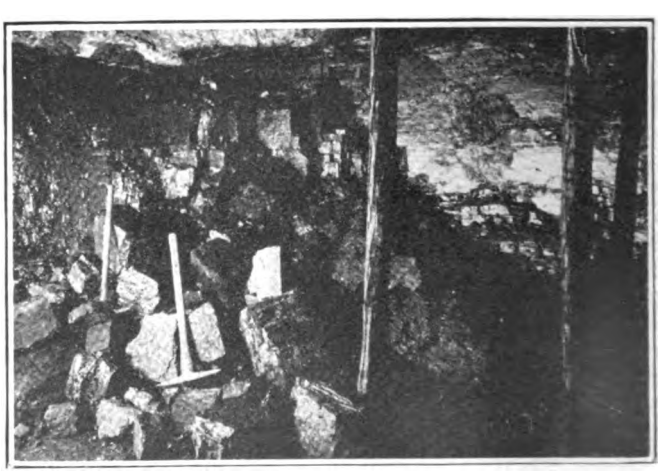

Fig. 9—Coal After a Successful Butt Shot

The condition of this coal was not staged; it shows the exact position that it assumed as the result of a shot. Much of it has been rolled out in lumps that can be conveniently handled by the miner. The coal which is still standing is sufficiently jarred and broken as to fall forward with little picking.

Digitized by Google

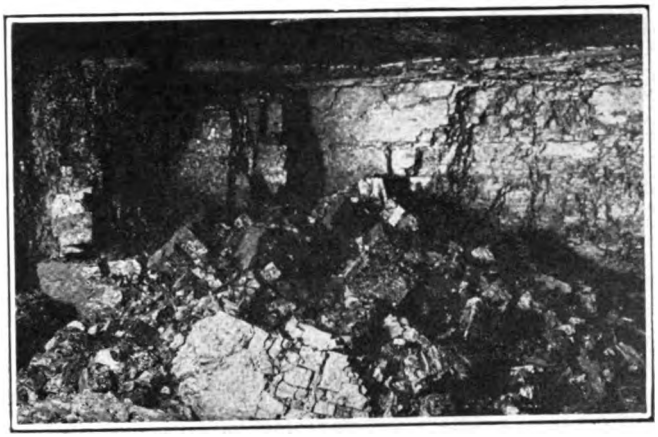

Fig. 10—Face After an Overcharged Butt Shot

Too much explosive in a butt shot has caused the coal to be unduly broken and blown for some distance from the solid face. Note how severely the material in the foreground has been shattered.

Clay is one of the best stemming materials that can be used. Care must be taken not to store it in wet places where it will soon become so soft and soggy as to be unsuited for stemming. It should be stored in crosscuts or room necks at distances convenient to the miners.

Education in blasting is sorely neglected at most mines. This is as true of the officials as of the men. Usually the method of blasting and the placing of holes that is practiced at any particular mine are believed to be the best possible not because they are the result of study and test, but because they are customary. The average mining man knows little or nothing of the characteristics of the different explosives on the market. What is true of explosives is true also of detonators, as also of the effect of the diameter of the cartridges and of the proper placing of the detonator in the explosive charge. Colliery superintendents should arrange to have at their safety meetings, men who know how to blast coal, so that they can teach the employees the most approved methods. Safety practices, as used by different companies should be studied and comparisons made in order that a safe and workable set of rules may be formulated. The shotfirers should attend such meetings whenever blasting is the topic for discussion. Suggestions and recommendations from these men should be given careful consideration.

To obtain an efficient blasting practice and to produce a satisfactory quality of coal, a thorough study must be made and a uniform practice instituted. This much having been accomplished, close supervision must be provided, and unofficial variations from standard practice must be prohibited.

Can Gas Be Made at Mines With Profit?

Big cities have frequently risen amid the mining areas that were the sources of their wealth and opportunity, but they now draw their supplies from a distance, for the mines have been depleted by their many years of operation. Thus mining installations become further and further removed from a possible market for gas. Some mines always had that disadvantage and many that did not have it would have found, had they tried to make gas, that they had an active competitor in natural gas such as would have made the artificial product an impossibly expensive fuel, wherever, at the mines or elsewhere, an attempt might have been made to manufacture it. The question arises therefore: should coal be shipped to the city for the manufacture of gas or should it be coked or otherwise gasified at the mines, the gas being conducted in pipe lines to the industrial centers?

Load Fluctuations Trouble Gas Men

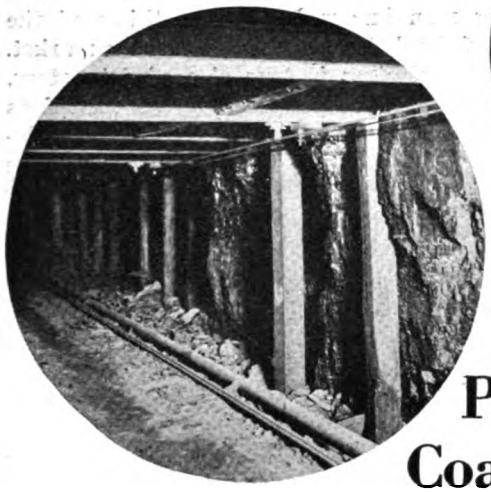
W. W. Freeman, of Cincinnati, president of the Union Gas & Electric Co., discussed this subject for the benefit of the members of the Charleston, W. Va., section of the American Institute of Mining & Metallurgical Engineers, giving the reasons why gas usually had to be manufactured out of coal on which a heavy freight charge had been paid instead of out of coal that was debited with no such charges.

He said that load fluctuations are the chief worry of the gas companies. It is impractical to build transmission pipe lines 150 to 175 miles long large enough to handle the usual ten- to fifteen-day maximum winter peak. For this reason the logical place for a gas-making plant to reinforce the supply of natural gas is at the point of distribution rather than at the mines.

The demand for gas in Cincinnati is normally 3½ times higher in the winter than in the summer, and about 50 per cent of the year's sale is during the four winter months. The encouragement given to house heating only makes the situation worse. The mixing of artificial and natural gas is a difficult problem because a marked change in the percentages requires a readjustment of the customers' burners.

In discussing the paper, Mr. Forrest described the manner in which peakloads are handled in Chicago. Sufficient byproduct ovens to satisfy the maximum winter demands would involve an expenditure entirely out of all reason. At present the coke ovens have a capacity of twelve to fourteen million cubic feet. Producer plants have a capacity of about twenty-five million, and water-gas plants another twenty-five million. These latter installations, which cost far less than byproduct coke ovens, take care of peakloads, but the gas they make costs far more than if made in a coke plant.

Near Fairmont, W. Va., a byproduct plant is now operating which delivers artificial gas into the mains originally laid for the purpose of supplying the natural product. The new plant supplements the wells, the production of which is slowly decreasing. S. A. Taylor, consulting engineer, of Pittsburgh, Pa., and president, A. I. M. E., said that locations remote from cities have been selected by a certain large gas company for the building of new plants. These locations are chosen so as to make effective use of the large investment already expended in pipe lines. As the lines are already installed, the plant can be located somewhere near the coal supply.



OVER ONE-FOURTH OF THE RAINFALL that falls on the surface above the mines percolates into the workings according to R. D. Leitch, associate chemical engineer, U. S. Bureau of Mines, Pittsburgh, Pa. In fact he quotes the figure as 27 per cent of the annual rainfall and adds that, except from shallow workings, the mine drainage flows are said to be quite constant and to vary little with the occurrence of rain, whereas the flow in surface streams varies considerably from time to time. The maximum and minimum discharge from mines varies only about 17 per cent from the average.

Rock-Dusting Promptly Checks Coal-Dust Explosions

Even Where Dust Is Wet Pulverized Rock Is Helpful—Not Only Roadways but Airways Also Should Be Strewn with Rock Dust — Barriers Valuable Especially at Strategic Points

By J. W. Paul and C. A. Herbert
U. S. Bureau of Mines

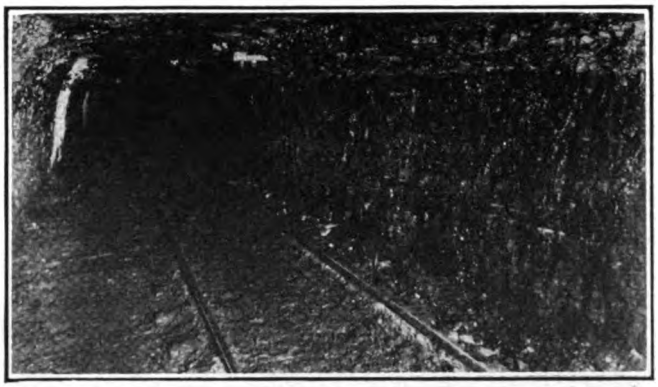
DESPITE THE ABSENCE of explosive gas, coal dust, when in a dense cloud in the air, may be ignited by an open light or an electric arc or by the flame from a non-permissible explosive, and being confined by the ribs, roof and bottom of the mine may quickly assume a rate of combustion that gives great and violent explosion effects.

A coal-dust explosion once started does not depend upon external application of heat or flame to keep it active, but may gradually or suddenly increase in violence in its travel through a mine. A coal-dust explosion is self-sustaining and will propagate so long as enough coal dust has been raised in its path to sustain combustion. Counteracting influences are of many kinds: (1) Obstructions which can be moved or destroyed, and which can thus transform some of the heat into kinetic energy, (2) The arrival of the explosion at places of large cross-section which permit of an expansion of the hot gases of combustion, thus reducing the heat, pressure and velocity of the gases to such an extent that the explosive violence declines and a sufficient density of coal dust is not raised in the path of the explosion, and (3) Long stretches in the roadways traversed by the explosion where roof, ribs and bottom are wet and thus retard combustion by the absorption of heat.

Nevertheless, where the advance air waves have carried an excess of coal dust, an explosion has been found to extend through a wet entry as much as 500 ft., continuing to propagate in the dry zone beyond with continued violence. Coal-dust explosions in mines have traveled with equal violenee in the intake and return air currents, and in a number of shaft mines the explosion has passed across the bottom of an intake shaft and continued along the intake current to all sections of the mine.

Many demonstrations in this country and in Europe have shown conclusively that coal-dust explosions may be prevented, controlled and stopped by the use of rock dust when it is either mixed with the coal dust or placed in barriers which drop it in large quantity in the path of the advancing flame of the explosion. In quenching the flame of a coal-dust explosion, rock dust acts as a heat absorber. It serves to best advantage when it is dry and capable of being raised into a cloud through the shock or concussion waves set in motion by the oncoming explosion.

Where a zone is moist, rock-dusting will also help. It has been found that when rock dust was strewn over or mixed with coal dust and, where through the humidity of the air current, surfaces become damp or wet, the moisture, by reason of the greater capillarity of the rock dust, wets the coal-dust particles with which the rock dust is in contact. Coal dust, when not mixed with an absorbent material, tends to repel water. Another advantage of damp or wet rock dust is that it imprisons the coal dust with which it comes in contact and in this manner prevents it from being raised in the air by concussion. Consequently, whether a zone is wet or dry, rock-dusting is of great value in the prevention of coal-dust explosions. However, dry rock dust is always preferable to wet, because of its readiness to rise as a cloud and dampen the flame of an explosion.



It has been shown in repeated tests in the Experimental Mine of the Bureau that rock dust when properly used is 100 per cent efficient.

The question then arises, What has been the efficiency of rock-dusting in coal mines where rock dust

---

Before Rock-Dusting, Main Haulage, Montour No. 10

A rib in the roadway of one of the mines of the Pittsburgh Coal Co. Its multiplicity of ledges holds quantities of dust ready to be blown into the air by the advance waves of an explosion.

has been applied and where it has had opportunity to show its beneficial effects in stopping, or in a manner controlling, the spread of an explosion?

Explosions in mines, where rock dust has been distributed both by the strewing, or broadcasting, methods and by barriers, have been studied both here and in Europe, and it has been found that the range of the explosion has been controlled by the rock dust when only one of a pair of parallel entries or tunnels has been thus treated, but in each case the range of the explosion was greater than where the other parallel entry had been similarly treated.

The reason for this is made clear by a study of the pressures developed by a coal-dust explosion and the velocity it attains. In order to propagate an explosion that has gotten under way, as at the face of a working place, a dense cloud of dust must be raised in front of the advancing flame. To accomplish this, *air* waves of a high velocity must be created, and these are dependent upon the relative pressures set up by the advancing *explosion* wave. If this pressure is sufficiently reduced, the explosion wave will lose speed, and the air waves will cease to stir up the coal dust in sufficient density to admit of its flammation and propagation.

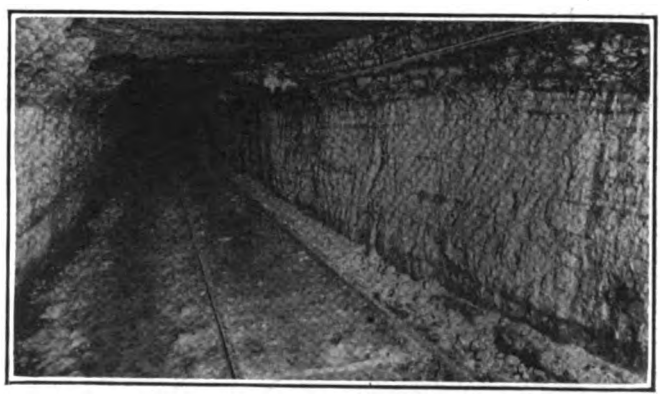
Both Entries Should Be Treated

It is apparent that, when rock dust is applied to only one of a pair of entries, the destruction will extend much further than if both had been rock-dusted, and this has been fully demonstrated in commercial mines where failure to rock-dust a trackless entry has permitted a dust explosion to extend over a relatively wide area, whereas the rock-dusted entry gave no evidence of the passage of flame.

Explosions which in some mines were of frequent occurrence have ceased to devastate such workings since they have been completely rock-dusted. In other mines that have been only partly rock-dusted, explosions have occurred and traveled relatively long distances, occasioning loss of life and doing much property damage. They were stopped only through the cumulative effect of the rock dust.

In mines relying wholly upon barriers, these protective devices have extinguished explosions only, however, after much violence has been exhibited and much destruction has been done. For this reason some mines originally equipped with barriers, have modified their practice and adopted that of strewing, or broadcasting, the rock dust throughout the mine, using barriers as supplementary only to the generalized rock dusting.

In a district where, under certain mining methods, previous explosions have extended throughout an entire mine or a large part of a mine, it has been noted that under similar mining conditions, where rock dust has been applied, explosions have been localized. It has been observed also that in a mine only partly treated with rock dust, the explosion covered a wider range. It, therefore, is essential that rock dust be applied throughout the mine if maximum safety is to be obtained. In concentrated methods of mining where machinery is used for cutting, loading and hauling the coal, many men may be at work within a small area, and to protect these men, rock-dusting should be applied as near the working places as conditions will admit.



The experience of the Old Ben mines in Illinois, as described by J. E. Jones, was that, though barriers had stopped several explosions, the damage done and the risk to life were such as to show that the barriers did not afford the most efficient means of protection. Broadcasting of rock dust was, therefore, adopted as more efficient. Since then there has been no record of an explosion gaining any headway in any of these mines.

All But One Might Have Survived

In a mine in western Kentucky, rock dust had been broadcasted throughout the roadways up to a certain point. While preparations were being made to finish the job, a gas explosion in the untreated section ignited the coal dust. All the men in the district that had not been rock-dusted were killed, but those in the adjacent rock-dusted entries escaped uninjured, the explosion having terminated when it reached the rock-dusted part of the mine. Had the affected portion of the workings been rock-dusted, probably all would have been saved but the person who ignited the gas.

The New Orient mine in Illinois had been rock-dusted and only a few of the entries remained to be treated when an explosion of gas started a coal-dust explosion. This traveled along the untreated entries until it reached the rock-dusted area, where it was stopped. Moisture along part of the zone that the explosion traveled no doubt assisted in its retardation by furnishing no additional coal dust for fuel. However, the explosion, carrying dry coal dust from inby points, would have continued indefinitely but for the rock-dusting beyond the damp zone.

It was brought out in the official hearing following the explosion at the Horning No. 4 Mine, near Pitts-

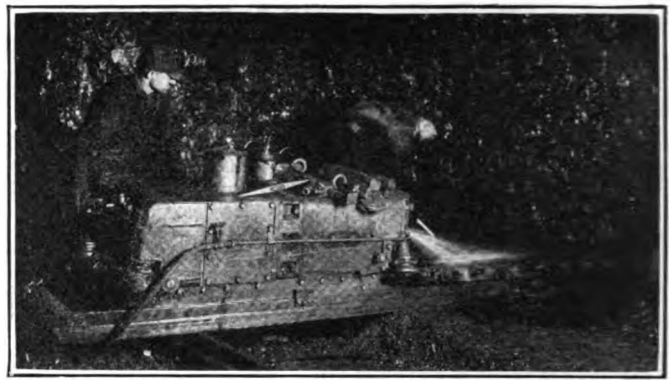
After Rock-Dusting, Main Haulage, Montour No. 10

The Pittsburgh Coal Co. has had heavy operating losses but nevertheless has been rock-dusting its mines faithfully, even to designing a machine for that purpose. An unsafe mine is not only an offense against society but an undesirable property to operate.

Digitized by Google

burgh, Pa., that the pair of entries in which the explosion occurred had been rock-dusted only on one entry and for a length of but 100 ft., however the main haulage up to the pair of entries had been treated with rock dust, and this was an important factor in the control of the violence of the explosion, which subsided through the cumulative influence of the rock dust in the part of the mine involved. This emphasizes the importance of applying rock dust to the airways and other parts not used as haulage roads.

In the study of a large number of mine explosions it has been found that where tight mine cars have been used without heaping the coal above the top, and where good track has been maintained, little, if any, coal has been spilled along the haulageway. In some of these mines the roof or bottom had been brushed to provide height, and this brushing had resulted in leaving an appreciable quantity of shale in a fine state which acted as rock dust. In these zones the violence of the explosion has been noticeably reduced, and in some cases the explosion has been checked or stopped, by the inert material which the advance wave of the explosion raised into a cloud.



Great risk is taken when only part of a mine is treated with rock dust, such as the haulage roads, leaving the aircourses and trackless entries without this protection. A practice such as this invites disaster and when an explosion travels any distance in a rock-dusted mine it is conclusive evidence that the rock-dusting has been neglected or that some part of the mine has not been treated.

Undercutting Coal Without the Use of Water

A dense cloud of dust was raised in undercutting. This, the illustration does not show clearly. It is easy to see how large a quantity of dust is formed to serve as a powerful explosive should it be raised in the air and then become ignited.

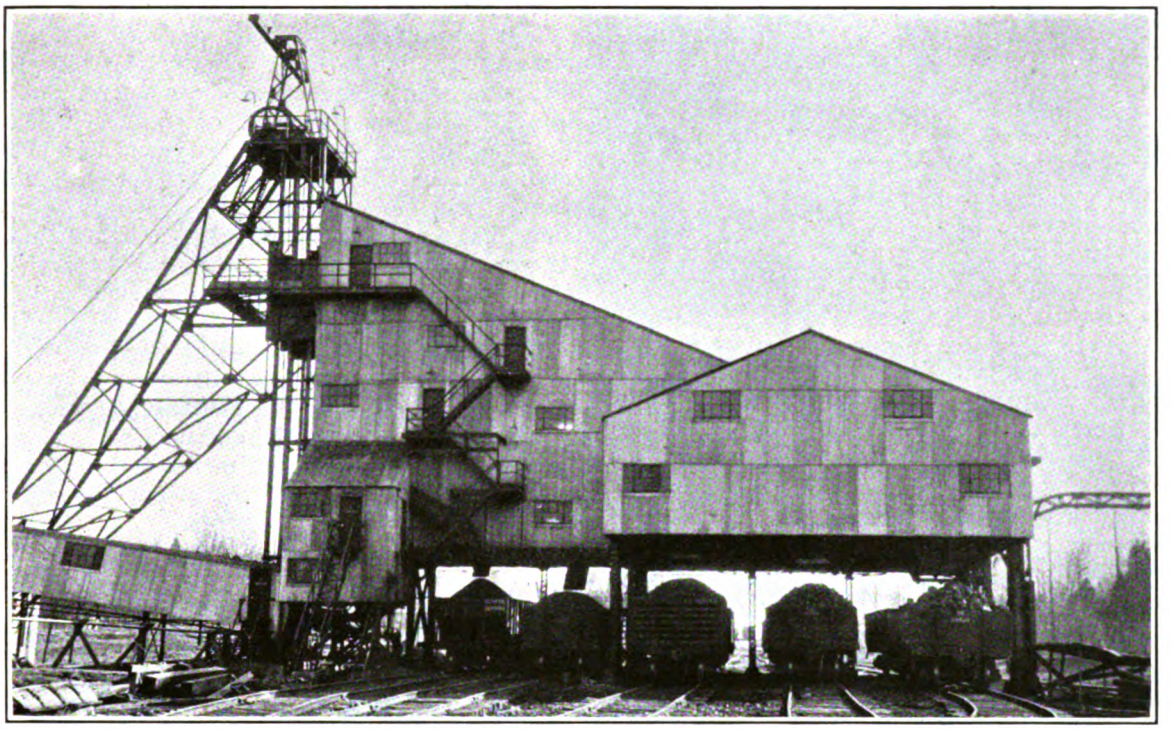
Rock-dusting calls for maintenance and this can be accomplished only by frequent sampling and analysis of the dust on the floor, rib, roof and timber to determine whether a new application of rock dust is needed. Rock dust, unlike water, does not evaporate and when applied in a mine it "stays put," but as coal dust is constantly being made and collects in the mine, in course of time the rock dust will need to be replenished if the combustible is to be kept at a minimum. In order to determine the need for a renewal of the rock dust samples should be taken from the roof and ribs in the various sections of mine. At the same places other samples should be collected by gathering the dust in a line across the floor. These samples should be kept separate for analysis or for determination by the volumeter, which latter gives a quick method for determining the inert material present. (This method is described in Bureau of Mines Technical Paper 144, which may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., for 10c.)

Undercutting with Water Playing on Cutter Bar

Thus dampened the air is cleared of dust particles, both while cutting the kerf and loading the dust. Fine coal does not blow off the cars in transport and if an underground dump is used less dust by far than is usual is set free to distribute itself on the mine timbers, rib ledges, floors of passages and other points of collection.

The strewing, scattering or broadcasting of rock dust is the most efficient method by which it can be applied. Where only dust barriers are provided they may fail to stop a weak explosion near its place of origin, as the explosion may travel some distance before it assumes such violence as will operate a barrier, and meanwhile the explosion will do much damage and may take many lives. Barriers are intended only as a second line of defense in connection with the broadcasting of rock dust and are best suited for installation in entries connecting two mines, at entrances to abandoned or worked-out areas and at the entrances to panels or sections of mine workings.

Rock dust properly applied and maintained is a panacea for coal-dust explosions, and when its use has become a daily routine at all bituminous coal mines, the wholesale loss of life in mines will be at an end. No longer will large numbers of lives be lost by explosions extending through a large portion of a mine.



V-Troughs Last Long and Are Cheap

"The proper placement of rock-dust barriers has been a matter of some discussion," remarked Robert M. Lambie and Gordon MacVean in an article delivered before the Charleston (W. Va.) section of the American Institute of Mining and Metallurgical Engineers. "It must be realized that they are essentially of the nature of a secondary defense. Their use is to isolate abandoned workings, to separate interconnected mines from each other, to protect entries which cannot be given a general coating of dust, such as aircourses.

"There are numerous types of barriers in use but by far the greater number are the so-called 'V-trough' barriers. In general, practice in this country so far has been to place this preventive equipment in the returns of all air splits, the barriers to carry 100 lb. per square foot of cross-section. Each V-trough holds about 200 lb. of dust. In a 7x5-ft. aircourse from fifteen to twenty troughs to a barrier would be needed.

"The cost per set of fifteen troughs at Mine No. 8, of the Pittsburgh Terminal Coal Co., has been given as $44.55; per set of twenty-one troughs at Naomi Mine of the Hillman Coal & Coke Co., $47.88. The cost per V-trough varies from $2.25 to $3.60.

Coal Industry Greatly Needs to Reorganize and Reconstruct Its Operating Methods

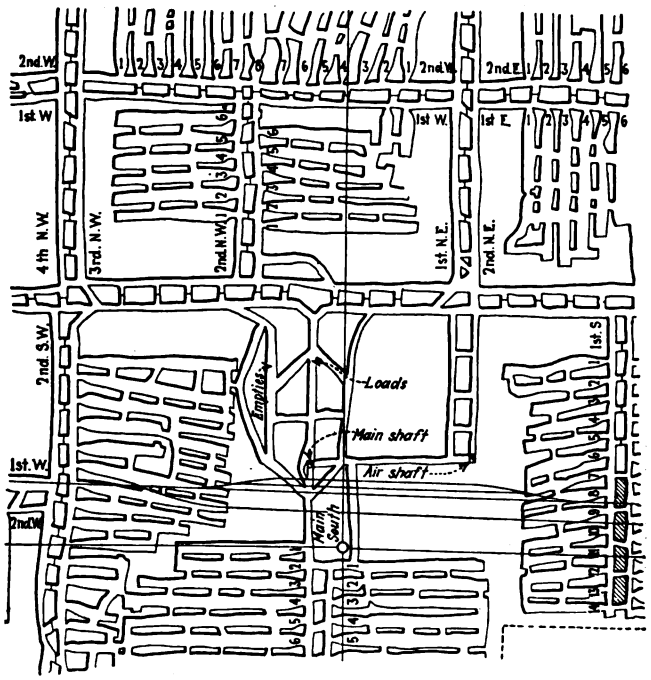
Mergers Do Not Reduce Excessive Output—Big Tonnage, Lower Cost and Falling Prices Form Vicious Circle — Specialized Brains Needed to Rèvamp Mines — Manufacturing Methods Should Be Adopted

By John A. Garcia
Consulting Engineer, Chicago, Ill.

MUCH CONFUSION between cause and effect exists in the mind of the public and in that of many coal operators as to the solution of the problems confronting the coal industry. One of the main reasons for the continued failure to attain stabilization is the repeated effort to cure the effect without removing the cause of the trouble. This, admittedly, is over production.

There are cries for mergers but such consolidations, with few exceptions, do not in practice reduce output, but in many cases actually increase the total production. Some of the mines merged may, it is true, be shut down or abandoned as a result of the merger, but the output of the consolidated property is likely to be, and usually is, larger than that of the many units out of which it was created.

And again, there are cries for a reduction in the wage scale, but the net result to the operator of such a decrease would be little, in either the union or the open-shop fields, unless the differential between the two were changed by the readjustment, for the margin between cost and revenue will remain fixed should the wages in the two sections advance or recede simultaneously and in the same ratio.



The coal industry travels in a cycle. Increased output is advocated for the purpose of decreasing cost, but the outcome of the large tonnage is a lower price that defeats the ends so diligently sought. Further efforts are made to increase tonnage so as to lower costs accordingly and that decreased cost is met by further price reductions. The cycle is vicious. Unless it is broken there is no prospect of rehabilitating the industry.

Although mergers tend, as has been often said, to lower the cost of selling and administration, they usually create an offsetting disadvantage by fastening on the industry fixed charges for the interest on bonds. Before the merger the properties were financed by stock, and consequently the reorganization has replaced an optional dividend with a legal demand that can be met only by the production of coal for less than the market price.

Instead of boosting output to get lower cost it appears logical, in view of the cycle just cited, to decrease cost and at the same time to reduce the capacity of the mines. This apparently rash suggestion may not appear so impossible after examining the operations and records of a few companies where the "New Idea" has found lodgment.

The headpiece shows a modern tipple where only one man is needed at the dump yet the capacity is 4,000 tons daily. Compare this with the tipple that heads the right column of page 731. Here eight men manage with difficulty to load 2,000 tons per day. Who shall say we do not progress?

Digitized by Google

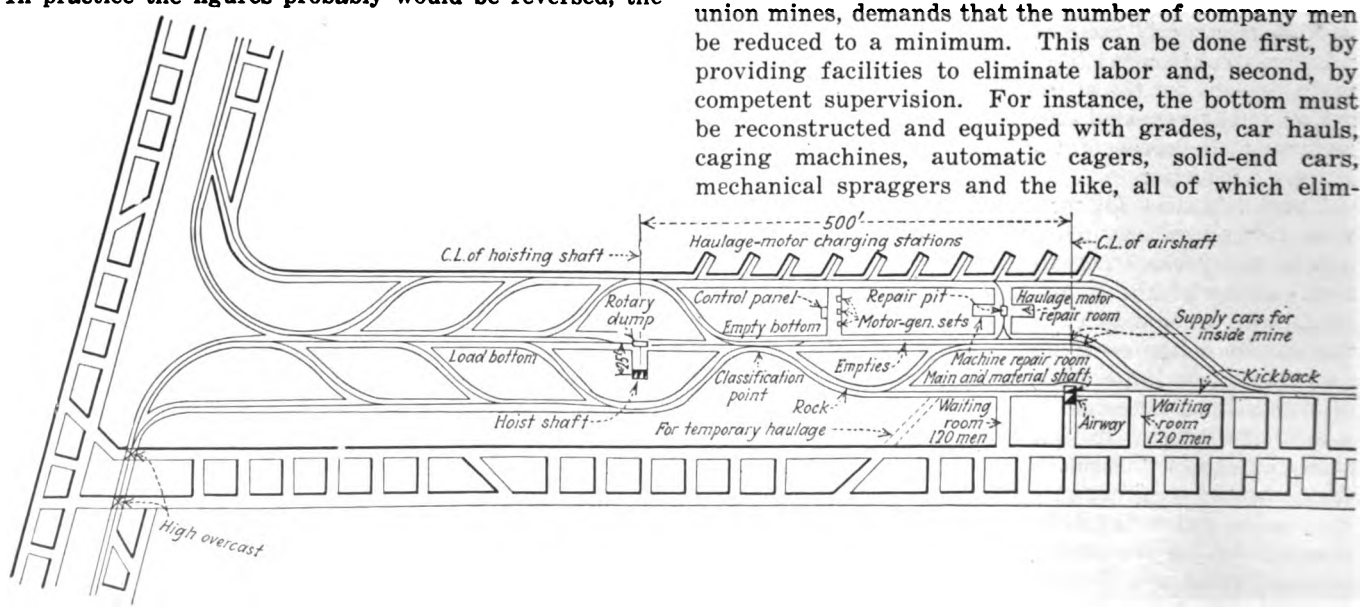
They Hoist 3,000 Tons at This Mine Daily

A great credit to the management that it thus overcomes the difficulties of layout and equipment. However it takes eight men to turn the trick. You can do wonders, if only you have the men, as Pharoah proved when he built the pyramids.

This plan, simply stated, is to regard the mine as a manufacturing plant and to upset the traditional notion that each miner shall be permitted to work in relative independence. In my opinion this may be done in part by replacing room-and-pillar mining with its many disadvantages by what is generally known as "modified longwall" thus permitting a real concentration of the workings.

In order to illustrate how concentration reduces the area of workings, assume a seam adapted to such concentration say 5 ft. thick. On a longwall face, 200 ft. long, with a 6-ft. undercut, 240 tons would be shot down. Even at the low average output of 12 tons per loader only twenty men would be required to shovel this coal. In practice the figures probably would be reversed, the tonnage per man would be 20 tons per day and the number of men employed twelve instead of twenty.

This same tonnage could be produced with rooms and pillars, only by working twenty-four places with a loader in each whose average production would be 10 tons. If the rooms were placed on about 40-ft. centers the lineal extent of development would be 960 ft. or almost five times as great a length as with a longwall face. This, however, may not represent actual conditions, but a mine that I recently examined showed only 12 per cent of the narrow-work coal being worked on the advance and 6 per cent being worked on the retreat or a total of 18 per cent.

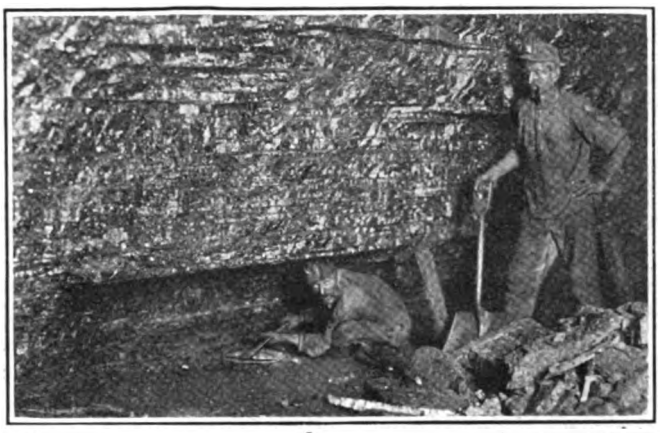


With face conveyors loaded by hand or with loading machines that place the coal directly into cars, whether the room-and-pillar or the modified longwall system is used, a different gathering and haulage system must be provided from that which serves for ordinary operations where such loading equipment has not been introduced.

MUST ADD SPACE, BINS AND CRUSHERS

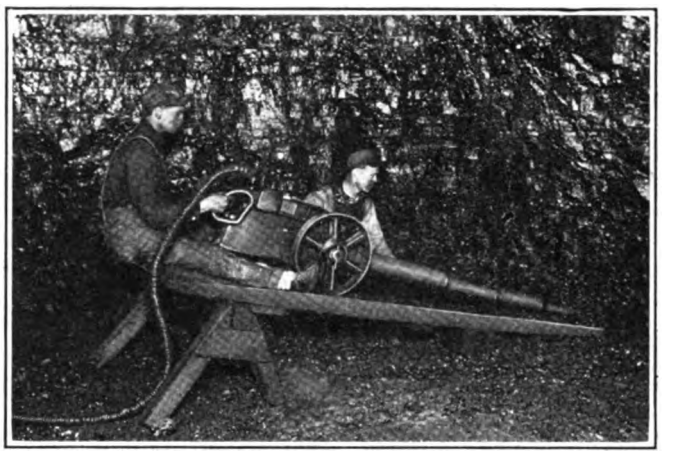
With mechanicalization of loading, a well-trained and intelligent operating staff is made necessary and the problem of coal cleaning is accentuated. Machine loading necessitates the reconstruction or, at least, the rearrangement of the surface facilities. The sized coal of over 3-in. diameter may be cleaned by hand, but the tables will have to be extended so as to provide additional space. Conveyors to handle the refuse will also be needed. Small crushers must be installed to reduce the burnable refuse to nut or screenings. Bins and storage facilities must also be provided to facilitate refuse disposal.

Coal of less than 3-in. diameter, and certainly all under 2 in. cannot be hand-picked economically, so that the reconstruction program will require a plant for cleaning this material. Several means are available for this service—water, air, oil, flotation, or combinations of these—each with its special advantage but all calling for new equipment, structures, skillful engineering and intelligent operation.



The high wage scale, especially that prevailing at union mines, demands that the number of company men be reduced to a minimum. This can be done first, by providing facilities to eliminate labor and, second, by competent supervision. For instance, the bottom must be reconstructed and equipped with grades, car hauls, caging machines, automatic cagers, solid-end cars, mechanical spraggers and the like, all of which elim-

Mine Bottom Designed for 10,000 Tons per Day with Only Five Men Needed



Here there is an adequate bottom for car storage, means for moving cars without labor, a rotary dump that empties cars without uncoupling and a skip shaft. This mine has produced 12,000 tons in a day. There are other facilities such as waiting rooms for men and motor charging stations which with their carefully chosen locations make matters for profitable study.

"Lest We Forget"—The Ways in Which Mining Used to Be Done but Rarely Is Performed Today

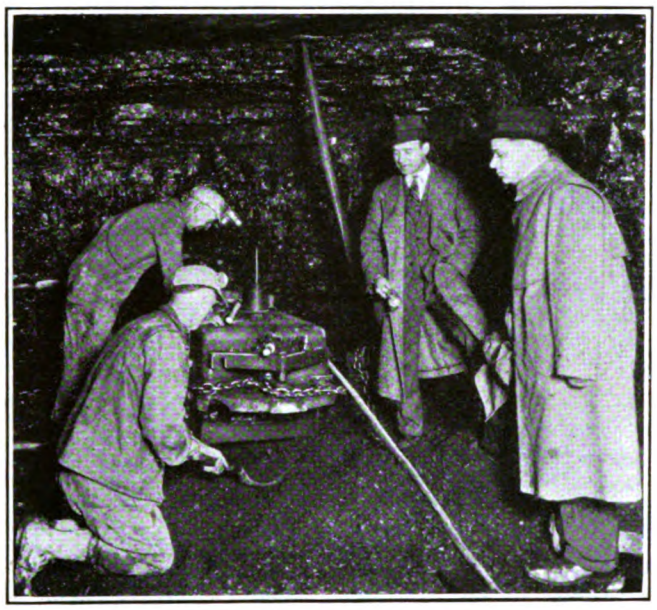
In the upper left illustration is shown the process of undercutting coal as it was actually done in 1900. Coal is said to be cut by hand pick in some mines today but as it is generally expressed we "let powder do the work." The lower left illustration shows the hoisting plant at Leaford, Ill. A few farmers' banks perhaps still use this means to raise coal. The upper right illustration features the mule. Less than thirty years ago a mule or a string of mules was quite generally the main-line unit. In the lower right illustration can be seen the coal puncher that in 1910 seemed to possess the field. "The electric cutters were large, heavy, expensive and of doubtful utility," some of us thought, but they came and conquered.

inate labor. Partings may be reduced in number and arranged for minimum labor cost in handling trips. Ample room, well-built switches, guard rails and other devices will prevent delays and de-railments. Cars must be so designed as to afford maximum capacity under the known conditions and a low maintenance cost with provision for easy oiling, and wheel replacement.

All construction work in permanent entries should be done in a manner and with materials that will avoid the constant renewal charge so common in many coal mines. The mainline stoppings should preferably be constructed of some permanent material, such as concrete, brick or tile, as should also the overcasts, pump rooms, repair shops, transformer stations and similar structures. The timbers on permanent roads, aircourses or manways should be of steel or treated wood, for in this item lies one of the most prolific sources of high repair costs.

The haulage system must be constructed for fast and safe traffic with roadway, drained and graded, and all timbering set with ample clearance. Maintaining a poorly built haulage system is an expensive item on the cost sheet, the work being done usually by the highest priced labor on the payroll, such as tracklayers, timbermen, and electricians, so that the best and most permanent construction at the start is the least expensive in the long run.

Savings in labor costs made possible by modernization may be illustrated by comparing a self-dumping cage mine with one using a stationary platform. In the former, not more than one man is needed at the dumping point, whereas, in a tipple where cars are pushed off the cage to the tipping point, the usual crew is eight men, making a difference in daily labor cost, at $6.50 per man per day, of $45. A great increase in hoisting capacity may also be realized with the first method.



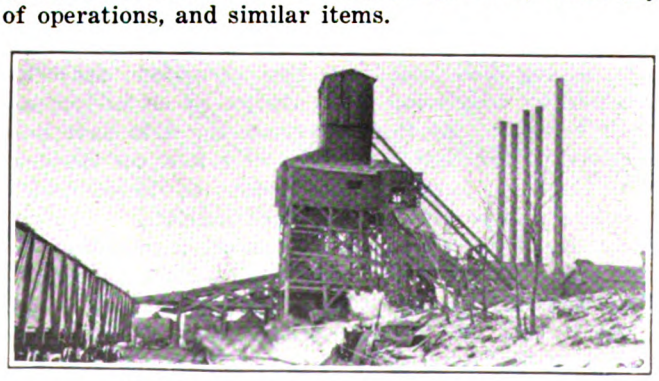
Again five men at the shaft bottom will handle 12,000 tons per day where underground continuous rotary dump and skips are used, whereas eight men will be required where self-dumping cages are installed, and the hoisting capacity will be only about 6,000 tons. In the first case 2,400 tons will be handled per man and in the second only 750 tons. Thus with a rotary dump and skips the performance per man will be 220 per cent greater than it would be with self-dumping cages.

With New Mine Cars Large Tonnage

Reconstruction of mine cars offers a fertile field for engineering skill, and large cost reductions are often possible by improving their design so as to increase their capacity. As this is written the data have been received on the first day's trial of a new car designed with the same governing dimensions as the equipment previously in service. The record indicates a capacity for the new car of 10,000 lb. against a maximum for the old car of 8,000 lb., or 25 per cent additional coal. This was accomplished with an increase in tare weight of only about 300 lb. It means that 25 per cent more coal may be hauled without any increase in cost, that fewer cars are handled all over the mine for the same output, and that dumping and hoisting operations are proportionally reduced.

Handling railroad cars on the surface is also a "point

Digitized by Google



How Coal Is Machine-Cut in Present Decade

The labor-saving process has greatly progressed. It was easier to cut by air and to keep the pick in line by pressure of the feet (for after all it was gravity that advanced the puncher cutter to the face) than to do it by dint of hard blows of a pick swung by one's arms, but with modern machinery once the machine is in place it moves itself to accomplish its work and in some cases it travels by power into the room and out of it under the control of its master.

of attack" for the engineer seeking to convert a mine into a manufacturing plant. There is much room for improvement in the present customary method of "dropping" cars down a grade to and from the tipple. Car retarders under this structure are great labor- and time-savers and there are opportunities for cost reduction in the use of shunter locomotives with combined gravity and flat tracks, car hauls, and the like.

Reconstruction of the power plant and electrical distribution system at the average coal mine is a highly essential item and in the modernizing program, for the usual costs for steam and current are far too high. The advisability of purchasing power must be determined by careful analysis of each individual case. At many operations power generated at the mine would cost less than if purchased from a service company.

Where an ample water supply of the right quality is available and the plant can be reconstructed for truly economical steam generation using crushed picking-table refuse as a fuel, it is usually better practice to make power locally, though full consideration must be given to the load factor, idle days, night load, continuity of operations, and similar items.

Before the Transformation Was Made

In early days hoist houses had to be high, for the coal went over the screens by gravity and even then the big railroad cars could scarcely get under the tipple and the screening was none too good. The degradation, of course, was excessive.

It is safe to say that most coal mines need to reconstruct their electrical distribution system, for with the customary 250-volt, direct-current methods of furnishing energy to outlying and isolated mining machines and motors, it is extremely difficult to obtain satisfactory results from the electrical equipment. Generation and distribution of alternating-current to rotaries installed at strategic points in the mine appears to be the logical system to use wherever the point of power consumption continually recedes from the generator. Life of mine, however, as well as cost of feeders, projected length of entries, state laws, and the like all must be considered in the study of this problem. Furthermore each mine must be treated individually.

All the items of reconstruction and many others entering into the complete conversion of a coal mine as now operated, into a plant for the manufacture of fuel call for a complete reorganization of the usual personnel in charge. Engineering skill of the best grade is needed during the period of rehabilitation. In operation, the haulage will require the same kind of brains that now manage the railroads; the generation, transmission and use of power must be accomplished with the same skill

After the New Tipple Was Built

The old rickety structure is replaced by steel, not so high as the old one but giving better preparation, more height for cars and allowing greater hoisting speed.

and management as is exercised by the officials of public utility companies and the cutting, drilling, shooting, loading and preparation, as well as the marketing of the coal must be regarded as much the same kind of problems as those confronted in the manufacture and sale of automobiles. Into these three lines of endeavor—railroads, public utility and automobile manufacture—has flowed the best engineering talent and executive ability that the land has produced, with the result that in these lines America today leads the world in efficiency, low cost, uninterrupted production, satisfied labor and continued development of new ideas and methods.

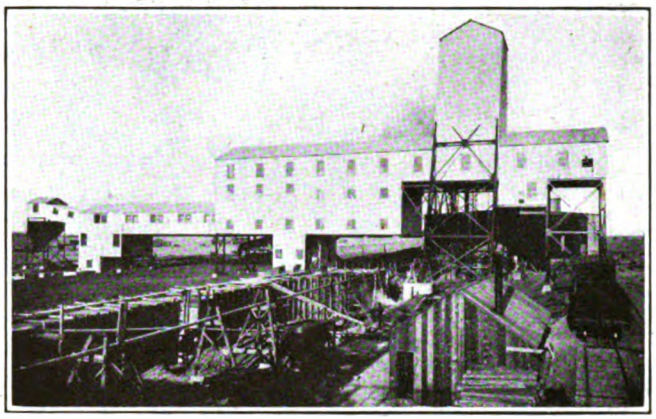
In bituminous-coal mining one district is pitted against another by differentials in labor rates, freight rates and natural conditions; interstate competition adds further confusion and, finally, the union and "open shop" sections of the country are in a constant struggle to satisfy a market the normal demand of which is about one-half the mine capacity.

Such a situation, without doubt, signifies the survival of the fittest, and no artificial reorganization of the industry such as mergers or reduced day-labor wage, can bring about stabilization. Such methods in order to be

Digitized by Google

effective must of necessity curtail output and reduce production costs in union fields. Reducing cost by cutting wages is the orthodox way of "managing" the average coal mine. It would appear, however, that this idea must pass and that the management of the profitable mine of the future will consider "tons per man" as of greater importance than "wages per day" and that permanent construction, both above and below ground, which is less expensive than temporary work with its high renewal and maintenance costs will in the future be regarded as preferable to the makeshift arrangements of the past.

The constantly decreasing number of young men who enter our mining schools and the pitifully small percentage of graduates entering the coal-mining industry is a true index of the reluctance, amounting almost to intolerance, with which coal-mine officials usually receive the infusion of trained brains. This is in marked contrast to the automobile, telephone, utility, railroad and other industries which not only welcome such men, but employ scouts to visit the technical schools and pick the best.



Coal mining is fundamentally and inherently a

Wood Must Go from Shaft Bottoms

The mine in which this photograph was taken was recently completely rehabilitated. The track shown provides storage for empty cars at the bottom of the hoisting shaft. The heavy concrete-and-steel construction indicates one of a number of changes needed to reconstruct an old plant.

science, and should be so considered. It requires a combination of engineering knowledge that no one man can fully absorb, for it is made up of structural, chemical, electrical and other branches of the profession to such a degree that individual knowledge becomes inadequate and organization alone will fill the requirements. To expect "factory" results from the management of a modern mine when the personnel is not made up of men trained in the technical, as well as the practical phases

A Fine Plant, but Eight Men Handle Only 2,000 Tons Daily

We move along rapidly and it seems difficult to convince anyone that what was standard a few years ago is obsolescent today, but so it is and, in financing, that fact should be remembered.

of the work, is just as futile as to hope for good results if engineers were not used in the construction and operation of a giant generating station, a railroad, or—to be specific—in the management of such concerns as the General Electric or Westinghouse companies.

The coal-mine operator deals in thousands of tons per day; the factory, the ordinary metal mine, the mill or the usual plant anywhere in hundreds of tons or even pounds. The coal miner does his work underground, in the dark, in the presence of unknown forces in roof pressure, water, gas, and the like, whereas the factory works to definite formulas in the daylight and on the surface of the ground. How much more necessary, therefore, is engineering in coal mining than in any other line of human activity? Thus far American operators have led the world in output per man, in lower production costs and in speed of development—all with practically no engineering at the average mine—but at what cost in extraction, in wrecked corporations, in overproduction, in tangled wage scales and in periodic chaos!

Reconstruction and reorganization of bituminous-coal mining will come either voluntarily step by step, with each individual company or by way of the more unhappy and violent method of bankruptcy. The choice lies with the coal operator and his banker. The interests of these two are mutual. The banker's vision and courage in many other phases of mining has been so clear and admirable that we may now quite logically look ahead with confidence to the dawn of a better day in the coal industry.

The Mules Next of Kin, the Electric Locomotive

The cars are rarely chunked with coal in the modern mine, as is shown here, but roughly heaped up in the center being filled hurriedly by a shovel or conveyor. For this reason larger cars than ever are needed if tonnage is to be maintained. Some are using side boards to obtain the needed height.

Reconstructing a Tipple, Time Had Made Obsolete

Many companies are rebuilding their surface plants, coal-handling and preparation equipment, thereby saving in labor and producing a better prepared coal. The reconstruction job here shown has since effected a saving per year equivalent to about 25 per cent on the investment.

Mine Inspectors' Institute in Pittsburgh, Plans

Uniform Hoisting Signals and Elim Mines Initiates Terrific Explosion in Shoot Clear Across Valley—Company

From a Staff

PRESSING necessity for cheaper coal with resultant trials of new mining methods has brought fresh problems to mine inspectors and safety engineers. This was apparent at the annual meeting of the Mine Inspectors' Institute of America held in Pittsburgh, Pa., May 11, 12 and 13.

The registered attendance of over 120 men and the large program alike indicate that the institute is maintaining the progress started last year. Old timers say that it was the best meeting since the days of 1912 to 1916. Twenty-seven new members were admitted during the Pittsburgh sessions. Changes made to the constitution broadened the policies of the institute and made provision for more publicity.

Frank Hillman, safety inspector of the Woodward Iron Co., Mulga, Ala., and president of the institute, acted as chairman at all the meetings. The first two days were occupied by business sessions but the entire third day was devoted to an inspection of the U. S. Bureau of Mines experiment station and to a demonstration at the Experimental Mine.

SINGLE ENTRIES DREW NO COMMENT

On the first day, the members discussed single entries, explosive regulations and sprinkling. The paper "New Methods of Mining Single Entries in Their Development," by James Dalrymple, chief inspector of mines, Denver, Colo., drew forth many comments. As might have been expected, Mr. Dalrymple strongly opposes the driving of a single entry, his ideas being summed up in the following dictum, "The single entry is as old as mining and is as inefficient as it is old. Its inefficiency and dangers increase with its age."

It was understood that the term "entry" as used in the paper meant what is more commonly termed a room, scraperway, conveyorway, or the like. Although no one disagreed with the paper, the institute took no specific action to condemn the driving of long single rooms. Some interpreted this as a sign that many of the inspectors feel that the method is sure to come and that the ventilation problem must be solved accordingly.

A paper entitled "Regulations for the Use of Permissible Explosives," by Dr. J. J. Rutledge of Maryland, was constructively criticized. P. J. Callaghan, state mine inspector, Bridgeville, Pa., favored the elimination of the safety fuse, with the comment that electric firing is almost the exclusive practice in his section. He questioned the advisability of the practice of bringing out left-over explosive at the end of each shift.

Richard Maize called attention to the fact that the Pennsylvania law requires only a 5-min. wait before examination of a misfire, instead of one-half hour as recommended by Dr. Rutledge. Mr. Maize thinks that 5-min. is enough and inquired if a rule calling for short-circuiting of the electric wires at the firing machine or battery would not be a measure that would increase safety.

C. A. McDowell, manager, industrial relations department, Davis Coal & Coke Co., Thomas, W. Va., said that in the mines of this corporation, the men place their explosives with checks in the separate compartments that are provided in cars specially built for that purpose and destined each for its respective section of the coal mine.

WATER GOOD BUT DUST BETTER

A paper by Ed. Flynn, safety inspector of the Tennessee Coal, Iron & R.R. Co., Pratt City, Ala., on "Complete Watering System for Dust Control in Coal Mines" proved a disappointment to many. They were primed for an argument, but Mr. Flynn opened his remarks by stating, in effect, "I have no quarrel with the advocates of rock dusting." He claimed, however, that it was possible to fight the dangers of coal dust by water, and at the same time said that he believed

Digitized by Google

# of America, Assembled Safety Regulations

ination of Fuse Sought—Bureau of Mouth of Experimental Mine—Flames Seeks to Sack Dust from Cutter Bits

Correspondent

that rock dust will do all in the way of explosion prevention that its advocates claim.

He insists that as yet dusting has not solved the problem at the face and that water on the cutter bar of a machine is a necessity. This, he said, requires a permanent piping system which can readily be utilized for sprinkling the major part of the mine. He said that rock dust should be used on the main slopes and in like places which are on the intake air. Answering a question regarding the cost of watering a mine Mr. Flynn said that in a certain mine covering 2,750 acres and containing 575 working places the sprinkling force consists of fourteen men in summer and twenty in winter.

On the evening of May 11, the institute was entertained at the factory of the Mine Safety Appliances Co., where the employees were held overtime to demonstrate the steps in the manufacture of mine-safety and first-aid products. Parts of the new McCaa oxygen-breathing apparatus were seen in the process of manufacture and the new continuous methane recorder was on exhibition. After a dinner on the top floor of the factory, professional talent entertained the members.

At the opening of the meeting on Wednesday two resolutions pertaining to safety were adopted. The first offered by V. E. Sullivan, of West Virginia, called for a uniform code of signals in all states where men are hoisted. The standardization committee was directed to prepare a report on this subject recommending a code to be submitted to next year's meeting. The second resolution by F. W. Cunningham, of Pennsylvania, declared that the use of fuse for blasting should be prohibited at all coal mines.

S. S. Hall, of Pennsylvania, read a paper on "Falls of Roof and Coal." He said that more serious accidents are chargeable to falls than to any other cause and that 75 per cent of these falls are due to disobedience, carelessness, and bad practices. His deductions indicate that the highest accident rate from falls is among men of 15 years' or more experience.

Mr. Dalrymple said that the efficiency of the individual must be increased before material reductions can be made in casualties. Mr. Maize cited a case of a company in his district which reduced accidents 80 per cent by strict supervision. Though education of the individual was not belittled, the consensus of opinion seemed to be that proper supervision and direction were the most important factors in reducing this class of accidents.

A paper by Edward Steidle reviewed the "Present

Officers of the Institute During the Past Official Year and the Pittsburgh Meeting

Mine Inspectors' Institute's New Leader

During the coming year E. J. Hoey will direct the business of the Institute as President. Mr. Hoey is district mine inspector, at Christopher, Ill.

Status of Rock Dusting in the United States." Five per cent of the bituminous mines, representing 12 per cent of the bituminous production of the United States is now dusted. An aggregate of 1,200 miles of entry has been treated. He emphasized the fact that rock dusting is only an additional safety measure or a line of second defense and that no other safety practices should be relaxed after dusting. He claims that the cost will not exceed 1c. per ton and that actual figures per ton from a number of mines run from 0.2c. to 0.9c.

Captain Steidle took occasion to criticize severely Harry Phythyon's book, "The Rock Dust Remedy." Mr. Phythyon was not in the meeting to defend his views but was in attendance at the banquet in the evening.

Dust Cannot Hold Enough Water

J. W. Paul, chief mining engineer, U. S. Bureau of Mines, called attention to the fact that tests have indicated that the dust of certain coals will not hold enough moisture to prevent propagation.

It was said that the Consumers Mining Co. is working on a plan to take coal dust from the cutting machine at the face by a suction fan and to sack it at that point.

Self-rescuers were described in a paper by George H. Deike. He stated that today protection can be afforded by suitable gas masks against every known industrial gas. The explosion at Overton No. 2 mine was cited as an example of what can be done where self-rescuers are available. At this disaster many lives were saved by the use of these devices. Although the self-rescuers are rated as of ½-hr. capacity, tests have indicated limits of from 1½ to 5½ hours.

E. J. Gleim, substituting for L. C. Ilsley, of the Bureau of Mines, gave an illustrated talk on "Permissible Electrical Mining Equipment." Among the pictures of the latest approvals were the Jeffrey conveyor loader and shortwaloader, also the Ohio Brass Co.'s junction box for portable cable connections.

Officials Have High Fatality Rate

The last paper, by Dr. T. T. Reed and J. J. Forbes, "Comparative Fatality Rates" was read by Mr. Forbes. He prefaced his remarks by calling attention to a statement by R. N. Hosler that the percentage of fatalities among mine officials in Pennsylvania is as high as among the workmen. The paper dealt with an investigation to determine if, in the period from 1915 to 1925, there is any relation between the production per death and the production per man per day.

The individual curves for each state show little or no relation between these factors, but the summation curves for all states indicate that the two factors may be in some slight degree related. Since 1920 the production per man per day, has steadily increased and production per death has decreased.

Officers Were Elected

The following were elected officers for the coming year: President, E. J. Hoey, district mine inspector, Christopher, Ill..; first vice-president, William Boncer, chief of coal-mine inspection, Richmond, Va.; second vice-president, W. H. Jones, chief mine inspector, Lexington, Ky.; third vice-president, Nicholas Evans, district inspector, Johnstown, Pa.; secretary, G. B. Butterfield, general manager, The Associated Companies, Hartford, Conn.; assistant secretary, J. H. Griftner, chief inspector, The Associated Companies, Champaign, Ill.; treasurer, J. J. Rutledge, chief mine engineer, Baltimore, Md.; editor-in-chief, James T. Beard, senior associate editor, *Coal Age* (retired), Danbury, Conn.

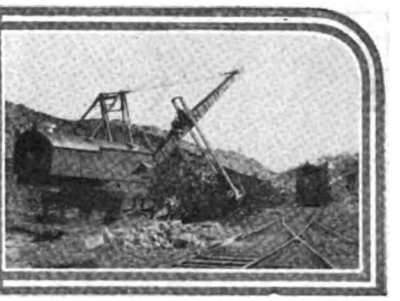
On Wednesday evening the Bituminous Mine Inspectors Advisory Association of Pennsylvania tendered a banquet to those attending the institute. J. T. Thomas, of Johnstown, acted as toastmaster, introducing the speakers: S. A. Taylor, J. J. Walsh, E. A. Holbrook, A. C. Fieldner, James Ashton, R. N. Hosler and J. T. Ryan. The climax of the evening was an address by a representative of the mining department of Russia, which representative proved to be the national entertainer, Luke Barnett.

Thursday morning, members of the Institute visited the various laboratories of the Pittsburgh experiment station of the U. S. Bureau of Mines. Among the new items seen were the continuous carbon monoxide recorder, the approved McCaa oxygen-breathing apparatus and the Fleuss-Davis breathing equipment which is also approved. The latter apparatus, which is made in England, uses an impregnated coke in a bag as the carbon-dioxide absorbent. This apparatus is a few pounds lighter than the Gibbs or McCaa.

To those who in the afternoon went out to the experimental mine at Bruceton, J. W. Paul promised, "probably the most spectacular coal-dust explosion that has been set off at the mine." None were disappointed. Flames shot out across the valley and gave the opposite hillside the most severe scorching it has ever had. The flames set the grass on fire in a number of places at least 100 ft. beyond the fence near the top of the opposing hill, thus extending 600 ft. or more from the mine portal.

Coal Dust Ignited Near Portal

In the preparation for this explosion no gas was used. Two pounds of coal dust per foot of entry was distributed from the mouth of the mine to a point 400 ft. inside of it. The dust was ignited by a blown-out shot consisting of 4 lb. of black blasting powder fired from a cannon at a point 180 ft. from the mine entrance and pointing outby.



This demonstration was but one of a number made during the afternoon at Bruceton, but it served as a fitting climax convincing any who might be skeptical that a blownout shot of black powder will produce an explosion of coal dust without the aid of gas.

Charleston was selected for the annual meeting to be held next year.

News Of the Industry

Consumers' Stocks of Soft Coal Total 40,000,000 Tons on April 1; 26 Days' Supply if Evenly Divided

Bituminous coal stocks in the hands of consumers on April 1, 1926, totaled 40,000,000 tons according to the U. S. Bureau of Mines. This is slightly lower than at a corresponding period last year, but about midway between the stock figures of June 1 and Sept. 1, 1925. The trend since the beginning of the year has been gradually downward to more normal proportions. Consumption continues to be more than production, which, during February and March, ranged downward from 12,167,000 to 9,626,000 tons a week, indicating greater inroads upon stocks.

At the rate of consumption prevailing during February and March this year, the supply on April 1 was sufficient to last 26 days. This is 11 days less supply than in March a year ago, the nearest like date for which figures are available for comparison, but four days greater supply than on March 1, 1923. If no substitution for anthracite had been necessary, the supply on Feb. 1 would have been sufficient for 31 days, but at the actual rate of consumption prevailing during January, the supply was enough for 28 days. The average days' supply figure, while useful for comparison with figures for other stock report dates, is not indicative of the true situation in many localities and industries, as individual supplies range from little or no coal on hand to very large reserves.

Upper Lake Stocks Near Normal

There were, in addition to the tonnage in consumers' hands on April 1, about 2,900,000 tons of coal on the Lake Superior and Lake Michigan docks; slightly less than 200,000 tons stored by the producers at the mines or at points between the mines and market; and approximately 1,000,000 tons loaded in cars but unbilled at mines. The first of these items is lower, as is normal at the end of the coal year, and the other two items higher, than on Feb. 1.

Anthracite and Substitutes. — With the resumption of anthracite operations in February, retail dealers' stocks of anthracite have increased considerably since the preceding date of stock taking, Feb. 1. Retail stocks of bituminous coal on April 1, while lower than at the time of the previous stock report, have not declined to any unusual or abnormally low level. Surplus stocks of byproduct coke at merchant plants on April 1, despite the record-breaking production during the two-month period under discussion, were even below the record-breaking minimum of Feb. 1, 1926, amounting to only 57,000 tons. At the beginning of the anthracite suspension, in September, byproduct coke stocks were 832,000 tons.

Estimates of the total quantity of soft coal in the hands of commercial consumers are based on practically complete reports from byproduct coke plants and steel plants, railroads and utilities, together with reports from a selected list of other industrial consumers and coal dealers—nearly 5,000 in all. The estimate for April 1, 40,000,000 tons, is believed to be accurate within 5,000,000 tons. It does not include coal in householders' bins, for which no estimate is possible, nor does it include the tonnage of steamship fuel in reserve. The tonnage on hand on the Lake docks also is omitted from this estimate but is included under the heading "Bituminous Coal in Transit."

Reports from consumers together with some supplemental information indicate that the average rate of all consumption plus exports during February and March was around 12,200,000 tons of bituminous coal per week. This rather high rate of consumption was caused partly by the activity of the coal-using industries typified by the large production of pig iron in March and the record breaking output of byproduct coke, and in part by the continued demand for anthracite substitutes. The weather continued cold and although production of anthracite was resumed Feb. 18, it was well into March before hard coal reached householders in volume sufficient to check the purchases of soft coal by householders who normally do not use it.

Comparison of the days' supply held by the principal consuming classes on April 1, 1926, with those on varying dates in 1919 to 1926 reveals that the reserves in every class were lower on April 1 than on Feb. 1, 1926. The greatest change was for coal-gas plants, which had a week's less supply on the last date than they had two months previously. The decline in supply held by other classes of consumers amounted to from one to five days only.

Reserves of soft coal on April 1, in terms of days' supply, differed widely, as usual, from state to state. The best indicators for this purpose are returns from the general industrial concerns, other than byproduct coke and steel plants. They are the largest single group of coal users, both as to number and tonnage consumed, and, being widely distributed throughout the country, their stores of coal are a sensitive barometer of conditions in the coal market. New England on April 1, was carrying considerable stocks of coal, four of the six states averaging close to 60 days' supply, the average for the entire region being 51 days. The stocks in the northern peninsula of Michigan also were maintained at a high figure the highest in terms of days' supply for any section of the country. In New York State stocks averaged 53 days, 6 days less supply than on Feb. 1. Lower Michigan was carrying 41 days' supply and Colorado 57 days. The remaining states show reserves varying from 8 to 45 days' supply, except Oklahoma, which shows heavy reserves.

As is customary, the utilities carried larger reserves than any of the other groups of consumers. The coal-gas plants on April 1 had a supply sufficient to run them, on the average, for 60 days, and the electric central stations had a 46-days' supply.

Byproduct coke and steel plants had a smaller tonnage in reserve than on Feb. 1, 1926, the decreases being two days' supply for each group. Complete returns from these important manufacturing classes indicate stocks on hand at recent dates as shown in Table II.

The total quantity of railroad fuel on hand April 1, according to information

Total Commercial Stocks of Bituminous Coal, July 15, 1918—April 1, 1926

Figures represent millions of net tons and include coal in the hands of railroads, industrial consumers, public utilities and retail dealers. Coal for steamship fuel, on lake docks, in transit and in the bins of householders is not included.

received from the American Railway Association, was 9,090,000 tons, or approximately a 23-days' supply.

Coal brought to the surface, made ready for the market, but not yet delivered to a retail dealer or a consumer may be considered "in transit." The largest element in this mobile reserve is the coal in railroad cars, which, though never accurately measured, is known to run into millions of tons.

A few bituminous producers store coal at their mines. The quantity stored April 1 was small. From a list of 43 companies who have at some time in the past stored in quantity at the mines or at some intermediate point, the Bureau has received reports of only 199,000 tons so held on April 1, or 30,000 tons more than the revised figure for Feb. 1, 1926, the date of the last stock report. In March, 1923, these same companies had 808,000 tons on hand.

The total quantity of unbilled coal in cars at the mines was 1,006,000 tons on April 1, as against 760,000 tons on Feb. 1, 504,000 tons on Nov. 1, 1925, and 600,000 tons on March 1, a year ago.

Reports from all companies show stocks of 5,176,000 tons on the Lake Superior and Lake Michigan docks on Feb. 1, and 2,892,000 on April 1, compared with 5,160,000 tons on March 1, 1922; 1,700,000 tons on March 1, 1923; 7,806,000 tons on Jan. 1, 1924; 3,840,000 tons on March 1, 1925.

Table II—Coal Stocks at Byproduct Coke and Steel Plants

BYPRODUCT COKE PLANTS

	Days' Supply as at Mar. 1, 1925	Feb. 1, 1926	Apr. 1, 1926
Low volatile	23	24	24
High volatile	26	23	21
Average	25	23	21

STEEL PLANTS

	Days' Supply as at Mar. 1, 1925	Feb. 1, 1926	Apr. 1, 1926
Steam coal	36	36	30
Gas coal	26	21	21
Average	31	26	24

By April 1, the date covered by this report, anthracite production had been resumed for about six weeks. It was not possible to obtain reports from all retail dealers, but a selected group who have been reporting regularly for seven years are covered in Table III. Of these dealers, 812 handled bituminous coal and 587 had handled anthracite on preceding dates. It will be seen that stocks of anthracite, which on Feb. 1 were the lowest for any date in recent years, except possibly in September, 1922, have been greatly increased, in fact more than trebled during the sixty-day period since the preceding stock report. Bituminous retail stocks, on the other hand, decreased nearly 400,000 tons during the two months, or slightly less than the increased tonnage of anthracite in the retail yards.

Table III—Coal in Yards of a Selected List of Retail Coal Dealers

(In Net Tons)

Date	Anthracite *a*	Bituminous *b*	Total
Jan. 1, 1919	958,225	1,499,737	2,457,962
March 1, 1920	737,139	631,431	1,368,570
April 1, 1921	1,126,973	1,007,638	2,134,611
March 1, 1922	1,074,628	1,089,871	2,164,499
March 1, 1923	272,378	763,525	1,035,903
June 1, 1923	643,780	1,087,880	1,731,660
June 1, 1924	1,071,894	1,035,485	2,107,379
March 1, 1925	1,150,534	1,069,352	2,219,886
June 1, 1925	1,221,840	980,947	2,202,787
Sept. 1, 1925	1,430,509	1,287,415	2,717,924
Feb. 1, 1926	200,737	1,278,972	1,479,709
April 1, 1926	625,959	898,924	1,524,883

a The number of dealers reporting their stocks of anthracite on each date was 587.

b The number of dealers reporting their stocks of bituminous coal on each date was 812.

A group of 21 byproduct coke plants supplying gas for city use reported only 51,000 tons of unsold coke on hand April 1, as against 246,000 on Jan. 1 and 87,000 tons on Feb. 1, 1926. The figure of 51,000 tons is the lowest one on record since October, 1923. Stocks of byproduct coke on other recent dates have been: March 1, 1922, 987,00 net tons; Jan. 1, 1923, 212,000 tons; Jan. 1, 1924, 772,000 tons; March 1, 1925, 606,000 tons.

Economy in Use of Fuel Stressed by Railway Men; Storage Not Practicable

Further fuel economies was the predominating thought among approximately 2,500 delegates at the eighteenth annual meeting of the International Railway Fuel Association, which opened a four days' session at Chicago, May 11. The program was filled with addresses and reports on fuel accounting, distribution and statistics, conservation and efficiencies in the consumption of fuel by the railroads.

Coal operators were prominent among the delegates. Thirty-one companies had placards in the "Coal Parlor" of the convention hall in the Hotel Sherman. W. H. Harris and Thomas Irwin, both of Chicago, were in charge of the coal division.

R. J. Elliott, purchasing agent of the Northern Pacific Ry., said that the railroads still buy and use about one-third of the 522,960,000 tons of bituminous coal produced annually, and that there is no indication of any great reduction of this consumption by reason of electrification, use of oil or other motive power, except purely local efforts in handling suburban traffic.

Storage of coal to equalize the fluctuations between the months of high and low demand is not considered practical because of the expense and inherent fire potentialities, according to the report of the association's standing committee on coal storage.

"The storage of coal," says this committee, "does not increase consumption, and so long as the available output of the mines is so far in excess of consumption, it is impracticable to equalize the monthly mine production by the storage of coal.

"Overproduction and excellent transportation produce keen competition with a resulting low price and a better quality of coal."

D. H. Pape, assistant to the executive secretary of the National Coal Association, suggested concerted buying of coal on an annual budget plan by private consumers, industrial users and railroads, in order to stabilize the mining industry and eliminate peaks and low production periods.

Railroad Fuel Costs Advance Slightly in March

Average cost of coal used by Class 1 railroads in locomotives in transportation train service during March was a little above the February figure, according to the Interstate Commerce Commission. The averages for the different districts are as follows: Eastern district, $2.72; Southern district, $2.22; Western district, $2.93; entire United States, $2.65.

These averages indicate an increase over February of 3c. per ton in the Eastern district; 1c. per ton in the Southern district; 2c. in the Western district, and 2c. for the whole United States. Compared with similar averages for March of 1925 there is a decrease of 14c. per ton in the Eastern district; 19c. in the Southern district; 18c. in the Western district, and 17c. for the whole country.

British Industry Nears Normal as Newspapers Reopen and Transport Service Resumes; Miners Still Out

The British labor situation is still grave. Although the general strike inaugurated at midnight May 3 was unconditionally called off by the Trades Union Congress on May 12, many men who went out in sympathy with the coal miners have not returned to work. In some cases employers refuse to discharge the volunteer workers who stepped into the breach. Peace apparently has been effected in the transport service through the signing of new agreements between the railways, city and interurban transportation systems and their men. Full-size newspapers also have reappeared.

The paralysis of coal production, however, continues. The government, in conformity with the promise made by Premier Baldwin, renewed its efforts at negotiating a new agreement in the coal fields as soon as the general strike order was recalled. Both owners and workers have asked for more time in which to consider the government proposals and the decision of the Miners' Federation will not be known until today.

Mr. Baldwin set out the government program in a letter to Evan Williams, representing the owners, and Herbert Smith, representing the miners. This program, made public in the House of Commons on Friday, provides:

(1) That steps shall be taken to put into practical effect the various recommendations for improving the organization and efficiency of the industry incorporated in the report of the Royal Coal Commission.

(2) That the government will grant an additional subsidy of £3,000,000 to be used in making up wage deficits during such period as may be necessary for the National Wages Board, with an independent chairman, to frame a national agreement which will govern the principles upon which district rates shall be ascertained and which will decide minimum percentages of base rates which must be paid.

(3) No reduction of subsistence rates below 45s. per week is to be made in the interim.

(4) That during this period there shall be a reduction in the minimum rates, other than subsistence wages, in all districts. The extent of the reductions is to be left to the negotiations set in motion by the government.

As the first steps in giving statutory effect to the Commission's recommendations, the government proposes to enact legislation on the amalgamations of undertakings (i.e., producing companies), a welfare levy on royalty owners, restriction of recruitment and the setting up of a wage board.

In the main, therefore, the government program is in accord with the memorandum submitted to the Trades Union Congress by Sir Herbert Samuel, chairman of the Coal Commission, as a basis for calling off the general strike. Sir Herbert, who appeared early last week in the rôle of peacemaker, proposed:

(1) That the coal subsidy be renewed for such reasonable time as might be required.

(2) That a national wage board, composed of representatives of the miners, mine owners and the public, with an independent chairman, be created and that this board revise the wage scales.

(3) That there be no revision of wages, however, without previous assurance that the reorganization of the coal industry recommended by the Commission would be executed.

(4) That a committee, with miner representation, be named by the government to prepare the legislative and executive measures necessary to effect a reconstruction of the coal industry.

Keystone View Co.

Sir Herbert L. Samuel

Chairman of Royal Commission, whose memorandum to the Trades Union Congress last week was the basis for calling off the general strike.

Lord Reading, former Viceroy of India, may be chosen neutral chairman of the suggested advisory committee for reorganizing the mining industry. Lord Reading has been in the Peers Gallery on every occasion on which the coal dispute was discussed and he was in conference with Premier Baldwin prior to the Cabinet meeting May 13, at which the whole situation was reviewed.

The lockout policy started by some British employers when the strikers applied for their old positions naturally has provoked considerable bitterness. The general dislocation of the industrial life of the nation has been so great that reports reaching this side of the water have given no clear measure of the extent of this lockout movement. When questioned as to his attitude on the subject, Premier Baldwin reiterated his pledge that those who had aided the government in the crisis should not suffer for their service. At the same time he expressed disapproval of retaliatory measures on the part of employers.

"I will not," he told the Commons on Thursday, "countenance any attempt upon the part of any employers to use the present occasion to get reductions in wages below those in force before the strike began, or to get an increase in hours. Last night I learned that a certain large group of employers was unwilling to meet the union concerned. I lost no time in broadcasting that I thought the essential associations of the employers and the unions concerned should meet immediately and discuss the many difficulties that arise in getting the men back to work."

Labor leaders in Parliament have protested vigorously against employers who decline to let the dead past bury

Ewing Galloway.

Miners' Wives Pick Coal from Big Colliery Waste Heap

Near Birmingham, Warwickshire, England. Apparently the men are leaving the work to the women, possibly arguing that it is a somewhat embarrassing situation being seen getting coal for themselves while denying the right of others either to get coal or to employ others to get it. Their answer probably would be, "One must live."

Digitized by Google

its dead and have hurled accusations of a campaign on the part of certain employers to smash the unions. To these charges the Premier has retorted that he would not countenance any such campaign. This particular flare-up arose out of the reported position taken by some of the railways. Later, however, through the good offices of the Premier, a settlement was effected.

By the terms of this settlement the railway unions involved admit that they committed a wrongful act in calling the strike and agree that they will not again instruct their members to walk out without previous negotiations. The unions promise no protection to members who engage in unauthorized strikes and exclude from the benefits of the agreement persons guilty of violence or intimidation. They further covenant that they will not encourage supervisory employees to take part in any strike. The settlement does not touch wages or working conditions. Neither does it provide that the reinstatement of the strikers waives any legal claim for damages which the railways may have against the men who walked out.

More Railroads Seek Bids

The Atlantic Coast Line will open bids on May 26 for its fuel requirements for the present year at its main offices at Wilmington, N. C. The exact tonnage to be let has not been learned. The bids provide for mine-run and 6-in. resultant, according to reports.

The Pere Marquette railroad will open bids at its main offices in Detroit on May 20 for its fuel business, which will consist of from 55,000 to 70,000 tons of coal for shipment into Canadian points and from 775,000 to 825,000 tons for use on its lines in the United States. Most of the coal to be shipped to points in this country will be delivered at Toledo and points in Michigan, it is reported. The company buys its coal on a basis of mine-run and 6-in. resultant prepared at the mines, and figures are submitted on this basis.

Sealed proposals will be opened by the Supt. of Lighthouses, Baltimore, Md., 2 p.m., May 27, 1926, for furnishing anthracite No. 3 coal and bituminous steaming coal for stations and vessels, 5th Lighthouse District, as required during the fiscal year ending June 30, 1927. Information upon application.

R. G. Archibald, state purchasing agent, Boise, Idaho, is preparing proposals for bids on the state's coal for the winter of 1926 and 1927. Approximately 15,000 tons will be required. Bids will be opened by Mr. Archibald on June 10.

Kansas Gas Blast Kills Four

Four miners were killed by a gas explosion at the Cigaret mine of the Lightning Creek Coal Co., Cherokee, Kans., May 14. James Jamison and George Hollis, top workers, were crushed under the tipple, which was wrecked by the explosion, and Hallie Jamison and Crockett Jamison, sons of James Jamison, met death underground.

Keystone View Co.

A. J. Cook

The secretary of the British Miners' Federation is frequently referred to as "Emperor" Cook, as he speaks his mind in no uncertain terms on labor policies.

Union Row Brings Suspension Of District President

Dissension among officials of District 21 (Arkansas and Oklahoma), United Mine Workers, culminated May 10 in the suspension of William Dalrymple as president by the district executive board, meeting at Muskogee, Okla. The vote was five to two. A hearing on secret charges will be held in Muskogee this week before the board.

Marine Corps Wants Coal

Bids will be received for coal requirements for the U. S. Marine Corps on May 27 at the office of the Quartermaster, Room 3207 Navy Building, Washington, D. C. Tenders are wanted on the following items: 29,000 tons of mine-run low-volatile bituminous steaming coal; 18,500 tons 2x4-in. semi-bituminous coal; 5,000 tons Pulaski (Va.) anthracite stove coal, and 4,000 tons of mine-run low-volatile semi-bituminous.

Denies Exclusive Right To Label Coal

Judge Foster Symes of the U. S. Court in Denver, Colo., has just released his decision denying an injunction to the Victor American Fuel Co., which filed a complaint a year ago against several coal companies in Colorado in connection with the labeling of coal. In its complaint the Victor American company alleged, first, that it had the exclusive right to label coal by virtue of copyright and, second, an infringement upon the label and the labeling of coal by their competitors. Judge Symes held that the complainant did not have a right to monopolize the labeling of coal and that there was no infringement upon the labeling of coal as alleged in the complaint.

Pittsburgh Non-Union Mines Have Another Recruit

The Clinton Block Coal Co. has opened its mine at Imperial, Pa., on the 1917 scale. This adds one more mine in the Pittsburgh district to the list of non-union operations, which are in excess of the remaining union operations. About 50 men went to work in the mine. One of the officials of this company is B. H. Canon, who was chairman of the executive committee of the Pittsburgh Coal Producers' Association at the time it dissolved.

The Lowber Gas Coal Co., which operates a mine near Fayette City, Pa., has posted proclamations in various places in Fayette City inviting its former employees to return to work on the 1917 scale. No date is given when operations will be started.

The Peters Creek Gas Coal Co., operating the Piney Fork mine, near Finleyville, Pa., has closed down. The mine has been operating on the Jacksonville scale. According to a report in Pittsburgh, the management asked the men to return to work on the 1917 scale and about 20 responded. Reopening was thereupon deferred for the time being. The Braznell Brothers are the heads of this company.

Two more strikes are on at mines in the Pittsburgh district which had been operating on the Jacksonville scale. In each case the reason given was operating other mines of the companies on the lower wage rate.

Close to 500 men are reported out at the Charleroi mine of the Youghiogheny & Ohio Coal Co. This company recently started its mine at Wyano, Pa., on the 1917 scale, although the location of the mine is generally considered to be in the non-union district.

A strike also was called at the Rich Hill mine of the McClane Mining Co. at Meadowlands.

Fuel Yard Bids Vary Widely

Bids on coal requirements of the Government Fuel Yards, U. S. Bureau of Mines, opened May 12, revealed a wide price range. On 22,000 gross tons of bituminous nut and slack the prices named ranged from $1.40 for ¾-in. to $2.30 for 1¼-in. For 148,000 tons of mine-run the lowest bid was $1.60 and the highest $2.56. Tenders on 1,800 tons of bituminous egg were from $1.85 to $4.46; Broad Top egg, $3.60 to $5.04. For 41,000 tons of mine-run, nut-and-slack or slack the bids ranged from $1.12 on nut-and-slack to $2.35 for mine-run. On 27,800 tons of mine-run, nut-and-slack or slack the quotations were from $1.12 to $2.25 for mine-run.

Coal Absorbs Trade Journal

Coal Trade Journal, beginning with this week's issue, will be merged with *Coal*. The Coal Publishing Corporation, publisher of *Coal*, according to an announcement May 12, has acquired ownership and control of the *Coal Trade Journal*, which was founded in 1869. R. C. Beadle becomes the publisher of the merged publications, and F. R. Wadleigh, editor of *Coal*, retains that post on the consolidated papers.

Coal Hearings Ended; Parker Bill Provides for Fact-Finding, Mediation And Emergency Distribution Control

By Sydney A. Hale

Washington, D. C., May 18.—Public hearings on coal legislation which have been going on intermittently before the House committee on interstate and foreign commerce since March 30, came to an end last Friday afternoon. Members of the committee now are considering what action they will take. Following an executive session this morning, it was intimated that the committee report might not be ready before next week.

In the opinion of many, however, the committee program is foreshadowed in a bill introduced in the House yesterday by Chairman James S. Parker. This bill, setting up fact-finding, mediation and emergency distribution control, follows the recommendations of Herbert Hoover, Secretary of Commerce, who appeared before the committee on May 14. In a sense, therefore, the Parker bill may be said to embody the ideas of the administration leaders on coal legislation. Its author hopes to see it enacted into a law before Congress adjourns.

The new bill makes the Bureau of Mines the coal fact-finding agency and compels the industry to furnish information to the Bureau. Refusal to do that would subject the offender to the danger of fine or imprisonment. In the event a labor dispute threatens production, the President may appoint mediators or direct the Secretary of Labor to endeavor to effect a settlement of the controversy. The Secretary of Labor may encourage arbitration, but no attempt is made to compel arbitration.

The bill also empowers the President to declare a state of emergency whenever labor disturbances or threatened labor disturbances menace the coal supply. If the menace becomes an actuality, the President may revive the Federal Fuel Distributor Act of 1922 and have the Federal Fuel Distributor co-operate with the Interstate Commerce Commission in controlling distribution.

Seizure Provision Unlikely

The likelihood that Chairman James S. Parker and his fellow committeemen will go further and seek to authorize government seizure and operation of mines during times of emergency is not strong. Such a provision was stricken from the Copeland bill when the Senate committee on education and labor reported out the New Yorker's measure last week. Neither the operators nor the miners favor such a proposal and it has found little support from most of the other witnesses who have appeared before the House committee.

Concluding his testimony on May 13, Walter Gordon Merritt, general counsel for the Anthracite Operators' Conference, stressed the fact that the power to regulate interstate commerce was subject to the other provisions of the Constitution and that Congress could not do indirectly what it was barred from doing directly. The Federal Fuel Distributor act, he felt, was of doubtful validity. Where transportation was adequate, Congress could not regulate coal by controlling transportation facilities. Neither could it seize coal for private purposes.

"Do you say," demanded Congressman Newton (Minnesota), "that Congress has no power to keep the wheels of industry moving?"

"There is no such power, in my opinion."

"I'd like to take a chance on it," retorted Mr. Newton.

Summarizing his remarks on publicity, Mr. Merritt pointed out that the industry already furnished voluminous reports on valuation, prices, profits, investment, expenses, depletion, insurance and taxes to the Bureau of Internal Revenue; data on employees, occupations and wages to the Department of Labor; detailed tonnage and realization reports to the Bureau of Mines, and various reports on operations, labor, earnings, prices and wages to the State of Pennsylvania. If Congress insisted upon fact-finding, he asked that it should not add to the burdens of reporting but arrange for duplicates of reports already filed.

Representative Dennison (Illinois) wanted to know whether the operators would object to making public their reports to the Treasury Department. Some producers, was the reply, would have very strong objections. Some operators, he added later, might carry any law passed to the Supreme Court. But fact-finding, he reiterated, would not cure the ills of the industry.

Competition Public's Protection

Competition from other fuels, said Mr. Merritt, was the best public protection against oppression. If operators were allowed full freedom to cooperate in production and distribution, they could save the public money—particularly in distribution—and fix responsibility for quality and price. Some operators think the rate relationships between bituminous and anthracite prejudicial to the latter and will endeavor to force readjustments, particularly on the steam sizes.

Mr. Merritt indorsed the recommendation of the Coal Commission that there be no fixed expiration for wage agreements, but that either party wishing a change in the rates and conditions give ninety days' notice. If at the end of thirty days no agreement had been reached, a Presidential board would have sixty days in which to study the question and make recommendations. Full freedom of action should be reserved to the workers at the expiration of the ninety-day period; not because the operators want it, he said, "but because the mine workers want it and are entitled to it."

Edgar L. Wallace, American Federation of Labor, centered his attack upon the mediation proposals. Any attempt to set up such agencies, he said, will only interfere with settlements within the industry. Men cannot compromise their differences or work in the spirit of collective bargaining when there is an adjudication board on the horizon. "Is it in the interests of the country that differences between the operators and the miners shall be settled by an outside party?" he asked. There was no general strike in the bituminous coal industry between 1897 and 1919; there would have been no strike in 1919, he declared, had it not been for government war-time intervention.

Secretary Hoover

Outside mediation, he contended, only increases the bitterness between capital and labor. Each side tries to make out a case by attacking the other and in time comes to believe "the facts" set up in argument, thus making real cooperation impossible. If the government fixes wages, it must also fix profits; because of varying costs, it would be compelled to fix such prices upon a basis which would yield the high-cost mines a profit.

Major legislative interest in the coal industry, stated Mr. Hoover in his testimony Friday, centers around the problem of labor relations. Given continuous production, the public is amply protected in prices by competitive processes. Transportation no longer looms up as an interrupting factor. The anthracite industry already has taken the first steps in settling its labor problems for a term of years. If the unionized section of the bituminous industry "could set up its own mediation board in the same terms as the anthracite industry, I believe Congress would be well justified in suspending any legislative action."

"If, however, there are to be periodic interruptions to bituminous mining, then outside mediation will be necessary. Most coal suspensions have been brought to an end sooner or later by such mediation, said Mr. Hoover. Power to appoint mediation boards, therefore, should be lodged with the President. The board, however, should not be a permanent agency, "as it is best to bring new minds and new men on the scene in such emergencies." These men cannot function without the basic facts on production, distribution, stocks, consumption, wages and average prices. "If the industry could

Digitized by Google

furnish these facts regularly and reliably of its own volition, it would be better that it do so than to put the government to the expense."

Where mediation fails and the suspension is widespread, some provision must be made for fueling essential services. "Thus it seems to me there are three things to be considered by the committee at the present time: An emergency mediation board, emergency authority to the Interstate Commerce Commission in coal distribution, and, in failure of provision by the industry, a more effective service as to primary facts. This is not regulatory legislation—and would come into action only in failure to maintain production."

The measures discussed before the committee, continued Mr. Hoover, deal only with symptoms of much more deep-seated diseases. The fundamental ills of the bituminous industry center around two main causes—too many mines and the seasonal character of the business. "The net result of all this is that we have part-time operation of too many mines and the final consequence that most workers, especially in the commercial mines, are only employed part time. While the daily wage is usually very high, it does not for some fraction of their number constitute even a decent annual living. The bituminous industry is in long view a losing business in the periods between famines and no unprofitable industry can give satisfaction either to consumer, worker or operator. From all these causes arise most of our labor friction."

Stabilizing Influences at Work

Mr. Hoover, however, saw certain forces at work remedying some of the fundamental ills. War stimulation has passed. Car shortages have disappeared. "The annual demand for coal will increase despite constant improvement in methods of fuel consumption. Oil and other substitutes are not likely to displace coal in so relatively large proportion in the future." Growth of public utilities and byproduct coke plants will help to stabilize production. Storage by large consumers also will help. Sharp competition has tended to a permanent closing of some of the high-cost mines, although its effects have been somewhat obscured by expansion in non-union areas. Some consolidations have been made. There has, in a broad sense, been steady improvement in methods and equipment.

"The various forces in motion are on balance making for greater stability in the industry—although obscured by cross-currents. I do not believe its fundamental difficulties can be corrected by regulatory legislation. There is no parallel in a competitive industry such as this with the railways or public utilities, which occupy a semi-monopoly of some area or market. Regulation of prices, profits, the right to produce or wages would not secure cheaper coal nor would it solve the major questions of labor relations—it would result in a score of worse ills. I dismiss government ownership and operation as a calamity to workers, consumers and government. What we must hope for is a greater vision of leadership in the industry to the correction of its own difficulties."

George Otis Smith

The claim of Philip Murray, international vice-president, United Mine Workers, that the term and rates embodied in the Jacksonville agreement had been suggested by the government (*Coal Age*, April 22, 1926; p. 577) was denied by Mr. Hoover. Answering a question of Congressman Merritt (Connecticut), the Secretary of Commerce said:

"So far as I am aware, no suggestion was ever made as to the term of the contract. Both Mr. Davis, Secretary of Labor, and myself urged the operators and miners to convene at Jacksonville. The Jacksonville conference was the sequence of a provision in their former agreement. Difficulty arose as to whether the operators would attend that conference, and Mr. Davis and I both devoted ourselves to urging that they should get together, in the hope that they would be able to settle their difficulties without a lockout or strike. We made no suggestion, or at least so far as I am aware, no suggestion was ever made as to the term of the contract or the rate of wages."

"Has the result of that agreement, such as they did make, been to throw a large part of the business into the non-union fields?" asked Mr. Merritt.

Non-Union Output Helped

"I think the result has been to increase the productivity in the non-union fields. I think that at least is the superficial appearance. You are dealing there with a hypothetical question. Assuming that the wage rate under the Jacksonville agreement had been 25 or 30 per cent less, it is probable that the non-union fields would have decreased their wages to some point 20 per cent below the standard, and the same effect would have taken place. So I do not believe that any one can say it is a certainty that the increase in the non-union fields would not have taken place if the Jacksonville agreement had not been fixed at such a rate."

The bituminous industry, he told Congressman Hoch (Kansas), was deficient in vital statistics on stocks and consumption. Such data would have a stabilizing influence. Emergency government operation, he said in answer to questions by Congressman Lea (California), would not cure the situation and would lead to great economic loss. "Most of our vital industries have managed to find a solution to the problem of continuous production and we practically forget their existence. I have never despaired that the bituminous industry also will find an answer."

The picture of conditions presented by the Coal Commission report, said Dr. Smith, is still a true one, but it is incomplete. What is needed is continuous, not sporadic, fact-finding. Justice to the public and to all parties in the industry can best come "and is most likely to come if and when the facts are known." Dr. Smith did not agree with those who contended that fact-finding would put an enormous financial burden on the industry and on the government, but "whatever the facts cost, the results will be well worth it."

Dr. Smith reiterated his opposition to government operation of the coal mines, but was as vigorous in denying that the government had no jurisdiction over the coal business. "Neither unregulated private operation nor inefficient government operation can be regarded as safe and economic." If we can regulate a public utility supplying energy in the form of gas or electric current, why may not coal, which supplies energy in a solid form, also be regulated? Regulation of public utilities has had no blighting effects upon efficiency or upon earnings.

Wants Labor Trust Controlled

"The real issue as I see it is the sovereignty of the American people in relation to those who own coal mines or work in coal mines. Is the people's right to an uninterrupted supply the dominant right? We have outlawed combinations of capital attempting restraint of trade or even control of prices and with public opinion strengthened by a full knowledge of the facts. I would like to see legalized such combinations of capital as intend to promote trade and lower prices, as larger and stronger companies surely can. But I wish also to see brought under legal control any countrywide combination of labor which has the declared purpose of enforcing its own decrees by creating public distress.

"Fact-finding is not the cure, but is the route toward betterment of the coal industry for all concerned. Private business depends upon public opinion and well-informed public opinion is both more effective and more just. I urge fact-finding as promising the best argument for the continuation of private initiative—as proved in the public regulated public utilities."

Ira C. Cochran, commissioner, American Wholesale Coal Association, the last witness heard, after analyzing the functions of the wholesaler, pointed to the various service orders issued by the Interstate Commerce Commission as evidence that provision already had been made for emergency distribution control. Compulsory fact-finding would throw a great and costly burden upon the coal man which would be included in the price of his product without giving the public any compensating advantage. "We believe," he concluded, "that the wholesale branch of the coal industry is functioning effectually and economically and we are unable to suggest any regulation that would further serve the public interest."

Urge Self-Government, Higher Efficiency And Less Waste in Business

Self-government in businss, but a self-government that recognized the social obligations of industry, was the keynote of the fourteenth annual convention of the Chamber of Commerce of the United States, held at the headquarters of the organization in Washington, D. C., May 10-13. "There is great hope," declared Herbert Hoover, Secretary of Commerce, at the annual dinner of the Chamber, "that America is finding herself upon the road to a solution of the greatest of all her problems—the method by which social satisfaction is to be attained with the preservation of private industry, or initiative, and a full opportunity for the development of the individual."

These newer ideals also received the attention of Governor Albert C. Ritchie of Maryland, who pointed out that business was no longer concerning itself solely with profits but was beginning to ask "whether the consumer is getting a square deal," whether distribution costs were out of line, whether concentration of industrial power and of wealth is going too far. "And when business once asks these questions and admits the need of an answer, I believe it can give it better than government can."

Another phase of the more advanced industrial thinking was elaborated upon by P. W. Litchfield, president, Goodyear Tire & Rubber Co., who took the position that wages should be the last to feel the force of business depression. "It used to be thought," he said, "that the first thing to cut when profits began to shrink was wages. It is now recognized that this condition should be met by increased efficiency, elimination of waste, the cutting down of overheads in production and distribution, and an attempt to maintain wages, because a general cutting down of wages curtails the demand for the finished products of industry, the demand for which is the very life-blood of prosperity."

Individualism Paramount

Business decays and civilization falters, asserted Julius H. Barnes, president, Barnes-Ames Co., when industry becomes the prey of oppressive governments and favoritism is substituted for equality of opportunity. This has been the history of the world from the hazy days of the Sumerian empire down through the dark years of the Middle Ages. Prosperity and society rest upon the possession of natural resources, the habits of industry and a stable and sound government. So long as America retains efficiency in its habits of industry and a sound government based upon the philosophy of individualism it can continue to enjoy the fruits of its heritage of natural wealth.

The problems peculiar to coal came up for consideration twice. The first time was when Walter Barnum, president, Pacific Coast Co., discussed the situation before the group meeting of the division of natural resources. At the conclusion of this address, in which Mr. Barnum insisted that the coal industry would and could function best in the national interest if left unhampered by government regulation, the group meeting adopted the following resolution:

"*Whereas*, Some citizens are making an increasing effort to persuade the federal government to inject itself into the business affairs of private industry, and

"*Whereas*, Proposed legislation now before Congress affecting the coal industry must mean, if enacted and sustained, the ultimate regulation and control of all branches of that industry, and

"*Whereas*, Such legislation would undo an improving situation by making it possible for either party to labor disputes to appeal to a political tribunal and would have a tendency to bring about conditions similar to those in Great Britain today, conditions directly traceable to governmental interference and continued appeal to the court of politics; therefore, be it

"*Resolved*, That the natural resources production division of the Chamber of Commerce of the United States hereby asserts its unalterable opposition. to and urges the Chamber to oppose legislation directed toward government interference in private business, whether it be coal or otherwise."

Oppose Coal Control

When the resolutions committee of the Chamber had finished its consideration of the proposal, the resolution reported to the Chamber and adopted by it read as follows:

"Regulation and control of the coal industry are proposed in divers ways by bills which are pending before Congress. We therefore consider it appropriate to reiterate the position of the Chamber of Commerce of the United States in opposition to proposals which have for their object the control of industries by governmental agencies."

According to Mr. Barnum, there is no more "coal problem" than there is the problem of obtaining a supply of other necessaries of life. Relatively and actually the coal industry can be proud of its record and there is nothing in proposals for government interference which justify a belief that such interference could improve the situation. Opposition of the industry to fact-finding as a form of regulation "is based solely on its compulsory feature and on the fact that no man can tell where it will end. You cannot give assurance of uniform profit to a business so widespread and so competitive within and without its own ranks as is the bituminous coal industry."

Notwithstanding the fact that coal must be produced where found, be it forest or plain, desert of mountain, efficiency is not a stranger to the coal business. Neither is stabilization unknown. In the ten years preceding the World War average spot mine prices on bituminous coal held to a $1@$1.25 level. There were, it was true, violent fluctuations during the war and reconstruction periods, but at no time did the American consumer pay as much as Continental European coal users.

These causes of fluctuation have been removed. The danger of a transportation shortage has been eliminated. The great increase in non-union operations makes an effective nationwide strike impossible. The curve of prices and realizations, therefore, is again flattening out. There will be no violent change "unless there is another war or government interference."

The industry also is co-operating to improve coal combustion processes and consumption technique. Its so-called overdevelopment, which has been the salvation of the country during strikes, is less than that of certain other industries held up as models of efficiency. It leads the world in output per man. The percentage of machine-mined coal is three times that of Great Britain. The product is sold at prices which have given the nation the cheapest power supply in the world.

America, said Mr. Hoover, is gradually adjusting its industrial system to the instincts of industrial freedom and equality of opportunity. The country is developing a new relationship in industry which is departing widely from the conceptions of the old world. In wages, American industry has discarded the theory that the lowest rates of pay and the longest hours marked the roads to the lowest production costs and the highest profits. Labor, too, is abannoning the idea that restriction of individual output guarantees employment to the many.

"No one will doubt that labor always has accepted the dictum of the high wage, but labor has only gradually come to the view that unrestricted individual effort, driving of machinery to its utmost, and elimination of waste in production are the only secure foundations upon which a high real wage can be builded, because the greater the production the greater will be the quantity to divide."

Co-operation Brings Betterment

The greater development of the cooperative sense in industry also is contributing to business and social betterment. Associations have been created and expanded. The ethics of business have been elevated. Larger production units are coming into play although the public thinking on size is muddied by old conceptions of the effectiveness of ruthless competition. But mass production does not necessarily imply monopoly. "What we sorely need is thoughtful consideration directed to the essential question of how to maintain real competition, instead of legalistic formula; how to substitute constructive competition for destructive competition."

Mutualization and diffusion of stock ownership in many industries have made management ascendant over ownership in the control of business policies. The lessened pressure to enlarge profits has in many cases brought decreased prices, higher wages and more liberal expenditures for scientific research.

"Some of our industries have lagged behind others in the march toward stability, although they have kept up the march of efficiency. The bituminous coal industry, due to war expansion, destructive competition and other causes; the textile industry due to migration South and West, and especially some important branches of the agricultural industry are not yet in that stable condition which the nation requires."

British Muddled Through Again in Ending Tie-Up, Is Washington Opinion

By Paul Wooton
Washington Correspondent of *Coal Age*

Settlement of the general strike in the United Kingdom appeals to some in Washington as being typical of the ability of the British to muddle through. The nation's genius for negotiation and compromise again has carried them through a situation which was loaded with more evil possibilities than any other world development since the great war.

From the somewhat conflicting reports available at this writing it appears that the struggle has been a test of the general strike more than a determination of the mine-wage dispute which caused it. It was inevitable that the general strike should be tried. As long as it was untried some would be sure to urge it periodically and it would have continued to hang, sword-like, over the British people.

The test has shown that the general strike is a much less formidable weapon than the unions supposed. It did not bring the country to its knees. At the end of the nine days food prices had increased but little. The reaction of the people of the country in favor of the government and against the group threatening constituted authority with force developed as it had been predicted by the spokesman for the government.

On the other hand, the strike was more effective than the Tory extremists predicted. The enormous loss of production, the stoppage of foreign trade and the effective way in which obstacles were placed in the path of most industrial activity impressed the government sufficiently that it was willing to make material concessions.

Dispute Back Where It Started

The memorandum of settlement, to which the Conservative leaders must have agreed, tacitly at least, although the only name connected with it is that of Sir Herbert Samuel, chairman of the Royal Coal Commission, simply throws the coal dispute back where it started. After vowing that it never would consent to a subsidy after May 1, the government now obligates itself to continue the subsidy for "a reasonable time." Instead of standing pat for the wage recommendation of the Commission the question is to be referred to the national wage board on which operators and miners are to be represented with the "neutral element" under an impartial chairman. What is this but our old friend arbitration?

The trend toward socialism in Great Britain has been increased by this policy of compromise and evasion. There was a shortage of housing, so the government embarked in the house-renting business. In 1923 the ratio of unemployed to the total population was no greater in Great Britain than it was in this country, but instead of arousing the Kingdom to a great co-operative effort to provide employment, as was done here, Great Britain provided a dole and is still paying it. Such policies as these have extinguished the initiative of the people.

Daniel T. Pierce
Vice-Chairman, Anthracite Operators' Conference

France had a general strike once but the authorities rose to the occasion—called all classes to the colors—and the strike lasted twenty-four hours. Germany is working her way up from the bottom and labor is co-operating. Mussolini has saved the people of Italy from just such a situation as developed in Great Britain. If he restores democratic government he will go down in history as one of the world's greatest political leaders.

Among the British there has been no general effort to get the industrial establishment on a better basis. There has been no increased installation of labor-saving devices. The scientific and economical methods of generating and distributing electricity have lagged. We have extended power to the elbow of every workman. London still is served by twenty-eight central power stations. Instead of taking advantage of an exceptionally advantageous position for the installation of a great superpower system the British were busy with compromises—doing such uneconomic things as shortening the hours of labor so there would be more jobs or paying out subsidies of one kind or another. As a result the "workshop of the world" no longer is able to compete.

Hardens Class Feeling

It is hard to see how any good can come from the strike. The results all seem to be liabilities. One effect has been to freeze class feeling and to pave the way for more radicalism.

Thanks to the virility of our business, industrial and political leadership we have come through the hardest period in the economic history of the country with socialism and radicalism less in evidence than at any time in twenty-five years. Despite the gigantic losses of the war, we have raised the standard of living to a higher point than ever has been reached before. This has been done by correcting fundamentals and not by trying to compromise things of a social and economic character.

One thing, however, is certain. The British have shown no disposition to abandon the ballot box in favor of class force.

Score Hard-Coal Preparation At Retailers' Convention

Washington, D. C., May 17.—Sharp criticism of post-strike preparation of coal by anthracite mines broke as an unexpected climax to the first day's session of the ninth annual convention of the National Retail Coal Merchants' Association at the New Willard Hotel today. Daniel T. Pierce, vice-chairman, Anthracite Operators Conference, had just finished an eloquent plea for greater co-operation between the producers and retail distributors and an exhortation to the industry to clean its own house, when the criticism was voiced. Roderick Stephens, chairman of the governmental relations committee of the association, asked the delegates whether he was correct in asserting that sizing standards had not generally been maintained since the strike ended and that shipments with more than the permissible percentage of undersize had been common. A sea of upraised hands indorsed his statement.

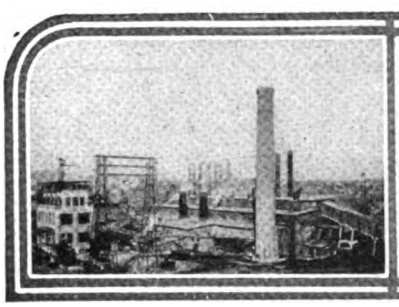
Mr. Pierce's address was the feature of the afternoon session. He declared that the door was wide open for contact between the producers and the retailers. The anthracite industry, he said, intended to fight to the limit to retain its markets and to maintain its standards. Reputable producers did not want to ship poor coal and did not intend to allow poor coal to be shipped. They planned to use the peace won by the recent wage pact to expand and intensify their merchandising program.

The morning session was devoted to the presentation of reports from officers and committees. President Samuel B. Crowell presided.

Columbus Mining Co. Obtains Four More Mines

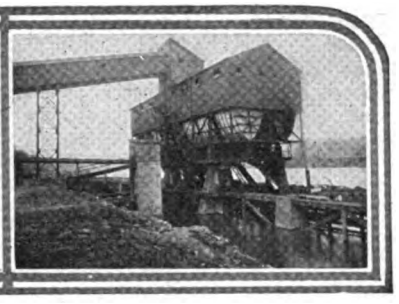
The Columbus Mining Co., eastern Kentucky operators with headquarters in Chicago, has taken over the sale and distribution of four additional mines in eastern Kentucky, it was learned last week. The company now has twelve mines in the field having an aggregate daily tonnage of between 6,000 and 8,000 in the Hazard and Elkhorn fields, producing from beds Nos. 4, 7 and 9.

The new mines are the Meens Haskins Coal Corporation operations No. 1 and No. 2, at Vicco; the Diamond Block Coal Co. mine at Diablock and the Apex Elkhorn Coal Co. operation at Millstone.



While the company is merely the selling agent for the mines in the new transactions it is expected that the operations will be controlled by outright purchase within thirty days.

The Columbus Mining Co. began in the eastern Kentucky field in 1917 with one mine and has expanded to its present capacity of twelve in nine years.



Halt Rail Efficiency Probe

Investigation into the efficiency and economy of management of the country's common carriers has been discontinued by the Interstate Commerce Commission. No reason was given for the action. The inquiry was instituted after the shopmen's strike in 1922.

News Items From Field and Trade

ALABAMA

The eighth annual Alabama first-aid contest will be held in the City Auditorium, Birmingham, July 10. The various committees on arrangements are now planning the details, and indications point to the most successful event of the kind yet held. Intensive training is being carried on at mining centers throughout the district, the work being aided by officials of the local Bureau of Mines, of which C. E. Saxon is foreman miner and F. E. Cash, district mining engineer. The Alabama Mining Institute, through its secretary, James L. Davidson, and assistant secretary, H. E. Mills, is giving the event its undivided attention.

Receiver for Goodwin Co.—The Goodwin Coal Co., with a mining operation at Goodwin, near Dora, Walker County, has filed a petition in bankruptcy in the U. S. District Court at Birmingham. Liabilities were given as $144,341 and assets $173,641.39, the latter consisting of notes, machinery, etc. Milton H. Fies, of Birmingham, was appointed receiver. The company began business in 1925.

Galloway Plant Burns.—The Galloway Coal Co., with head offices in Memphis, Tenn., and a number of operations in the Carbon Hill section of Walker County, suffered a loss of $75,000 to $100,000 when fire destroyed its tipple and washery at Holley Grove mine on the night of May 7. It is understood that the plant will be rebuilt at once.

ILLINOIS

No. 7 mine of the Consolidated Coal Co. of St. Louis, one of the biggest at Herrin, has been shut down for an indefinite period. Slack market and necessary repairs were the reasons for the shut down. The mine employed about 500 men.

New Record by O'Gara.—The O'Gara Coal Co.'s mine No. 1, just south of Harrisburg, broke the company's record for daily production on May 1, when 3,202 tons of coal was mined, hoisted and placed in railroad cars in an eight-hour shift. This broke the record of 3,137 tons held by the company's No. 9 mine.

The Taylor-English mine, located nine miles southwest of Danville, which employs about 600 men when working at capacity, reopened early in May, after having been closed since June, 1, 1925.

The tipple and all top buildings at the Firbury mine were destroyed by fire May 9. It is improbable that they will be rebuilt as the expense of a steel tipple and other items required by law, coupled with the high costs of operating, will make it impossible for the mine to compete with non-union shafts.

INDIANA

Evidence to show that the abandonment of the Central Indiana R.R. between Muncie and Brazil is justified on account of operating losses, was submitted before Clyde H. Jones, member of the Public Service Commission, by representatives of the Big Four and the Pennsylvania railroads, joint owners of the line. Opposition to the abandonment of the road was voiced before the Commissioner by business men, farmers and others living in the territory through which the road operates.

The Vandalia Coal Corporation, a Delaware corporation, has qualified to engage in coal mining in Indiana. The company has 14,128 shares, of no par value. Agent for service of process, Robert W. McBride, 1239 State Life Building, Indianapolis.

KANSAS

The Stephenson-Fenimore Coal Co., of Pittsburg, Kan., was granted a charter May 7 by the Kansas state charter board. The company, of which J. J. Stephenson and James Fenimore are principals, is capitalized at $100,000. It has purchased and will operate a strip pit, known as Reliance No. 1, near Midway. The purchase was made from the Reliance Coal Co. and included the steam shovel at the mine and fee to 100 acres of coal land. A mining lease on 400 adjacent acres, of which about 100 acres is underlaid with coal, also was obtained. Mr. Stephenson and his son opened the mine in 1914 and operated it until 1917, when they sold it to the Reliance company, which operated it until the sale, late in April to the new company. The 400 acres of leased land also belonged to the Stephensons until 1917. They sold it then to Hugh Beasley, from whom the Stephenson-Fenimore company leased it.

MINNESOTA

Ford to Acquire Superior Dock.—Indications are that the Ford interests will close the purchase of the old Superior Coal & Dock Co. dock at Duluth. A decision has been reached in the matter of taxes, which had been in litigation, and it seems likely that the purchase will be made.

The Brown Coal Co. has moved its offices from the Security Building, Minneapolis, to the new Baker Building.

MISSOURI

Coal Development is being undertaken in the northeastern part of Barton County, which, if successful will extend the Pittsburg field. The Duvall Loan Co. and the Sherwood Coal Co. have opened offices in Milford. Both concerns own large acreage and are optioning additional land for purchase at $40 to $70 an acre. The Duvall company has much drilling and J. B. Duvall, the field manager, has indicated that the results warrant the installation of steam shovels.

U. P. to Build—The Union Pacific Coal Co. will spend $359,904 for new buildings and new machinery during the next year, according to the budget recently adopted by the board of directors. One of the chief improvements will be the erection of a new building in Rock Springs to house all general offices of the company, which are at present in three buildings; the company store, and the Southern Wyoming Electric Co.'s sales division.

The Kolb Coal Co. announces the removal of its offices to suite 718 to 721 Louderman Building, Eleventh & Locust Sts., St. Louis.

The contract to supply coal to the public schools of St. Louis was awarded to the Hawthorne Coal Co., of St. Louis for $3.65 for Standard lump delivered in the bins. The contract is for about 32,000 tons.

MONTANA

The Interior Department will lease at public auction 40 acres of public coal land in Big Horn County, through the land office at Billings, requiring an initial investment of $500 during the first three years, with a minimum production of 275 tons annually commencing the fourth year, the government to receive a royalty of 15c. per ton, mine-run, on coal produced.

OHIO

The Stalter-Essex Coal Co., announces the reopening of Mine No. 7, near Pomeroy, in the Pomeroy Bend field, which had been closed for about a month, due to the embargo on lake shipments. This mine employs 100 men and together with Mine No. 5, in the same field, produces 1,800 tons daily. Both mines are operated under the 1917 wage scale. The product has been contracted for in the lake trade, according to Fred Essex, head of the company. The Ohio Mining Co., another subsidiary, is operating mines Nos. 87 and 144, at Jacksonville, Ohio. These mines are being operated under the Jacksonville scale.

Digitized by Google

Coal Financing Closes Bank.—Protecting T. S. Jones' coal interests in West Virginia, closed up the Union Savings Bank of Yorkville, but everything is expected to turn out all right, so that the bank can open again. The state bank examiners closed the institution as a result, it was said, of a loan of $305,000 to Jones, who is vice-president of the bank. C. W. Heil, president of the bank, said the loan was given to protect Jones' investments in West Virginia. But the bank examiners said no banking institution may lend more than 10 per cent of its capital, and as the institution is capitalized at $100,000, the law was violated. The resources of the bank are said to be more than $1,000,000. No charges were filed against anyone.

Columbus Opens School Bids.—Bids opened May 13 by the Columbus Board of Education for 15,000 tons of lump or mine-run coal and 2,000 tons of nut, pea and slack for the public schools were as follows: West Virginia and Kentucky lump—Bell Coal Co., Columbus, $4.48; Colonial Fuel Co., Columbus, $4.32; Reliable Coal & Supply Co., Columbus, $4.79. West Virginia nut, pea and slack—Bell Coal Co., $4.29; Burns Coal Co., Columbus, $3.69; Colonial Fuel Co., $3.58; Franklin Builders' Supply & Coal Co., Columbus, $4.29; William Miller, Columbus, $3.93. Ohio lump—Bell Coal Co., $3.94; Burns Coal Co., $4.30; Franklin Builders' Supply & Coal Co., $4.55; Hub Builders' Supply & Coal Co., Columbus, $4; William Miller, $3.94. Ohio mine-run—Bell Coal Co., $3.86; Franklin Builders' Supply & Coal Co., $4.36; William Miller, $3.74; Third Avenue Coal Co., Columbus, $4.34. Ohio nut, pea and slack—Franklin Builders' Supply & Coal Co., $3.66; William Miller, $3.30.

PENNSYLVANIA

The Snowdon Coke Co., near Brownsville, is firing 75 additional ovens that were put out with the settlement of the anthracite strike. All of the company's 295 ovens now are in blast. Five ovens are permanently out of commission due to the erection of a coal bin over these ovens in connection with a coal tipple that is being built.

First-quarter earnings of Pittsburgh Terminal Coal Corporation were $114,665 after all charges but before federal taxes, compared with net deficit of $91,813 in the first quarter of 1925. The company closed down five of its mines last month, leaving only two in operation.

Sweeney Brothers, of Scranton, have just put through an agreement with the Delaware & Hudson Co. whereby they obtain a five-year lease on a culm dump near White's Crossing on the Honesdale branch of the railroad. The contractors are to pay the railroad royalty of 50c. a ton and put up a bond of $10,000 as a guarantee that they will market 20,000 tons before the lease expires.

The Jones & Laughlin Steel Co. is engaged in placing gantry cranes on Neville Island for the purpose of unloading coal from barges to its cold-storage plant. A number of these cranes are being brought on barges up the river from Memphis.

Glen Alden Defers Dividend.—Directors of the Glen Alden Coal Co., at Scranton, failed to take action May 11 on the semi-annual dividend which is due at this time. The expectation was that the dividend rate would be increased or that an extra disbursement would be declared. Final action on this matter, however, was postponed until the June meeting.

The Hillman Coal & Coke Co. has given an order to the American Bridge Co. for the construction of 20 all-steel barges for the coal towing trade. Each of these barges will be 175 ft. long, 26 ft. wide and 11 ft. deep. There will be 3,200 tons of steel in their construction.

The mine of the Clearfield Bituminous Coal Corp. located at Rossiter has resumed work after having been idle for a few weeks. The tipple at the mine was recently destroyed by fire. Loss, including machinery, was $60,000. About 750 men are employed.

Passes 50,000 Tons Daily. — Open-shop mines of the Pittsburgh Coal Co. attained an output of 50,162 tons from 11 mines for the first time during the week ended May 8, it is just announced by the company. This total does not include Delmont mine, in Westmoreland County, which has always been a non-union mine, but only the former union pits in western Pennsylvania. The company has 2,500 men at work.

Reading Conversion Time Extended.—Further extension of time for converting old stock to the new issue in connection with the segregation of the Reading Company's interest in coal and railroad properties, as decreed by the federal courts, was granted in Philadelphia early last week. Certificate holders now have until July 1, 1927, to exchange their rights for new shares, the U. S. Circuit Court of Appeals having previously extended the time until Jan. 1, 1927. Counsel for the company urged that the hard-coal strike had interfered with the exercise of the rights of conversion. Joseph Wayne, Jr., Philadelphia, was appointed a trustee of the new coal company's stock, succeeding the late Joseph B. McCall, Philadelphia. The other trustee is N. H. Fairbanks, Springfield, Ill.

WEST VIRGINIA

The West Run Coal & Coke Co., Scottdale, Pa., a West Virginia corporation, has surrendered its charter, according to a certificate filed in the office of the Secretary of State in Charleston.

The Vulcan store of the Elkhorn Piney Coal Mining Co., at Powellton, was completely destroyed by fire on April 15, together with the entire stock of goods. When discovered the blaze had gained such headway that it was impossible to save the building.

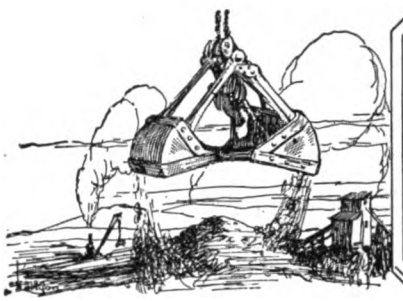
The meeting of the West Virginia Coal Mining Institute, which was scheduled to have been held in Bluefield on June 1 and 2, has been postponed until July 13 and 14, according to an announcement made by Robert M. Lambie, chief of the state Department of Mines, who is president of the institute. Because of the many meetings arranged to attract coal operators and tradesmen the meeting of the state organization was deferred.

A modern rotary dump and a new system of mine cars have been added to the facilities of Brooklyn Mine of the Scotia Coal & Coke Co. near Finlow, Fayette County.

Officials of the United States Coal and Coke Co. at Gary were officially congratulated last week in a telegram from Herbert Hoover, Secretary of Commerce. The message was prompted by the winning of the national safety trophy by the Gary No. 6 mine and of honorable mention in the national safety contest by Gary No. 3 mine.

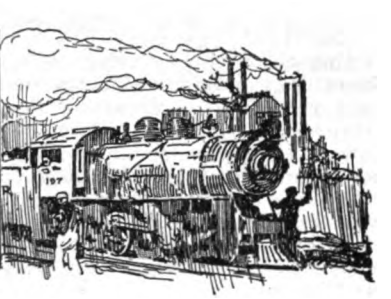
Plans are being made to celebrate Safety Day in West Virginia by holding a first-aid and mine rescue-contest at Huntington on Aug. 31, when a large gathering of mining men from all parts of the state will be in attendance. Prominent mining men from West Virginia and other states will address the banquet in the evening. Prior to the observance of Safety Day there will be a series of safety meetings in all parts of the state.

A new tipple is being erected at mine No. 4 of the Winding Gulf Collieries Co., at Winding Gulf, Raleigh County. Uprights have been erected and the work will be completed by July 1.



Coal mines along the Norfolk & Western Railway in April loaded 3,162,230 tons of coal compared to 3,353,480 tons in March. Production in the various fields last month were as follows: Pocahontas, 30,175 cars; Tug River, 11,475 cars; Thacker, 3,298 cars; Kenova, 3,593 cars.

Mining extension students, who took the course offered jointly by the federal government under the Smith-Hughes act and West Virginia University, Morgantown, are planning a banquet to be held in Welch on Friday evening, May 21. Robert M. Lambie, chief of the state Department of Mines, has been asked to act as toastmaster.



CANADA

Coal Probe to Begin.—Organization of the special committee named by the House at Ottawa last week to investigate the domestic coal question in Canada will begin this week. Edmond A. Lapierre (Nipissing) is likely to be chosen chairman. As a result of the debate in the House it is probable that the scope of the committee will be widened to probe the cost of production and distribution of domestic coal, mined in Alberta and the Maritime Provinces, and the committee is likely to avail itself of the data now in the hands of the Dominion Railway Board on this matter following its inquiry on the instructions of an Order-in-Council a few weeks more. Another question which may be discussed is that brought up by James Malcolm (North Bruce), who urged the government to consider the question of control of production, especially in the Alberta region. He thought some form of control would help to distribute production more evenly, afford more stable employment to the miners and thereby help to reduce the cost of producing the coal. It was only by such a cut in the cost of production, he said, that coal delivered in Ontario could be enabled to compete successfully with United States coal.

Production And the Market

Market Outlook Brighter as Lake Movement Picks Up; British Strike Discounted

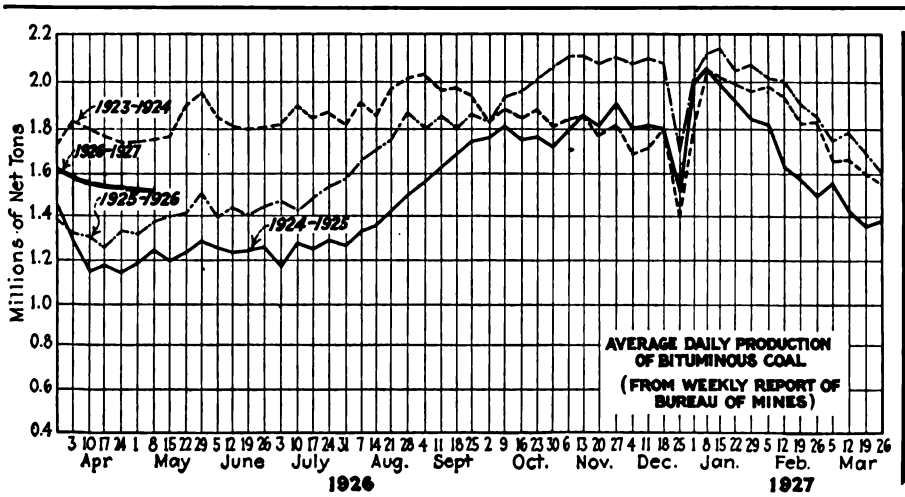
The British strike did not last long enough to have much effect on the bituminous-coal markets of the United States; as a matter of fact, for even its limited duration its influence was far from important, being of an indirect character. While there was an appreciable expansion of inquiries from sources normally dependent upon British coal, accompanied by a pronounced hardening in quotations for West Virginia smokeless coals, there was no impressive spot buying. Though the British miners have not yet returned to work and each day that they stay out will have a bearing on the usual British markets, potential production on this side is such that the effect will be quickly discounted.

Smokeless coal has reappeared in the Midwest market, with lump and egg priced at about $3 and nut at $2. Southern Illinois producers continue to hold to their circular, aided by a spell of unusually cold weather for May, which has kept domestic demand active. The placing of a number of large railroad contracts has helped the steam-coal situation considerably.

Embargoes on Lake Coal Lifted

Lifting of embargoes on lake coal movement to Toledo and Sandusky has brightened the outlook in central and southern Ohio. Although Ohio coal will play a small part in the lake business, the volume of distress coal has been lightened and competition for all-rail business lessened. In Kentucky too the outlook is brighter; railroad and industrial buying are substantial and domestic demand is somewhat better. Full headway on lake movement will be a further stimulus.

Unloading of cargoes at the Head of the Lakes has been heavy. Movement from the docks, however, has been only moderate, but as the industrial outlook is good there is no apprehension. During the week ended May 16 dumpings at the lower ports included 1,144,712 tons of cargo bituminous and 47,748 tons of vessel fuel. The total for the season to that date was 2,790,618 tons, as compared with 3,427,720 tons a year ago and 2,337,287 tons in 1924.



The policy of operators in scaling down output to the level of demand continues to show results. Production during the week ended May 8 was estimated by the Bureau of Mines at 9,031,000 net tons, a decrease of 94,000 tons from the revised figure for the preceding week. Nevertheless Kentucky and West Virginia coals are bringing conspicuously low prices in Midwest markets. While "no bills" are slightly less in evidence on the whole, Ohio markets suffer keenly from this evil.

Spot Prices Suffer Reaction

Coal Age Index of spot bituminous prices dropped back after last week's advance. As of May 17 the index figure stood at 159 and the corresponding price was $1.93, as against 161 and $1.95 the week before.

Heavy production of anthracite has taken the snap out of the hard-coal market. Company producers are moving domestic sizes with comparative ease, but the independents are finding their work cut out for them to induce purchasers to pay fancy premiums for their product. Consumers are in no hurry to lay in supplies for next winter, though it is expected that the present retail stocks, which are fair, will be pared down by pre-vacation fill-ups. The steam sizes are inactive.

The spot market for Connellsville coke is sluggish. Production continues to be reduced, but nevertheless there is a mad rush for what little spot business there is and prices are sliding.

Estimates of Production

(Net Tons)

BITUMINOUS

	1925	1926
April 24	8,030,000	9,271,000
May 1 (a)	7,987,000	9,125,000
May 8 (b)	8,277,000	9,031,000
Daily average	1,380,000	1,505,000

Cool Wave Helps Middle West

Unusually cold weather last week kept the Midwest domestic market alive, an unexpectedly favorable tonnage of prepared coal moving forward. Very low prices prevailed on eastern Kentucky and West Virginia fuels. Some operators have quoted as low as $1.85 per ton, f.o.b. mines, for shaker screened 4-in. block, and West Virginia 4x2-in. egg in some instances has gone as low as $1.40 per ton.

Producers of smokeless coal are now back on the market, and their quotations are on the basis of approximately $3 for lump and egg, and $2 for nut. Southern Illinois operators are continuing to hold their circular at the $2.60 level for 6-in. lump, and report a fair volume of business.

There has been some activity in the steam market during the past few days. Prices have strengthened on all grades of screenings, from No. 5 duff to full 2-in., and a number of large railroad contracts have recently been placed.

Business continues quiet in Williamson, Franklin and Saline counties. Lump and egg are piling up at the mines that are working and nut is not moving as fast as it is being produced. Nearly all the shaft mines that have crushers are using them. A few additional mines have been reported as suspending operations for the summer. Stripping operations seem to be showing up fairly well and working steadily, although the prices they are receiving are somewhat uncertain.

A late cool spring at St. Louis has caused demand for domestic tonnage in small quantities, principally of the cheaper grades.

Kentucky Outlook Brightens

The outlook in the Kentucky field is brightening. Although lake coal has not yet started to move in volume from the eastern part of the state, there is a fair tonnage going to all-rail destinations in the southeast and north of the Ohio River. Western Kentucky mines also are enjoying a good run of business to northern markets. Domestic demand has improved slightly, and industrial buying absorbs all the screenings offered. Railroad purchases, too, are on a substantial basis. Spot quotations on screenings are stronger and there has been no weakening in prices on other sizes in either field.

Dock companies at the Head of the Lakes have been kept busy unloading the heavy run of cargoes. Between May 5 and 10 67 boats were discharged and 15 additional cargoes were en route. Coal men at Superior and Duluth expect to handle about 900,000 tons of anthracite and to make further recoveries of bituminous business that has been going to Illinois and Indiana mines.

Shipments from the docks during the past fortnight have been on a modest basis, but this causes no uneasiness. The industrial outlook is healthy and prices are well maintained. During April shipments aggregated 11,855 cars, as compared with 14,836 cars in March and 9,210 cars in April, 1925. Present

Digitized by Google

estimates place the May total at approximately 11,000 cars. Contracts with large consumers are being renewed with little difficulty.

Inflow of coal by cargo to Milwaukee continues steady, but is slower than during the opening weeks of last year because of ice conditions in Lake Erie. Up to May 13 only 20,000 tons of anthracite had been received in Milwaukee, against 168,908 tons at the same date in 1925. Bituminous coal received up to May 13 totaled 203,809 tons as against 339,660 up to the same date last May. The market continues satisfactory.

Wisconsin to Probe Prices

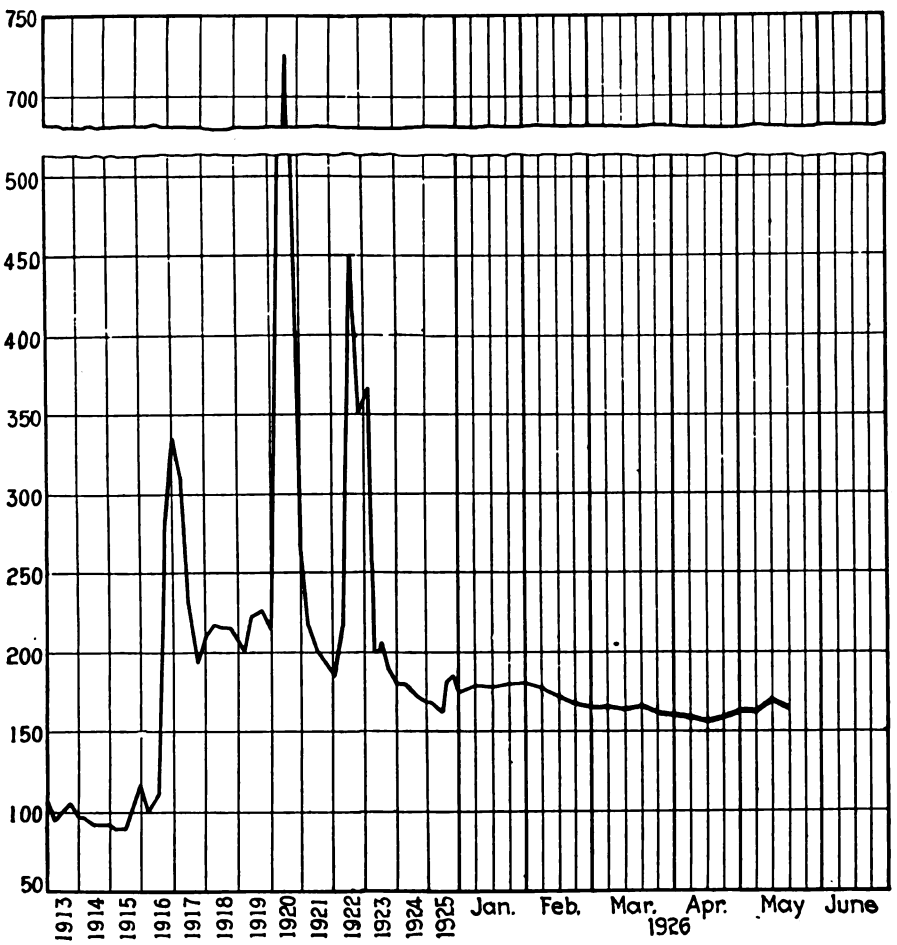
Milwaukee dealers are disturbed by the announcement of a state investigation of prices of fuel in Milwaukee and interior points. The state Market Commissioner says a report by an official committee "shows a difference of $5.20 a ton in the retail price of prepared Pocahontas coal in Wisconsin cities during the winter months of 1925-26."

Usual early season quiet in the Twin Cities has been intensified by slack commercial conditions and erratic weather. Little progress has been made in lining up future business. Several railroads have been considering contracts, but little aside from these has been available. The local market has held fairly firm, with little offering at concessions. Prices are fairly well maintained on the basis prevailing for some time. Southern Illinois lump is $2.60; central Illinois, $2.25; western Kentucky, $1.75.

Current Business Slow in Kansas

In the Southwest operators are receiving few orders for immediate delivery, though a fair list for future delivery is accumulating. While some summer storage is reported, it is not sufficient to have any noticeable effect on the market. Kansas lump and nut are accumulating at the mines but in smaller quantities than in former years when crushers were not so generally used throughout the Southwest. Crushing of strip-pit production to fill steam orders is preventing any shortage in that market.

There has been a slight recession in domestic demand for Colorado coal, particularly in Nebraska, Kansas and Oklahoma. The Denver local market, on the other hand, is active. Industrial buying also holds up. The price situation with respect to both Colorado and Wyoming coals is unchanged. Except for belated cold weather in the Salt Lake City retail market, the general situation in the Utah field shows no material variation from that prevailing in recent weeks.



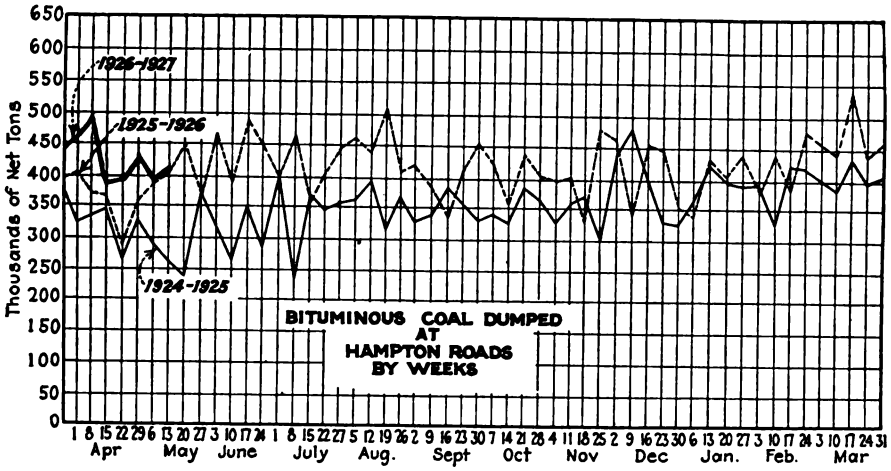
Smokeless Stiffens at Cincinnati

Lake business, now getting its start six weeks late and with a huge tonnage to pass over the unloaders, has given snap to the Cincinnati market. Smokeless has bettered more than other lines. All standard stuff is firmly held at $3 for lump and egg, with some specialty offerings as high as $3.25 spot. Direct sales offices say they are sold up on their make of prepared. Nut goes all the way from $1.75 to $2.50, depending on selling conditions at the mines. Low-volatile mine-run is a bit better. Not so much $1.75 coal is to be had and even on large orders $1.90 is reasonably obtainable. The better part of the screenings shipments go at $1.25, though some large sales have been made at $1.35 where the grading was exceptional or suited for a specific purpose.

In high volatile slack has stiffened once more, so that $1 is low, good by-products and gases bringing around $1.10 and $1.15. Mine-run is $1.25@$1.35 for steam, though byproduct is still firmly held. Egg still ranges at $1.50@$1.75. Two-inch for the lakes sells all the way from $1.65 to $1.90 with the inquiry bettering.

Retail business has tapered off due to warmer weather. River business continues in volume, but little or no storage stuff is going to the stockpiles.

Lifting of the embargoes on lake coal to Toledo and Sandusky has dissipated the gloom which has been enshrouding central and southern Ohio trade for the past few months. Although Ohio operators expect only a



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	May 17	May 10	May 3	April 26	May 18	May 19
Weighted average price	$1.93	$1.95	$1.92	$1.93	$1.95	$2.05
Index	159	161	159	159	161	169

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

meager share of the lake tonnage, the opening of the season takes off the pressure of distress coal, and somewhat lessens non-union competition for all-rail business. Large consumers are showing more interest and a few contracts have been closed. Contract prices, however, are low.

Domestic demand is at a standstill. This situation helps to maintain a strong market for screenings and prices on that grade are firmer. Production is still at a low ebb. Most of the larger mines in southern Ohio are down and the output from those running does not exceed 15 to 18 per cent of the potential capacity of the field.

Buying in eastern Ohio is very slow, practically all prices are now at or below the cost of production, and lethargy is pronounced. There is considerable "no bill" coal on track at the mines. Aside from vessel fuel, the No. 8 district is doing comparatively little in the lake trade. During the week ended May 8, this district produced 210,000 tons or about 30 per cent of potential capacity. This is an increase of 21,000 tons over the preceding week, but 7,000 tons under the corresponding week a year ago.

Pittsburgh Depression Increases

The only change noted in the Pittsburgh district last week was a slight softening in the market for spot screenings. Demand continues light. Most of the union production of western Pennsylvania is now coming from mines on the Pan Handle and they are not averaging over two or three days a week. Some of the Bessemer district open-shop operations are doing better in running time, but there is no profit in the tonnage. The Pittsburgh district as a whole is not averaging over 20 to 25 per cent of capacity and a large part of this comes from captive mines. Over 50 per cent of the commercial production is being mined by open-shop operations.

The new month brought a slight gain in central Pennsylvania production. Loadings for the first week in May were 14,233 cars, or approximately 2,000 cars more than in the first week of April. Approximately 80 per cent of the tonnage is non-union. Pool 1 coal is quoted at $2.45@$2.60; pool 71, $2.15@$2.25; pool 9, $1.95@$2.15; pool 10, $1.75@$1.85; pools 11 and 18, $1.60 @$1.70.

Pessimism is unabated in the Buffalo bituminous trade. Complaint is made that coal is forced and prices suffer. Slack has weakened. Nominal quotations are: Fairmont lump, $1.50@ $1.65; mine-run, $1.30@$1.45; slack, $1.10; Youghiogheny gas lump, $2.15@ $2.35; Pittsburgh and No. 8 steam lump, $1.85@$2.10; gas and steam slack, $1.30 @$1.50; Allegheny Valley mine-run, $1.60@$1.85.

Demand Quiet in New England

In New England there is no spot buying of any moment. Smokeless coals are firmer than a week ago, but this is owing partly to actual purchases already made for users of British coals, although most of the price advance can be attributed to possible export demand later on. Consumers apparently are not at all anxious over prices the next few weeks. Potential production is so great that the effect of the British strike lasting but a few weeks will be discounted.

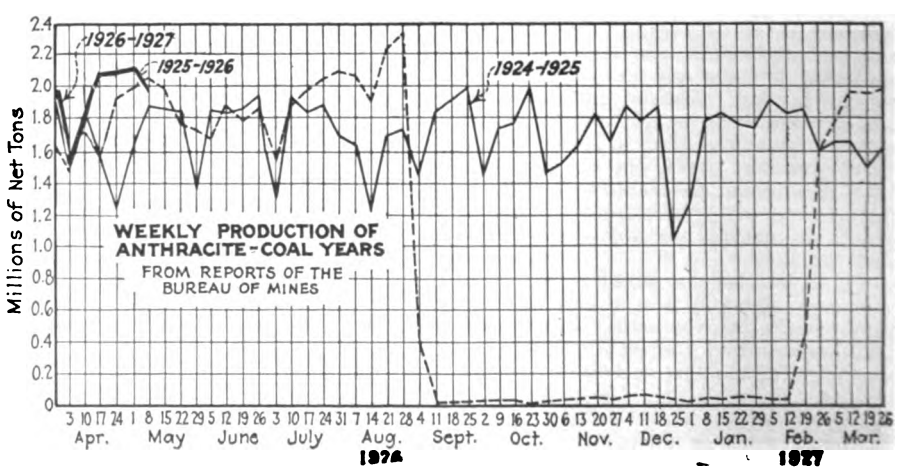
On board vessels at Hampton Roads the asking price ranges $4.75@$5 per gross ton, a marked upswing from the April average. So much depends upon the course of export business the next week or two that it is difficult to forecast conditions on Pocahontas and New River, but if the Welsh mines do resume soon the market here will again sag to the pre-strike basis.

Central Pennsylvania remains in the doldrums. Only a minimum tonnage is moving and the totals for this territory must be relatively small. Even high grade forge coals are in extremely light demand.

On cars Boston and Providence for inland delivery there is only mild request. Most factors have on hand coal that was received on the April basis and quotations are only moderately firm. A few are asking $5.75 per gross ton, but inquiries for 20- to 50-car lots disclose a willingness to shade that figure considerably.

New York Bituminous Trade Quiet

"Calling off" the British strike made no impression on the New York bituminous market because there had been so few orders placed for foreign shipment. Distress tonnage has practically disappeared, but domestic industrial consumers show no disposition to increase their stocks of coal. There is, however, a fair volume of tonnage moving to meet current requirements.



Philadelphia was another market in which the British situation had no influence. As at New York, buyers seem content to let things drift on as they are and little contract business has progressed beyond the inquiry stage. At Baltimore, on the other hand, there has been a revival of interest on the part of the consumers of steam tonnage, but the revival was not strong enough to lift up the spot-price levels.

Seasonal declines are less marked than usual in Birmingham territory. The small surplus of better grade coals thrown on the spot market is easily absorbed, but the lower grades are less fortunate. Contract customers are taking their full quotas. The bulk of the domestic coal now moving is on contracts. Nut and egg are in better demand than lump. The lower grades of white ash still are backward. Domestic coke is a little stronger at $3.25@ $3.50 for nut and $4.75@$5 for egg. The foundry market is quiet; spot coke is $6@$6.50 and contract, $5.50.

Anthracite Market Sluggish

There is no snap to the anthracite market at New York. Company domestic tonnage, however, is moving steadily, but buyers will not pay fancy premiums for independent coal. Retail stocks are fair, but it is expected that these will be reduced by pre-vacation fill-ups. The steam sizes are sluggish. No. 1 buckwheat is the weakest, but rice also is soft. Barley shines by contrast.

Demand for domestic sizes at Philadelphia is dwindling. Householders are reluctant to order their next winter's fuel and dealers do not want to accumulate heavy stocks. The majority of the shippers have unbilled loads at the mines and independents are shading

April 30, 1925	337,181	160,913	.....	.....

nut quotations to effect sales. Pea is scarce. Of the larger sizes, stove is in the most active demand. Barley moves with little difficulty, but No. 1 buckwheat is offered as low as $2 and rice quotations are off 25 to 35c. The Baltimore trade is quiet.

Lake shipping is well under way at Buffalo. The latest weekly report shows clearances of 59,600 tons, of which 29,000 tons went to Milwaukee, 11,000 tons to Sheboygan, 8,000 tons to Chicago, 6,900 tons to Washburn and 4,700 tons to Manitowoc. Local business has been sustained by weather conditions. The temperature also has been responsible for retail activity at Toronto, but this is easing off. There is a growing demand in Ontario for Welsh coal.

Dullness still characterizes the spot market for Connellsville coke. Despite curtailed production, there is still a scramble for the little spot business that appears from time to time, with the result that some spot furnace coke has sold down to $2.90. Small lots are held at $3. Spot foundry holds at $4 @$4.50, but the undertone is weak.

Output from the Connellsville and Lower Connellsville ovens during the week ended May 8 declined 9,070 tons, according to the Connellsville *Courier* The greater part of this loss was in the output of the furnace ovens. The total from those ovens was 89,500 tons, a decrease of 7,900 tons. Merchant-oven output, 70,840 tons, was 1,170 tons less than during the preceding week.

Foreign Market And Export News

How British Coal Strike Affects Europe

Continental Europe industries normally dependent upon Great Britain for a substantial portion of their coal supplies view the tie-up of the British coal mines with growing concern. Coal-producing interests of those countries, on the other hand, express great confidence in their ability to keep the wheels of trade turning by speeding up their output.

The Spanish iron mines, says a late cable to Washington, are anticipating serious inconvenience as a result of the British strike, although the coal-mining industry is optimistic regarding its ability to supply the demand. The iron industry probably is not seriously affected because of the restrictions recently decreed by the Spanish Government against the use of British coal.

The French coal industry is pushing production in an effort to fill the gap made by the stoppage of British deliveries, while prices have not as yet been affected. Probably Belgian and German shipments will supply the deficit, especially if the restriction on free German coal (that not imported on reparations account) is removed.

French production of coal and lignite totaled in March 4,566,000 metric tons as compared with 4,088,000 in February. Coke production amounted to 319,000 tons in March, which is over 40,000 tons more than in February, while the production of briquets reached 327,000 tons in March, a slight reduction when compared with the previous month. Production during April is estimated to have reached new high levels in anticipation of the British strike.

Prices of industrial fuel are as yet unchanged but increases are expected should the strike in Great Britain continue. The price of indemnity metallurgical coke is to be approximately 190 fr. per metric ton on June 1, an increase of 47 fr. in five months.

At a general meeting of the Czechoslovak coal miners' union on May 6, it was resolved that no increase in coal exports be permitted during the British coal strike. The railway unions support the action.

Owing to large existing stocks of coal in Italy, no apprehension is felt on account of the British coal strike. Buyers are declining to place orders at higher prices.

No Change in Belgian Situation

Brussels, Belgium, May 7. — There has been no marked change in the Belgian coal situation. The undercurrent of improvement noted in recent reports continues. Industrial demand is good. The rate of foreign exchange, the absence of German competition and the strike in Great Britain all combine to give the Belgian mines the full advantage of this situation. The Borinage district in particular is feeling the beneficial effects of these factors.

Inquiry is very strong for semi-bituminous and lean beans 8 mm. x 20 mm. of the stocks are almost exhausted. Semi-bituminous and lean peas also are in good demand. Coking smalls are sought after between 87 and 88 fr. as well as lime duffs at the newly increased price of 72 fr. per ton. Lean duffs and cement duffs are asked for and even fairly scarce at 42@45 fr. per ton.

The situation in domestic fuels also is improved.

During March Belgium imported 701,665 metric tons of coal, 226,031 tons of coke and 7,304 tons of patent fuel. Germany was the principal source of supply. During the same month Belgium exported 127,214 tons of coal, 84,995 tons of coke and 65,420 tons of patent fuel. France was her best customer.

Coal Strike Threatens Poland

The Polish Silesian coal fields, which are the principal source of Poland's coal supply, are threatened with a possible tie-up because of demoralization of the railroads and the likelihood of a miners' strike. The operators are unable to move their daily output of 80,000 tons. The miners are demanding a 30-per cent increase in wages, asserting that the German miners across the border are receiving 500 per cent more than they.

New Equipment

Fuse Shows When It Blows

Non-renewable and of distinctive design, the new fuse plugs shown in the accompanying illustration was recently placed on the market by the Trico Fuse Manufacturing Co., of Milwaukee, Wis. It is known as the Cleartop and consists of a separate porcelain base and body. The base is provided with a long baffle chamber that extends to the inside top of the body and holds the mica window in place. Body and base are held together by a heavy brass screw shell, the body being finished in a dull black that gives it the appearance of molded insulation.

Plug of Improved Construction

Shows side view and cross-section of new fuse plug. Construction is simple and rugged. The device is guaranteed to give unmistakable evidence of failure.

Some of the distinctive features and advantages claimed for this plug by the maker are: A large heavy knurl embraces the top edge, a clear India window is provided, as is also a visible link with the amperage stamped directly upon it, and a large central contact is employed. Each fuse is guaranteed to "show when it blows." This fuse is approved by the Underwriters Laboratories and is packed for the market in cartons of fifty.

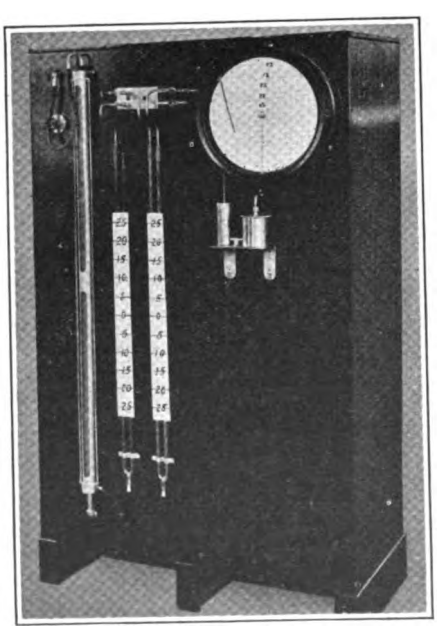
Pen Charts Methane Content Of Mine Atmosphere

A continuous methane recorder has been developed by the Mine Safety Appliances Co., of Pittsburgh, Pa., and the new instrument will be placed on public exhibition for the first time at the American Mining Congress convention in Cincinnati, Ohio. This device is designed to reduce the probability of methane explosions in mines, as it will provide a means of continuously recording the proportion of methane in any split. It will likewise serve as a guide for regulating the fan or fans so that the content of this gas may be kept well below the explosive limit.

It has been demonstrated that rock-dusting will render coal dust non-explosive. If then the ventilation be properly regulated by means of one of these methane recorders the probability of a gas explosion, which is the only kind of explosion possible in a properly rock-dusted mine, will be greatly reduced.

In this recorder an electrically driven pump continuously draws in a sample of the mine atmosphere. This is then passed through a purifying chamber in which all dust or other particles of a solid nature are removed. It next passes through a canister containing chemicals that absorb all moisture and carbon dioxide.

It is then led to a flow meter that maintains a constant head or pressure in forcing it through an orifice of 0.014-in. diameter. This pressure is so regulated as to force ½ liter per minute through this orifice, any excess being bypassed to the outside air.

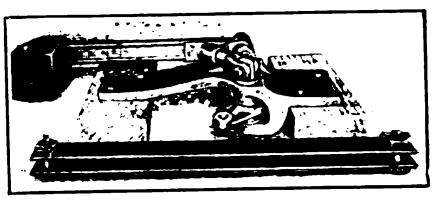


This ½ liter of the sample is then led through a fused silica tube containing platinized asbestos which by means of an electric furnace is maintained at a temperature of 800 deg. C., or 1,472 deg. F.

This high temperature and the catalytic action of the material within the tube serve completely to oxidize any methane that may be present to carbine dioxide and water. Another canister filled with chemicals completely removes these products of combustion.

The remainder of the sample is next led through an equalizer that brings it back to its original temperature. It is then forced through a second orifice of the same diameter as the first namely, 0.014 in.

If no methane is present in the first instance, the volume will remain constant, and the head, or pressure, required to force it through the second orifice will be the same as that necessary to drive it through the first. If methane is present in the original sample the volume of gas passing the second orifice will be less than that passing through the first, and the pressure required to force it through naturally will proportionately be smaller. This difference in head is registered by means of a sensitive pressure gage, the chart used being calibrated to read in percentages of methane.



The chart employed covers a range from zero to 4 per cent and, it is said, can be read with accuracy to a few hundredths of one per cent of methane.

A glance at this chart will thus show the proportion of methane present in the mine atmosphere at any moment. The chart is made for one day's operation and the two canisters of chemicals are good for one week. Keeping the instrument in service is said to be a simple operation.

Parallel-Throw Switch Is Low, Compact and Durable

Designed to afford maximum service at minimum cost, the new parallel-throw switch stand shown in the accompanying illustration has been placed on the market by the West Virginia Rail Co., of Huntington, W. Va. This stand is made in two sizes, the first intended for rails weighing up to 40 lb. per yard and the second for those weighing 45 to 60 lb. per yard. Both crank and lever shafts are supported by double bearings. In consequence none of the working parts overhang and the inevitable bending stress and wear are avoided.

Switch Stand and Rod

This stand is low and of unusually rugged construction. When the connecting rod is rigid as here shown the switch is self-locking, but when provided with a spring it becomes automatic in operation.

All bearings are reamed from the solid metal, assuring the best conditions for slow-moving journals. The design is such that an increasing pressure is applied to the switch points at the extremities of the throw. The stand is low, thus offering a minimum of obstruction. When equipped with a rigid connecting rod as shown in the illustration the device is self-locking.

A hexagonal hole in the crank accurately fits the hexagon steel crankshaft, making transmission of the turning movement positive. The crank is placed at such a height as to be in alignment with the switch bar, thus avoiding offsets and consequent bending stresses in the connecting rod. As a special safety connecting-rod bolt is used to hold the rod, both stand and switch points are protected from breakage should a trip run through the switch, provided the rod is of the rigid type. This bolt is easily replaceable when broken or sheared. The entire stand is made of steel and malleable iron and is thus extremely strong and durable.

A New Welding Torch

To meet the demand for a small welding torch, the Alexander Milburn Co. has developed a torch that is 18 in. long and weighs 25 oz. It is known as the type J-Jr. In design it is sturdy and compact. It uses the same tips as are supplied with the standard torches of larger size and is said to be adaptable to all classes of welding. It can use gas supplied either from generators or compressed in tanks. It uses low and comparatively equal pressures of oxygen and acetylene.

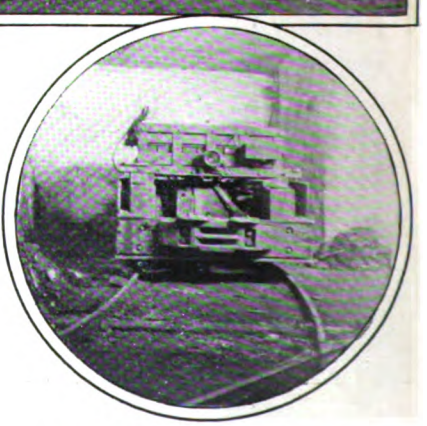
Could your haulage motors handle more coal if it were not for one or two steep grades they must climb? Then equip those motors with Exide-Ironclad Batteries and they won't stop for steep hills or extra-heavy loads. When extra power is needed, this battery has the peculiar ability to deliver current much faster than the normal rate.

Keeping the coal coming constant



Do your motors always get back to the charging barn at night under their own power? Seldom if ever does an Exide-Ironclad-equipped motor have to be towed in. The voltage of this battery remains high, even when the battery is almost discharged. And so rugged is it that it almost never gets out of order.

Another car over the tipple! How many will there be at the end of the shift? One thing is certain. More cars will be loaded where the mine's haulage motors are equipped with Exide-Ironclad Batteries, for these batteries increase the speed, smoothness, and efficiency of any haulage system.

Exide IRONCLAD BATTERIES

This miner has shot down his coal and is waiting for the gathering motor to bring him an empty. Miners seldom have to wait for empties where the haulage motors are powered by Exide-Ironclad Batteries. The great speed and pep of this battery hustles the loads out and the empties in without delay. What is more, this speed holds up well all day long.

Send for a free copy of our booklet, "Facts for Consideration in Selecting a Battery for Locomotive Service." Form No. 1791.

The charging efficiency of an Exide-Ironclad is enough to delight the heart of any mine electrician. This battery takes current in quickly, easily and with very little waste.

Post-Convention Issue

The Convention draws to a close. It has been a striking exhibit of the interest of mining men in the technique of their industry and in the ability of manufacturers to supply tools and materials for their use.

Coal Age had no less than five editors present to record and to gather data. In the pages of next week's issue will be found a full account of the meeting which means so much to the industry. You will find a record in which you can read what you have heard, thus getting a second time the benefit of the meeting and the exposition. If your notes are incomplete, if attendance at the booths or discussions of problems with friends caused you to miss sessions, *Coal Age's* pages will make up for the deficiency.

And if the mines held you at home *Coal Age* will be of some assistance to you in retrieving what you have lost, and never forget it is a great loss you sustain by your absence. Many a man who has gone to such a meeting has learned how and where he can get information, has gained a knowledge of those who are authorities in the work of the industry, has met men who, at some time later, can be of assistance in solving the problems of his mines.

Here in *Coal Age* will be a permanent record to which you will have recourse in later months, when new developments at your mines increase your interest in some phases of the industry, or when your notes prove meager or are lost and memory wanes.

The Convention and Exposition will leave their impress behind. They are another big step in the progress of the industry, which is moving forward daily. In *Coal Age* week by week you will get additional data to add to what you have acquired.

You have met the men of the industry, and you will have a personal as well as a technical interest in their achievements that will aid your reading and deepen your understanding of the problems of the industry. To a man who attends a convention all its progress is dramatized. The *dramatis personae* being known, the play has thereafter a more direct appeal.

Bet on Bulldog!

when it comes to the test of time—

OTHER dogs may display more fancy tactics. Their various characteristics may have one claim or another on your affections. But when it comes to the simple question of an endurance contest, the bulldog gets his grip and settles down to hold it—forever if need be.

Same way with trolley clamps! When your Bulldog Trolley Clamp once sets its jaws on the wire it is there to stay. A turn or two on the nut sets an unshakable grip which neither vibration nor the ravages of Time can loosen. Yet if ever the line is to be removed, it requires but a turn of the wrench to back the nut and release the wire. The clamp itself can be removed and used again and again.

Where Statistics Would Help

AS TO HOW FAR, if at all, the federal government should go in setting up a system of compulsory fact-finding in the coal industry there is much honest difference of opinion. Even some of those who are most sympathetic toward the idea are in doubt as to the constitutionality of proposed legislation. Opponents who rely upon constitutional guarantees offer a formidable list of court decisions to bulwark their argument that such an innovation would be beyond the authority of Congress. At least until the Supreme Court of the United States shall have spoken in the *Claire Furnace* and *Maynard Coal Co.* cases, confusion and disagreement will continue.

There are, however, certain statistical activities that the federal government properly might expand or inaugurate. Concerning these there could be no challenge. These statistics relate to production, distribution and consumption. The government is, of course, and has been for some time, collecting and publishing weekly data on production. The only criticism which may be leveled against those figures is their lack of detail. A big step forward was taken when the production figures were broken down into tonnages by states. But the analysis should go further. The state figures should supply information as to the output of the important producing districts. The Bureau of Mines already is working on this particular problem, and it should be encouraged in its undertaking.

It is several years since any attempt was made to publish data on distribution. Yet such data are a necessary complement to the production figures. The latter tell only half the story. There are no insurmountable difficulties to the collection and compilation of distribution statistics. It is merely a question of setting the proper machinery in motion. For years the Illinois and Indiana Coal Traffic Bureau, a railroad organization, has been compiling such data with respect to the distribution of the production of those two states. The Ohio Bureau of Coal Statistics has been performing a similar but less voluminous service for certain other fields. In neither case, however, are these monthly reports available to the general public or to the coal industry at large.

The activities of these bureaus in their limited areas suggests how the problem of collecting statistics, national in scope, should be met. The railroads have the basic data. The task of assembling it from the carriers' records would be comparatively simple. The task of collating individual reports from thousands of operators every month would be almost impossible.

Moreover many producers selling through sales agencies do not know the final destination of part of their tonnage. The Interstate Commerce Commission might well issue an order requiring the railroads under its jurisdiction to furnish it with monthly distribution reports. In fact, no other agency is so well situated for the collection and publication of this information.

With complete data on production and distribution available, there still would remain statistics on stocks in the hands of consumers and consumption. These statistics are essential to a well-rounded picture. They are necessary if the industry is to conduct its business intelligently and if the consumer is to place his orders wisely. The coal industry cannot supply these figures. The consumer alone has the data. The Bureau of the Census, in co-operation with the Bureau of Mines, has made some studies of this situation, but the studies to date have been neither comprehensive enough nor issued with sufficient frequency to serve as a sensitive barometer of conditions. The work should be expanded and quickened.

Post-Convention Soliloquies

A CONVENTION is much what we make it. The seed is good if, as at Cincinnati, it is well chosen, but the growth depends on the soil in which it is sown. Quick planting stimulates growth. A convention a month old has little of its vitality left, so try and arrange affairs in a manner that will permit of quick action. Companies which have sent men should take care that the gain made is not lost by inaction.

There is need that the problems of the industry be seen in a large way. Little improvements in practice are good, but vital changes are better. Some striking development should be planned; further data should be accumulated; visits should be made to places where improved operation is in actual practice. The pile of letters on the desk should be promptly reduced, so as to leave the manager and superintendent time to plan. It is to be remembered that the business of an alert mine official is not to travel the old well-beaten paths of his predecessors, but to break a new road to efficiency.

Have you no reserve of imagination? Will you let your negations be more numerous and more potent than your affirmations? Have you attended the convention with a firm conviction that what is new is not true, and what is true is not new? If so the convention is lost to you. The world moves along. There have been hundreds who questioned all that was original, but the few who saw and believed what was worth seeing and believing advanced industry and profited, and with them the world.

In conventions the wisdom of many men is pooled. We learn what has succeeded, and if anything has failed why it did not succeed. From this we can chart a safe course to larger accomplishment, but no one succeeds who does not act. It is perhaps easier to rest immobile, but those who do so get nowhere. The convention at Cincinnati will move many men forward and leave the rest to muddle along unhappily toward

Digitized by Google

failure and bankruptcy, for in a moving line those who stand still gravitate rapidly to the rear where are found the misfits and ne'er-do-wells whose lamentations would have us believe that the coal industry is without awards and opportunities for any.

Free of Detail

MOST OF THE men around a mining plant have a daily grind to perform, an endless succession of duties that makes them servants rather than masters of their jobs. The superintendent is responsible for everything. He must pull every string. Perhaps we hold him too closely for every fault that his subordinates make. In consequence he has no time to think, plan, read, visit other mines or attend conventions.

Some companies keep a research engineer to make inquiries into new methods of achieving results. He can spend a week or a month visiting the workings under consideration and other mines at remote points. He prepares estimates. He suggests the necessary surveys. He consults with manufacturers' representatives. He discusses the suggested improvement with men who have tried it, if any have done so, and in the end he gathers up his data and puts his conclusions into a carefully planned report, and then, after consultation, his chiefs decide on the merits of the suggested improvement, keeping in mind the return on the necessary capital investment, which should be about 15 per cent for safety and should have long enough life to return the capital expended. This is the modern way. Our coal mines have all too few research engineers.

A Virtue in Delay

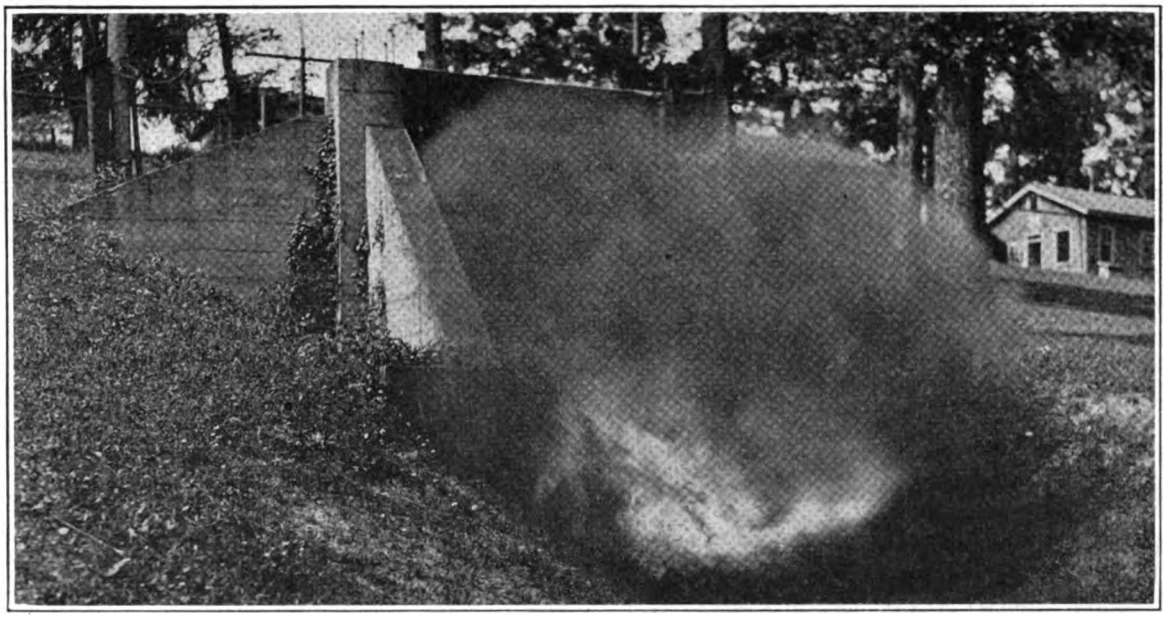
EUCLID AVE., Cleveland, extends for over one hundred blocks. It was decided in an evil hour to regulate the signals at the various crossings by an electrical current, so that all would indicate "Stop" at one time. But when the scheme was tried, all the street cars on the avenue were stopped and started at the same moment and as there were many of them the starting brought such a heavy load on the substation that the plan was discarded. Furthermore, the city's plan tended to disrupt Cleveland's diversity factor.

Much the same effect is experienced when power fails in the mine and is suddenly restored. Every motorman, every machine cutter, every pumpman wants his motor, cutter or pump, whichever it may be, to get immediately into action. It takes more power to start than to run machinery, so the demand for power is abnormal for the first minute after the restoration of the current. The Davis Coal & Coke Co. has met the difficulty with its motormen by instructing half of them to wait one minute after power is restored before attempting to start. In consequence a power failure does not cause a heavy peak. The men respond quite readily, which perhaps is strange, because the average motorman irks at waiting and wants to be up and doing.

It has been suggested, however, that it might be possible to put a time-limiting relay on a locomotive that would make it dead till a certain fixed length of time after the power is re-established. That would, however, come into action every time the trolley wheel was adjusted to the wire. So perhaps it is best to leave the matter in the hands of the motormen and others.

Guessing or Knowing

TOO OFTEN the mine foreman does not know at anytime in the day just how many men there are in the workings and in what section these men may be found. How, then, can he arrange his trips and his gathering forces? In the early morning he assumes that all the places are cut that should have been cut and that every man who ought to be working is at work or that a certain proportion of the men are present, the number depending on the remoteness of a past, or the nearness of a coming payday, on the hunting season, on sheriff's sales, the circus, or other counter-attractions. As a result of the foreman's lack of knowledge, drivers and motormen travel through the headings, hunting in some places for coal to haul and at other times having more coal to haul than they can handle.



All this may be avoided if, early in the day, the telephone is used to advantage by someone who endeavors to ascertain how many men are out. Further information will be available if the men check into the mine and the night force leaves a record as to what has been done during that shift. Sometimes places are not cut, a switch is not laid, water compels a man to lay off, men are sick or have sickness at home. When these facts are ascertained, drivers can be dispatched here or there; roadmen sent to clean up; tracklayers directed to lay switches; bratticemen sent to mend a fallen stopping or build one in the nearest outby crosscut wherever a new crosscut has been completed.

After an hour's investigation, the mine force can be apportioned with efficiency. Perhaps the full complement of gathering units is not needed, and the foreman will be saved from the necessity of looking for a miner to replace some motorman or driver who has laid off for the day. Planning is necessary in directing anything so scattered as a mine, and how shall a man plan unless he knows the facts?

Obtaining that knowledge should be not the foreman's but a subordinate's duty. The foreman should be given the data so that he can act on them. Nothing aids morale more than a fast-working fact-finding arrangement. Many a man leaves the mine because he finds he cannot work as soon as he reaches his place and doubts if he will get service. He comes out to argue with the boss when he should know that he can stay in his place and get the service he needs. He should be told just when he will get it. Many a needless trip will be saved if someone is collecting facts and distributing word from the boss that the service will shortly be forthcoming.

Anything that prevents men from jumping loaded trips to come to the surface decreases the possibility of accident. Furthermore, when props are delivered promptly in answer to a telephone demand the miner is less likely to take a chance in an improperly timbered room. Many a word passed to a motorman fails to reach the right person at the surface and by appointing a man to receive such information action is made more certain. The telephone and a man to answer it having a pad on which he can take notes and a ruled and tabulated sheet on which he can correlate information will save a boss much annoyance and help him plan his work methodically. The mine foreman always has plenty to do and every assistance should be afforded him in the doing of it. Perhaps this service can be restricted in a small mine to certain hours, but in the early morning it should certainly be afforded.

How Mines with Underground Dumps Are Trying To Eliminate Coal-Dust Hazard

No Complete Cure Has Been Found, but Shafts Are Being Made Dead as to Ventilation, Automatic Doors Installed to Keep Dust from Mine and Coal Is Being Wetted at Face and Dump

By C. W. Owings* and V. C. Allison†
U. S. Bureau of Mines, Pittsburgh, Pa.

IN THE LAST FIVE YEARS there has been a growing use of underground dumping in shaft coal mines where large production is desired. This is largely due to the economies resulting from dumping into underground bins and hoisting the coal with skips or conveyors and to the fact that more coal can be hoisted from a single opening in this way than is possible with the usual method of car hoisting. However, as many hoisting shafts are used as intake or downcast airways, the coal dust resulting from dumping operations is carried back into the mine, augmenting the ever-present danger of a coal-dust explosion, unless some provision is made to intercept the dust.

The danger from accumulations of coal dust is apparently fully realized by coal-mine operators and in every installation visited, provisions have been made to nullify this hazard. The Bureau of Mines has made a preliminary survey of a number of schemes for combating the coal-dust hazard that have been put into practice in mines equipped with underground dumping systems. The purpose of this paper is, by describing the methods now in use, to bring to the attention of operators contemplating the use of such a system some of the difficulties involved in its use.

The explosibility of coal dust when in a dense cloud is universally recognized by coal-mining men. For coal dust to ignite or explode, there are three necessary factors, namely, a source of ignition; a sufficient quantity of dry coal dust and an agent which will raise the coal dust into a dense cloud.

There are two general sources of ignition common to coal mines—open lights and arcs from electric wires or electrical equipment. According to Tracy in 1892, at Durham, England, a cloud of coal dust, raised by men shoveling pulverized coal in a coal bin, was ignited by open lights hung near the bottom of the bin. The resulting explosion killed three men. At a western coal mine material from an old dump was being loaded by steam shovels, and in order to loosen the material, shots were fired. This resulted in unburned coal dust, which had been loaded from the tipple onto the top of the rock pile, being raised in a dense cloud which, coming in contact with the flames of the burning refuse, ignited and burned nearby workmen.

The Bureau of Mines has repeatedly demonstrated that an open light will ignite a cloud of coal dust in the absence of gas. One method of making such a test is as follows: Near the portal of the main entry at the Experimental Mine, Bruceton, Pa., coal dust is piled on a V-shaped shelf laid across the entry near the roof. An open-flame lamp is suspended about 6 ft. outby the shelf. By means of compressed air the coal dust is blown in a dense cloud down upon the flame. Immediately the dust ignites and burns rapidly, a swirling, boiling mass of flame passing out of the entry. An observer standing inby the point of ignition is made

Published by permission of Director, Bureau of Mines. The information contained in this article, in regard to specific mines is used through the courtesy of the mine managements concerned and with their full permission.

The headpiece shows the flame emerging from the Experimental Mine of the Bureau of Mines at Bruceton, Pa., from an explosion caused by allowing fine coal dust to fall from a V-shaped shelf onto a flame or electric arc located about 6 ft. outby the shelf.

fully aware of the pressure being developed by the crackling of his ear drums and by the way in which his body is swayed back and forth by the pressure wave developed.

A similar test is made, substituting an electric arc lamp for the open-flame lamp. The resulting ignition of the dust is similar to that obtained by using the open-flame lamp. In the headpiece the mass of flame from one of these tests is shown issuing from the mine mouth, the volume of this mass of flame being about 1,600 cu.ft.

The exhibition coal-dust explosion gallery of the bureau has been extensively used over the United States in the last two years in effectively demonstrating the

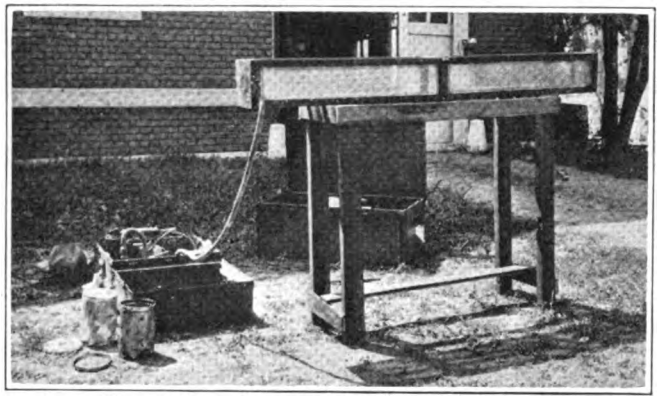

Fig. 1—Miniature Reproduction of Mine Gallery

This box, which is 6 ft. long and of 6x6 in. cross-section, is provided with means to blow compressed air into a pile of coal dust within the box thus raising a cloud. An open-flame lamp placed inside the "gallery" ignites the dust, causing an explosion which can be clearly seen through the glass walls. As no gas is present, the dust is demonstrated to be capable of causing an explosion without the aid of gas.

explosibility of coal dust from open flames in the absence of gas. This gallery is 6 ft. long and 6x6 in. square, with all four sides of glass; the rear end may be tightly closed. One-half oz. of coal dust is placed upon the floor of the gallery at the rear and blown by compressed air down over a carbide lamp placed 18 in. inby the open end of the gallery. The coal-dust cloud ignites and a mass of flame, sometimes of a volume of 200 cu.ft., issues from the mouth of the gallery. This miniature entry way is shown in Fig. 1.

These tests prove the probability that explosions will occur from the ignition of coal dust when no gas is present. They substantiate the conclusions reached after the Starkville (Colo.) explosion of 1910, the Dolomite No. 3 mine explosion at Dolomite, Ala., in 1922 and the Dawson No. 1 Mine explosion, Dawson, N. M., in 1923. The second explosion mentioned was caused by cars breaking loose, running down a slope, wrecking themselves and stirring up a coal-dust cloud, which was ignited by an electric arc of a ruptured power cable.

The first and third explosions were caused by wrecked trips knocking out timbers and also raising dense coal-dust clouds which were ignited by arcs from short-circuited trolley wires. These accidents confirm the experimental results, which show that coal dust can be ignited with open lights or electric arcs in the absence of explosive gas.

Underground dumping presents a similar hazard. In the dumping operation, frequently a dense cloud of coal dust is put into suspension. In many mines open-flame lamps are worn by the workmen. Electrical equipment for dumping is frequently installed and even where pneumatic dumps are employed, electrically driven car hauls are used nearby.

The mine may, therefore, have an extremely hazardous condition—a known source of ignition and the likelihood of a dense coal-dust cloud. It is a solution of this problem that confronts the coal-mine operators where underground dumping of coal is practiced or is in contemplation.

It is interesting to observe that every mine visited during this preliminary investigation had adopted some method to prevent the coal dust that is formed in underground dumping from traveling back into the mine workings. There are two predominating systems which are often combined. One is to put a dump on a separate split of air and the other to use a water spray.

A notable example of having the dump on a separate split is the Harmar Mine of the Consumers Mining Co., Harmarville, Pa. When the two-car rotary dump and skip hoist were first installed as the shaft was downcast, coal dust accumulated in dangerous quantities at the shaft bottom and on the intake airways. In order to overcome this condition, the hoisting shaft was made neutral and 12,000 cu.ft. of air per minute was passed over the dump, approaching it from both sides.

CUT A HOLE IN CONCRETE LINING

About 10 ft. inby the shaft a hole about 5x5 ft. was cut in the concrete lining, allowing the air to pass through a crosscut, over an overcast and thence to the fan shaft (Fig. 2). The cross-section of the crosscut is about 6x12 ft., and the sudden decrease in velocity of the air in passing from the smaller to the larger area causes a large quantity of the dust to settle on the floor. The air exhaust from the dump plays upon the threshold of the 5x5-ft. hole and thus prevents accumulation of dust there. Fig. 2 is a sketch showing the layout at the shaft bottom and the direction of the air through the bypass.

The shaft entry has been lined with concrete and thoroughly rock-dusted. Any coal dust settling on the white surface would be readily discerned, but only slight quantities were seen on the inby side of the dump. The atmosphere is very clear during dumping. In order to further remove the coal dust from the air passing through the bypass, the company is considering installing a water spray at the 5x5-ft. port.

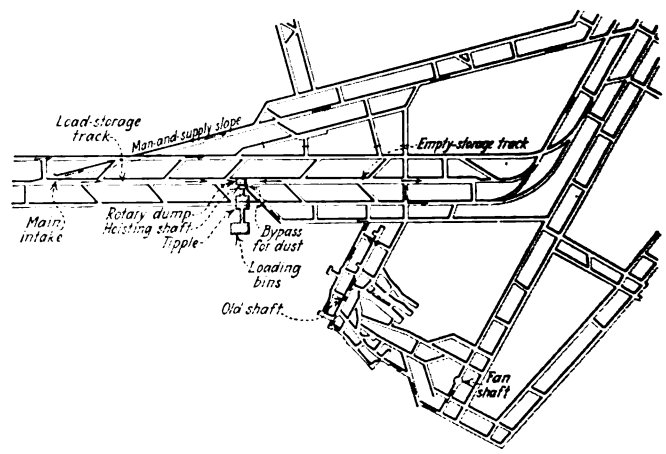

Fig. 2—Dust Prevention at Harmar Mine

The shaft has been made neutral as far as ventilation is concerned, but a hole 5x5 ft. in cross-section, has been cut in the concrete lining of the shaft bottom, which hole is connected with the return. Into it air is drawn from the mine. The air exhaust plays on the threshold of the hole and thus prevents dust from accumulating at that point.

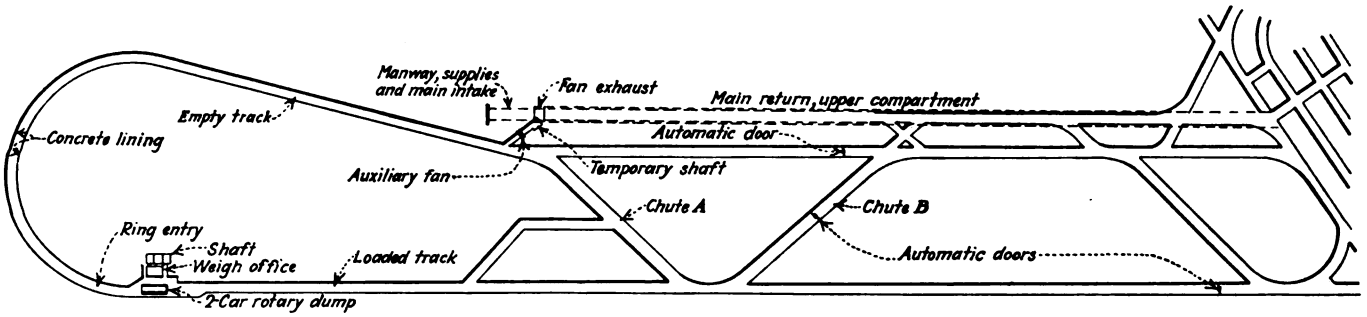

Fig. 3—Powhatan Dump Is at Foot of an Upcast Shaft; Much Dust Settles on Timbers

Three automatic mine doors have been introduced to prevent the dust from entering the mine when the air is reversed. An auxiliary fan of a capacity of 50,000 cu.ft. per minute causes air to flow along the empty track to the dump where it joins the air coming through chute *A* and through the trackway for loads. This air passes up the shaft. In this instance the dust accumulates on the stairway and buntons in the hoisting shaft as well as on all surfaces on the shaft bottom. The latter is flushed with water every night, and a water line is being laid for the flushing of the shaft from the surface.

The Springdale Mine of the Allegheny Pittsburgh Coal Co., Logans Ferry, Pa., is unique, in that the hoisting shaft is reached by a pair of entries driven under the Allegheny River. The coal is dumped by a two-car pneumatic rotary dump into chutes which load directly into a double-deck skip. A thick cloud of dust is raised during this operation.

An auxiliary fan, delivering 50,000 cu.ft. of air per minute ventilates these under-river entries the air passing up the hoisting shaft. At present only single doors are placed on the haulage roads at the beginning of the split. Whenever these doors are opened there is a reversal of the air current, which tends to draw the coal dust back into the mine.

Plans have been made to install automatic doors forming an air lock of sufficient length to accommodate a trip of cars, thereby eliminating the reversal of the air current. As the river entries are very wet, little dust passes into the main part of the mine, which is rock-dusted.

Automatic Doors Keep Dust from Mine

The Powhatan Mine of the Powhatan Mining Co., Powhatan, Ohio, dumps the coal into a skip hoist by means of a two-car rotary dump at the bottom of an upcast shaft. Much coal dust is raised into suspension while the coal is being dumped. In order to prevent this coal dust from returning into the mine, automatic doors have been installed on the two shaft entries and a connecting chute *B* (Fig. 3) and an auxiliary fan, delivering 50,000 cu.ft. of air per minute, causes air to flow along the empty track to the dump, where it joins the air coming through chute *A* and the loaded track, and from thence passes up the shaft. Much of the coal dust thrown into suspension when dumping accumulates on the stairway and buntons in the hoisting shaft, as well as on all surfaces at the shaft bottom. Every night the shaft bottom is flushed with water and on the surface a water line is being laid to the top of the shaft to provide a means of flushing out the shaft.

The shaft entries are rock-dusted. Coal dust accumulates on the surfaces of these entries, especially from the dump inby to chute *A*, due to the reversal of air whenever the automatic doors are opened.

Mine No. 3, National Mining Co., Cowden, Pa., which uses skip hoists, has a rotary dump at the bottom of a shaft, which is downcast. The dump is, therefore, on the intake air, but the air velocity over the dump is low. In an attempt to prevent the dust, formed in dumping the coal, from being carried back into the mine, water sprays were first tried but they were abandoned for the present method.

Steel plates saparate the shaft from the dump and in this plate have been cut two openings, 1 ft. 6 in. x 3 ft. Opposite the dump is a crosscut in which is placed a concrete stopping. A bleeder opening 15 x 22 in. permits a small quantity of air to short-circuit and pass into the return airway.

Rock Dust Sifts Down on Coal Particles

Directly over this opening is placed a steel hopper (Fig. 4) with a capacity of about 350 lb. of rock dust. A perforated iron strap, 2 in. wide is placed in the bottom of the hopper, to each end of which is attached a steel rope which passes over a pulley and thence to the weigh basket.

As the weigh basket moves, the iron strap also moves back and forth, the holes register with holes in the bottom of the hopper thereby causing rock dust to sift down over the opening and mix with the coal-dust cloud. It will be necessary, however, to install an agitator to prevent the rock dust from packing. The rock-dusted entry on which the dump is located shows that little coal dust passes back into the mine.

The installation of a single-car rotary dump and skip hoist in the Harwick Coal Co.'s mine at Harwick, Pa., immediately presented a great coal-dust hazard. In a single day coal dust would accumulate from ¼ to ⅜ in. thick for 100 ft. inby the dump. To overcome this condition a 12-in. pipe was connected to the upcast shaft and brought to the dump. A strong suction was obtained at the end of this pipe, but being located at the roof and against the left rib, considerable quantities of the dust passed into the entry beyond.

The dump is on a strong intake current, and the necessity of preventing the coal dust returning into the mine is fully appreciated. The pipe was not entirely successful, so arrangements have been made to install water-spray curtains. Also a canopy or hood may be placed over the dump and connected with the suction pipe or a horizontal slit run across the entry at the roof and connected with the upcast shaft through the pipe.

When the H. C. Frick Coke Co. consolidated its Colonial Nos. 1, 3 and 4 mines and installed the now-famous belt conveyor, 22,930 ft. long, means were taken to provide enough coal to keep the belts loaded at all times. Two rotary dumps, 374 ft. long were installed, with a capacity of from thirty-five to forty cars each. The coal dust formed in dumping such a large number of cars is not great. Red signal lights at one end of the dump may be easily seen from the other end, 374 ft.

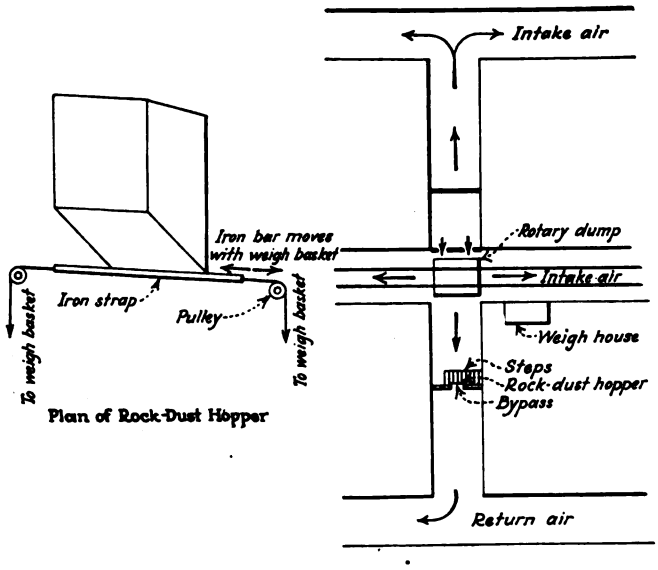

Fig. 4—In Downcast Shaft at National Mine No. 3 Return Air Is Bypassed Through Dump

The air velocity in the shaft is low and it was thought that water sprays would be adequate to prevent dust from entering the mine. These failed, however. So air was brought through a crosscut and through the steel plates between the shaft and dump, whence it passed into the return airway. The bin shown on the left is kept supplied with powdered rock. The movement of the weigh hopper opens holes in the bottom of this bin causing the pulverized rock to be sprinkled on the coal dust.

distant, while trips are being dumped. The small quantity of dust is due to the thorough wetting of the coal at the face by the miner.

However, to prevent any dust returning into the mine, about 26,000 cu.ft. of air is brought into the dump at each end and then passes upward and out of openings, three of them on the right side and four on the left, to the return airways. At each opening is installed a water spray to beat down coal dust from the air passing into the return.

Another mine in the same district also uses water on the cutter bars of the mining machines, and the miners sprinkle the coal before it is loaded out. As a further means of laying the coal dust, the rotary dump, which is used in connection with a skip hoist in a neutral shaft is covered with a steel hood.

Curtain Spray from Water Ring

As the cars are turned over the coal dust is beaten down by a curtain spray from a water ring composed of 2-in. pipe, placed on all four sides of the dump, in which ⅛-in. holes are drilled every 3 in.; the water is under a pressure of about 95 lb. per square inch. No dust was seen anywhere on the bottom. The walls, although whitewashed about nine months previously, were fresh and white.

Where the hoisting shaft is downcast and the dump is on the intake airway, as in the Harwick and National No. 3 mines, there is a great tendency for the coal dust to be carried back into the mine. The use of a single suction pipe with no special nozzle or no hood or canopy over the dump has failed at the former mine. The bypass in the National mine appears to remove the greater part of the coal dust from the air. In each case there was considerable coal dust on the floor and down in the chamber below where the weigh basket was located. This coal dust must be loaded out every night.

The Springdale and Powhatan Mines, by making the shaft upcast prevents the dust from returning into the mine, except when the connecting doors on the haulage roads cause a reversal of the air. Air locks will eliminate this feature, but accumulations of explosive dust in the shaft affect the most vital part of the mine. Danger would result from an explosion in the shaft. Dust accumulations at the shaft bottom and in the pit below the dump are added dangers. Some solution of the problem will doubtless be worked out.

A neutral shaft, as at the Harmar Mine, allows the dust to be collected through a bypass. However, here again we are confronted with dust accumulations on and below the dump. Undoubtedly the neutral shaft is the best means of providing for dust collection and elimination but a bypass with dry-collecting methods have not satisfactorily met the problem.

Water at Face at Colonial Mines

The Colonial Mines' use of water at the face, is a step forward toward the solution, but above, on and below the dumps, there is an accumulation of dry dust. The lessening of dust where water is used on the cutter bars of the mining machines and the sprinkling of the coal by the miner, as well as a strong water spray in an enclosed dump and a neutral shaft gives at least one solution of the problem. In the bins and the chambers surrounding them there was no dry dust, thereby reducing the dust hazard to a minimum.

Much dust is formed by cutting machines, by blasting and by the miner in picking down the coal and shoveling it into the mine car. The dust problem at the underground dump is materially helped by the application of water on the cutter bar and by the wetting the coal before it is loaded at the face. In the shaft the accumulation of dry dust may be much lessened by use of a water ring in connection with a neutral shaft, which, however, in winter would require a small split of warm return air to prevent the water from freezing.

The use of water may be impractical in some mines; more especially where the dump is on the downcast which may result in freezing the water in winter. Satisfactory removal of the coal dust formed in dumping may be obtained under these conditions if the shaft or slope be made neutral, a bypass be provided at or near the dump, and a water spray installed to remove the dust from the air in the bypass.

In addition, the bypassed air should be allowed to expand immediately after leaving the dump and before reaching the return air. This is done at the Harmar mine and the result of this sudden decrease in velocity of the moving air is to deposit about 75 per cent of its coal dust before reaching the return airway. This method prevents coal dust being carried back into the mine, but has the disadvantage of allowing dry coal to accumulate around the dump.

Several large coal companies are investigating the possibilities of a dust-collecting system which will remove the coal dust from the bypassed air and deliver the cleaned air to the return airway. It is the opinion of several well-known ventilating and dust-collecting engineers that some such system could be adapted to mine conditions, one which would be practicable, and would collect at least 85 per cent of the dust.

It will be seen that the coal-dust problem from dumping underground has not yet reached a fully satisfactory conclusion for all conditions of shaft and ventilation layout, but there is every reason to believe that in time the problem will be solved.

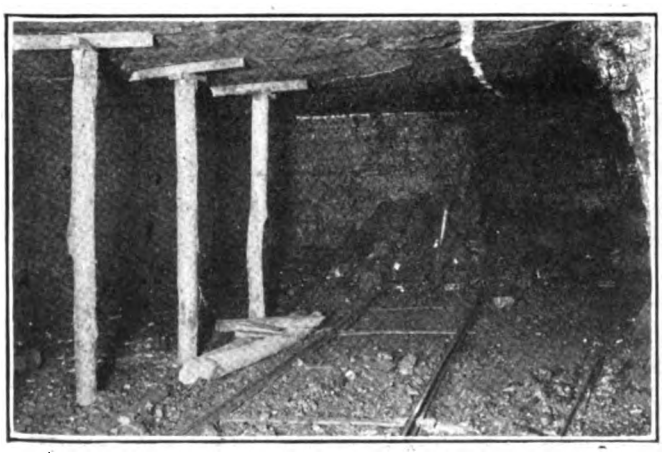
Crozer Roadways Having Reached Boundaries of Property, Mines Now Work in Full Retreat



Drainage and Haulage Grades Planned Before Roads Were Driven — Advancing-Work Profit Paid Development Cost—4¼-Mile Haul—Track Laid Like Railroad as to Lines and Grades

By a Staff Correspondent

THE OPENING UP of the Crozer mines of the Crozer Coal & Coke Co., at Elkhorn, McDowell County, W. Va., which is midway between Bluefield and Welch, dates back to the early days of the Pocahontas field, when coal land sold for a song. At that time the Crozer Land Association acquired connected fee tracts aggregating over 10,000 acres underlaid with the Pocahontas No. 3 seam. This property has been mined for nearly forty years and will not be entirely exhausted a quarter century hence and perhaps not even then. The acreage is being mined by the Crozer Coal & Coke Co., the Upland Coal & Coke Co. and the Page Coal & Coke Co., all of which are subsidiaries of the land company. Several companies also have leased from the Crozer concern. It is with the systematic methods by which this property has been operated in the past, as exemplified by present methods at one of the plants, namely, that of the Crozer Coal & Coke Co., that this article deals.

The territory allotted to this plant consisted of 1,838 acres of thick coal belonging to the Pocahontas No. 3 seam. The mine started operations in 1887. Of this acreage, 1,064 acres have been mined out during the last thirty-eight years. Of the coal that remains 145 acres are in pillars and 629 acres in the solid. The average recovery during the past life of the property is 86.7 per cent, but in late years it has been about 90 per cent.

One of the Rooms in the Crozer Mines

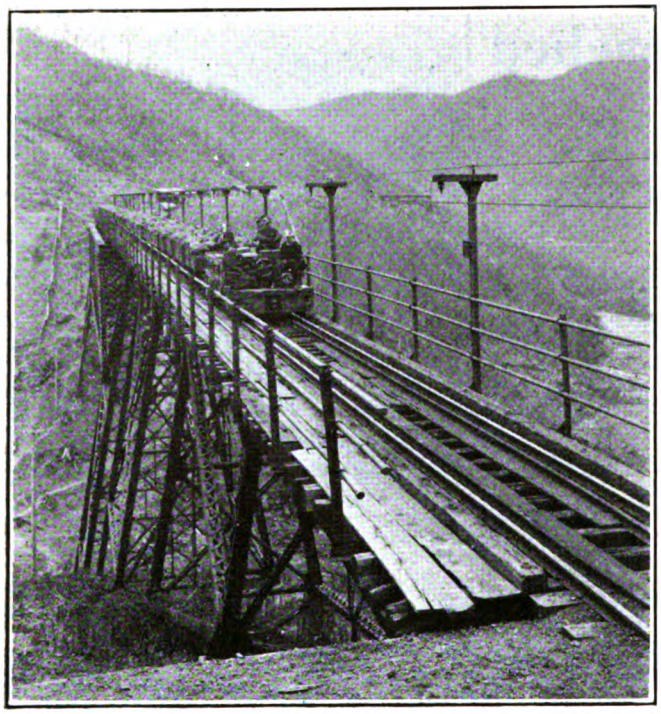
The seam is 7 ft. 10 in. thick. Note that the sight line has been extended to the face and that a supply of timber, cap pieces and wedges are kept on hand. This place is 18 ft. wide.

The headpiece shows the town and plant of the Crozer Coal & Coke Co., at Elkhorn, W. Va. Most of the power consumed in the Crozer mine is generated in the steam plant shown. The office and store building occupies the center of this picture. The railroad in the valley is the Norfolk & Western which is electrified along this stretch.

The operation consists of five mines, all of which lie under one hill. A fingered hollow almost completely divides the property into two territories which are connected by a rather narrow neck. Of these two areas that which is adjacent to the Norfolk & Western R.R., which serves this operation, is by far the larger.

Within the boundaries of this larger territory are Mines Nos. 1 and 2. Mine No. 2 is exhausted to such an extent that in it the coal being mined is derived solely from the barrier and chain pillars of the main entry which is on the retreat. No. 3 mine is now entirely mined out. During its life coal from it was hauled through the narrow neck which joins the two main territories and through No. 2 mine to the tipple.

Decided to Advance Entries to Crop



No. 1 mine is depleted except for the barrier and chain pillars of the main entry and a few room pillars which are being mined in the final stages of the retreat toward this entry. As this main heading of No. 1 mine must serve as a part of the main haulway from Mines Nos. 4 and 5, the pillar coal which protects it will not be mined until after the latter operations are finished. Mines Nos. 4 and 5 which lie in the smaller of the two main territories already mentioned, are comparatively new operations.

The development of these two mines was started in 1915 and was continued through the years of the World War when most of the coal produced at this plant came from Mines Nos. 1 and 2. It was decided at the beginning of this period to advance the entries in these new mines, leaving the coal practically intact until the boundaries were reached, and then to remove by rooms and pillars the coal thus developed, working all the time on a full retreat.

The high prices for coal obtained during the last few years of the Twenties did not swerve the management from its predetermined plan. The company balanced the high cost of this development work in its two new mines by the lower cost of the coal from its old mines. During the prosperous years, while the old mines were on the retreat, the new mines were being developed on the advance.

Today, as already intimated, little coal is being produced by the old mines, but the plant nevertheless produces about 1,700 tons per day. Most of this coal is being won in the new mines which, having been de-

By This Bridge a Circuitous Roadway Is Obviated

This steel structure is 630 ft. long and incorporates a 210-ft. span. Its elevation above the bottom of the valley is 115 ft. By its erection the road was shortened and straightened. Had it not been built, the tramway would have been compelled to follow the outcrop up the ravine, tracing the contour of the hill in most of its many erratic turns.

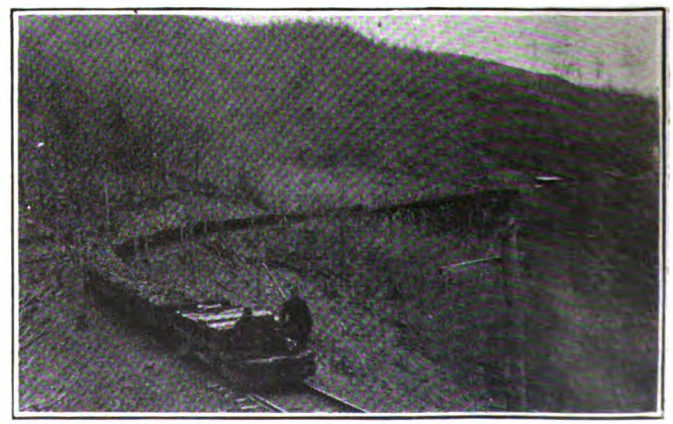
veloped to their boundaries, are now on the retreat. In 1925 the Crozer plant produced 443,000 tons. In recent years prior to the last it maintained its standing as a big producer in the field, a fact which under the circumstances indicates the value of a nice balance between the high cost and lesser productivity of territory under development on the one hand, and the lower cost and greater productivity of territory being mined by rooms and pillars on the other.

PROJECTED LINES AND GRADES

Prior to the beginning of the development work in Mines Nos. 4 and 5, the area to be traversed by these mines was surveyed. Levels also were taken to determine what would be the most logical layout. This preliminary work was carefully collated so as to obtain in advance the data necessary for predetermining a layout with particular reference to grades and drainage and to the possibility of easy access to the areas lying within promontories in the crop line. Accordingly, entries were projected on the map, and this layout has since been followed to advantage with scarcely any variation.

The success of this scheme shows that it is good policy to plan a mining operation with almost the same exactness with which a surface development is designed. Many mines in regular seams are extended on short-time projections which are chosen without much regard for the future of the property. In contradistinction the program at Crozer embraced operations over long periods of time.

The Pocahontas No. 3 seam in these mines has an average thickness of 94 in. and contains two partings. One of these is a 2-in. hard shale occurring about 9 in. from the roof, which the miners call a sulphur band, and the other is a 4-in. bed of bony coal which occurs about 55 in. from the bottom. No attempt is made to remove these impurities at the face. The separation is made by hand picking at the tipple and by means of a Bradford breaker in accordance with a procedure which is described elsewhere in these pages.



The mining system provides for the greatest possible degree of concentration in mining the rooms and pillars. Rooms are driven only as needed and the pillars are drawn immediately in a retreat from the limits of the property and on a 45-deg. extraction line. Each room entry provides an average of nine working places, of which five are advancing rooms and four are retreating room pillars. Rooms are driven 18 ft. wide on 70-ft. centers and are 330 ft. long. Entries are driven 12 ft. wide on 70-ft. centers. The major entries are protected by barriers which in width vary from 150 to 500 ft.

NINETY PER CENT RECOVERY

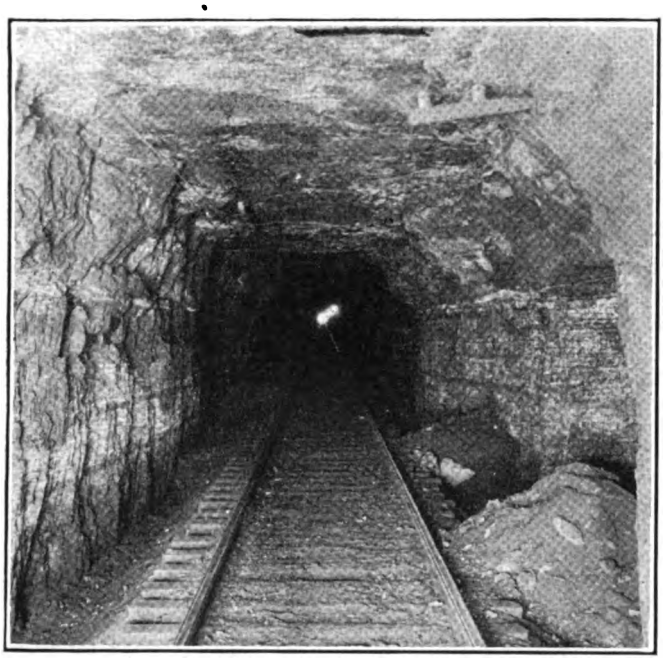
Although the necessity for concentration of working places in the room-and-pillar system of mining has for many years been realized, until recently few companies followed this practice. The Crozer Coal & Coke Co. is numbered among that few. By practicing concentration during the last 38 years, it has recovered 86.7 per cent of the coal in the area mined. Due to further refinements of its methods in recent years, its recovery has been about 90 per cent.

Practically none of the roof, which is of shale, is taken with the coal. The thickness of cover above these mines varies from 250 to 500 ft., of which 60 to 70 per cent consists of sandstone. The sandstone beds are more or less shaly, except the Eckman, which is massive. This bed varies from 20 to 50 ft. in thickness and occurs 75 to 100 ft. above the coal seam. Perhaps no other seam in the country breaks less readily. Nevertheless it is being controlled without much difficulty by concentration methods. This would not be the case, nor would the recovery be nearly as high, if the rooms had been driven promiscuously and pillars drawn irregularly.

The fact that a projection was determined before work commenced in Mines Nos. 4 and 5 has already been mentioned, but something should be said as to the accuracy with which the development is made in accordance with that plan and as to the manner in which that accuracy is attained. All entries and rooms are driven on sights. On the entries, sight spads are put

Loaded Trip En Route to Tipple

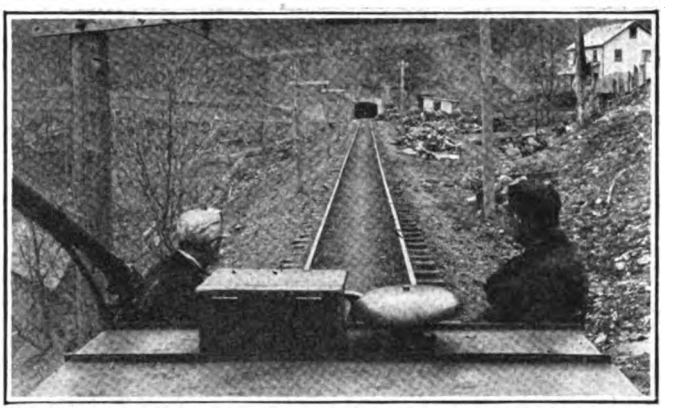
Coal from the face to the tipple at the Crozer mines is handled in two lifts. It is hauled one-third of the way by 15-ton locomotives to a sidetrack which adjoins the far end of the bridge and by 20-ton locomotives from this point to the tipple. Here is shown a 20-ton motor coupled to a standard trip of 40 cars. Each car holds 3½ tons of coal.



Digitized by Google

in place by the engineering corps at intervals of 200 to 250 ft. Sight lines in rooms are painted by the trackmen. Levels are run every three months to determine drainage and grades. These are taken at intervals of 50 ft. on all entries and in all rooms which dip to excess.

Such details as listed above are more or less the routine of the engineering corps at any modern mine. However, the duty and responsibility of the Crozer corporation does not stop here. The engineering department keeps in close touch with the operating management and keeps informed as to the "strategy" which must be followed in driving rooms and pulling pillars. The mine officials of course have their say in determining what this strategy shall be. The engineering corps not only locates proposed working places, but it also informs the underground officials as to when this or that room or entry shall be started and when work on a pillar shall be started or stopped.



Between visits of the corps the underground officials naturally must have jurisdiction, and furthermore may make an appeal against any decision of the former with regard to the sequence of working. This three-sided arrangement gives each of the factions which compose it an opportunity to make suggestions and obtain a clear knowledge of the purposes underlying the system of extraction.

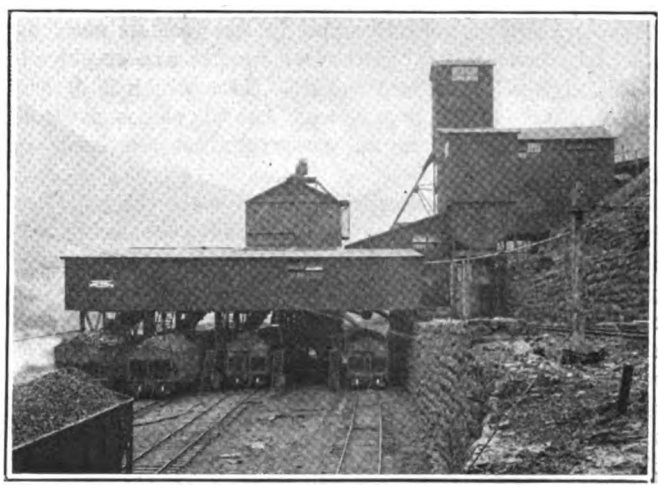
At the beginning of a retreat from the boundaries, the hauls must of necessity be unusually long. The distance from the innermost point on the main haul in No. 4 mine to daylight is about 5,000 ft.; in No. 5 mine this distance is about 7,200 ft. From the main portal of No. 4 mine, which also serves as an exit for trips from No. 5 mine, the haulage to No. 1 mine consists of an outside tram road, 3,100 ft. long, which spans by a bridge the mouth of a deep hollow. This bridge is a steel structure which is 630 ft. long and lies at a maximum level of 115 ft. above the hollow. Without this bridge the haulage would have been compelled to follow a circuitous path along the crop line of this ravine.

A Long Straight Haul Through No. 1 Mine

Derailments on the main haulageroad in the Crozer mines are practically unknown. This stretch of straight track is 5,800 ft. long. The rails weigh 56 lb. per yard and are laid on 6x8-in. oak ties. A uniform grade of 0.7 per cent against the loads has been established on the stretch. Note the track cleanings on the side, which is a further indication that every precaution is taken to make haulage efficient and safe.

Good Track Makes Derailments Infrequent

From face to tipple on the main haul, through a distance of about 4 miles, the track is as good as that here shown. Note how carefully the trolley wire has been hung and aligned.

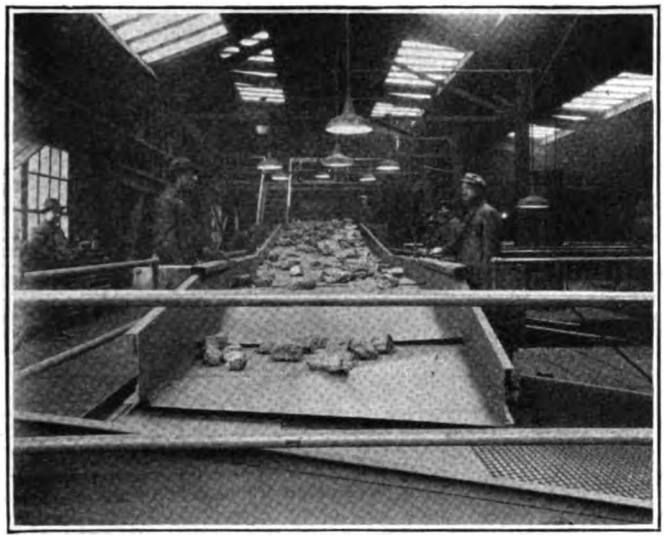


The length of the main haul through No. 1 mine is about 8,300 ft., and from this mine to the tipple along an outside tram road the distance is about 3,750 ft. The maximum haul from No. 4 mine to the tipple, therefore, is 20,150 ft. or 3.81 miles and from No. 5 mine to the tipple 22,350 ft. or 4.23 miles.

Long Haul But Few Derailments

Generally speaking, the chance of derailments is proportional to the length of the haul. Conditions being the same in a haul of one mile as in a haul of two, derailments in the latter are likely to occur twice as often as in the former. In the Crozer mines derailments on the main 4-mile haulways are indeed rare.

The tracks in the rooms are laid with 20-lb. rails and rest on steel ties; room entries are tracked with 30-lb. rails and the main haulways with 56-lb. rails. The heavy rails in the latter case are laid on 6x8-in. oak ties spaced at 15- to 18-in. centers. These main tracks are ballasted with cinders from the boiler house, the company generating the larger portion of the power used at its mines.



As shown by several accompanying illustrations of stretches of track, inside and outside the mine, the rails are aligned and ballasted with a precision which rivals that of steam railroads. Grades are flattened out as much as possible over long stretches which are generally

Tipple Recently Built to Replace Older Structure

Lump, egg, nut, pea and slack are prepared in this tipple. Refuse is handled from a mine track which has been built on the embankment between the two-stepped stone walls.

straight. One stretch of faultlessly straight track in the No. 1 mine is 5,800 ft. long, the grade being 0.7 per cent against the loaded trips.

Where curves are required they are described on a long radius. On the main haulways leading to No. 5 mine are two curves, one of 500-ft. radius and the other of 400 ft.

The mine sidetracks are of such length as to accommodate 20 mine cars. They are so located as to be not more than 1,000 ft. and not less than 600 ft. from the working places they serve.

LOCOMOTIVES BETTER THAN MULES

Coal, in the concentrated workings of Nos. 4 and 5, is gathered by seven 6-ton, storage-battery and one cable-reel locomotive. What little pillar coal is now being mined in Mines Nos. 1 and 2 is being gathered by mules. In 1925 the average daily duty of each of the storage-battery locomotives was 45 cars of 3½ tons capacity. The cable-reel locomotive last year gathered on average only 36 cars per day, due to the fact that the working places which it covered were scattered.

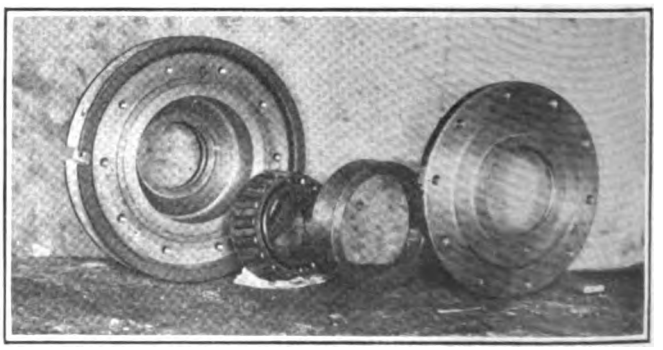
Four single teams and one double team of mules each gathered an average of 28 cars per day. The grades, which at most mines would not be considered heavy, are approximately equal in the various sections in which these several gathering agents are employed. The maximum grade in a working place which is driven on the dip is about 3 per cent, but as places are not thus driven the maximum grade against the loads is less.

The duty of the gathering locomotives in the past has not been high, because as the entries were being advanced to the boundaries in all directions their faces were widely scattered. Now that the limits of the property have been reached and the direction of mining has been turned from an advance to a retreat, the management is in a fair position to derive those advantages which go hand in hand with concentration. In consequence the day's work of the gathering locomotives should be measurably increased.

From the underground sidetracks in Mines Nos. 4 and 5 loaded cars in trips of twenty are hauled by two 15-ton locomotives to the "daylight sidetrack." This parting is about 800 ft. long. At this point two 20-ton locomotives operating individually haul trips of 40 cars to the tipple, these trips arriving at the dump at 25-min. intervals. A third 20-ton locomotive is maintained as a spare.

Will Test Value of Roller Bearings for Locomotive Armatures

The Pennsylvania Coal & Coke Co., of Cresson, Pa., is testing the application of tapered roller bearings to the armatures of its locomotives and will make careful study of their availability for this service. Play caused by radial and end-thrust wear will be taken up as is done with the bearings of automobile wheels.

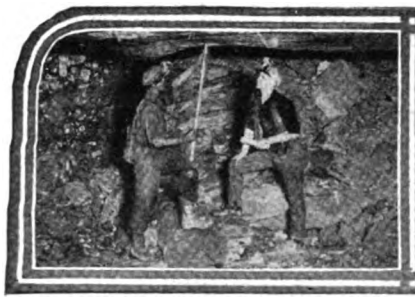


J. F. MacWilliams, the electrical engineer of the company, has worked out an assembly which he believes makes it possible to use the housings now in place. The chief advantages claimed for this design are ease in assembling and taking apart, a provision for adjustment, and ruggedness of the retaining plate and locking device. The accompanying illustration shows the application of the bearing to 10-ton locomotives.

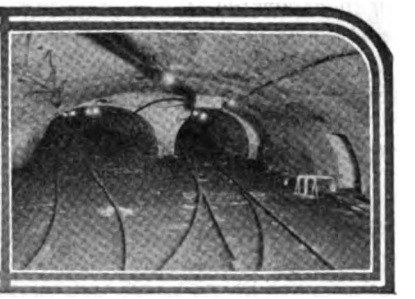
On the commutator end, the armature shaft is left the same size as that which was formerly used. The shoulder on this shaft, however, is turned farther back and this portion of the shaft threaded for the bearing sleeve. This sleeve carries a shoulder against which the inner race of the bearing fits, and is locked by a ¼x¼-in. key fitting in a slot cut in the end of the shaft. A locknut holds this key in place.

The inner race is renewed by unscrewing the sleeve from the shaft. It is the intention to apply the inner race to the sleeve only at the main shop, thus avoiding possible abuse of the race in the hands of unskilled repair men. A retaining plate is fastened over the end of the bearing by six studs which extend through holes drilled in the housing and are electrically welded at the rear end. When a new bearing is applied filler shims are placed between the retaining plate and the housing. These can be removed to take up bearing wear.

Arrangement of the pinion-end bearing is somewhat similar to that on the commutator end. A steel sleeve is put on the shaft and a cast-steel bushing is pressed into the housing. This bushing is necessary because the bearing formerly used was of larger diameter than the roller bearing. The retaining plate on this end of the shaft is made from a piece of 1¼-in. boiler plate. Ten ½-in. cap screws hold it in place.



The company now has three locomotives operating with roller-bearing armatures.



Pinion-End Roller-Bearing Parts

In case the "fit" of the old housing is worn it is built up by means of the oxy-acetylene torch and a manganese-bronze filler rod, after which it is machined to proper size. The housing cap is held firmly in place by means of cap screws.

Underground Operation

What Concrete-Block Stoppings Cost And What They Achieve

Average Cost Under Forty Dollars—Each Stopping Holds 100 Cu.Ft. of Air That Wood Brattice Had Been Passing — Blocks Made in Mine

By G. N. Pfeiffer
Consulting Engineer,
Herrin, Ill.

Cement-block stoppings have proved their value at No. 5 Mine of the Franklin County Coal Co., Herrin, Ill. They prevent losses of air where wood brattices gave no direct evidence of leakage, were found ineffective. The following data regarding their method of construction and cost have been supplied by T. Pilkington, the mine manager:

Cost of Cement Blocks at a Herrin Mine

Material		Cents per Block
Cement, 10 blocks to a sack	7.50	
Sand, 360 blocks to a cubic yard	0.56	
Coal oil for molding plates	0.05	
		8.11
Hauling		
Water	0.50	
Ashes, sand and cement	1.65	
		2.15
Labor		
Screening and loading ashes	3.04	
Making blocks	8.33	
		11.37
Depreciation of machine and tools		1.37
Cost per block in cents		23.00

Cost of Cement-Block Stopping

		Cost, Average Stopping
Blocks 85@23c. each		$19.55
Mortar		
Lime, ½ bbl.	$1.10	
Sand, ½ yd.	0.51	
Cement, 1 sack	0.75	
		$2.36
Hauling water and material		2.38
Labor		
Hitches and cleaning	$3.75	
Mason	11.25	
		$15.00
Total		$39.29

The blocks which are solid and measure 8x8x16 in. are hand-tamped in a small machine. The mixture by volume consists of 1 part cement, ¾ part sand, 6 parts of ashes and 1½ parts of water. The cement costs 75c. a sack at the mine. Ordinary river sand is used which costs $1.50 a ton delivered at the mine. The ashes, from the mine boilers, are screened by hand over a ¼-in. screen, the cost of the operation being on an average $3.50 for 115 blocks. It takes a trifle more than 2½ cu.yd. of screened ashes for 115 blocks.

This high cost is due to the fact that the ashes made from the coal at this mine are relatively free from clinker. Even when the refuse from the picking tables is burned the ash seldom fuses so as to cause trouble. The cement, sand and screened ashes are loaded into mine cars during the day.

Send Blocks Down at Night

These cars are lowered into the mine on the night shift when the regular mine material is sent down. The labor of delivering the material to the point where the blocks are made is the equivalent of two hours' work for one man. The cost of delivery of the material, therefore, is about $1.90.

The location selected for making the blocks is a room not yet abandoned and located nearly a mile from the shaft. No extra track has had to be laid and no new timbering has been necessary. When the room is abandoned it will be easy to move the equipment.

The temperature and humidity of the air is practically the same, winter and summer. Consequently there is no danger that the blocks will freeze in the winter or dry too fast in the summer; considerations that might be harassing if the blocks were made on the surface.

With good mine tracks and delivering other mine supplies on the same trip the cost of hauling the materials is practically the same whether the location selected is a mile or a thousand feet from the shaft. The illumination in the improvised block factory is furnished by the carbide lamp of the man who makes the blocks.

The only place in the mine where water is pumped to the surface is at the shaft. Some of the working places, it is true, make a small quantity of water. This is baled into barrels and hauled away to the shaft or old workings by the night shift. In some cases the water is used for sprinkling the roadways.

Use as Little Water as Possible

The water used for the blocks and for building the stoppings really costs nothing, but a charge has been made for water in figuring the cost of both manufacturing the blocks and building the stoppings. This water contains 2 to 3 per cent of salt. It is not acid, at least not to the extent that it will corrode pipes or a pump.

The quantity of water used depends upon the dryness of the sand and ashes as received in the mine where the mixing is done. The mixture is kept as dry as possible consistent with the need to make a block so coherent that it can be removed from the machine without breaking.

Blocks Set on Bottom Plate

A bottom plate is placed in the machine for each block, and the product is removed from the machine resting on the plate on which it is allowed to remain for 24 hr. during which time the cement takes its permanent set. After this the blocks are cured for 9 days. The plates are wiped with coal oil. This makes them separate easily from the concrete.

In the process of manufacture, the material for the blocks is well tamped by hand into the mold so that the block will be so dense that the air will not leak through it when it

Digitized by Google

is incorporated into a stopping. As a tight joint between the blocks and the coal is necessary, the practice is to clean away the accumulated gob and to cut hitches 6 in. deep into the solid coal for the blocks and mortar.

Such stoppings are highly efficient. Ordinary wood stoppings are usually erected when the entries are driven, block stoppings being added when more air is needed at the face. The block stoppings are erected without disturbing the old wood brattices which, on examination, appear practically tight.

Air Goes Through Wood Stoppings

When, however, a block stopping is erected in front of one of them the mason frequently is annoyed in placing the last block or two because of the high velocity of the air passing through the uncompleted part of his work.

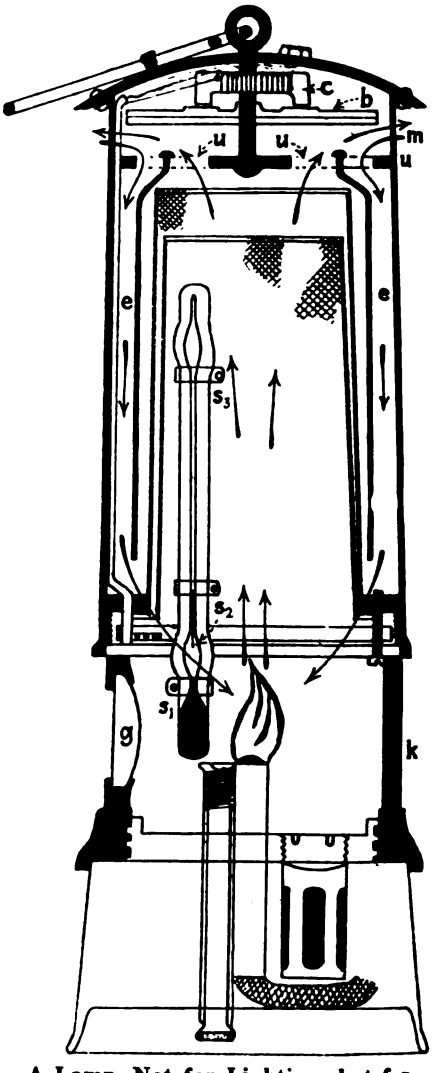
The efficiency of the block stoppings is well proved by the air readings taken before and during erection. As a result of such readings it has been determined that if a pair of entries is passing 20,000 or 25,000 cu.ft. of air per minute, the air at the last crosscut under average conditions will be increased 1,000 cu.ft. per minute for every ten block stoppings erected—quite a sizeable gain in ventilation.

Should Make 45,000 Blocks

In figuring cost no allowance was made for superintendence, as the mine manager and other bosses are on a salary basis and the supervision of the construction of the stoppings is considered a part of their routine work. The allowance for depreciation is at best a guess. The machine now used has already made 4,500 blocks. For this mine alone the machine is expected to make 40,000 more. It cost $250. To be on the safe side the depreciation was based on the assumption that the machine would make 25,000 blocks without replacement.

Sounds Alarm if Methane Or Bad Air Is Present

Many have been the attempts to devise equipment for detecting the presence of dangerous gas in a mine. In this country the flame safety lamp is the all but universal means employed for this purpose. It is subject to many shortcomings, however, and in other countries trials are constantly being made of other devices. One of the latest of these is known as the Czechie-Sliva firedamp indicator and alarm. This is described by the *Iron and Coal Trades Review* in part as follows:



This device, invented by Milosh Sliva, a Czech miner, now in France, consists of two fairly distinct elements, the one serving as an indicator and the other as an alarm. The two are connected electrically. The indicator portion resembles a Wolf bottom-feed safety lamp and burns benzine. Both the air inlet and exit are placed in the uppermost portion of the outside cover of the lamp (see *m*, in the accompanying cross-section). Air entering at this point travels down the outside of a sheet-iron tube *e* placed between the gauze bonnet and the outside lamp casing. Below the air inlets is a perforated cover *u*, above which is suspended by means of a small solenoid *c* an asbestos-lined sheet-iron plate *b*. If this plate drops it cuts off the air supply to the flame.

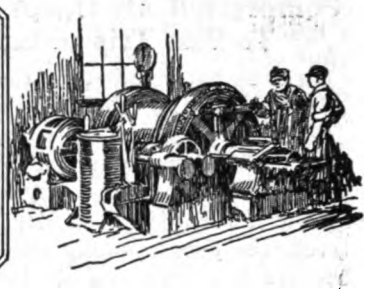
Beside the flame is a thermometer fitted with three electrical contacts. The bulb of this thermometer is on a level with the flame and its distance from it governs the speed of operation of the alarm. At a mean temperature of 260 deg. C the indicator records the presence of gas in not to exceed 15 sec. The glass chimney of the ordinary safety lamp is replaced in this device with a metal cylinder *k* in the side of which is placed a lens *g* for purposes of observation.

Alarm Separate from Lamp

The alarm portion of this device is a separate appliance being connected to the indicator by means of a 3-conductor cable. When the lamp is lighted the mercury in the thermometer expands until it touches the electrical contacts S_1 and S_2. The current thus flowing from the battery in the alarm box energizes the solenoid *c* which holds the plate *b* in suspension and allows the lamp to burn. Should flammable gas be encountered the extra heat generated within the lamp causes the mercury to rise in the thermometer until the contact S_3 is reached. This short circuits a fuse in the alarm box and burns it off. The solenoid is thus demagnetized dropping the disk *b* which cuts off the air supply to the lamp extinguishing it, as well as the burning methane. Should the lamp be extinguished from the presence of an inert gas a signal light shows in the alarm equipment and a buzzer is sounded.

Tests have been conducted on this apparatus at the French National Mining Institute's station at Frameries. In a current of air containing 9 per cent of methane moving at the rate of 6 ft. 7 in. per second the lamp was extinguished, and the alarm device came into operation in from 10 to 15 sec. In a second test the percentage of gas was so regulated as to cause the flame to be elongated until it reached the gauze. After about two minutes the mercury short-circuited the apparatus and sounded the alarm.

A Lamp, Not for Lighting, but for Indicating Gas Electrically



This portion of the apparatus much resembles an ordinary safety lamp. If a dangerous quantity of methane is encountered the flame is extinguished and a warning sounded in the other element or alarm box. If inert gas is entered the flame is smothered, an electric bulb lights up and a buzzer is set in operation.

As a result of these and other trials the appartus was modified somewhat in detail with the idea of making its action somewhat more positive.

Practical Pointers For Electrical And Mechanical Men

Seamless Tubing and Arc Makes Bearings

In a period of six or seven years electric welding has come into such general use at coal mines that the lack of a welder in a repair shop of any size is a matter of comment. When a shop has a lathe and a power drill press, one expects to find that some sort of electric welding equipment is also provided.

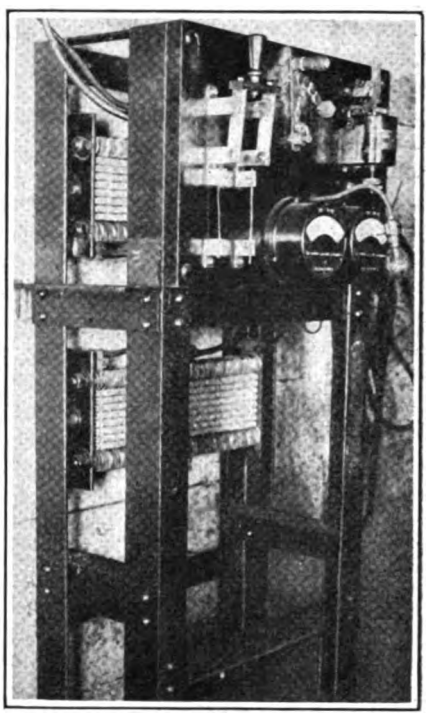
The combination of an arc welder and a lathe makes possible the handling of a wide range of work. This may vary from complicated repair jobs, to the manufacture of parts in an emergency or in cases where a saving can be effected.

Two arc-lathe jobs photographed in the central repair shop of the Pennsylvania Coal & Coke Corp., near Cresson, Pa., are shown in the accompanying illustration. At the left are two solid bearing boxes and at the right is the field frame of a mine locomotive motor.

Seamless Steel Tubing

The boxes were made by welding short pieces of seamless steel tubing onto pieces of bar steel. A hole was then drilled through the bar, the tubing bored out, faced and fitted with a bronze bushing. It is by this same plan that the boxes are made for the portable 20-ft. belt conveyors which the company uses in several of its mines. By keeping in stock a few short lengths of tubing of various sizes, bearings can be made on short notice.

The motor field frame in the photograph has had the worn fits of the axle boxes and the bearing housings filled ready for machining. This finishing is done by means of a special boring bar set up in a lathe. The motor frame is clamped on the carriage during the boring process.



The numerous welding jobs to be seen in this shop show how J. F. MacWilliams, the electrical engineer, utilizes to the full the possibilities of autogenous welding. In addition to the electric welder, an oxy-acetylene outfit is used for welding cast iron and on other jobs where a manganese-bronze filler rod is considered best.

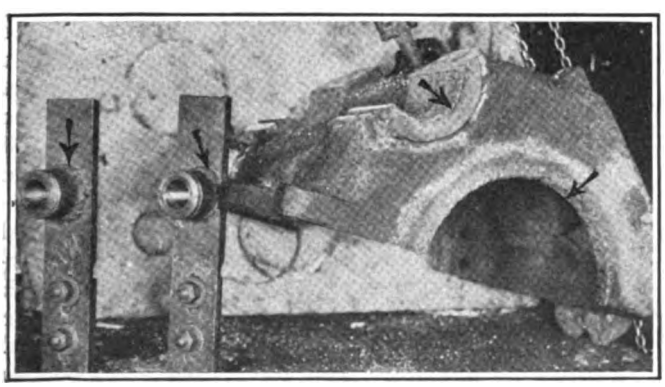
Charging Panels Constructed Specially for Mine Use

Mine equipment should be built sufficiently rugged for the rough service expected of it. This need for more rugged equipment was kept in mind by the Kingston-Pocahontas Coal Co. when they built their panels for charging battery locomotives in the Exeter mine, at Hemphill, near Welch, W. Va.

It was desired also to have panels which were semi-portable, for the reason that as charging is done from the 275-volt trolley circuit the stations can be, and often are, moved to suit the progressive development of the mine. One of the homemade panels, mounted in the combination pumproom and locomotive-charging station, is shown in the accompanying illustration.

The panel proper, which is 20x30 in., is made of 1¼-in. asbestos board and is painted black. The knife switch, instruments and automatic-

This Panel Will Not "Get Wobbly"



The corner angles are 4x4x⅜ in. and rivets are used in the assembly. Asbestos board 1¼ in. thick forms the panel on which the switches and indicating instruments are mounted.

reclosing breaker are standard parts, but the dial switch was made in the company's machine shop.

Standard Material Used

Resistors for limiting the charging current are made from grids and other parts regularly kept in stock for use in the mine locomotives, which feature is advantageous from the standpoint of maintenance. The four corner members of the frame are 4x4x⅜-in. angles and the bracing is such as to make the assembly quite rigid.

Although the panels are of a liberal design in so far as weight of material is concerned, it is reported that the cost of assembling in the company shop was not in any way excessive.

Welded Parts

The solid boxes are made by welding short pieces of seamless steel tubing to a flat bar. The motor field frame will be like new after the welded fill is machined. Arrows show welds.

Compressed Air Opens Door To Pass Trip or Car

In a recent number of the *South African Mining and Engineering Journal* is described an air-operated door. The mine gangway is closed by a pair of doors set at right angles and at an angle of 45 deg. to the track, the doors coming together at the track center. A double-acting cylinder controlled by a four-way valve operates two radius rods which are attached to the doors. A spring supported ramp between the rails is depressed by the mine car, and this by a system of levers operates the four-way valve admitting compressed air to one side of the air-cylinder piston and opening the doors. The ramp is extended on both sides of the opening so that as the car or trip leaves the ramp, the depressed springs restore it to its original position and close the doors. The cylinder is attached to the top and center of the gangway. Strips of discarded belting are attached to the outer surface of the doors to serve as buffers when the doors are opened and pressed back against the timbers.

MADE IN TWO SECTIONS

F. C. Isaac, resident engineer of the Modder Deep, designed the door. Making it in two sections reduces the size of the parts to be opened and thus makes the contrivance more readily operated. The 45-deg. angle of the doors reduces the swing to 45 deg., but other angles appear to be worthy of consideration. For example, a pair of doors set at an angle of 15 deg. to the track gives a swing of 75 deg. With gangway 6 ft. wide, each door will have a width of 3¼ ft., whereas the 45-deg. door has a width of slightly more than 4¼ ft.

Assuming radius rods 3½ ft. in length and attached to the center of each door near the top, a cylinder stroke of 2¼ ft. would be required as against a cylinder stroke of 1⅞ ft. for the 45-deg. door. A door placed at an angle of 30 deg. would have a swing of 60 deg. and would require a cylinder stroke of 2 ft. and a width of 3½ ft. With the 30-deg. door there would be a saving of 1½ ft. of door width for both doors. The smaller doors are easier to construct and without doubt can be more easily operated.

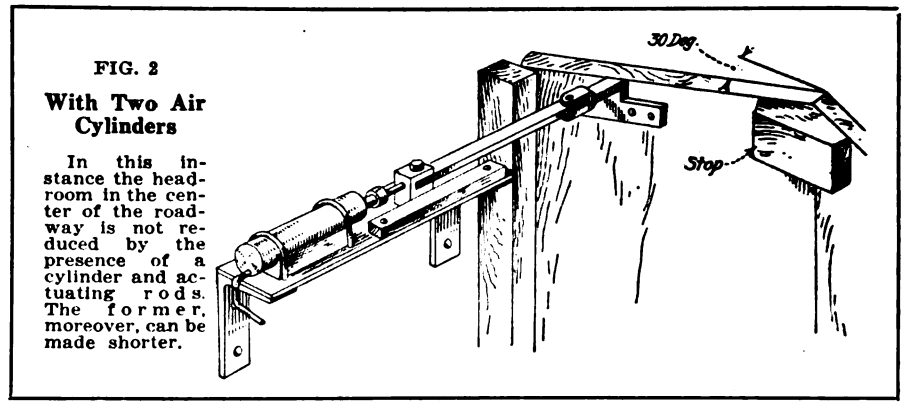

FIG. 2

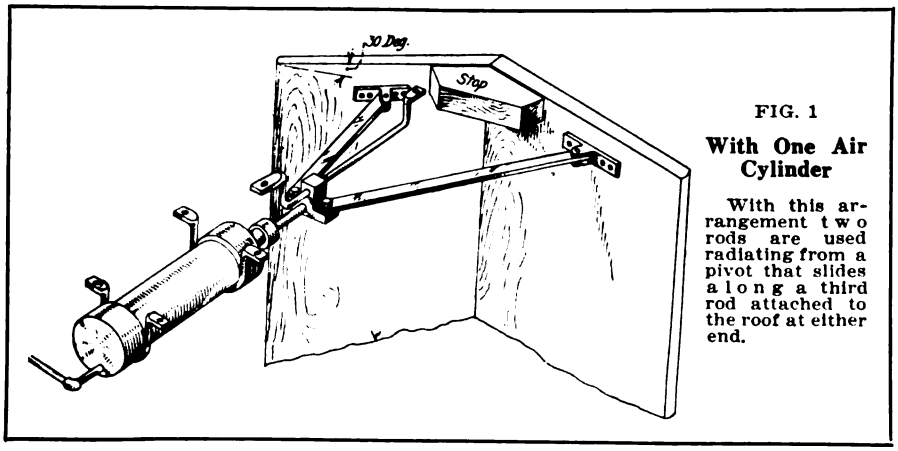
With Two Air Cylinders

In this instance the headroom in the center of the roadway is not reduced by the presence of a cylinder and actuating rods. The former, moreover, can be made shorter.

CAN AVOID SKIMPY HEADROOM

In Fig. 1, a cylinder rig is sketched for the 30-deg. door. An objection that might be made against this arrangement is the restriction of headroom in the center of the gangway. To avoid this objection a pair of cylinders, one for each door, could be arranged as shown in Fig. 2. A comparatively short cylinder and link would be required for this design, the details of which can be readily worked out. The operation of the four-way valve can be controlled by wire-rope pulls instead of a ramp, which has the advantage of automatic operation and would be especially suitable for one or a few cars, but would not be especially advantageous for train operation. As an alternative to the ramp and to the wire-rope pulls, an electric solenoid rig could be devised to operate the four-way valve from either side of the door.



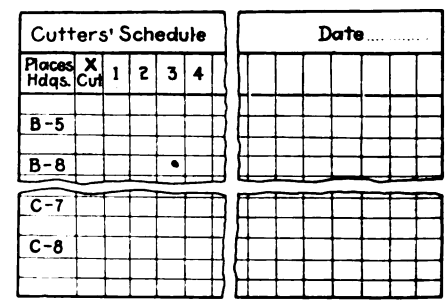


FIG. 1

With One Air Cylinder

With this arrangement two rods are used radiating from a pivot that slides along a third rod attached to the roof at either end.

Dispatch Board Saves Time Of Cutting Crews

A board such as illustarted will be found useful in giving cutting crews, when the cutting is done at night, information as to the location of places ready to be cut. One of these boards is placed at the entrance to each section of the mine, at the main entrance or at some location that all the loaders pass.

Blackboard for Recording What Places Await Cutting Crew

This is placed near a mine or a section entrance to inform the cutting crews as to the location where places are ready to cut. It is useful whenever the cutting is to be done at night. Such a board saves the time of cutters and prevents their overlooking any rooms needing their services.

The miner on his way home marks the board at the point corresponding to his working place if it is ready to cut. If it is not ready he does not make any mark. As every miner is anxious to have his place cut ready for work on the next working day he is not likely to fail to make the necessary mark on the board.

He is far more disposed to do his part than would be the foreman to do it for him, for he is the person most at interest. The foreman, furthermore, is at a disadvantage in routing cutters because he cannot tell just what places have been cleaned up and he must depend on the uncertain information of drivers and motormen, who look upon the collection of such data as a duty in which they have little interest and for which they have no time to spare. Those who have used such boards have found them satisfactory.

Mine Locomotives Will Give Poor Service If Not Given Special Attention

Any Equipment on Wheels Is Subject to Constant Shocks Which Cause Looseness of Parts and Misalignment—Failure of One Part Affects All

By O. E. Kenworthy
Electric Field Engineer, Lehigh Valley Coal Co.
Wilkes Barre, Pa.

TOO many believe that an electric locomotive is a rugged piece of equipment. Possibly this is so, but it cannot be denied that a locomotive possesses some characteristics which put it into another class. It does not possess the ruggedness of a hoist despite opinions to the contrary. To prove that this is true, let us compare the two.

First of all, locomotives are mounted on wheels, and the journal bearings have to carry their weight and to take the shocks due to their inertia. This is a considerable disadvantage which cannot be overcome by any design, however careful. It will wreck the machine if the proper alignment of bearings is not maintained.

HOIST BEARINGS ESCAPE SHOCKS

A hoist, on the other hand, has the greater part of its weight rigidly supported on a firm and immovable foundation, and its bearings are not subjected to repeated shocks. Only wear is likely to destroy the hoist. The attention necessary to keep a hoist bearing in alignment is almost negligible compared with that which will keep in condition the bearings of an electric mine locomotive.

The costs of maintenance and operation of an electric locomotive are large because its weight rests on wheels rather than on solid ground under them. This statement is the gist of the whole story. If the reader were to make a detailed analysis of the cost of operation he would find that the items of "sets of wheels and axles," "rear-axle brasses," "gears," "pinions," "journal brasses," "journal boxes," and "journal-box guides" all rise together. This is true because the wear on any one of these parts affects the wear on all the rest. The wheels and axles, of course, are the most expensive parts to replace, and worn journals are to be avoided as much as possible because with new journals axles must be purchased.

Gears and pinions do not always wear out. Sometimes they are pounded to pieces and teeth broken, because the rear-axle brasses are not kept tight. This is easy to understand, and it is just as easy to realize that motor casings will have to be renewed or rebuilt because of the pounding action between the gear and the pinion. The loosening of the studs in the brass caps of the rear axle causes a backlash between the gear and pinion which in turn transmits a shock to the stud. These shocks sometimes break the studs and then the flapping of the cap wears the armature casing at this point. Worn gears and pinions cause backlash, and when this occurs the condition is aggravated.

MISALIGNMENT CAUSES TROUBLE

It is not difficult to visualize the multiplicity of troubles that will be occasioned by misalignment of these parts. For example, journal boxes and journal-box guides have to take the shock of the inertia of the locomotive whenever it rounds a curve or strikes a latch. Should the side play between the axles and guides of the journal be too great, it is obvious that the boxes and guides of the journal brasses will be pounded rather than worn. The inertia places a thrust on the wearing plate which is transmitted to the guides.

Further trouble can develop by letting bumpers get out of condition. Loose bumpers will in time wear the studs which hold the corners of the frame and this in turn will throw the whole locomotive out of alignment. A locomotive should never be allowed to travel with a loose bumper even for a short time.

Thus far, only the mechanical "running gear" of the locomotive has been discussed. It is only a step further to visualize the effect that a bad condition of "running gear" will have on the electrical parts of the locomotive. The pounding of gears against pinions is further responsible for increased cost of armature bearings and if these bearings are not properly maintained burned-out armatures may result. Vibration, which also attends misalignment, has a bad effect on field coils.

Not only is pounding responsible for damaged armature bearings and burned-out armatures, but it also increases friction, overloading the motor. It means heavier currents through the controller with the consequent burning of fingers and segments. In most cases of trouble with the electrical equipment of a mine locomotive, the fault lies with the mechanical parts.

FOLLOW MAKER'S ADVICE

In the operation of a mine locomotive it is well to consider the advice given in the instruction books of every locomotive manufacturer as to the care and maintenance of such equipment. Rigid inspection of mine locomotives is indeed imperative.

The following is a quotation from an instruction book published by a prominent manufacturer: "Give special attention to the examination of all bolts and nuts to see that they are kept tight. Mine locomotives, perhaps more than any other class of equipment, are subject to severe shocks and vibration. Bolts, nuts, etc., are, therefore, liable to get loose and for that reason, should be given painstaking care. Failure to give thorough attention to this point may involve costly repairs and sometimes serious accidents, particularly in connection with brake rigging and motor-suspension parts."

Batteries on Line Are New Only at Coal Mines

Mr. Edwards' article on the use of storage batteries to reduce power peaks in the April 22 issue of *Coal Age* shows that others have recognized the advantage of an installation such as I have had in my mind for some time. It is gratifying to see that the Pond Creek Pocahontas Coal Co. has utilized one of its batteries in this way, and many other companies could, in a similar manner, smooth out their peaks and reduce their current bills appreciably.

Digitized by Google

A number of the public-utility companies are using storage batteries for standby service, including such concerns as the New York Edison Co., New York; the Commonwealth Edison Co., of Chicago, Ill.; the Edison Electric Illuminating Co. of Boston, and others.

The batteries used are of different sizes, but a typical installation may be considered as 150 cells of from 77 to 141 plates per cell, each plate measuring 30⅛ x 5⅞ in. The Consolidated Electric Light & Gas Co., of Baltimore, has in service a 170-cell standby battery with a capacity of 10,500 amp.-hr. at the one-hour rate.

Too Early to Make Standards For Face Conveyors

Wherever face conveyors are being used successfully, working areas have been concentrated so that equal tonnage is produced with fewer men, mining hazards have been lessened, a larger percentage of the coal available in the seam mined has been prepared for market, the mining force has been kept under more adequate supervision, men of a higher degree of intelligence have been willing to engage in loading and, most important of all, the cost of coal has been sufficient to permit active competition in the market.

But unless careful forethought is given to the needs of face conveying, the same difficulties which have retarded the progress and application of the loading machine will hinder the advance of the face conveyor. Whenever and wherever the loading machine has failed, that failure has retarded the initiative of those who purposed the introduction of these machines into their mines, though any one of them might have made a success of the same machine, operating under nearly, if not quite, the same conditions. This fact has not only militated against a more rapid development in design by the manufacturer. But against a more general use of the machine by the industry.

FLEXIBLE STANDARDS NEEDED

The loading machines we have today have been developed more or less with a sense that standardization should be immediately attained. Their makers have attempted to produce a loading machine that could be used everywhere. They have sought to create a single standard for an industry that by the very nature of the elements with which it works cannot use a single standard but must have several.

Many years ago conveying was reduced from an art to a science. There are many companies which have engineers in their employ who are capable of designing the right type of conveyor to accomplish any kind of work. However, this does not mean that these conveyor engineers also are mining engineers. They cannot and should not be expected to submit a mining plan to be used in connection with a face conveyor of their design.

To date no one, in or out of the industry, has been able to devise a system of mining, using hand, loading machine or face conveyor, which would be applicable to even a small minority of the mines. Each mine presents an individual problem, and every mine needs to apply a form of mechanism for gathering and transferring the product appropriate to its needs.

Therefore, face conveyors cannot be standardized until such time as they have been successfully applied to conditions sufficiently varied to permit of such a course. The coal operator who tries to apply a standard unit built to fit general conditions, should prepare for trouble, unless his property is exceptionally well suited for the equipment available.

CAN CORRELATE EFFORTS

Many operators are insistent on the purchase of standard units. If the manufacturer, however, is not asked to show how standard equipment can be made to give best results under the mine conditions existing, but to design equipment that will best meet those conditions of operation, then the chances for a successful installation will be greatly enhanced.

Many will say that such a plan is impracticable and, if not impracticable, too costly. But it has been proved that the initial cost of a specially designed conveyor is little greater than that of those that are called standard. The difference in cost is a low price to pay to insure success.

Some day face conveyors and loading machines will be numerous enough so that standards can be made for them, but until that time more progress will be made and more benefits will accrue to the industry if face conveying is treated as an engineering problem and not one to be standardized for the benefit of the manufacturer.

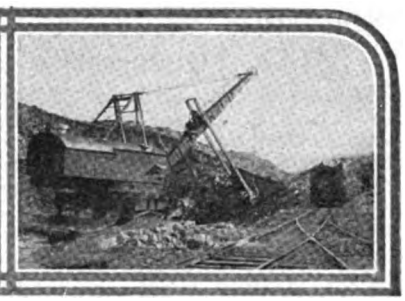
Chicago, Ill. REX MARTIN.

Does Oxidation of Face Cause Increased Movement?

On p. 436 of your issue of March 25, F. C. Cornet refers to the increase of temperature in certain coal mines which becomes quickly apparent when the ventilating current is interrupted and which is accompanied, at least at times, by a more rapid transpiration of gas, than is normal to the mine. Mr. Cornet's explanation of this rapid evolution of gas is that the increase of temperature accelerates the expansion of the seam and that this movement accompanied by cracking causes the increased outflow of gas. All that seems to be lacking is an explanation of the increase in temperature.

TEMPERATURE RISES—WHY?

This rise in the temperature of the seam may be due to the more rapid absorption of oxygen which follows a smaller increase of temperature due to the stopping of the ventilating current. So long as this current is moving the surface of the coal is slightly cooled, and this is especially apparent if moisture is present. Even a slight increase of temperature results in a more rapid absorption of oxygen, which in turn raises temperature and further increases oxygen absorption. As is well known this process, in the case of coal stored in piles, frequently continues until active combustion occurs.



Unless the evolution of gas is so rapid as to prevent the entrance of oxygen into the fissures of the coal, the existence of gas in these fissures will not be an obstacle to oxidation because the diffusion of gases will permit penetration of oxygen into the crevices. It has been demonstrated that the evolution of gas from coal is increased by a rise of temperature as well as by the increase of surface due to the cracking of the coal. It would seem therefore justifiable to assume that the phenomena described by Mr. Cornet may be due to the increase of temperature consequent upon oxidation of the coal face.

News Of the Industry

Fate of Proposed Coal Legislation Is Uncertain; Parker and Copeland Favor President's Recommendations

The fate of the proposed federal coal legislation in this session of Congress is very much in doubt.

There is a strong sentiment among some members of the House committee on interstate and foreign commerce, which gave the better part of two months to hearing advocates and opponents of federal control, to postpone consideration of the question until the next session of Congress. Representations to that effect have been made to the President.

On the other hand, Chairman James S. Parker has several times announced that his committee would report out a bill before the expiration of the present session of Congress and that he entertains hopes that the House, at least, will pass the committee's bill. Early last week there was talk of having the powerful rules committee give the measure a preferred place on the legislative program, but nothing further has been heard along that line in the past few days.

President Desires Action

The President, too, has indicated his desire for some action upon the recommendations which he has twice made in messages to Congress. It is understood, however, that the Chief Executive is not disposed to force the issue to the point of demanding that the party leaders drive the bill through before adjournment. But proponents of regulation continue to carry their pleas to the White House. In the past week Senator Copeland of New York and Representative Treadway of Massachusetts have seen Mr. Cooldige on this matter. Representative Fish of New York added his voice to these pleas in a White House conference on May 24.

Representatives Merritt of Connecticut and Wyant of Pennsylvania have appeared as spokesmen for a policy of delay. After a conference with the President on May 21 these two members of the House committee expressed the opinion that legislation at this time would have a bad effect upon the industry now struggling to recover from the losses caused by the anthracite strike. With 75 per cent of the bituminous production non-union and a four and one-half year agreement in the anthracite region, there is little danger, said these Congressmen, that labor disturbances can menace the coal supply. The manner in which the railroads are handling traffic offered them eliminates the possibility of a runaway market caused by a car shortage.

Mr. Treadway, one of the most persistent advocates of regulation, insists that his position is in accord with the recommendations of President Coolidge. Senator Copeland, after a White House visit last Thursday, said that he "was pleased to find that President Coolidge has no objections to any features of my bill. The President looks upon the measure as one which carries out his recommendations in his last two messages to Congress."

The Senator from New York seems determined to force action on his bill, which already is on the Senate calendar. It came up in the regular order on May 18, but was passed over at the request of Senator Willis of Ohio, who stated that the Senator from Pennsylvania objected to consideration of the measure in his absence. Senator Neely of West Virginia interrupted the brief debate that day to insert into the record two newspaper articles hostile to government regulation.

Representative James S. Parker

Chairman of the House committee on interstate foreign commerce, who has announced that his committee would report out coal legislation before the expiration of this session of Congress. He has hopes that the House will pass the measure.

Photo International

Senator Royal S. Copeland

After a visit to the White House last Thursday the New York Senator expressed gratification that President Coolidge "had no objections to any features" of the Copeland bill. The doctor apparently intends to bring pressure for action on his measure.

The Copeland bill, S. 4177, was offered as a measure "to regulate interstate and foreign commerce in coal and to promote the general welfare dependent on the use of coal, and for other purposes." The Parker bill, H. R. 12209, is entitled a bill "to protect the government and the public from shortages of coal." Its purpose, as stated in the enacting clause, is "to protect the government and its agencies, the instrumentalities of interstate or foreign commerce, and the public from shortages of coal, and to have adequate and necessary facts available, in the event of an emergency, for the immediate enactment of such further legislation as Congress may deem advisable and for the proper execution of existing law."

In this clause it is apparent that the author of the bill has endeavored to incorporate every justification which witnesses before the committee conceded might possibly exist for the exercise of fact-finding powers. Unlike the Copeland bill, however, there is no specific authorization giving the Bureau of Mines, as the proposed government fact-finding agency, "access to and the right to copy any book, account, record, paper or correspondence relating to any method which the Bureau of Mines is authorized to investigate." On the other hand, the Copeland bill names no penalty to be inflicted upon persons or corporations refusing to give information or make reports requested.

Sloan Bans Further Mining At Cassidy Operation

William Sloan, Minister of Mines for British Columbia, has ordered the permanent closing of a large section of the Granby Consolidated Mining, Smelting & Power Co.'s Cassidy colliery, near Nanaimo, on Vancouver Island, because of the danger of "blowouts," one of which caused the death of two miners on April 6, last. There were two fatalities from this cause also in 1921. The company is to be allowed to withdraw all coal that has been mined from the condemned area, but must not mine any more coal.

The colliery has been a poor investment for the Granby company. Harassed for a supply of coke for its smelter by strikes and lockouts in the Vancouver Island mines, the company purchased the coal lands about ten years ago, and proceeded to develop the colliery. As soon as the colliery had been put into operation the company's title to the land was questioned by Canadian Pacific Ry. interests, which had received large grants of land on Vancouver Island as a consideration for constructing the Esquimalt & Nanaimo Ry. A series of costly law suits followed, in which the Granby company ultimately was successful. Then it was found that the Cassidy coal failed to make a satisfactory metallurgical coke, and about 35 per cent of coal from mines in Alberta had to be blended with it.

The company now has developed a large hydro-electric plant at its smelter, which entirely eliminates the use of coal for power purposes, except during one or two months in unusually cold weather, when the creeks supplying the water become frozen, and the elaborate series of reservoirs that it has built are not sufficient to carry the company over the period of water shortage. Thus, it is expected that by the time the coal already mined has been raised the company will be fairly independent of other collieries, having substituted other things for that one-time cheap and useful commodity, coal.

Gealy Informs Engineers of Opportunities for Profit

At Wilkes-Barre, Pa., May 20, E. J. Gealy, of *Coal Age* described to the Engineers' Society of Northeastern Pennsylvania the results of his inquiries into the possibility of making savings in the production of anthracite, the outcome of a survey of conditions in hard- and soft-coal mines. He cited many cases in which savings had been made, without, however, violating confidences by naming the mines or the companies by which those reductions in cost had been achieved. As this paper will be published later it will not be necessary to describe it at length in this notice.

In discussion of the paper, C. R. Seem, president of the society, who acted as chairman, said that the use of oil had made inroads into the anthracite market, even though oil was a more expensive fuel. He added that electric drives necessitated much less steam energy in electric turbines than for supplying steam direct to mine steam engines. Good steam-driven machinery at most mines requires more than 40 lb. of steam per horsepower-hour, whereas the amount required to do the same work by electricity generated in a modern turbo-generator was about 8 to 9 lb. per hour. When electrical energy is generated in turbo-generators, he pointed out, steam can be bled from the turbine to heat the buildings.

R. D. Hall made a few remarks on the past services of the mining engineer, declaring that in early days the mining engineer led in almost all mechanical progress, but said that modern industry had done much to advance all the developments that the mine industry had initiated. It was time for mining engineers to add to their originating ability a power to borrow from other industries, notably the public utilities and the electric railroads, and thus decrease costs. By establishing engineers with limited ranges of service, such as ventilation, turbine and pump engineers, men could be chosen with special aptitudes who would be able to follow developments in their respective lines, not only in coal mines but in all related lines.

Rock Springs (Wyo.) Landmark Disappears

Entrance to the manway of old No. 1 mine of the Union Pacific Coal Co. being filled in. It was one of the old familiar sights of the town, having stood for nearly fifty years.—*Courtesy Union Pacific Coal Co.*

Business Speaks Its Mind at Washington

Where the associated business interests of the country stand on the important economic and social problems of the day was disclosed at Washington, D. C., May 10-13, when 3,000 delegates attended the fourteenth annual convention of the Chamber of Commerce of the United States. After listening to addresses, committee reports and discussions from the floor, the committee on resolutions summarized the opinions expressed in a series of resolutions, which were unanimously adopted in the closing session of the convention. According to these resolutions, business stands for:

(1) Full co-operation in crime prevention.

(2) Continuation of the Federal Reserve System.

(3) Co-operation with farmers in solving farmers' problems.

(4) Refusal to recognize Soviet Russia.

(5) Permanent establishment of a federal foreign commerce service under the Secretary of Commerce.

(6) Simplification of customs formalities.

(7) Change in methods of conducting tariff investigations abroad..

(8) International highway conferences.

(9) Removal of restrictions on parcels post with Cuba.

(10) Issuance of certificates of arrival to immigrants, but no compulsory registration of all aliens in the United States.

(11) The budget system for state and local government expenditures.

(12) A substantial reduction in the existing federal corporation income taxes.

(13) Changes in methods of forest taxation for the purpose of promoting conservation and reforestation.

(14) Opposition to control of coal and other industries by governmental agencies.

(15) Proper control and utilization of the forage resources of the public domain.

(16) Performance of public construction projects, wherever possible, by contract and not by hiring day labor.

(17) Promotion of civil aeronautics, with reasonable federal regulation.

(18) Reasonable federal regulation of radio service.

(19) Creation of government radio facilities where private service is not available, but discontinuance of such service upon the establishment of adequate privately owned facilities.

(20) Opposition to compulsory automobile accident insurance.

(21) Opposition to regional appointments to the Interstate Commerce Commission.

(22) Compilation of vital statistics and a uniform system for recording such statistics.

British Coal Strike Unsettled; Mine Workers and Owners Reject Premier Baldwin's Peace Proposals

The deadlock in the British coal strike is unbroken.

While industry generally is trying to repair the damage done by the general walk-out of May 3, both the mine owners and the mine workers have rejected the peace proposals put forward by Premier Baldwin.

The owners objected to the government program because of the constitution of the proposed national wage board and also took exception to the use of the March quarter in fixing rates of pay.

The miners attacked the proposals because they involved an immediate wage reduction of approximately 10 per cent. They contend that the general reorganization of the industry outlined in the recommendations of the Royal Coal Commission should precede such a reduction. They are equally firm in rejecting the owners' proposals for a longer working day. "Not a penny off, not a minute more," is their rallying cry.

The Premier, in letters sent to the representatives of both parties to the controversy last Saturday, warns the miners that the government's offer of a temporary subsidy will be withdrawn with the end of the month and accuses the owners of uncompromising obstinacy.

"The Premier," said the letter to the mine owners, "profoundly disagrees with your association in attributing the troubles in the mining industry to 'political interference.' The government repeatedly has made it clear that they do not desire to interfere in trade disputes where there is indication the parties are able and willing to settle the disputes for themselves.

Interference Due to Incapacity

"But the Premier would point out that what is called political interference in the mining industry has been entirely due to the incapacity, now again so conspicuously shown, of that industry, unlike other industries, to settle its disputes for itself.

"He deplores your association's apparent inability to recognize it was quite impossible for any government to have stood aside in matters where the national well-being was so vitally and disastrously affected.

"The essential feature of the proposal laid before you by the government was that both sides should agree to leave the crucial point of the dispute—the figure of the minimum percentage on a basis in various districts —to be determined in last resort by arbitration. This is a principle that has been accepted over and over again by other great industries.

"It is true the attitude of the other side makes it impossible of application in the present dispute, but the Premier cannot refrain from the comment that, in summarily rejecting this proposal as one that 'seeks to impart an element of coercion into the machinery of the negotiations,' your association appears to show an inadequate appreciation both of the nature of the proposal and of the gravity of the present situation."

Further attempts to effect an agreement probably will be made as soon as the Whitsuntide celebrations are over.

In the meantime there have been some sharp exchanges between union leaders and government officials. The executives of the Trades Union Council are under attack for their action in calling off the general strike. A. J. Cook, secretary of the Miners' Federation, accuses them of a betrayal, and advocates nationalization.

Three members of the Council charged Sir Herbert Samuel with giving them definite assurance that his peace proposals would be accepted as a basis of negotiation by the government. Sir Herbert retorted that, to the best of his recollection, the protestants had not been present at the conferences, and that he had made it plain at those parleys that he was acting in an unofficial capacity.

Von Giesche Mines in Poland Now in American Control

Control of the Polish holdings of the George von Giesche heirs passed to the Anaconda Copper Mining Co. and W. A. Harriman & Co., American bankers, last week after negotiations lasting since last November. The Von Giesches control 10 per cent of the world's zinc production and own some of the finest coal mines in Germany, besides lead and silver smelting works, brick factories and porcelain works, three basalt quarries and artificial silk and sulphuric-acid factories.

George von Giesche founded the firm in 1704, and the shares in the concern have been handed down from generation to generation. Outsiders were barred for a long time, but recently the former German Crown Prince was permitted to become a shareholder.

In 1913 the Von Giesches valued their possessions at 300,000,000 marks, the highest valuation of any undertaking in Germany, not excepting the Krupps. When the World War broke out the concern bought German war bonds for 100,000,000 gold marks.

The partitioning of Upper Silesia when Germany lost the war found four-fifths of the Von Giesche possessions under the Polish flag. The 100,000,000 marks invested in the war loans became almost worthless, the cash reserves melted away, and the Von Giesches had to go borrowing.

The offer of the Americans for the Von Giesche property in Poland was heartily welcomed by the Polish Government and the shareholders approved the proposition, but it took six months to iron out the legal, financial, political and administrative problems.

At the request of the Prussian State Government, the Harriman-Anaconda representatives agreed not to interfere with the ore exploitation operations of the Von Giesche properties in Germany.

American Mining Congress And Machinery Exposition Opens with Big Attendance

With thirty principal speakers, an equal number pledged to contribute discussion and ninety-two exhibiting companies the National Exposition of Coal-Mine Equipment of the American Mining Congress opened auspiciously May 24 at the Music Hall, Cincinnati, Ohio. A large number of members and delegates were in attendance.

The first session culminated in a request to the chairman, S. A. Taylor, to nominate a committee to plan a course of action relative to water pollution for the coal and metal industries. J. F. Callbreath, secretary of the Congress, stated that in Idaho the courts had decided that water removed from streams must be returned to them in the same condition as when removed. This would destroy the whole lead industry of the state, which is the main source of income of that commonwealth. The coal and metal men, said Mr. Callbreath, should fight their battles together, with a proper conception, however, as to the ends rightly to be attained. H. N. Eavenson, H. I. Young and J. J. Rutledge were nominated on this committee.

Reforestation and conservation of timber are to be standardized for coal mines by a new subcommittee, No. 6, of the mine timbering committee, standardization division. R. E. Krape, in charge of timber and supplies, Rochester & Pittsburgh Coal & Iron Co., becomes chairman, mine timbering committee, in place of R. L. Adams. J. D. Snyder, division engineer, Consolidation Coal Co., becomes chairman subcommittee on use of structual steel for mine timbers. George M. Hunt, chairman, preservation of mine timbers subcommittee, is abroad studying preservatives not involving the use of creosote.

At a luncheon held Tuesday L. E. Young, Union Colliery Co., St. Louis, Mo., was elected chairman of mining and loading equipment standardization subcommittee. At the meeting of the manufacturers' division on Monday H. K. Porter, Hyatt Roller Bearing Co., was elected chairman; H. A. Buzby, Keystone Lubricating Co., and F. J. Maple, John A. Roebling's Sons Co., vice-chairmen, and J. C. Wilson, Ohio Brass Co., and N. S. Greensfelder, Hercules Powder Co., honorary chairmen. Porter, Wilson and Callbreath were appointed on the convention committee of this division.

Summer Course at Carnegie Tech

Carnegie Institute of Technology, Pittsburgh, Pa., announces a four weeks' summer course in coal mining beginning June 14. Sessions at Carnegie Tech in the morning will include studies of mine laws and regulations, mine ventilation, mine gases, safety lamps, methods of working mine explosives, mine timbering and mine arithmetic. In the afternoons at the U. S. Bureau of Mines station the subjects will include mine-rescue and first-aid training, coal-dust explosion and permissible-explosives demonstrations at the experimental mine, and lectures and motion pictures on mine safety.

Both Sides on Legislation In Washington Point to British Coal Situation

By Paul Wooton

Washington Correspondent of *Coal Age*

Interest in Washington continues to center on the British situation, despite the effort being made on each side of the Capitol to obtain coal legislation. Many expect to see the British work out a plan for cheaper coal for use at home rather than try to dominate the world's sea-borne trade. Any such adjustment naturally would have an important bearing on our export trade in coal, and for that matter on our trade in other commodities and on our merchant marine problem.

It long has been accepted that the availability of coal for outbound cargo has been the principal element in the great export trade of Great Britain, tending to keep low the inbound freight on foods and raw material.

As some analyze Britain's foreign trade, there is no such close relationship between outbound and inbound cargoes. The great bulk of British exports go to France and the Netherlands and to points on the Rhine and on the Baltic. Heavy shipments to those destinations would have no effect on the inbound freight rates on wool from Australia or wheat from Argentina. There is some movement of coal to the Argentine, but not sufficient to balance the inbound movement of meat, grain and other commodities. A large proportion of ships leave in ballast for River Plate points. The balance is not between particular ports, such as those on the Tyne and on the Bristol Channel, on the one hand, and Buenos Aires and Calcutta on the other. It is rather between Western Europe and South America.

Coal Trade Traditions Upset

This view is upsetting to the notions of most persons interested in the world coal trade, particularly to the British themselves, but in the reorganization of the industry in the United Kingdom this phase of the situation is certain to be considered. The British may find it more to their advantage to shrink their production to the capacity of their lower cost mines and use a larger proportion of that coal at home, so that the outbound cargoes will consist more of manufactured material rather than raw material which has to be sold at small profit.

The British situation also is furnishing ammunition for each side in Congress. Those who are urging coal legislation see in the unrest of the British miners proof that trouble of the same character lies ahead in this country. Attention is called to the approaching end of the Jacksonville agreement, which leads to the demand that legislation be provided to meet a possible strike.

Spokesmen for the industry and others who oppose such legislation see in the British trouble the consequences of the government in business. They point out that since the war the British Government has not withdrawn definitely and completely from the field of private industry. As a consequence it cannot avoid taking part in the recurring crises.

From parliamentary intervention for the fixing of the length of the working day the government has been drawn into arbitration, into subsidy payments and finally was forced to break a strike. Had the government never placed itself in a position of quasi-responsibility the general strike never would have been called, argue the opponents of coal legislation for this country.

Industrial Board Observes Tenth Birthday

The tenth anniversary of the founding of the National Industrial Conference Board was celebrated May 20 at a meeting in New York City. Frederick P. Fish, chairman of the board since its organization, has declined re-election and has been elected honorary chairman. He has been succeeded by Loyall A. Osborne, president of the Westinghouse Electric International Co. Magnus W. Alexander continues as president.

Reporting on the ten years of activity Mr. Alexander pointed out that the board now spends approximately $300,000 a year in getting facts regarding industry and related business and social conditions. The results of the board's work have been given to business through 115 research and 35 special reports and many monographs. Sixteen bulletins have been issued on industrial-economic conditions in the United States, 132 charts on current economic trends and conditions here and abroad, and a graphic analysis of the growth of manufacturing from 1849 to 1920. In addition much special service has been rendered to subscribers of the board, governmental organizations and others through the exhaustive files of non-published material.

Investigations of the Board have covered such subjects as wages and hours of work, cost of living, industrial pensions, employment of young persons, cost of government, tax burdens and public expenditures, the economic significance and legal status of trade associations, public regulation of competitive practices, interallied debts, and the agricultural problem as related to industrial activity.

New Haven R. R. Wants Coal

The New York, New Haven & Hartford R.R. requests bids for 360,000 to 400,000 net tons of high-volatile bituminous mine-run coal required on the east end of its line, or on 200,000 to 225,000 tons for the Boston district. Deliveries are to be made alongside the company's coal-discharging plant at South Boston in approximately equal monthly quantities between July 1, 1926, and July 1, 1927. Complete specifications may be obtained at the office of the company's fuel agent, J. F. Manning, New Haven, Conn. Bids will be opened at noon on June 4.

Burns Bros. Likely to Buy Rubel Coal Co.

Negotiations now said to be under way foreshadow the early acquisition by Burns Brothers of the Rubel Coal & Ice Corporation, one of the largest distributors of coal in Brooklyn and adjacent sections of Long Island.

Sanders Wertheim, president of Burns Bros., refused to confirm or deny reports of negotiations for the purchase of the Rubel company. "I do not want to make a statement about it now," he said, but did deny a report that the deal had been closed, saying positively, "We have not bought them."

Samuel Rubel, president of the Rubel Coal & Ice Corporation, when asked about the report, answered through his secretary that he knew nothing about it. From other quarters, however, it is learned that conferences on a proposed merger of the two companies have been held and it is believed that a consolidation is likely soon.

The Rubel Coal & Ice Corporation has expanded rapidly from the days when it was started by Samuel Rubel, a poor Russian emigrant, with a coal peddling wagon. In the past year it has had a particularly rapid growth. About a year ago Mr. Rubel acquired a large number of independent coal and ice companies in Queens County. More recently his company bought the Commonwealth Fuel Corporation, one of the leading distributors in Brooklyn with large pockets strategically located both on the waterfront and alongside railroads.

The Burns Bros. company last year added to its facilities in Brooklyn by the acquisition of the Wyoming Valley Coal Co.

Dalrymple Flouts Suspension; Incompetence Charged

Fort Smith, Ark., May 24.—District No. 21, United Mine Workers, has two presidents, but the muddle may be cleared up here when William R. Dalrymple, supposed to be suspended, is tried on charges alleging incompetence in office. Gomer Jones, vice-president of the district, has been appointed acting president by the Executive Board, which suspended Dalrymple. Dalrymple has ignored the action of the board, however, and has retained charge of the Muskogee district headquarters.

George Patterson, secretary, said that Dalrymple regards the board as a "rump" organization and that he has refused to turn over the office to Jones without instruction from international President John L. Lewis, who never has recognized Jones as acting president.

According to Patterson, only five of the seven members of the board were present when Dalrymple was suspended, making the action illegal, according to interpretation of the by-laws. All five voted for Dalrymple's suspension, however.

"The rump board meeting charges Dalrymple with everything in the world," Patterson said. "Their main grievance, however, is his refusal to meet with the coal operators and discuss wage reductions."

Uniform, Acceptable Preparation of Anthracite Demanded by Retailers; Voice Opposition to Federal Control

Strict maintenance of uniform and acceptable standards of anthracite preparation was demanded by the National Retail Coal Merchants' Association at its ninth annual convention, held at the New Willard Hotel, Washington, D. C., May 17-19. Producers also were asked to inform each distributor of the standards in force so that dealers may "test all shipments and obtain proper adjustment on all tonnage that does not conform to the standards so established."

The association, in a resolution adopted the closing day of the convention, reiterated its opposition to government control. Attempts to regulate mine labor, it declared, are futile. To single out coal would not only be discriminatory but dangerous in that it would "create a precedent for the injection of government and a federal bureaucracy into the field of business, which should not be allowed to become a battle ground of politics."

The stand taken on anthracite preparation was foreshadowed the first day of the convention, when a majority of the delegates agreed that most producers were shipping coal containing more than the permissible maximum percentage of undersize. "In the old days," said Roderick Stephens, chairman, government relations committee, who opened the attack, "we heard a lot about 'flexible standards of operation.' Whenever the situation arose where it seemed necessary to 'ease the situation,' it was done, and no operator felt that he was guilty of any improper or unethical standard if he adjusted his production. However, it seems to me that an operator, generally speaking, would look down with scorn on any dealer who mixed pea coal with chestnut and sold it as nut, or sold buckwheat and mixed rice with it. I submit that that practice on the part of the retailers is equivalent to fraud. I do not charge the operators with fraud because I do not think we have put it up to them right, but I think it is up to us to do it, and I think we can with the buyer's help."

General Complaint of Undersize

The resolution as reported to the convention stated it had been "the general experience of the retail trade since the termination of the strike that a large amount of chestnut, pea and buckwheat had contained a greater quantity of undersize than authorized under the new standards." This was modified to read: "It has been the general complaint." In indorsing this change, Mr. Stephens said he believed the retailers could develop specific facts to warrant their accusations, but that it might be unfair to make the flat assertion in a formal resolution until supporting data had been put on record. There was, however, no question that "complaint" had been general.

Part of the present difficulties confronting the dealers in moving anthracite, in the opinion of some of the New York State groups, lies in the trade nomenclature. These groups urged that the operators abandon the name "chestnut" and give a new designation to that size. The suggestion was referred to the resolutions committee, headed by W. A. Clark, president, New England Retail Coal Dealers' Association. That committee, however, took no action in the matter, preferring to leave the question for the consideration of the incoming board of directors.

The first session of the convention was devoted to the presentation of reports of officers and standing committees. President Samuel B. Crowell pointed to the English situation as a warning against government regulation of coal and declared an unhampered industry could function best in the public interest. Joseph E. O'Toole, resident vice-president, urged greater financial support of the organization. Mr. Stephens reviewed the legislative situation. There is, he said, no justification for omitting coke and fuel oil from a regulatory program, but the public interest will be best served if there is no regulation of any kind.

Operators Seek Good Will

Daniel T. Pierce, vice-chairman, Anthracite Operators' Conference, said "there never was a time when the operators were so anxious to discharge their responsibility, so eager for the good influence of the public, for the cooperation and the help of the dealers, and generally so determined to maintain their position in spite of every obstacle." The producers proposed to use the four and one-half years' freedom from labor troubles under the new agreement to engage in an intensive merchandising campaign.

Mr. Pierce expressed the hope that the industry, "within a short time," would adopt standards under which certified coal "will be sold by dealers handling only certified coal." With such machinery in operation, "it would not be a question of putting it up to the dealer to 'kick' about coal he thought was not up to specifications." The coal "would be subject to inspection that would dispose of that and relieve the dealer of any embarrassment in dealing with such cases."

Disclaiming any intention of uttering a threat, the speaker asked the retailers what they would do if they had $750,000.000 invested in the business, "and the dealers who were distributing the products were, in a good many cases, quite as much interested in soft coal." He was certain, he said, that the anthracite operators "are not going to allow this product to be handled as the adjunct of an oil business or as the tail-end of a soft-coal business." Retailers who would co-operate with the anthracite industry, he declared, would find the door wide open. "If you don't know us better, if you don't get out of us what you want, it is going to be very largely your own fault."

Photo Underwood & Underwood

James C. Tattersall

Newly elected president of the National Retail Coal Merchants' Association.

"Trade-Marked Coal" was the first topic of discussion at the meeting on May 18. Mr. Pierce thought it impossible to physically brand the coal, but agreed there should be some protection which would assure the dealer he was actually receiving what he purchased. Stanley C. Higgins, secretary, New River Coal Operators' Association, said that one shipper actually labeled some of the coal.

Mr. Clark decried the policy of many coke producers who distributed their product direct to the consumer. Lester C. Bosler, of Madeira, Hill & Co., and D. H. Pape, assistant to the executive secretary of the National Coal Association, discussed methods of meeting fuel-oil competition.

Domestic Future for Smokeless

W. C. Atwater, president, Pocahontas Operators' Association, the principal speaker on May 19, predicted a big domestic future for screened smokeless coal. He cited the growth of deliveries of that fuel in his own retail business at Fall River, Mass., to support his belief. Low-volatile coal, he said, was too good to burn under steam boilers. "In New England, so far as our coal is concerned, it is entirely in your hands. You can make us or you can break us. We are here; we have a fine product and we are going all the while. We are not afraid of gas; we are not afraid of oil; we are not afraid of anthracite. If you could visualize twenty-five or fifty years from now you would see in New England a place where coal from southern West Virginia is known in every household."

James C. Tattersall, Trenton, N. J., was elected president, succeeding Mr. Crowell, who declined to consider another term. Rudolph Reimer, Brooklyn, was chosen as treasurer. Milton E. Robinson, Jr., Chicago; J. Maury Dove, Jr., Washington, D. C. (re-elected); W. A. Clark, Boston, Mass. (re-elected); G. W. Malcomson, Detroit, Mich.; C. B. Staats, Albany, N. Y. (re-elected), and George T. Kinney, Kansas City, Mo., were elected vice-presidents.

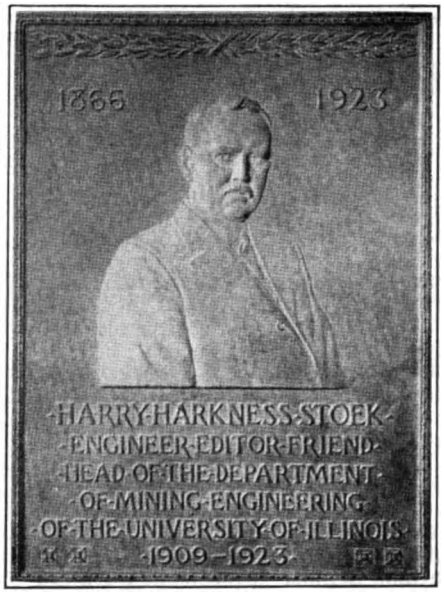
Desist Order Issued To Midwest Retailers; Sanborn Co. Absolved

The Federal Trade Commission has issued a cease and desist order directed to the Mid-West Retail Coal Association, formerly known as the Missouri State Retail Coal Merchants' Association, its officers and members. The respondent association, according to its constitution, made eligible for membership those engaged in the business of selling coal, coke or other fuel at retail with facilities and stocks sufficient to meet the reasonable demands of the public in their respective communities. The association's office is in St. Louis.

The proceedings against the J. B. Sanborn Co., of Chicago, Ill., named as a respondent in the complaint, were dismissed by the Commission.

The Commission found that the respondents, co-operating together and acting in concert, hindered and prevented the purchase of coal in interstate commerce by and between producers, jobbers and wholesale dealers and individuals by various unfair means.

Cites Alleged Unfair Practice



The unfair methods used by the respondents, according to the Commission, and which the order specifically prohibits, are indicated by the terms of the order, which state that the respondents must discontinue:

(1) Arbitrarily classifying sellers and purchasers of coal and shipments thereof as "Snowbird" shippers, "Snowbirds" and "Snowbird" shipments, respectively, or by any similar or other terms because of or according to the extent or degree of equipment owned by the said purchasers or employed by them in the sale, movement or distribution of coal, or causing any such classification to be published in any trade paper or other publication, or to be communicated to others or among themselves, in that or any other manner.

(2) Designating or causing to be designated, in articles or editorials in any trade paper or other publication, or in any other manner or by any other means, any individual, firm, corporation or association, or groups thereof, as the vendor or purchaser of coal, or their shipments of coal by using or causing to be used denunciatory, scurrilous, abusive or derogatory language of and concerning them or either of them.

(3) Soliciting or receiving between or among themselves or with others and or circulating between and among themselves or with others communications or reports, either printed, written or verbal, having the purpose, tendency or the effect of inducing, coercing or compelling producers, jobbers or wholesale dealers in coal, their agents or their brokers, directly or indirectly, to refuse to deal with or to sell coal to any person, firm, corporation or association.

(4) Threatening with loss of patronage or custom, any producer, jobber or wholesale dealer in coal, or his agent or broker, for selling or agreeing to sell to any person, firm, corporation or association, or from persuading any such producer, jobber or wholesale dealer in coal not to sell coal to any person, firm, corporation or association.

Memorial Tablet to Professor Stoek

Friends Present Stoek Tablet To Illinois University

Memorial exercises in honor of Prof. Harry Harkness Stoek, who died on March 1, 1923, were held in the engineering library at the University of Illinois on May 2, when a tablet in commemoration of his work was presented to the university.

Prof. A. N. Talbot, head of the department of theoretical and applied mechanics, presided. E. A. Holbrook, dean of the School of Mines of Pennsylvania State College, delivered an address emphasizing the work of Prof. Stoek as engineer, editor and educator. Prof. S. W. Parr's topic was "Professor Stoek —Friend."

The tablet, which is of bronze, about 42 by 60 in. in size, was the gift of nearly two hundred friends of Prof. Stoek. It was presented to the University on behalf of the Stoek Memorial Committee by Prof. A. C. Callen, head of the department of mining engineering, and was accepted for the university by Prof. A. P. Carman, head of the department of physics. The memorial tablet is the work of the noted sculptor Lorado Taft, of Chicago.

Sonman Shaft Coal Co. Sold

One of the most important coal deals in central Pennsylvania in several years has just been closed, through which the Sonman Shaft Coal Co., with holdings at Sonman, Cambria County, has been sold by Thorne, Neale & Co., of Philadelphia and New York, to A. H. Powell & Co., Inc., of New Haven, Conn. The new owners will take over the property on June 1. J. Malcolm MacDougall, of Johnstown, general superintendent, and all of the other officials will be retained.

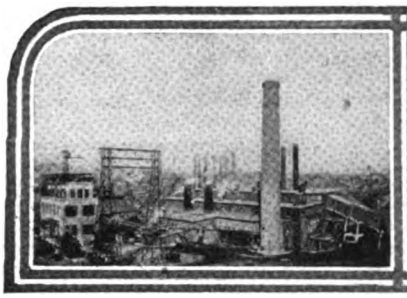
The Sonman Shaft Coal Co. property comprises more than 3,000 acres of coal. At the present time the company is working three seams and has a capacity of 750,000 tons a year. The operation employs more than 750 men when the mines are working at capacity. At present 600 men are at work.

California Dealers' Prepare To Combat Oil and Gas

California railroads, gas plants and manufacturing establishments largely rely upon petroleum for fuel. Hydroelectric power development has grown to a noteworthy extent and transmission lines lead to every important center. Marine bunkering has shrunk to insignificant proportions. Solid fuel has been displaced by liquid fuel until practically only the house-heating field remains and even in this the competition of both gas and oil is keenly felt. Although population has doubled in the past ten years, the solid-fuel business has remained practically stationary in aggregate sales and has diminished in number of distributors. Active selling campaigns by gas- and electric-appliance men have made inroads upon the field of solid fuel.

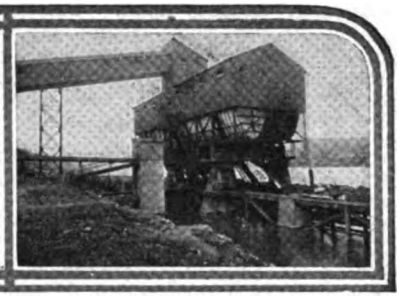
To study to conserve their market, the retail coal dealers formed the California Retail Fuel Dealers' Association, which held its annual meeting at Del Monte April 24 to 26. R. E. Wilcox is president of the Association and J. B. Muir, secretary.

In the report of the executive committee, it was stated that progress has been made in obtaining correct weight and less spillage on coal deliveries; the need for statewide advertising of better appliances for burning coal was touched upon; a summer storage advertising of better appliances for burning coal was touched upon; a summer storage advertising campaign was stated to have been successful; advertising coal on its merits was advocated; better preparation of coal by the mines was discussed and the need of co-operation between coal operators and dealers was stressed.



See Chance for Lower Rates

In the report of the traffic committee, J. C. Ewing stated that a new freight rate from Utah to Pacific Coast points to encourage the movement of pig iron has been made and as this is lower than that prevailing for coal, efforts were being made to obtain a similar rate for coal.



A paper by Louis Ross on the psychology of advertising was read by Secretary Muir. Mr. Ross said that coal merchants have not advanced beyond the point of telling the public that they have the coal for sale. The use of coal has many possibilities—the public has to be convinced that it needs coal and that there are many advantages attendant upon its use.

B. D. Myers, district freight agent of the Southern Pacific Co., who addressed the convention on the general subject of co-operation, made the announcement that the Southern Pacific was converting 48 freight locomotives from oil to coal burners and would return to coal on its El Paso division. M. F. Murry discussed the efficiency of coal furnaces and showed the necessity for good furnace construction and proper flue proportions. J. F. Mullen presented a report on the efforts now being made to amend the building ordinances by providing minimum flue dimensions for different situations as well as adequate chimney extensions.

News Items From Field and Trade

ALABAMA

The Southeastern Coal Co. is building fifty 5-room dwellings for its employees at Gorgas, or Winona, formerly operated by the Winona Coal Co. This mine is located in Walker County, on the Warrior River, adjacent to the Gorgas steam plant of the Alabama Power Co., which consumes the output of the mine, the operating company being a subsidiary of the power company.

Output High in Alabama.—Alabama produced 20,408,656 tons of coal during the calendar year 1925 according to official figures of State Mine Inspector Charles H. Nesbitt. This represents a gain of 792,725 tons over the output of 1924, which was 19,615,931 tons, and has been exceeded only twice before in the history of the industry in this state, 20,413,811 tons being mined in 1917 and 20,919,303 tons in 1923. Production to date this year is showing about a 5 per cent gain over 1925. Other statistics on the industry for 1925 are not yet available.

The commissary, office and supply houses of the Pratt Fuel Corporation at Dora No. 1 mine were destroyed by fire which started in the store building May 5. The loss is estimated in the neighborhood of $50,000. Walter Moore is president of the company, the offices of which are in Birmingham.

Dedicate Stadium.—The large new stadium of the Tennessee Coal, Iron & Railroad Co., recently completed at Fairfield, was formally opened May 19, with the spring festival of the social science department of the corporation. About 3,000 employees of the company were in attendance. The stadium is of concrete and steel construction and will accommodate about 10,000 people.

Construction by the Frisco line of the connecting link between its main line at Aberdeen, Miss., and Kimbrough, Ala., the northern terminus of the Muscle Shoals, Birmingham & Pensacola R.R., recently acquired by the Frisco, for which permission is now pending before the Interstate Commerce Commission, would afford a direct route from the coal fields of Walker County to the Port of Pensacola. It is planned to eventually construct a line from Bessemer, in the Birmingham district, to Magnolia, where it will tap the new line.

Railway Fuel Tipple Completed.—The new steel tipple of the Railway Fuel Co. at its Parrish Mine, in Walker County, has been completed and placed in operation. The cost of the structure was approximately $50,000. Two rotary dumps were installed and other improvements made which will allow an increased production from this operation, which is one of the largest in the Walker County field. The operating company is a subsidiary of the Southern Railway Co., the total output of which, around 2,500 tons per day, is used on the lines of the railroad system.

Mill Creek Washery Open.—A new washery has been completed at the Chickasaw mine of the Mill Creek Coal Co., near Carbon Hill, Walker County. This is an opening on the Jagger seam and is served by the Frisco railroad. The company also operates the Mill Creek mine, in the same vicinity.

Suspected Firebugs Caught.—According to reports from the State Fire Marshal's office in Montgomery, two men are under arrest in connection with the mysterious destruction by fire recently of the tipple and washer plant of the Galloway Coal Co. at Holly Grove, Walker County, which entailed a loss of about $75,000, with insurance of only $30,000. The fire is believed to have been of incendiary origin.

ILLINOIS

Kathleen Mine Mechanized. — The Kathleen mine, at Dowell, five miles south of Duquoin, is again operating after a period of no work and is now producing coal which is mechanically cut, loaded and hauled. While the mine was idle arrangements were made to bring into use a large number of loading machines which were already installed in the mine but had never been put into practical operation. With the machines in use fewer men are employed than formerly.

After a long period of idleness three hundred men have returned to work at Paulton No. 3 mine, near Marion, owned by the Cosgrove-Meehan Coal Co.

The Coal Belt Electric Ry., a short coal road in Williamson County, has filed a petition with the Illinois Commerce Commission for permission to discontinue operation of its line which runs from Marion to Energy, Energy to Carterville, and Energy to Herrin, a distance of 13.46 miles in all. The petition of the company states that it has not made operating expenses for the past ten years. In recent years it has suffered increasing loss owing to greater traffic by truck and autmobiles.

Peabody Mine No. 6 hoisted 4,727 tons of coal in one day recently, which broke the record of the Springfield subdistrict.

A company is being formed at McLeansboro to open coal mines in and around McLeansboro in Hamilton County, it has just been announced. Shaft mines will be driven.

Catlin Mine to Resume.—The Taylor-English Coal Co. is making preparations to reopen its mine at Catlin, a few miles from Danville. The mine has not been in operation for the last twelve months.

Involuntary bankruptcy proceedings have been begun against the Earl Mapleton Co-operative Coal Co., at Peoria, by creditors whose claims are $1,000. The company has assets of $15,000 and liabilities of $22,000.

Seven hundred men have been thrown out of employment by the shutdown of Peabody Mine No. 8, at Tovey. The mine, which had been working steadily for some time, will be closed until next November.

The closing down of Wasdon Coal Mine No. 1, east of Harrisburg, has been followed by the opening of Wasson Mine No. 2, just west of Carrier Mills. This mine had been closed about two years.

INDIANA

Modernization Advances.—The Knox Consolidated Coal Co., which owns the Indiana Creek, the Westphalia Fifth Vein and other mines in Knox County, is building a new steel tipple at the Indian Creek shaft and is converting the Westphalia mine into an electrically operated plant. Work at the latter place has gone on without interrupting the mining. The Indian Creek has been idle several months, due to destruction of the old tipple by fire. The new one is to be completed by July 1. It is to be fireproof and have two tracks. It will load four kinds of coal at the same time. The company employes about 2,100 men normally, excluding the Bruceville mine, which has been idle several years.

One of the most disastrous mine fires in the history of Indiana was sealed in the depths of the Ebbwvale mine, three miles south of Sullivan, last week after efforts to extinguish it proved unavailing. One hundred volunteers had fought the flames five hours. Three men who were in the mine when the fire broke out escaped unharmed.

Charles W. Cook, wealthy ice manufacturer of Evansville, has acquired an interest in the Stock coal mine, at Chandler.

Twenty-two union miners indicted for rioting at the Hampton-Schimmel mine near Newburg, on Feb. 16, were acquitted by a jury in Warrick County Circuit Court, at Boonville, May 15. Perjury charges may grow out of certain testimony offered by some of the defendants, Prosecutor Warren Martin declared. A grand jury will be asked to make an investigation, Circuit Judge

Digitized by Google

Caleb J. Lindsey said. Thirty-eight union miners were found guilty of assault and battery in the court three weeks ago on charges growing out of demonstrations at other southern Indiana mines on the same date.

The third mysterious fire in properties of the Knox Consolidated Coal Co. this year occurred May 13, when the tipple of the Fourth Vein coal mine, near Vincennes, burned. The loss is estimated at $50,000. Between 200 and 300 men were thrown out of work by the fire. The tipple will be rebuilt immediately, it was announced at headquarters of the company, at Indianapolis.

While pulling into the "high bank" under heavy strain the boom of one of the steam shovels at the mine of the Pike County Collieries broke, causing a repair job that may last 30 days. The men working on the shovel and in the coal pit below escaped injury.

IOWA

Work on the coal mine at Eldora is progressing steadily. Two shifts are now at work. The shaft is to be sunk 125 ft., where a good seam of coal is located.

KANSAS

Sinking New Mine. — The Pittsburg Coal Co. has begun sinking a new mine a mile south of Cherokee. Drillings show that the coal, which is at a depth of 120 ft., is of good quality and ranges from 3 to 4 ft. in thickness. The company plans to equip the mine with electric hoist, mining machines, electric haulage and other electrical equipment. When the shaft is fully developed it will employ 100 men. The company has operated extensively in the northern part of the Pittsburg field but this mine is its first development in the southern part.

KENTUCKY

Pays $23,300 for Coal Property.— W. O. B. Wright, president of the Cedar Creek Lumber Co., at Pineville, has purchased for $23,300 the bankrupt Kentucky Elkhorn By-Products Co. mines at Dorton, which were closed on Jan. 6. The properties three years ago were valued at $300,000, and $225,000 was refused. Improvements represent an outlay of $247,000. There is a tipple, side tracks, 41 miners' homes, commissary and a large coal tract including 221 acres in fee simple. One seam has 500 acres of 6-ft. coal; another 1,000 acres of 4-ft. coal and a third seam, unworked, has 1,110 acres. The buyer plans to start operations within thirty days, operating as the Wright-Elkhorn Coal Co.

Indications are that the Federal Power Commission will refuse the application of the Cumberland Hydro-Electric Co. for a permit to harness the Cumberland Falls, on the Cumberland River, as the result of a wave of protest against destroying a thing of beauty. The company, which is a subsidiary of the Kentucky Hydro-Electric Co. and the Kentucky Utilities Co., would supply current to a network of lines that carry current to many mines and towns over the state.

The State Tax Commission has reduced the recent 20 per cent special raise on Henderson County coal right assessment to 10 per cent. The original increase was $56,000, but as it now stands it will be only $28,000.

Elk Horn Coal Corporation reports for the quarter ended March 31, 1926 net profit of $61,653 after depreciation, depletion, interest and federal taxes. The company reported a deficit in corresponding period a year ago.

Ready for Heavier Loads.—W. F. Sheridan, superintendent of the Louisville division of the Louisville & Nashville R.R., reports that the road has started using much larger locomotives in the western Kentucky fields, due to replacement of some trestles with heavy fills and reduction of the grade over Muldraugh Hill, about forty miles south of Louisville.

L. & N. Surveying Coal Lands.—Surveying crews are reported to be working up the Middle Fork of Kentucky River, near Krypton, in Perry County, past Hyden and as far as Greasy Creek, on the southern edge of Leslie County, where there is much fine coal land, but no railroads. It is understood that the Louisville & Nashville R.R. is making the surveys.

The machine shop, supply houses, commissary, etc., of the Southeast Coal Co., at Seco, in Letcher County, near Whitesburg, was burned on May 16, in a $40,000 fire. The building will be rebuilt at once.

NEW YORK

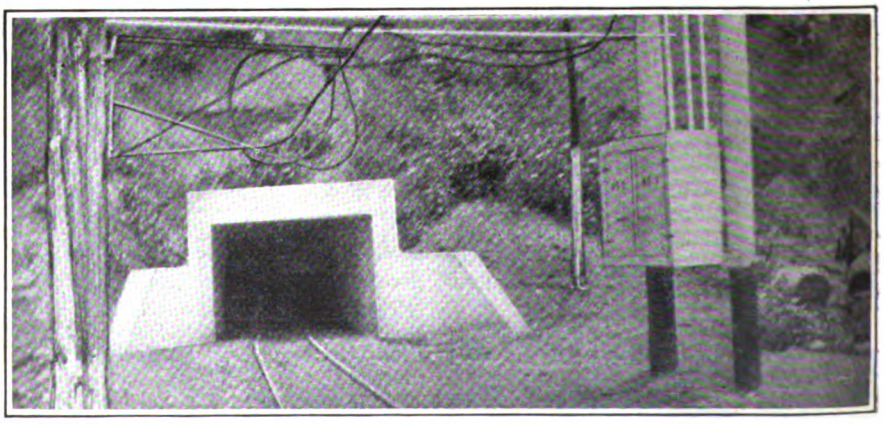
More Semet-Solvay Ovens.—Semet-Solvay Co. has announced that construction of an additional battery of coke ovens which will result in doubling the capacity of its present plant near Buffalo is to begin soon. It is expected that the new ovens will be in operation in about a year.

Coal Maintenance Corporation, New York City, has filed a certificate in the Office of the Secretary of State at Albany increasing its number of shares from 500 shares preferred stock of $100 par value to 1,000 shares preferred of $100 par value and 100 shares common stock of no par value to 2,500 shares common of no par value. Max Silverstein, 305 Broadway, New York City, is attorney for the corporation.

The four steamers of the Eastern Grain, Mill & Elevator Co., of Buffalo, built in Scotland for the coal and grain trade are about ready for business from Buffalo. The "John S. Pillsbury" recently unloaded a cargo of coal at Toronto, and the other three, with two cargoes of coal and one of fluorspar, are at Montreal on the way in.

OKLAHOMA

Earl Wells and Frank Barrow, of Henryetta, have acquired the Sorrels coal mines, at Poteau, and will develop them.

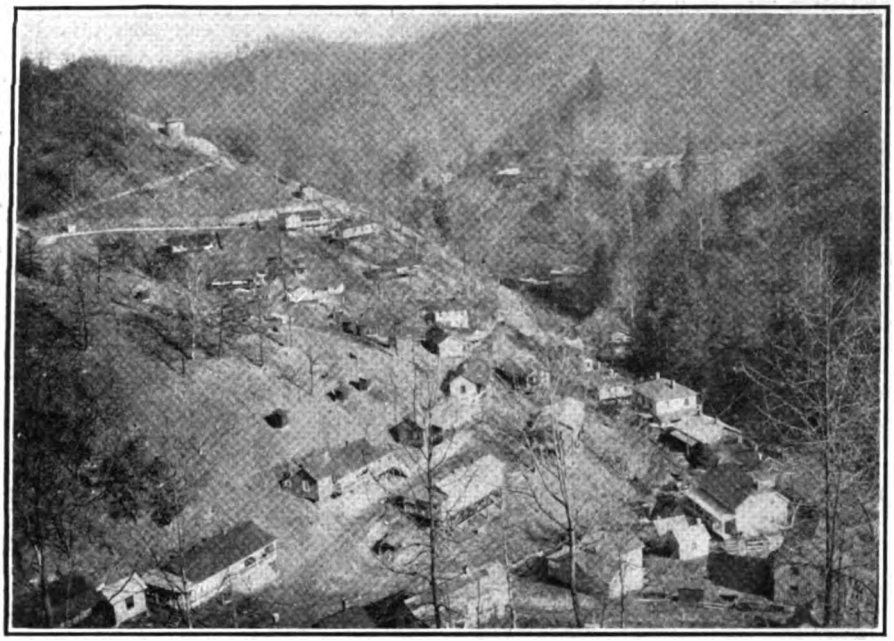


PENNSYLVANIA

Gas Blast Injures Three.—An explosion of gas at 8 a.m., May 14, in the Red Ash vein of the Nottingham colliery of the Lehigh & Wilkes-Barre Coal Co., at Plymouth, resulted in three mine workers being injured, one seriously burned about the head, face, hands and body, and the other two sustaining scalp wounds and bruises about the ribs. Assistant Superintendent Ted Griffith found that the blast occurred in the face of a chamber in No. 12 slope, 11th East Red Ash Vein. A pocket of gas was ignited, but just what set it off is not known.

The Vesta Coal Co., a subsidiary of the Jones & Laughlin Steel Corporation, has contracted for the erection of 150 dwelling houses for the new development being started in Greene County.

The Republic Iron & Steel Co. coal mines in the Connellsville coke region, which had been working nearly full for several weeks, are laying off one or two days a week.



Union Grip Waning.—Eighty per cent of the coal now being produced in central Pennsylvania bituminous district is being mined on a non-union

Anna Louise Portal, Plymouth Mines

Operation of the Hatfield-Reliance Coal Co., at Plymouth, near Winfield, W. Va., in Putnam County just below Charleston on the Kanawha River. Coal is loaded on the Kanawha and on the Kanawha & Michigan R.R. tracks. The track gage is 30-in.

Portion of the Mining Town of Six, W. Va.

The narrowness of the valley made it necessary to build some of the houses on the mountain side. Storage for the town water supply is in the tank at the upper left. In the center background are a dumphouse and retarding conveyor.

basis, Charles O'Neil, secretary of the Central Pennsylvania Coal Producers' Association, said. "Cambria is the only county among the 14 comprising the district that has retained the union scale and it is believed the mines there will soon be obliged to follow the other counties in order to sell in competition with sections east of the Ohio River," he said.

City Gets Bargain Coal.—The Philadelphia Board of Education has awarded a contract for delivery of 60,000 tons of buckwheat to Frank F. Mathers at $4.87 delivered in the cellars of the schools. The price has caused endless comment in the trade on account of its extreme lowness when compared with current company quotations. Based on the contract price of $2.50 of the biggest company shipper, plus freight of $2.14, on one-car price would be $4.64. As no one presumes that delivery can be made for 23c., it is conjectured that some large producer rather than store buckwheat on the ground at a cost of $1 a ton to lay it down and pick it up again, not to mention interest charges, simply deducted this charge from the price of the coal, which would give the dealer delivering it a margin of about $1.23.

Wooden Breaker for Hazle Brook.—A contract has been awarded for the erection of a new breaker at Keffers for the Hazle Brook Coal Co. It is understood that 1,000,000 ft. of lumber will be used in the new structure, which will be one of the few modernly equipped breakers in the anthracite field in which lumber will be used in preference to steel. The Hazle Brook company also is planning to construct sidings leading from the new breaker to the Philadelphia & Reading Ry.

Stripping Uses Big Blast.—One of the largest test blasts of dynamite in the history of the Shenandoah region was set off recently at the Shenandoah City colliery stripping when 7,000 lb. of dynamite lifted 12,000 cu.ft. of rock and earth and bared a long stretch of available coal. The dynamite was discharged from 36 holes varying from 25 to 50 ft. in depth. The charge exploded with a loud roar but the work was not spectacular for the rock and dirt appeared to be gently lifted a few feet into the air and then rolled down to the base of the stripping hole.

Idle Washery Destroyed.—Fire recently destroyed a washery at Dunmore owned by the Quinn Coal Co. The plant had been idle for several months, but the owner intended to resume operations.

Abandoned Breaker Burns.—Fire recently destroyed the abandoned breaker of the Madeira-Hill Coal Co. at New Boston. Fireman saved a valuable exposed coal vein, a culm bank and also prevented the flames from starting a forest fire in Broad Mountain.

WEST VIRGINIA

Production Report Nearly Ready.—The state Department of Mines announces that coal production in West Virginia in 1925 was approximately 122,000,000 net tons. These figures are in sight with only two reports lacking to complete the tabulations.

Rock-Dust Four Miles at Eccles.—No. 5 mine of the Crab Orchard Improvement Co., at Eccles, Raleigh County, where an explosion occurred in March, now has four miles of the entries rock-dusted.

Safety day will be observed in the mines of West Virginia on Aug. 31, according to Robert M. Lambie, chief of the state Department of Mines. Safety meetings will be held all over the state on that day, it is reported.

Modernizing Red Jacket.—The Red Jacket Consolidated Coal & Coke Co., Inc., Red Jacket, Mingo County, is rebuilding its tipple at No. 5 mine and is installing screens and making other improvements. At the No. 6 mine a new gathering motor recently was installed.

Postpone Institute Meeting.—Instead of holding the semi-annual meeting of the West Virginia Coal Mining Institute on June 1 and 2 as originally planned, Robert M. Lambie, chief of the West Virginia Department of Mines and president of the institute, announces that the meeting will be held on July 13 and 14. Inasmuch as many meetings are scheduled to be held in various parts of the state during the early part of June, postponement of the meeting of the institute was thought to be desirable so that the attendance might not be adversely affected.

Four hundred miners and their families attended a safety meeting at Havaco, McDowell County, on April 23, which was one of the largest of the present series. Addresses were made by Robert M. Lambie, chief of the state Department of Mines; W. H. Forbes, division engineer of the U. S. Bureau of Mines, and others. The mine of the New River-Pocahontas Consolidated Coal Co. is located there.

CANADA

To Merge River Hebert Mines.—A merger of coal operating companies in the River Hebert region is being effected under the title of the Canadian Coal Co. Randolph Emmerson, who is active in the negotiations, predicts the arrangement of final details within a few weeks. The intention is to float a bond issue of approximately $1,250,000, all of which to be placed in England, Ireland and Scotland. New shipping piers will be erected at Joggins, which would reduce the cost of shipping the coal by water. According to Mr. Emmerson, the new company will absorb practically all the companies operating in the River Hebert area except the Maritime Coal, Railway & Power Co., which will continue as a unit.

The Bras d'Or Coal Co., operating in the Bras d'Or Lakes territory, has placed a fleet of steam and a sailing craft in commission between the mines of the company and ports in the maritime provinces, New England and Newfoundland. George Burchell, president of this company, recently added the schooner "Arabia" to the fleet, and the fleet is now complete for the shipping operations of this year. Mr. Burchell expects the company's own fleet to create a big reduction in the cost of shipping the coal from the Bras d'Or pits this year. Hitherto, the company had to depend on chartered vessels and on the railroads.

Lowest Alberta Rate Is $9.—The Canadian National Rys. will not change its stand that $9 per ton is the lowest rate at which Alberta coal can be brought east, Sir Henry Thornton, president of the road, said on his arrival in Toronto. If instructions were issued that a lower rate should be fixed, Sir Henry said, it would be done, but, he added, someone would have to pay the cost.

Digitized by Google

Among the Coal Men

B. E. Riggs, mining engineer, who has been chief inspector for the Central Pocahontas Coal Co. at Welch, W. Va., will take a fling at the sales end of the business. He succeeds F. E. Yarnell as representative of the company at Fort Wayne, Ind. Mr. Yarnell some time since purchased a sand and gravel business in Philadelphia, which now requires his whole attention. He formerly was mining engineer and chief inspector for the company.

Lester E. Westenfelder, principal of mining at the U. S. Marine Corps Institute, Washington, D. C., announces the recent graduation of the following students in the firebosses' course: First Lieutenant Carl Gardner and Corporals Oliver Pauley, Frank D. Quinn and John Nagy.

Ben H. English, formerly superintendent of the Pemberton Coal & Coke Co., with headquarters at Affinity, W. Va., has assumed the duties of superintendent at Ashland, in the McDowell County field. He had been connected with the Pemberton company for the last five years.

Earl Harmon, formerly of the Carnegie Coal Co., Pittsburgh, Pa., has become associated with the General Fuel Co. of Philadelphia and Pittsburgh, in charge of the Pittsburgh office.

Francis Winslow, who has been in charge of the metal-mining branch of the Natural Resources Division of the Chamber of Commerce of the United States, will hereafter also direct the coal activities of the Chamber. This work previously was in charge of Major C. T. Starr, who recently resigned to accept the post of assistant to the president of the Pittsburgh Terminal Coal Corporation, with headquarters in Pittsburgh, Pa.

Leonard E. Adams, purchasing agent for the Knight Fuel Co., Salt Lake City, Utah, for the past decade, has been appointed general sales manager, succeeding J. A. Stallings, who died some months ago after holding that position for several years. The new purchasing agent is **D. Vern Shurtliff**.

A. D. Grasso, who left Buffalo about two years ago to become sales manager of the Valley Coal Co., at Brockway, Pa., which he had represented at Buffalo for some time, has organized a new coal company bearing his name, and takes over the Liberty mine in that vicinity with present output of about 400 tons. He has become president of the company. The Valley Coal Co. mine is shut down.

Col. C. W. Watson, president of the Consolidation Coal Co., with headquarters at New York, and other executives of the company inspected the mines of the Pocahontas and New River division of the company, on May 10. Others in the party were G. J. Anderson, executive vice-president, New York; F. R. Lyon, operating vice-president, Fairmont; G. W. Hay, general manager of operations, Fairmont; R. E. Rightmire, engineer of tests, Fairmont; C. S. Moss, general manager of stores, Fairmont; A. T. Watson, director of purchases and stores, Fairmont; H. T. Giffin, architect, Fairmont, and R. S. Melendy, New York. F. K. Day and other officials of the Pocahontas-New River division accompanied the executives on their tour of company properties in the southern West Virginia field.

Photo by Harris & Ewing

Wayne P. Ellis

Wayne P. Ellis was appointed Northwestern sales agent of the Berwind Fuel Co., with offices in Minneapolis, Minn., on May 1. Mr. Ellis organized the Ellis Coal Bureau nearly a year ago, previous to which time he was secretary of the Northwest Coal Dock Operators' Association. During the strike of 1922 he was in the employ of the U. S. Government, following two years as secretary of the Davis Coal & Coke Co.

Frank M. Davis, long connected with the Buffalo & Susquehanna Coal & Coke Co., has been made vice-president and manager of sales of the company. Dynamiters have lately tried to blow up the company's mine at DuBois, Pa., which is operating at a reduced wage rate.

"It's a good year for coal; I can't say much about steel," said **J. E. McLurg**, vice-president in charge of British Empire Steel Corporation operations, after a conference with President R. M. Wolvin. The vice-president would say nothing about rumors in circulation concerning a reorganization of the British Empire Steel Corporation.

J. G. Puterbaugh, president of the McAlester Fuel Co., McAlester, Okla., who is interested in a number of producing companies in Oklahoma and Arkansas and is a director of the National Coal Associaton, addressed the Texas Retail Dealers' Association, at Dallas, on May 17; the Oklahoma Retail Dealers' Association, at Enid, Okla., on May 18 and also talked to the Mid-Continent Retail Coal Dealers' Association at Kansas City, Mo., on May 25.

A. B. Lemmon, formerly Chicago manager of the Consolidation Coal Co., has been appointed Western sales manager of the Cleveland-Cliffs Iron Co., with headquarters at Green Bay, Wis. Mr. Lemmon is a son of Captain T. A. Lemmon, formerly connected with the Chicago, Wilmington & Vermilion Coal Co., predecessor of the Chicago, Wilmington & Franklin Coal Co.

Charles A. Cabell, president of the Carbon Fuel Co., Charleston, W. Va., has gone to Micco, Fla., to recuperate. He became ill with influenza at his home in Charleston and was threatened with pneumonia, being confined to his home for almost a month.

Harold Butt was appointed controller of the Colorado Fuel & Iron Co. and its subsidiaries effective May 1.

Obituary

Daniel F. Lepley, 64 years old, president and general manager of the Connellsville Manufacturing & Mine Supply Co., Connellsville, Pa., and an authority on mine machinery and mine equipment, died May 17 in the Connellsville State Hospital. His death was due to heart trouble, pneumonia developing. He organized the mine supply company in 1901 and became its general manager, succeeding to the presidency about three years ago, when Rockwell Marietta died. Mr. Lepley was considered one of the greatest mechanical engineers of this country. He had a very wide acquaintanceship with the leading engineers in his field. Machinery from his plant is to be found in all mining regions of this country and in the biggest mines in this country as well as in many foreign lands.

James C. Schallcross, president of the American Cannel Coal Co., of Cannelton, Ind., died at a hospital at Louisville, Ky., on May 12. He had been in the hospital for about three weeks. Mr. Schallcross was born in Kentucky, but had lived in Cannelton most of his life. Early in life he became interested in coal mining and for many years had been president and general manager of the American Cannel Coal Co. and for the past several years had had complete control of the management of the affairs of the company.

James R. Barnes, who was active in the development of the Klondyke and Greene County coal fields of western Pennsylvania, died May 8 in Hopwood, near Uniontown, Pa., in his 66th year. He worked in the mines with his father in early life, but, realizing the value of undeveloped fields, transferred his activity to the marketing of acreage.

Jacob F. Straight, former secretary and treasurer of the Rivesville Coal Co., Fairmont, W. Va., and for the last three years interested in the coal and real estate business in Florida, died May 17 in Jefferson Hospital, Philadelphia, as a result of diseased glands of the neck, resulting from pneumonia and influenza.

Traffic News

Illinois Rate Differentials Re-established

The Illinois Commerce Commission has vacated its suspension order on the re-establishment of freight differentials on coal traffic in Illinois, as authorized by the Interstate Commerce Commission a year ago last February. Revisions in rates from all fields to northern Illinois points were immediately made by railroads, which became effective last Thursday.

The case is known as the Illinois Blue Book Docket No. 14891 and tariffs under suspension were originally filed to restore recognized relationships as between various origin groups, effective Feb. 19, 1925. The effective date of these tariffs was postponed from time to time, and the expiration date of the last suspension was May 20, 1926. Hearings were held before the Illinois Commerce Commission on Nov. 10, 1925, Jan. 12, 13, 14 and 15, and Feb. 8, 9 and 10, 1926.

The Commission in its decision found that its order of suspension should be vacated and that the proposed rates should be permitted to become effective. The finding was made with the express understanding that consideration at a later date will be given to the complaint of the northern Illinois operators and to protests filed by consuming interests at Dixon, Rockford and Freeport, Ill.

In its order the Commission also stated that the recent revision in rates from all Illinois mines to East St. Louis and from the Danville group to Chicago made pursuant to its orders, should remain as now published.

In 1920 the Interstate Commerce Commission decided to make an investigation of the differential rates. Five years later the Commission authorized the railroads to promulgate what were considered more equitable rates.

Immediately the Illinois Commerce Commission suspended the rates on intrastate traffic, which gave Saline County operators in southern Illinois an advantage over other shippers in and outside the state. The new rates correct this situation and restore a differential from southern Illinois to northern Illinois destinations of approximately 70c. a ton as against $1 which previously applied.

Iowa Operators Lack Interest In Rate Question

Lack of interest on the part of Iowa coal mine operators stands in the way of the calling of a hearing by the state Railroad Commission to investigate intrastate freight rates on coal, as requested by Governor Hammill's Agricultural and Industrial Commission. This was revealed by Dwight Lewis, of Des Moines, chairman of the commission, four months after questionnaires were sent to every mine owner or operator in the state. Only five operators have replied, and none of the replies, Lewis said, contains any evidence that Iowa coal mines are being prevented from moving coal to the home market by freight rates.

The Governor's Agricultural and Industrial Commission, investigating the coal industry, suggested the rate probe, in a preliminary report to the Governor, showing that many miners are unemployed because of the comparatively small demand in Iowa for the home product.

Hard-Coal Rates to Iowa Held Unreasonable

The Interstate Commerce Commission has found that rates on anthracite from mines in Pennsylvania to points in Iowa are unreasonable as compared with the rates to Chicago and Peoria, Ill.; St. Louis, Mo., and St. Paul, Minn.

The Commission ruled that through rates on prepared sizes on anthracite from the Pennsylvania mines to Iowa points should be reduced where the present rate per ton is $7.20 or $7.33 to $6.81; from $8.22 to $7.40; from $8.34 to $7.66; from $8.46 to $7.86; from $8.58 to $8.06; from $8.71 to $8.26; from $8.83 to $8.38; from $8.75 to $8.50. For the smaller sizes of anthracite the roads were ordered to maintain the same spread under the rates for the prepared sizes as now exist.

Rates on Colorado Coal to Kansas Unreasonable

Reductions in rates from Colorado and northern New Mexico to local points in Kansas on the St. Louis-San Francisco, Midland Valley and Missouri-Kansas-Texas railways are ordered by the Interstate Commerce Commission in *Public Utilities Commission of Kansas vs. Atchison, Topeka & Santa Fe Ry. Co. et al.* The Commission finds that the rates on lump from the Walsenburg district should not exceed $4.60 to local points on the Frisco between Ellsworth and Augusta, $4.85 to local points on the Frisco between Augusta and Arkansas City, and to local points on the Midland Valley between Wichita and Arkansas City, and $5 to M.K.T. local points in Kansas and to certain Frisco local points in Kansas.

Rates on lump coal also are found unjust, unreasonable and prejudicial to the following extent: From the Canon City district to the extent that they exceed or may exceed the rates prescribed from the Walsenburg district, and from the other districts named to the extent that they exceed or may exceed the Walsenburg rates prescribed by more than the existing differences between the rates maintained from Walsenburg and the other districts to junction joints in the same general territory.

Charge of Discrimination in Car Supply Upheld

The Interstate Commerce Commission, in a second report in *A. Spates vs. Baltimore & Ohio R.R. Co. et al.*, decided May 10, holds that the Baltimore & Ohio, in according Western Maryland Ry. service to mines of the West Virginia Coal & Coke Co. on the Coalton branch of the B. & O. from Oct. 14, 1922, to April 1, 1923, while failing to accord similar service to complainant's mine located intermediate thereto unduly prejudiced the complainant in the matter of car supply. To this extent the previous findings of the Commission, 192 I. C. C. 19, are reversed, and the case is held open to permit complainant to file a petition for a further hearing on the question of damages.

Production And the Market

Prevalence of Seasonal Elements in Coal Market Robs Spot Trade of Notable Features

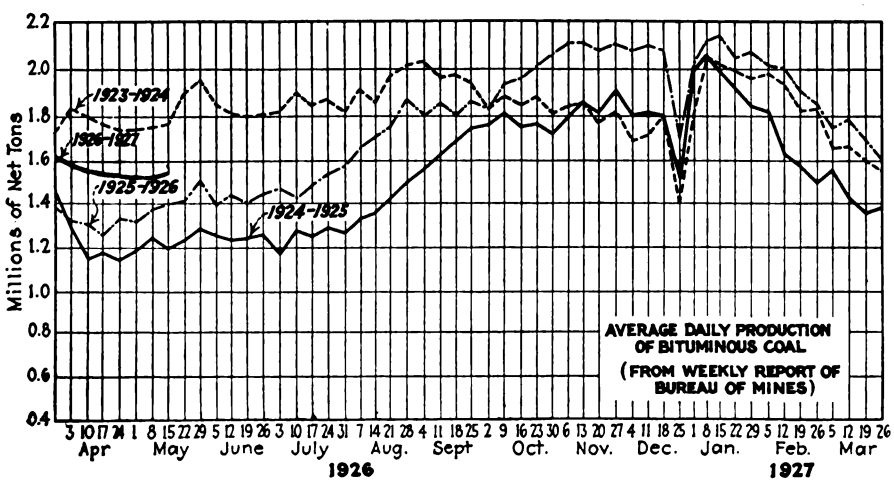
The bituminous coal markets of the United States are running true to seasonal form. That means that a good volume of tonnage is moving every day, but that the spot markets lack those elements of surprise and suspense which make for feverish trading. Even the British strike—for the time being at least—has lost its power to jar the soft-coal business on this side of the waters out of its unemotional routine.

The preponderance of non-union tonnage entering into the channels of commerce, however, is reflected in further declines in average spot prices. *Coal Age* Index of spot bituminous prices on May 24 stood at 157. The corresponding price was $1.89. The week previous the figures were 159 and $1.93, respectively. Sharp declines in quotations on low-volatile coals for New England, a weaker market at Pittsburgh and an easier tone to certain sizes of Kentucky and West Virginia coals were the underlying causes of the lower figures.

In the Middle West there has been a greater steadiness in prices. This has been achieved at the cost of drastic curtailment in production. Seaboard markets other than Boston also have shown more price stability, but the menace of distress coal still lurks in the background. An unbalanced demand as between sizes is a handicap under which almost every producing field in the country labors at the present time.

Slight Drop in Lake Loadings

Lake loadings at the lower ports showed a slight drop during the week ended May 23. The total tonnage dumped as cargo fuel was 993,444 tons. In addition, the vessels took on 40,300 tons for bunker purposes. For the season to date the total dumpings were 3,824,362 net tons, as compared with 4,161,821 tons a year ago.



Production for the country as a whole took a slight upturn during the week ended May 15. The total for that week is estimated at 9,289,000 net tons, an increase of 2.8 per cent over the preceding week and the largest weekly output since mid-April. This upswing follows the rhythm of production in preceding years. The actual rate of output lies between that of 1923-24 and 1925-26.

Anthracite Output Declines

The disinclination of the public to stock heavily with anthracite coal finds statistical confirmation in recent figures on hard coal production. During the week ended May 15, according to the Bureau of Mines, the tonnage produced fell to 1,904,000 net tons, as compared with 1,985,000 tons the week preceding and 2,098,000 tons the week ended May 1.

Sales resistance in anthracite territory is increasing. There is little doubt that the consumers welcomed the return of hard coal at the close of the strike. But with winter behind them, the householders, in many cases, are willing to let somebody else carry the load of stocking. There are many retailers who feel that there are definite limits to what they can do. As a result premium coal is moving with difficulty and buyers are more discriminating in their choice of sizes.

The Connellsville coke trade weakens with the passing weeks. Spot prices on furnace coke are easier and little spot foundry coke moves at more than the minimum quotations on that grade. Production, too, is declining. Byproduct output, which reached its peak for the year in January, also is diminishing. The estimated production last month was 3,602,000 net tons, as compared with 3,777,000 tons in March.

Estimates of Production

Non-Union Coal Holds Down Prices

Heavy shipments of western Kentucky coal into Chicago and other markets of the Middle West are keeping down prices in the face of a steady demand for steam coal. Some western Kentucky mine-run is selling at 80c. Producers of high-grade southern Illinois coal, on the other hand, are trying to maintain $1.50@$2 on screenings and at times are slashing prices on "no bill" lump to clear their tracks for the shipment of steam sizes.

Domestic business is quiet. In the southern field few shaft mines are doing better than three days a week and most of these are depending upon railroad fuel orders. There is a steady accumulation of "no bills." Railroad business also is the saving factor in the Duquoin and Jackson County field. Mt. Olive, too, looks to railroad tonnage for its chief support. Domestic demand is so light that some producers are crushing coal to fill steam contracts. The standard district is hard hit on all sides.

The central Illinois and Indiana producing districts also suffer from the diminished demand for prepared sizes. For the most part, however, prices are well maintained. Breaks come when it is necessary to dispose of this coal to take care of steam business. The local St. Louis market has been helped by chilly weather, but there is little forward buying. Steam business is active because buying is on a hand-to-mouth basis.

Sun Shines Brighter on Kentucky

Low temperatures have turned the thoughts of domestic consumers in Louisville territory toward coal and there has been some buying for fall and winter use. Spot steam demand holds up, although general industrial consumers still fight shy of contracts. Railroad and public utility buying is on a seasonable basis. A number of state and municipal contracts are about to be placed on bids recently submitted.

With the opening of the lakes, eastern Kentucky operations find their prospects improved. Western Kentucky is moving considerable coal to northern industrial markets. Screenings top the list in the matter of strength to such an extent that mine-run and prepared sizes have been sacrificed to make way for the fine coal. Both fields are asking $1@$1.25 for slack, but western Kentucky mine-run has sold down to $1 and eastern Kentucky to $1.25.

Some western Kentucky block has been moved at $1.50, but the general range is $1.65@$1.85. Lump, egg and nut are $1.35@$1.65; mine-run and screenings, $1@$1.40. Eastern Kentucky block is held at $1.75@$2.25, with occasional sales of special grades at $2.50. Lump, egg and nut bring $1.75 @$2; slack, $1@$1.25; mine-run, $1.25 @$1.65.

Northwestern Buying Light

Patrons of the docks at the Head of the Lakes are confining their buying to immediate requirements. Contract renewals have been held back by an unsettled spot market in which cuts up

*Net tons, f.o.b. mines. †Advances over previous week shown in **heavy type**; declines in *italics*

Digitized by Google

to 50c. per ton have been made on lump and dock-run bituminous. The price war was started by two companies pooling forces against a third accused of persistent underselling. So far, screenings have escaped the price decline.

Several cargoes of anthracite already have been unloaded at Superior and Duluth. Many householders are ready to buy now despite the fact that prices are on the winter basis. There has been a heavy run of bituminous cargoes to the docks. These have been handled promptly. The industrial outlook is good. The market at the Twin Cities is marking time.

Business in the Milwaukee dock territory is on a satisfactory basis. Interest is centered largely upon the rapid unloading of incoming vessels. Up to May 20, Milwaukee had received 410,209 tons of bituminous and 54,400 tons of anthracite via the lakes, as compared with 390,660 tons of bituminous and 193,915 tons of anthracite during the corresponding period last year. Local quotations on buckwheat have been shaded, but other retail prices are unchanged.

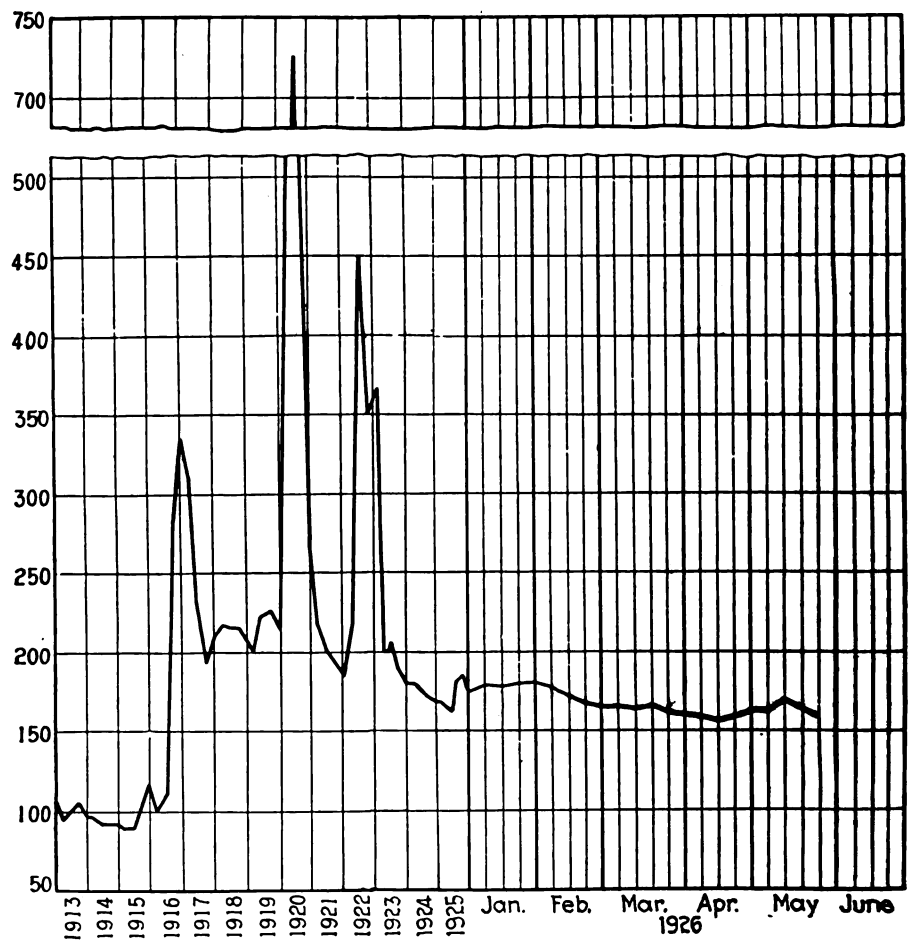
Southwestern Domestic Trade Dull

Dullness is the outstanding characteristic of the domestic markets of the Southwest. Orders for threshing coal are trickling in to Kansas operators and there has been some school buying for late summer delivery. Shoppers do not find it difficult to obtain concessions in prices on prepared sizes of Kansas coal, and Arkansas semi-anthracite lump, officially listed at $4.75@$5.25, has sold as low as $4.

Colorado mines are averaging 60 to 65 per cent running time. Steam trade is the backbone of this business. Prices on Colorado coals and on domestic sizes from the Kemmerer-Rock Springs field are unchanged. Wyoming steam coal is quoted at $1.25@$1.40. In an effort to stimulate the movement of prepared sizes leading operators in Utah have named summer storage prices, offering lump and nut at $3, screened slack at $2.25 and straight slack at $1.50.

Cincinnati Market Steadier

The Southeast has settled down to a steady production grind to keep lake coal moving in an even stream. Prices at Cincinnati reflect this acceptance of things as they are. The outstanding exception is the break of New River mine-run to $1.75@$1.90, and that is a reaction from an earlier attempt to capitalize on the British strike. Lump and egg are firm at $3, nut is $2.25@$2.50 and slack does not rise above the $1.25@$1.35 level.



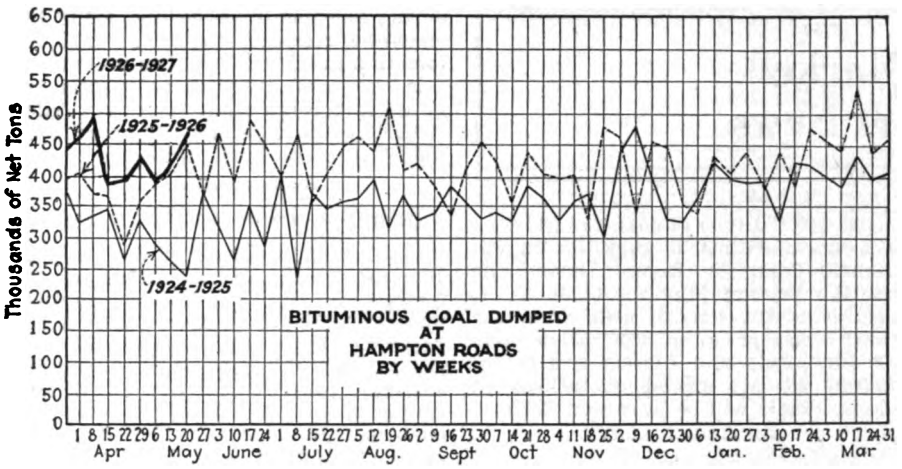
The high-volatile division of the trade seems resigned to a season without sensational developments. Hazard shippers are angling for $2.10 on lump, Harlan asks $2@$2.25 and extra choice Elkhorn and Jellico find buyers willing to pay $2.50@$3. Logan County block brings $1.75@$2. Steam mine-run from West Virginia and Kentucky swings between $1.25 and $1.35, gas moves at $1.40@$1.50 and byproduct coal demands $1.50@$1.75. Kentucky slack is 90c.@$1.15; West Virginia, $1@$1.10.

May retail business, season considered, has been excellent. River traffic is without feature. Movement of rail coal through the Cincinnati gateways is on the increase. During the second week of the month there were 10,897 loads, including 2,210 cars en route for the lakes, interchanged. More empties were on the way to the mines.

Pressure Lifting at Columbus

The flow of tonnage to the lakes has relieved some of the pressure on the Columbus market, but central Ohio prices and demand still are depressed. Little southern Ohio coal is being loaded for the lakes and that little is coming from mines with dock affiliations. Hopes that the late opening of the season would mean higher prices have been doomed. The prevailing quotation is $1.50, mine-run basis.

Most of the large industrial consumers are content to play the open market. To make matters worse, some are depending upon stockpiles already accumulated. Several railroad contracts still hang fire and public utilities are buying less freely. These factors



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	May 24	May 17	May 10	May 3	May 25	May 26
Weighted average price	$1.89	$1.93	$1.95	$1.92	$1.96	$2.02
Index	157	159	161	159	161	167

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, obtained was compared with the average for the twelve months ended June, 1914, as 100, and second, with respect to the tonnage of each normally produced. The average thus after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

and a windfall in the way of vessel fuel to Pomeroy Bend have further weakened screenings. The southern Ohio output approximates 15 to 18 per cent of capacity.

Operators in the northern Ohio field are groping for market stability. Spot prices at Cleveland are less erratic and there have been some modest advances recorded. Steam demand, however, is very light and railroad buying is not up to the mark. The inauguration of the lake season has eased the slack situation, but prices have not declined. Eastern Ohio mines are running about 30 per cent of capacity. "No bills" are the rule.

Pittsburgh Still on Dead Center

The unprofitable *status quo* of the Pittsburgh district was undisturbed last week. If there was a slight recession in union production, it was offset by a corresponding gain in open-shop tonnage—and neither group claimed any profit for their efforts. The increasing percentage of non-union tonnage, however, is having a depressing effect upon prices. Youghiogheny three-quarter gas is $2.20@$2.30—a loss of 10@15c. Three-quarter steam has dropped from $2.10 and up to $1.90@$2.15. Gas mine-run and steam and gas slack also have weakened slightly.

Central Pennsylvania production the first half of the month showed a small increase over figures for the first two weeks in April. The district, however, reports 2,000 "no bills" on hand. Prices are unchanged.

The Buffalo bituminous trade continues to wallow in a slough of unrelieved gloom. As coal men there see it, the only relief possible must come through a further drastic reduction in output. Prices on Pittsburgh and No. 8 steam lump are off 20@25c. and Allegheny Valley mine-run has declined a dime. There is less consignment coal to upset the market.

Atlantic Seaboard Quiet

Atlantic seaboard bituminous markets are inactive. A moderate tonnage for export—contingent upon the duration of the British strike—is moving offshore, but steam demand in New England, for example, probably is less than a fortnight ago. Navy Standard is easy at $4.50 gross, f.o.b. Hampton Roads. Pool 2 can be had at $4.25 and slack still lower. On cars at Boston and Providence, pool 1 coal is offered for inland delivery at less than $5.50.

Little interest is displayed by New England in central Pennsylvania offerings. A few venturesome operators loaded coal in the hope of finding an extra outlet in the Northeast, but they have been unable to locate prompt buyers for their product. What little spot New England demand develops is concentrated upon West Virginia coals.

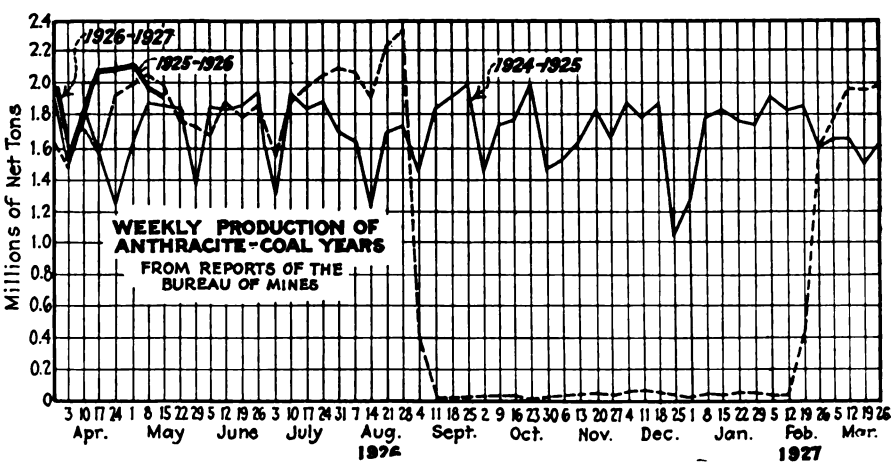
Consumers buying in the New York market are withholding orders. The tidewater market, however, gained in bunker business as a result of the British strike and there is very little distress tonnage left in the harbor. Bunkering also is the most active feature of the Philadelphia spot market. In the line trade, slack is the only bright spot; some plants are supplementing shipments with purchases of mine-run. Baltimore bituminous trade is colorless.

Alabama Slows Down

The Birmingham market is feeling the effects of the gradual slowing up in demand. The comparative inactivity however, is wholly seasonal in character. It presses most heavily upon the lower grade fuels, but there are no troublesome accumulations of unsold coal to plague the shippers as production is trimmed to more nearly meet the existing spot and contract demand. Very little tonnage is offered at cut prices. The coke market is quiet.

Independent anthracite producers are finding it difficult to sell coal at a premium over company prices in the New York market. Consumer buying is still backward, but distributors are taking egg and stove freely. Pea retains its strength. The steam market drags.

Practically the same situation with respect to independent tonnage prevails at Philadelphia, and some quiet, but not altogether successful, price cutting has been indulged in in the effort to move coal. The companies, however, seem to be able to sell their domestic output, although there have been some cancellations. It is recognized, of course, that the opening of the lake season has helped the larger producers.



Use Pea to Move Nut Coal

Pea, while still popular, is not the leader that it was some weeks ago. Independents are using it, however, to force retailers to take in nut coal. In some cases the distributors decline to swallow this bait. Steam trade, as at New York, is sluggish, with No. 1 buckwheat the weakest size in the group. Baltimore householders show no anxiety over anthracite.

Local Buffalo demand for anthracite and coke is disappointing. Weather conditions again have interfered with the lake trade, slowing up the movement of coal. Anthracite shipments for the week totaled 87,200 tons, of which 18,300 tons were cleared for Chicago, 55,700 tons for Duluth and Superior, 7,200 tons for Green Bay and 6,000 tons for Milwaukee.

Coke Market Weaker

The Connellsville coke market is distinctly weaker. Spot furnace coke has sunk to $2.85@$3. Standard furnace holds to $4@$4.50, but the bulk of the limited spot tonnage moves at the lower figure and some off-grade fuel has moved at less than $4. Production during the week ended May 15 totaled 154,870 tons, according to the Connellsville *Courier*. Furnace oven output was 90,700 tons, an increase of 1,200 tons over the preceding week. Merchant oven output was 64,170 tons, a decrease of 6,670 tons.

Foreign Market And Export News

German Operators Favor Export Pact with Britain

Berlin, Germany, May 11.—The strike in Great Britain undoubtedly has brought the problem of a German-British coal agreement nearer maturity. When the question was taken up informally some months ago German operators were averse to such an understanding. Since then the British state subsidies have changed the situation.

The German export business has been maintained only at a considerable sacrifice in prices. The Ruhr syndicate suffered a loss averaging about four gold marks per ton on coal exported in competition with British coal. While there are no signs of retreat the large majority of German operators now are convinced that a British-German coal agreement is absolutely necessary in the interest of both parties and have obviously decided on the alternative of a price-cutting war or an agreement.

In the minds of the German operators it would be a desirable course of events if the British industry would create for itself an organization similar to that prevailing in Germany, either a uniform syndicate or local syndicates acting under central direction. As far as has been heard, the German syndicates are quite willing to come to an understanding with the British industry with regard to a price policy as well as the combined control of the export markets.

The German idea is that the export markets should be divided between Great Britain and Germany at a certain ratio of supplies—if possible the pre-war ratio. In the event of such an understanding the Ruhr coal syndicate is even prepared to abandon all attempts to eliminate British coal from German markets. It is hoped in German circles that the situation in the British coal industry after the end of the strike will accelerate an accord.

Strike Spurs French Market

Paris, France, May 12.—Stronger demand for French coals is the first reaction to the British strike felt in this country. Prices, too, are rising. In the Nord and Pas de Calais areas wage agreements which expire May 15 will be replaced by new contracts granting the workers a 10 per cent increase in base rates and a 15 per cent bonus on the cost of living. This means a maximum increase of 2.80 fr. daily and a minimum of 1.30 fr.

Industrial stocks are low. Inquiry for domestic fuels is increasing and shipments of ovoids seem insufficient to meet demands. High prices for pitch have discouraged the patent-fuel manufacturers. Quotations in the Centre, the South and in the Sarre are rising.

Receipts of indemnity fuels are declining. During April the O. H. S. received 410,800 tons of coal, 288,600 tons of coke and 29,000 tons of lignite briquets from the Ruhr. During the first ten days of May the O. R. C. A. received 85,200 tons of coke from the Ruhr. The price on reparation coke for June, July and August will be increased 20 fr.; official quotations on coking smalls will be advanced 12 fr.

Belgian Market Stronger

Brussels, Belgium, May 12.—The British strike has had a favorable influence upon the Belgian coal trade. As long, however, as Ruhr stocks are so large there can be no great boom. Nevertheless inroads are being made upon supplies in the Borinage and stocks of lean bituminous and 8x20mm. beans have been exhausted. Coking smalls are commanding 90@90.50 fr. Lime duffs are 70@74 fr. Coke, too, is firmer; the range is 130@135 fr., but up to 137.50@140 fr. have been offered.

April Foreign Coal Trade Below March Levels

Exports of coal from the United States last month did not come up to the March levels. Bituminous shipments declined approximately 80,000 tons and there was a slight drop in anthracite. The totals, however, were greater than in February.

April exports by countries were as follows:

Totals	294,802	1,094,247	54,912

Bituminous imports in April amounted to 43,000 tons which was slightly less than in March. Anthracite received from abroad reached 59,000 tons as compared with five times this amount during the month preceding, while the amount of coke arriving fell from 85,500 tons in March to 20,000 tons in April.

Bunker coal supplied to vessels engaged in foreign trade in April totaled 400,638 gross tons, as compared with 353,149 tons in April, 1925.

Brazilian Imports Up in 1925

Coal imports during 1925 at Rio de Janeiro, which receives most of the foreign coal for Brazilian consumption, totaled 1,117,000 metric tons, which exceeded those of the two preceding years. The United States supplied 502,783 tons and Great Britain furnished 614,033 tons of the total coal imports. In 1924 the United States supplied 561,292 tons and Great Britain 403,947 tons.

Prices in 1925 averaged approximately 36 to 37s. for British coal and $9 for American.

Coming Meetings

West Virginia Coal Mining Institute. Annual meeting, June 1-2, Bluefield, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

Coal Operators' Association of 5th and 9th Districts of Illinois. Annual meeting, St. Louis, Mo., June 8. Secretary, O. L. Lumaghi, St. Louis, Mo.

Southwestern Interstate Coal Operator's Association. Annual meeting, Kansas City, Mo., June 8. Assistant Secretary, George Manuel, Kansas City, Mo.

National Coal Association, June 9-11, at Drake Hotel, Chicago, Ill. Executive secretary, Harry L. Gandy, Southern Bldg., Washington, D. C.

The National Association of Purchasing Agents. Annual convention at Los Angeles, Calif., June 9-12. Secretary, W. L. Chandler, Cleveland, Ohio.

American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Illinois Mining Institute. Annual summer meeting on steamer "Cape Girardeau," leaving St. Louis, Mo., June 24 and returning June 26. Secretary, Frank F. Tirre, Central National Bank Bldg., St. Louis, Mo.

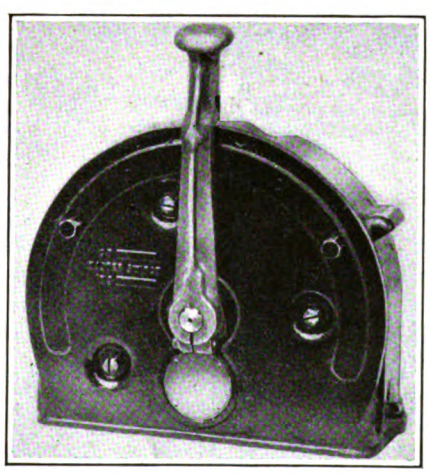
American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

Illinois and Wisconsin Retail Coal Dealers' Association. Thirty-first annual convention, Highland Hotel, Lake Delavan, Wis., June 28-30. Managing Director, N. H. Kendall, Great Northern Hotel, Chicago, Ill.

Fifth International First-Aid and Mine-Rescue Contest, San Francisco, Calif., during the first week of September, 1926, under the auspices of the Bureau of Mines, Department of Commerce.

Coal Mining Institute of America. Annual meeting, Chamber of Commerce, Pittsburgh, Pa., Dec. 8, 9 and 10. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

New Publications



American Blower Co., Detroit, Mich., has issued Bulletin No. 1608, superseding No. 8, Series 6, illustrating and describing its Type P "A B C" **Pressure Blowers and Exhausters.**

New Equipment

Lever-Thrown Master Switch

A lever-operated master switch for installation where exceptional strength and durability are important factors has recently been announced by the General Electric Co., of Schenectady, N. Y. The new switch is particularly suitable for grouping and for operation by one man.

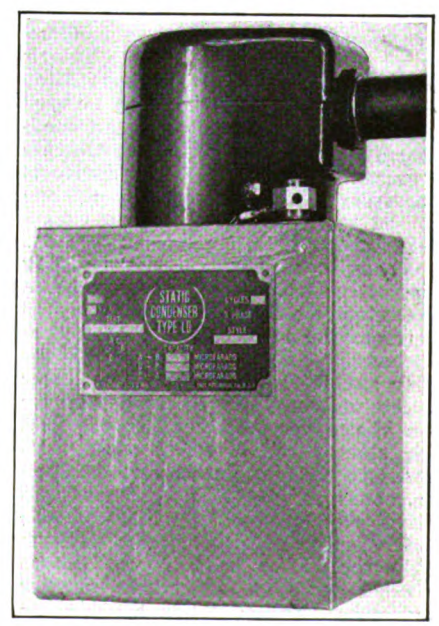
This master switch is flat and semicircular in general shape consisting of a cast-iron frame and cover totally inclosing the contact mechanism. This design readily permits convenient grouping within easy reach of one operator. The handle is of the vertical type, operating through a radius of 40 deg. on a one-point switch and through a 100-deg. total radius on switches of the three-point type. This handle is mushroom-shaped so that it may be grasped easily and quickly. Operation from one position to another is quite free, there being no gears or other friction surfaces other than the bearings and contact fingers. The handle is held in the "off" position by a spring roller device.

Switch Affords Safety from Shock

This switch is devoid of all friction surfaces except the bearing and the contact fingers. It is fitted with a mushroom top lever and is especially adapted to grouping.

Approval Accorded to Cable With Non-Metallic Sheath

The non-metallic sheathed electric cable, known as RomeX and manufactured by the Rome Wire Co., of Rome, N. Y., which has been a subject of much debate in the electrical industry during the last four years, has finally been approved by the National Fire Protective Association. This action will permit the Rome Wire Co. to begin production of this product and place it on the market in competition with other insulated wiring now used on all types of circuits under 300-volt potential. The accompanying sketch shows the construction of this wiring. The core or beginning of RomeX cable is a standard rubber-covered code wire, marked *A* in the sketch. *B* is a close wrap of fibrous tape formed from six thicknesses of long-fiber kraft paper. The cotton braid *C* is then applied and carefully saturated with fire-resistant compound. Another wrap *D* of the long fiber kraft tape is next applied and two or more of the conductors are thus sheathed together with filler cords *E* under a heavy braided outer jacket *F*. The materials marked *D*, *E* and *F* are treated to make them fireproof and moisture-proof.



For All Circuits Under 300 Volts

Paper and cotton braid the only coverings. The various coats are treated so as to make them both fire- and moisture-proof.

Static Condenser Designed for Individual Motors

Development of a line of static condensers for application to 220-, 440-, and 550-volts two- and three-phase individual motor circuits has been announced by the Westinghouse Electric & Mfg. Co., of East Pittsburgh, Pa. The new condenser consists of insulation inclosed in a sheet-metal container and a porcelain terminal housing arranged for conduit connections.

By the corrective effect at the motor that these condensers afford many advantages are said to be obtained: The losses are less than ½ per cent regardless of the kilovolt-ampere rating; the power factor is corrected immediately; because of the reduction of the line current the voltage regulation at the motor

Corrects Power Factor

This static condenser may be installed beside the motor it serves. When additional motors are needed more condensers may be purchased or those already in use may be shifted. At present it is available in capacities up to 5 kva.

Digitized by Google

or on the feeders is improved; the power-factor correction is flexible and applied where needed. There are other advantages but these are the most outstanding.

Better Furnaces

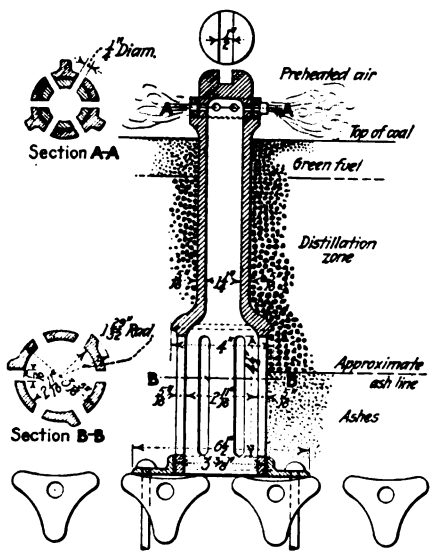
Furnishes Air to Gases for Complete Combustion

Heretofore, the principle of the bunsen burner has been applied to gaseous, liquid or powdered fuels only. What is termed the CO_2 Combustion Tube, adapting this principle in practically its entirety to the burning of solid fuel on grates in domestic furnaces, recently was developed and patented by James C. Law, of Scranton, Pa.

In the past, aside from natural draft, two means have been employed for supplying air to the fire in the ordinary house furnace. These were pressure blowers delivering air to the ashpit under the grates and various forms of diaphragmed inlets admitting air to the combustion space above the fuel bed. Most of these latter devices are attached to the inner surface of the firing door, drawing their air supply through a rotary damper therein.

Ordinarily, but especially when burning a smoky coal, air for the combustion of the gases distilled from the fuel must be supplied above the fire. Hence the sliding or rotary damper in the firing door. If the combustion of these gases is not completed, smoke is evolved, and as much as 15 per cent or even more of the heat derivable from the fuel is lost up the stack.

Approaching Perfect Conditions



When a sufficient quantity of air from the ashpit is conveyed through the fire bed, preheated during its passage, and then released at or near the upper surface of the fuel, the conditions necessary for complete combustion are closely approximated. This is the function that the CO_2 Combustion Tube seeks to perform. It may be used with either natural draft or an inexpensive volume blower. A forced-draft or pressure blower with this device is unnecessary; furthermore, should one be used it would tend to form excess clinker and to consume fuel too rapidly.

As may be seen in the accompanying illustration, this device consists of a tube extending upward through the fuel bed from the regular grate of a furnace and terminating just above the upper surface of the bed. The lower portion of this tube is made larger than the upper part and is provided with slots through which air is delivered to the distillation and combustion zones of the fire. Above this slotted portion the diameter of the tube is restricted and remains uniform to the top. Here several small holes, provided with an adjustable shutter ring, spray the air, which has become highly heated in its passage through the tube, into the combustion space above the fuel bed. This hot air then mixes thoroughly with the combustible gases released from the fire, thus furnishing oxygen in a regulated volume for their consumption. A slot or depression is provided in the apex of the tube, thus furnishing a means of rotating it on its base by the insertion of a bar or poker through the firing door. Such a movement of the tube breaks up any clinker that may have formed around its slotted portion and allows a free passage for air directly to the distillation zone of the fire bed.

Application of this tube to a furnace is extremely simple. It is provided with a base of limited diameter but sufficient to span two grate bars. Holes in the flange of this base allow two ordinary rivets to be inserted. These extend downward through opposite interstices of the grate bars. The tube is thus held centrally positioned even though the grate bars upon which it rests may be rocked in the ordinary way to remove ashes and light clinker. The grate bars, however, must not be completely turned over.

Utilizes Small Sizes

This tube is intended to assist in the utilization in domestic furnaces, of the small sizes of anthracite such as No. 1 buckwheat or mixtures of pea and buckwheat, as well as domestic grades of bituminous coal. It is stated that when used with fuels of the latter type, regardless of percentage of volatile matter, the volume of smoke issuing from the chimney is reduced 40 to 50 per cent; also that the flashing or "puffing" of the gases and the possibility of destructive gas explosions is precluded regardless of the firing method employed. Furthermore, this tube, by its slotted section, provides the equivalent of a 10 per cent increase in the grate area in the furnace to which it is applied, and affords a general increase in combustion effectiveness of 15 per cent or more. No change in furnace structure is required, and as the device is extremely simple no tools are necessary for its installation.

Supplies Heated Air for Gas Combustion

This tube is built to withstand high temperatures. It rests upon the grate bars which may be rocked in the ordinary way and it supplies heated air to both the combustion zone of the fire and for burning the gases above the fuel bed.

Industrial Notes

J. L. Latture Equipment Co., 354 Belmont Street, Portland, Ore., has been appointed sales representative in Oregon, Washington and Idaho of the Climax Engineering Co., Clinton, Iowa, manufacturers of engines and power units.

The Electric Service Supplies Co., Philadelphia, Pa., removed its Pittsburgh office from Room 829, Oliver Building, to Room 1123, Bessemer Building, on April 1.

Maurice R. Hart, who has been with the Morse Chain Co. for several years in the production department and the last two years in the sales department, has been appointed manager of the Buffalo district, with an office in the Ellicott Square Building.

Harlan A. Pratt has been appointed manager of the oil- and gas-engine department of the Ingersoll-Rand Co., 11 Broadway, New York City. Mr. Pratt was connected for many years with the sales department of the Westinghouse Electric & Mfg. Co., later becoming sales manager of the Atlantic Elevator Co., exclusive agents in the East for Westinghouse gearless traction elevators. For the past three years he has been sales manager of the Elevator Supplies Co., of Hoboken, N. J.

The Stoker Corporation, Dover, Del., manufacturing coal stokers, W. W. Murphy, president, chartered under Delaware laws, has filed a certificate in the office of the Secretary of State of New York to allow it to do business in New York State with $525,000 capital. The New York office is 150 Broadway, New York City.

The Hyatt Roller Bearing Co., Newark, N. J., announces these recent changes in its mine car division organization: T. V. Picraux has been placed in charge of Western territory with headquarters in St. Louis, succeeding Leo Shea, recently transferred to the tractor and implement division, Chicago. Alex Hunt assumes charge of the Huntington (W. Va.) office, relieving Charles Perry, who has left the company.

Samuel B. Belden, has resigned as vice-president of the Jeffrey Manufacturing Co., manufacturers of coal-mining machinery, Columbus, Ohio.

David F. Reid has organized the **Pocahontas Mining Co., Inc.**, of which he is president, with headquarters in McDowell County, W. Va., on the Norfolk & Western Ry., where it has opened a mine in the Douglas or Red Jacket seam of coal and is opening the seam above it. The plant is electrically equipped, power being purchased from the Appalachian Power Co.

The Duff Manufacturing Co., Pittsburgh, Pa., manufacturers of jacks, announce the appointment of Albert Roberts as district manager of the Southern territory, with offices in the Candler Building, Atlanta, Ga. Mr. Roberts was formerly associated with the Grip Nut Co., of Chicago.

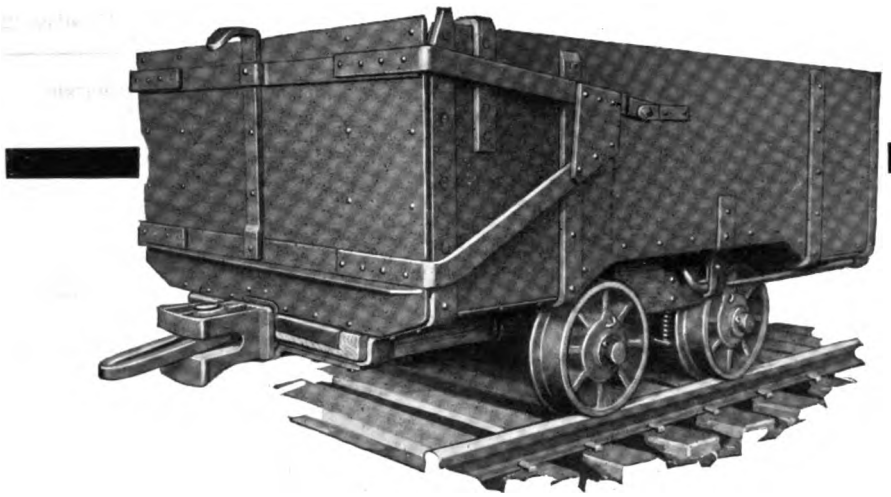
Fairmont control of installations means just this:

The design is Fairmont creation that meets your individual needs.

The fabrication of steel and the construction of units is done in Fairmont shops.

The erection and testing is done by Fairmont erection crews.



All these effect a saving of time and money for the operator. And Fairmont has another thoroughly satisfied customer.

Consult our engineers on your coal handling and preparation problems.

There is no obligation.

FAIRMONT MINING MACHINERY COMPANY
FAIRMONT, W. VA.

Over a thousand of the cars illustrated have been made for a large western Pennsylvania mine. The coal capacity is four tons (water level capacity 120 cubic feet), and the overall length 10 feet five inches.

The car is of the composite type, for use in cross-over dumps. It has cast steel bumpers, and spring draft gear. There is maximum capacity for its height.

Your transportation problem may be properly solved only by designing cars to fit your specific requirements.

Over a thousand types, for as many applications, have been designed and produced by Hockensmith. All this accumulated experience is at your call, to help make your transportation system more effective and economical.

Five Editors at Cincinnati

You will find in this issue a full account of the convention and exposition at Cincinnati. With such a large attendance and such general interest *Coal Age* has found ample justification for arranging that no less than five editors be present. You will see the results of their labors in this week's issue. The important events of that momentous meeting are well portrayed in the pages before you, and he would be unwise indeed who would delay his perusal of the matter thus adequately presented.

Read the Advertisements Also

Manufacturers are specialists. They know what the user of machinery has to confront. It is said that the purchaser of equipment is not slow to say what he thinks of it and to say it at times loud, hard and persistently. So the manufacturer gets to have new viewpoints as soon as he introduces a new line of equipment.

After he has proved and perfected his new line, he advertises it and what he has seen and heard in the coal field he puts in his copy. So what he writes is well-seasoned, well-tested material. He knows, and if you read what he has to say, you will know also. He can give you suggestions which will enable you to save money.

Advertisements are written to instruct and to inform. You can get new ideas from them. The big executives, the successful managers, the best engineers read the advertising pages to keep abreast of the times whether they meditate buying or not. *Coal Age* is not properly digested unless the advertisements as well as the editorial text are properly perused.

Bet on Bulldog!

for lowest cost—

O-B Bulldog Clamps

IT is a pretty safe bet that the intruder who doesn't belong on your premises won't linger if you have a healthy watchdog. False economy, working his way in through the appeal of cheaper products, is an unwanted visitor on many mining properties.

O-B Bulldog Trolley Clamps are not the cheapest ones you can buy, but they are proving themselves the most truly economical ones. The positive unshakable grip of these devices has reduced overhead maintenance and operating delays in every mine where they are used. The easy nut adjustment for tightening them has made trolley work less expensive on every job. And their sturdy, made-right construction outlasts the cheaper ones every time.

It is not a gamble to bet on Bulldogs! It is a sure thing that they'll bite large chunks out of maintenance expenses.

O-B Mine Equipment

Trolley Materials:
- Hangers
- Clamps
- Splicers
- Frogs
- Cross-overs
- Section Switches
- Expansion Bolts
- Pole Brackets

Insulators
Feeder Wire Fittings
Locomotive Headlights
Trolley Wheels and Harps
Rail Bonds and Accessories and other miscellaneous devices.

Volume 29 NEW YORK, JUNE 3, 1926 Number 22

Cincinnati's Convention

DURING THE past year not much that is really new has been introduced, but that does not mean that there has been no progress. In fact the technique of mining appears to have advanced as much as in any previous year. The large number of new devices of a few years back are now getting into regular operation. One hears less of what can be done in a record run and more of everyday experience.

The schemes of past years are gradually being digested. Machines are beginning to cut their repair bills. Mines are being adapted to the new systems of operation. Superintendents are gradually assimilating the new technique. If, as Eugene McAuliffe says, the success of the new equipment lies 90 per cent in management, and if we are to interpret that as meaning an attitude of mind, then we are making real progress. Where before it was said, "will it work?" we have now advanced to the question, "how will it work best?" We have ceased to question whether the new methods of mining are going to replace the old.

Conveyors have made the most progress, especially shaking conveyors. The United States is getting in line with England and Germany, which countries by the way got their first ideas on this subject from this country. The American mines initiated slushing for backfilling and conveying for coal and then turned the cold shoulder to both. Conveying is coming back, partly with American devices and partly taking advantage of German and English machines.

Rock-dusting was probably advocated here by G. S. Rice before the British devised it for their own needs and on their own initiative. But now with their example and that of France it is being introduced here. In no long period of time every mine not naturally rock-dusted will adopt it and perhaps all will find it well to introduce the manufactured article because of the uncertainty of natural rock-dusting. Here again the convention proved helpful in suggesting methods of distributing the dust as much as in advocating the practice.

No one can doubt that Mr. McAuliffe is right in emphasizing the importance of ventilation and coal-dust suppression. The U. S. Bureau of Mines is doubtless in full accord, but to advocate too many improvements is usually an effective way to dull the edge of one's advice. One strand at a time is an easier way to sever a rope than to try cutting the whole cable at a single stroke. This year it is rock dust that receives the emphasis. When that advance is assured, then perhaps we shall find due stress accorded to the other two. If a thousand lives yearly can be saved by rock dust, a big gain in safety will be achieved.

After all rock-dusting is a protective device that can be seen and evaluated. It lasts for months. Ventilation on the other hand is not so readily assured. It may be sufficient today and inadequate the day following, and an explosion will wipe away all evidence of the adequacy or inadequacy of temporary stoppings and doors. Rock dust on the other hand will remain after the explosion to show that it was present to guard the haulway.

The convention has done a good work. It has brought up many new ideas and dramatized and revised many not so new. A year from now we shall see what it has done without realizing to the full perhaps how much of the progress should be attributed to its influence.

Pending Coal Legislation

THE COAL industry, in considering the bills now before Congress which are designed to ameliorate the difficulties under which the industry is suffering, will do well to view the problem in a judicial and unexcitable mood. These bills, it must be realized, are put forward by Congress, not on account of a pressure from the President and the Executive branch of the government so to do, but from a pressure of public opinion, voiced through the press and communicated from their constituents through the different senators and congressmen, that "something must be done." When this pressure is coupled with reproaches from the Democratic representatives and senators that the Republicans have done nothing, it is clear that a gesture in the way of legislation is inevitable.

The attitude of the Executive branch of the administration toward the subject—that the industry, if it were humanly possible, should be left to work out its own problems, provided it did address itself to that task—was clearly shown by the President's attitude during the anthracite strike, when his wise "hands off" policy, in the face of public clamor and complaint on Capitol Hill, produced the most satisfactory results.

Concerning the present legislation a certain attitude, such as is exhibited by certain spokesmen for the industry, indicates a belief that the administration is seeking no exert some control over the coal industry, for the sake of aggrandizing its power over business. There is nothing in the record to support this view. Not only the President's attitude during the strike, but the testimony of the Secretary of Commerce at the coal hearing of the House of Representatives show this; reading of Mr. Hoover's testimony shows that he abhors compulsion of any sort, and moreover, that he did not favor present legislation. The imputations that the bills were drafted by or with the help of the Department of Commerce are quite unfounded.

It is indeed unlikely that the present legislation, though introduced, will be passed this session: the political exigencies of the situation are for the moment satisfied by their introduction. But that does not mean that the economic and political problems of the coal industry are settled: only a fair, progressive and

Digitized by Google

tolerant attitude on the part of coal operators and coal miners alike can avert future troubles, and a further loss of public sympathy toward both sides of the quarrel.

It is not sufficient for the coal industry simply to repel all these pressures, as was explained in the editorial on "The Dangers of Negation" in our issue of April 22. The coal industry should be allowed to solve its problems by itself, always providing that it takes advantage of that privilege and permission. It must not, however, deny or minimize the power of public opinion, the greatest ruling influence in the modern world.

Coal Age is opposed to the passing of the pending legislation at the present time and is opposed to all legislation if it can be avoided. It does, however, see clearly the folly of a *laissez-faire* policy on the part of the industry. Constructive, not destructive leadership is necessary on the part of operators and miners alike; and, moreover, tolerance and co-operation between these two groups of leaders.

Will Mine-Water Pollution Increase?

EXTREMELY GLUM were the reflections of Andrew Crichton in his address on the pollution of streams by mine water at the American Mining Congress convention last week. His was a sort of unrhymed threnody, or dirge. Only 400 square miles of the coal on the Monongahela River drainage area have been mined. Some 6,600 square miles remain. Already the water is acid part of the year. Soon it will be acid all the time. Soon it would be so acid it could not be treated.

What can be done? To treat the mine water would be excessively expensive. There is apparently no way out except by state purchase of idle coal lands. These were the saddening reflections presented by Mr. Crichton, and no one can aver that he overstated the problem.

There are, however, some signs of improvement. Without planning for less pollution, probably much is being done all unwittingly to decrease it. Much of the acid water in old abandoned mines is doubtless derived from the slack coal that in early years was left in the mines. Pyrite in slack is particularly susceptible to oxidation by waters carrying oxygen.

In early days less slack was made than today. In a 3-ft. bed perhaps a third was fine coal and in a 6-ft. about one-fifth. When we realize that the sulphur in the bed will run from 1 to 6 per cent, assuming all the sulphur to be pyritic which is, of course, not correct, the acid that could be formed would run from 3 to 18 per cent. If a third was pyrite, there would be 1 to 6 lb. of acid for every 100 lb. or from 20 to 120 lb. for every ton of slack, that is from 4 to 40 lb. for every ton of coal mined.

Furthermore, in early days the coal was not extracted with any degree of completeness. About a third of the mineral was left. This coal became crushed and in time all of it will be leached of its sulphur, thus increasing the figures given materially. Today not only is all the slack loaded out, but the pillars are more completely removed. The extent of that removal is constantly increased, thus again reducing the quantity of acid formed.

Coal, however, is left in the roof and floor. That in the roof is badly crushed and will doubtless give trouble for years. That in the floor is probably almost intact, though floor movements break it up a little. The floor coal is the most sulphury of any. Where it is not, it is mined and shipped, now as in past times. We are not clear to what extent it was left in the mines in earlier years, but probably it was removed as the market was not as finical as today, for coal was less used for metallurgical purposes.

Other sources of pollution are the rooster coals and perhaps some of the measures that are void of coal but contain sulphur. The shale and sandrock measures are thicker than the coal beds, but their sulphur content is lower. Nevertheless the stalactites in the mine bear evidence of the presence of iron and therefore possibly of pyrite.

One would not be so ready, however, to make that assumption, were it not that droppers are noted to be acid in some mines, as has been proved by their action on mine piping. These droppers may, however, be acid only because they have passed through superincumbent coal seams or through rooster, or "wild" coal beds.

The effect of sealing a mine is to prevent oxidation by free air. Such sealing might be fairly effective, though that is a matter for proof. Unfortunately oxidized waters from the surface would undoubtedly reach the coal, especially when the cover is light. Then if the water escaped through the outcrops it would be extremely acid, all the more so that the water would remain in the workings long enough to oxidize the pyrite and to reach levels well above the floor of the mine.

The coal operator who pumps water is interested in keeping his water free frm acid. What should he do to this end? That is another story and well worth the telling.

Wasting Human Lives

USING EIGHT or more men when one or two would serve to do the work and could do it more efficaciously and easily is wasting human lives and depriving the public of its right to buy coal at the price for which coal should sell and incidentally is not profitable to the operator who does it. These wastes of human effort which need correction are found not only in dumping practice, though there they are not infrequent and are larger, perhaps, than elsewhere, but they occur in many departments of work in mining and in other industries. They are not peculiar to mining. One can find such wastes everywhere if one looks.

Those who believe the function of the superintendent is just to keep men working greatly misapprehend the real purpose of that functionary. Many a mine does good work for its owner when scarcely a man is actually laboring. At such mines machines are at work and the men merely direct their operation. "Hustle" was a big word in the nineties when human effort almost alone achieved results, but smooth, well-adjusted mechanical operation is the desideratum of today. We have no words yet to express this notion as emphatically as we express activity of the body, effort, grind and labor by the word "hustle," but that is a sign that the present decade does not know itself yet, has not recognized its own conditions, has not visualized its aims. When it does it will have words and synonyms aplenty for the job that runs itself—that is automatic, propelled by the nind and not by the body. Who will invent the word of power that will set our thinking straight on modern ways of operation? Words are the tools of thought, but here we are with a new condition in our lives, and a new thought for which we have no word.

Can Coal Companies Improve Their Acid Water Effluents?

Air as Well as Water Needed to Turn Pyrite into Acid—Sealed up Mines Eventually Leak Again—Abandoned Mines Worse Than Those Working

By Staff Correspondent

THAT THE complete neutralization of all mine waters, to say nothing as to their softening, is a task almost beyond immediate contemplation was the view taken by most of the engineers present at the morning session of Tuesday, May 25, on "Mine-Water Pollution." Yet it was realized by nearly all that it would be wrong to take an irreconcilable attitude in regard to the matter. The industry cannot afford to assume an air of indifference towards the rights of others.

The consuming public needs the use of the waters, and the coal operator would do well to endeavor, if it be possible, not to pollute them excessively, for that action would be tantamount to attempting to deny to the public its use of those waters.

LEGISLATION IMMINENT

S. A. Taylor, president of the American Institute of Mining and Metallurgical Engineers and consulting engineer of Pittsburgh, who took the chair, said that the coal industry though unfortunate in the low prices it received for its product and in its excessive production did not stand alone when it faced these troubles. Farming and the metal industries were equally inflated as to production and equally deflated as to prices. The coal industry, however, found the legislators disposed to interfere to the disadvantage of the industry, whereas Congress was always active in attempting to alleviate the plight of the farmer. Governmental interference was prone to make more difficult the pathway of the coal operator, whereas the farmer was likely to find the action of Government and legislatures friendly and helpful.

Comparing the coal industry with those producing metal, Mr. Taylor said that the coal fields were operated by such a large number of companies that it was impossible for the coal operator to look for any great amelioration of his troubles. Mergers in metal mining were likely to help the metal industries, but the coal industry had far to go to gain much assistance by that means.

ACCORDING to Mr. Crichton, mine water contains 80 to 100 grains of acid per U. S. gallon. If water from a stream or lake contains four grains of acid per gallon it will be necessary to treat it, and twelve grains will make it so impure that it cannot be made a suitable boiler feed. In part of the year the streams are already acid.

Andrew Crichton, consulting engineer, Johnstown, Pa., delivered the first address which was on "Mine-Drainage Stream Pollution." This will appear in another place in this issue. Mr. Crichton emphasized the problems that confronted the coal industry and the great expense that might be incurred if even a neutralized water were demanded. To soften the water would cost even more.

S. A. Taylor said that the difficulty with mine-water pollution was that it did not come to an end with the closing of the mine. A tannery or cannery might have an extremely objectionable effluent, but as soon as the factory ceased to tan or can respectively, the objection was removed. At coal mines the pollution would continue for years after the mines were abandoned, that pollution often becoming worse as time went on.

H. N. Eavenson in his discussion of the paper said that Mr. Crichton had rather underestimated the effects of the decision in the Indian Creek pollution case. The court had defended the riparian rights of those whose lands bordered on the stream as well as the rights of those who distributed the water in pipes. The decision, unfortunately, would apply to almost any stream.

He wondered who would neutralize the water from abandoned mines. True, the mines might be sealed. That, for a while, would solve the difficulty, but after a time the water would escape through the outcrop, and the last condition might be worse than the first.

Mr. Eavenson said that the railroads could hardly expect to be given soft water. They were already treating stream water even where no mine drainage water had been allowed to enter it. He questioned whether the public had any right to ask that the water in the streams be made as pure as rain water.

COURTS HIT LEAD MINES

J. F. Callbreath remarked that the lead mines in Idaho had been required by the courts to return the water to the stream as pure as it was when it was removed. As Idaho is largely dependent on its lead mines, it is easy to imagine what a blow this decision will be to the state, seeing that the prosperity of most of its citizens is dependent on the operation of the mines.

Replying to Mr. Eavenson, Mr. Crichton said that if sealing would shut off the air, the water could do no harm. It could not dissolve the pyrite appreciably. It was only after

The headpiece shows a refuse dump surrounded by blooming dogwood trees outside the mines of the Harvey Coal Co. at Harveyton, in the Hazard region of Kentucky. The way in which vegetation continues to thrive close by rock dumps from which run acid water shows that acid is not so injurious to plant life as is often stated.

Digitized by Google

the pyrite had been oxidized that sulphuric acid would be formed.

C. E. Lesher, assistant to the president, Pittsburgh Coal Co., said that the smelter problem had been at one time as acute as the water problem is today. A solution was ultimately found in that case. One would probably be found in the water-pollution difficulty also. The smelters had to be allowed to continue in operation, and surely the mines cannot be shut down without injury to everyone.

Dr. J. J. Rutledge remarked that all beds were not equally productive of acid water. The Bakerstown and Kittanning seams did not pollute water as much as the beds in the Upper Productive coal measures. H. I. Young, of Mascot, Tenn., said that the wastes from his copper mines were not in any manner harmful but were alleged to discolor the water in the stream. Proceedings had been brought to prevent the continuance of operations causing such discoloration.

Would Treat Free Acid

James O. Handy, director, Pittsburgh Testing Laboratory, Pittsburgh, Pa., then read a paper on "Mine-Water Purification," which he prefaced by saying that what Mr. Crichton had said was impossible, he proposed to attempt. He believed that mine water could be treated to remove free acid. Mr. Handy said that all sulphates were not harmful, the sulphates of lime and magnesia for instance.

Mr. Handy declared that the addition of lime to water was not considered harmful, but with that statement Mr. Crichton later took issue, saying that magnesium and calcium sulphates had been found to cause pitting in boilers. Mr. Handy said that the Bureau of Mines had found that in most cases the water entering the mine through the roof or at the working face is not acid but that it received its acid content in traveling through the mine, especially when the water was allowed to pass over slack. Some of the acid comes also from the exposed coal faces. He thought that a study should be made of the exact causes of water pollution.

Mr. Withrow declared that acidity did not kill the fish in the streams directly. They died because the acid removed the oxygen and made it impossible for the fish to get air from that source. He believed that Mr. Crichton had overstated the case in saying that 12 grains of sulphates per gallon would render the water incapable of successful treatment. In the Allegheny regions the waters were in general relatively free of lime, but in the West there was far more, yet industry had been quite able to cope with that difficulty.

COST of treatment to neutralize acid with present area of developed and abandoned mines will be from 80 to 110 million dollars yearly, said Mr. Crichton. The treatment plants would cost 145 million dollars, and the water would still be hard.

As regards the iron-ore sludge resulting from mine water it would not discolor the banks of a stream if after deposition in a reservoir it was later flushed down the valley. In such cases it was washed down like clay and had no power to grip to the rocks as when first deposited. He advocated that some streams be kept free of pollution and that others be recognized as sewers into which industrial wastes be allowed to enter.

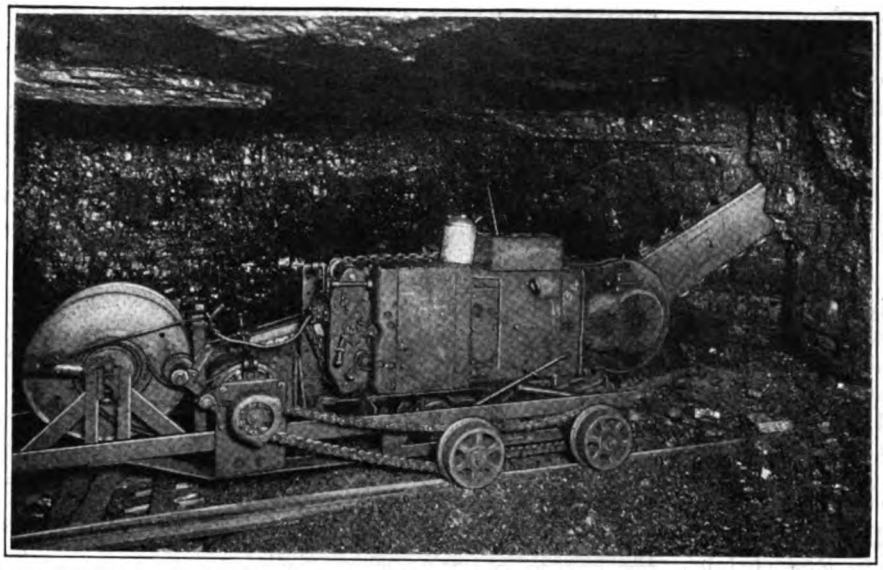
S. A. Taylor, in commenting on Mr. Handy's paper said the sulphur would leach from the floor coal for years. That coal was left because it had such a high percentage of sulphur. The impurity appeared to have been concentrated from the rest of the bed and found lodgment in the lower part of the coal measure.

William L. Stevenson, chief engineer, Sanitary Water Board of Pennsylvania, addressed the convention on the "Restriction of Stream Pollution." Mr. Stevenson said that the coal industry should be willing to enter into a co-operative investigation to ascertain what can be done to keep the streams reasonably free from pollution. The tannery interests and those of the paper and pulp industry have arranged for such co-operation.

It would not be well for the coal men to show indifference to the demands of the public and thus invite crippling legislation, nor should the public or the state work against its own interest by passing unreasonable laws that would destroy an industry upon which its own prosperity depends. Already about one hundred public water supplies in the state are being more or less affected by coal-mine drainage.

Mr. Stevenson would divide the streams into three classes namely those (1) in a pristine condition which should be preserved from pollution, those (2) which are more or less polluted, where pollution should be controlled and those (3) so greatly polluted that they should be regarded as natural sewers.

R. S. Ture said that it was to the interest of everyone that treatment should be effected before the dilution of the impure water as that was the more economical method. The manufacturer and the producer of coal should purify the effluents consequent on their operations. In conclusion a committee was formed to consider the mine-water pollution problem, a resolution to that effect having been passed by those present. The committee will consist of H. N. Eavenson, H. I. Young, and J. J. Rutledge.



The tanneries have appointed three chief engineers and three chief chemists of the tanning companies on a committee with Mr. Stevenson as chairman. The committee will make laboratory researches, will actually operate a full-scale experimental tannery-waste treatment works and will make observations of the streams below the works to determine the assimilating power of the stream to receive untreated waste and also to take care of the effluent of the treatment works with various degrees of purification.

How Should Coal Be Cut for Machine Loading?

Two Shears in Face Increase Tonnage per Machine 45 per Cent And Lump Coal 5 per Cent—Cushion-Blasting Not Suited to All Mines—Face Snubbed by Pop Shots—Cutting in Clay Bottom

By Staff Correspondent

WITH A TONNAGE of 3,500 tons daily, dating from May 1, the Union Colliery Co., of St. Louis, Mo., and Dr. L. E. Young, its general manager, are already taking an important part in the mechanization of the coal industry. Dr. Young contributed the opening paper at the Tuesday afternoon session, his talk being entitled "The Cutting and Shearing of Coal for Mechanical Loading."

At last year's meeting Dr. Young outlined the experiments he had made in snubbing, the purpose of which was to see if it was not possible to prepare the coal for shooting so that it could be brought down and loaded by mechanical means with minimum degradation. Since then Dr. Young has advanced a long way toward his goal which is to mine coal entirely by mechanical means.

Frank B. Dunbar, general superintendent, Hillman Coal & Coke Co., of Pittsburgh, presided in place of W. L. Affelder, assistant to the president of the same company.

The coal being mined by his company is the No. 6 seam which varies in thickness from 8 to 11 ft. About 1½ ft. from the bottom of this seam occurs a blue band or shale parting. From 1 to 1½ ft. of top coal is left in mining chiefly to hold the roof. Rooms are driven 26 to 28 ft. wide on 45-ft. centers. The coal is shot at the end of the day shift, the shooting of more than three shots at any one time not being permitted.

Snubbing Costs Excessive

The company has found by experience that the labor cost of snubbing coal by hand is greater than that of manual loading. It has also discovered that at its mines the coal cannot be snubbed with powder to advantage, as this practice in mines where shooting is not permitted in the day shift, requires the working of too many places. This would defeat the primary purpose of mechanical mining, which is, to concentrate the operations of men and machinery.

In the first experiment in shearing tried by the Union Colliery Co. an improvised cutting machine on a mine-car truck was used. As the bar of this machine could not be adjusted laterally, the shearing cut had to be made in line with it. The general practice being to lay the room track along the left-hand rib the coal was necessarily sheared at some distance from the room center.

The test revealed the fact that in this seam with a single shearing cut the snubbing of the coal is still necessary. As the coal is laminated hand snubbing is hazardous.

As a second experiment a machine which would cut vertically was mounted on a sled which could be slewed so as to touch either rib or be located at some intermediate position. But here again the results were not satisfactory as the shearing cut would not reach to the rib unless it was pointed diagonally. Nevertheless the experiment indicated that two shearing cuts contributed greater capacity to the loading machines. A shearing machine, mounted on a caterpillar tractor was also tried.

Less Powder Required

The coal was loosened by two pop shots which were placed 8 ft. from the ribs and by two shots which served to break down the bulk of the coal and to square the corners. Without shearing, 1 lb. of powder produced 5 tons of coal; with one shearing cut 10 tons of coal were obtained for each pound of powder used and with two shearing cuts 15 to 20 tons of coal were dislodged per pound of powder.

S. Farnum, of the Goodman Manufacturing Co., related his ex-

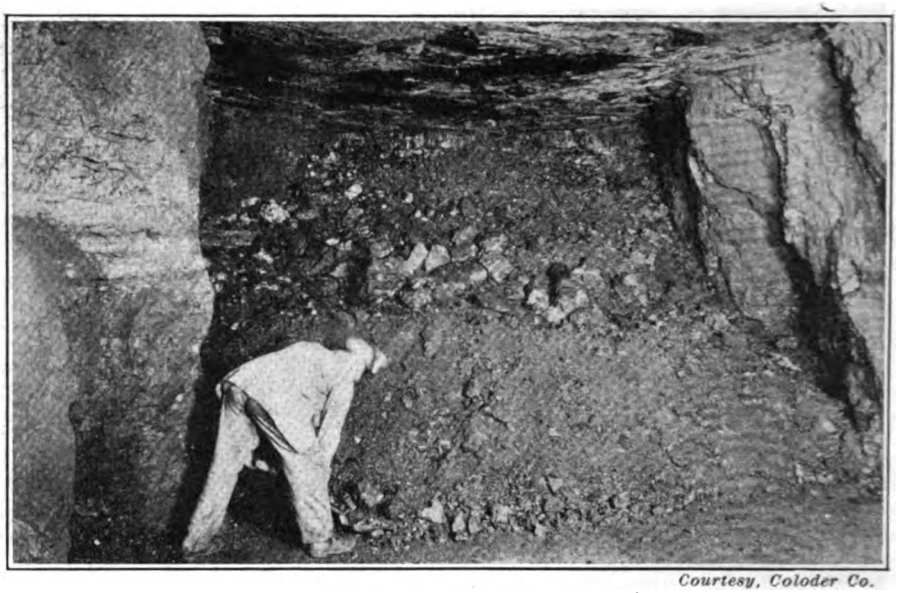
Digitized by Google

periences in shearing the thin seams of Kansas twenty-five years ago. Though they produced bigger lumps than could be obtained otherwise, those early experiments were not successful, because they increased the percentage of screenings. Inasmuch as shearing by modern machines increases the capacity of the loading machine and produces better lump coal, shearing, he thought should be justified, despite the additional expense which it involves.

W. R. Jarvis, of the Sullivan Machinery Co., said that his experience with shearing was confined to the Uniontown field of Pennsylvania, In this instance shearing resulted in the production of better coal. It also made it easier to load coal by hand. The adoption of the vertical cut decreased the consumption of powder by one-third and also caused the coal near the roof to arch in a manner which could not be attained by any other means. At the same time it made props unnecessary in places 10 to 11 ft. wide.



In a mine in northern West Virginia, according to Walter M. Drake, of the Joy Machine Co., center shearing was employed to cut through heavy "bearing-in" bands in a 14-ft. room. The practice increased the tonnage per machine per shift.

SHEARING AIDS PRODUCTION

Dr. Young said that shearing has been adopted in the mines of his company solely to increase the capacity of the loading machine. A year ago his machines were each producing 185 tons per shift. One shearing cut increased this output 35 per cent, and two have boosted the average to 275 tons as determined over a period of one month. He closed with the remark that the vertical cut has not only increased the output of the loading machines but has also raised the yield of lump coal 5 per cent.

In a paper on "Blasting Coal for Mechanical Loading" B. L. Lubelsky, explosives engineer of the Pittsburgh Coal Co., declared that with the introduction of mechanical loading will come a need to use small charges and a greater number of boreholes. His paper will appear in a later issue of this magazine.

David Ingle, president of the Ayrshire Coal Co., of Oakland City, Ind., in a discussion of Mr. Lubelsky's paper said he had been loading coal mechanically for about four years. He found that too much time and effort are lost in mechanical loading for reasons which cannot be attributed to the machine itself.

Courtesy, Coloder Co.

Pillar Shot Ready for Loader to Lift into Mine Cars

Shows the effect of a shot in the Pocahontas No. 3 seam in one of the Pocahontas Fuel Co.'s mines. As the coal is quite soft and friable a comparatively large percentage of fines is formed. A snub cut has caused the coal to roll out as shown. The man is trimming the pile so that the loading machine will not have to waste time, running around to get coal.

In his mines the rooms are driven 21 to 24 ft. wide. Under what he chose to term "the old system of hand-loading," the officials of his company paid little attention to methods of shooting. The advent of mechanical loading rudely awakened them to the necessity for skilled shooting. The number of holes was increased from two to three. Investigation uncovered several bad practices. Undercuts were generally inclined outwardly so as to grip the ribs, thus forming triangular pockets, and the boreholes were drilled so as to be parallel to these offsets.

TRAFFIC PROBLEMS TO SOLVE

The management now finds that where holes are drilled by hand they are frequently not extended to a sufficient depth. Though the common practice is to drill the shotholes electrically, hand drilling is sometimes necessary because of difficulty in keeping the electrical drills in order. He said that the drills cause more trouble than any other machine in his mines. His force has not yet reached a final decision as to the methods of shooting that will best meet local conditions.

A shearing machine has been tried in the mines of the Ayrshire Coal Co. Though the machine accomplished the purposes for which it was introduced, it caused much confusion when an attempt was made to keep it at work. This was only partially avoided by operating the shearing machine between visits of the cutting and the loading machines.

In justice to this machine, Mr. Ingle said that a cycle involving the operation of three different machines for as many purposes could not be co-ordinated because the cutting and the loading machines operate 24 hours a day keeping the roadways cluttered with traffic. He said that, in all probability, he would again try shearing. All sorts of experiments are being tried by his company in an attempt to arrive at more efficient practices in mechanical loading. His observations in brief are that "If the machine loader is to be successful it must not be compelled to fight tight coal."

A paper on "Results from Cushion Blasting" was read by C. W. Nelson, explosives engineer of the Hillman Coal & Coke Co. He thinks mining men should not condemn cushion blasting on no better ground than that it has proved unsuccessful under the conditions prevailing at their mines. They should be willing to concede that, under different conditions, the method might produce more favorable results.

TEST FOR PROPER AIR SPACE

Before one decides whether the method is adaptable to one's mine, one must know the purpose for which cushion blasting is intended. In most machine-cut coal the resistances from the back of the drillhole to the kerf and from the same

Digitized by Google

point to the front of the cut are not the same. If the resistance offered in these two directions were the same, the proper location for the explosives charge would be as near the back of the hole as possible. Except in very thick coal, the resistance is usually greater in the horizontal direction. The charge must be so located or distributed as to balance the burden upon it.

Mr. Nelson recommends that the proper length of the air cushion for given conditions be determined by careful tests. He suggests that the air space be increased in 3-in. steps until the point is reached where the breaking shots begin to hang at the back of the cut and then gradually decreased until the correct length for a balanced shot is attained. The length will vary with the seam and to a small degree as between various places in the same mine.

Conditions Determine Methods

In thick seams, cushion blasting has not been successful where the coal is being worked on the butt, chiefly because planes of greatest weakness run parallel to the direction of the drillholes, in which case the line of least resistance is toward the front of the cut. Under this condition the charge should be concentrated as much as possible at the back of the hole.

He believes that at best rock-dust stemming is merely a makeshift for a true blasting cushion. Its value depends upon the compressibility of the dust, upon the density of the dummy and upon the care with which the hole is charged and tamped. These factors are so variable as to make exact control of the shooting impossible. The necessity for storing and keeping the rock dust dry despite the dampness of the mine is a difficult problem in itself.

Air Spacing Works Here

A method of cushion blasting for mechanical loading in the thick Freeport bed and another for use in the Pittsburgh seam were described in a discussion by John G. Bart, general manager, Union Collieries Co., Renton, Pa. The former seam in the No. 3 mine is about 86 in. thick and consists of two benches equally divided by a 10-in. bone parting. The coal is undercut to a depth of 6 ft.

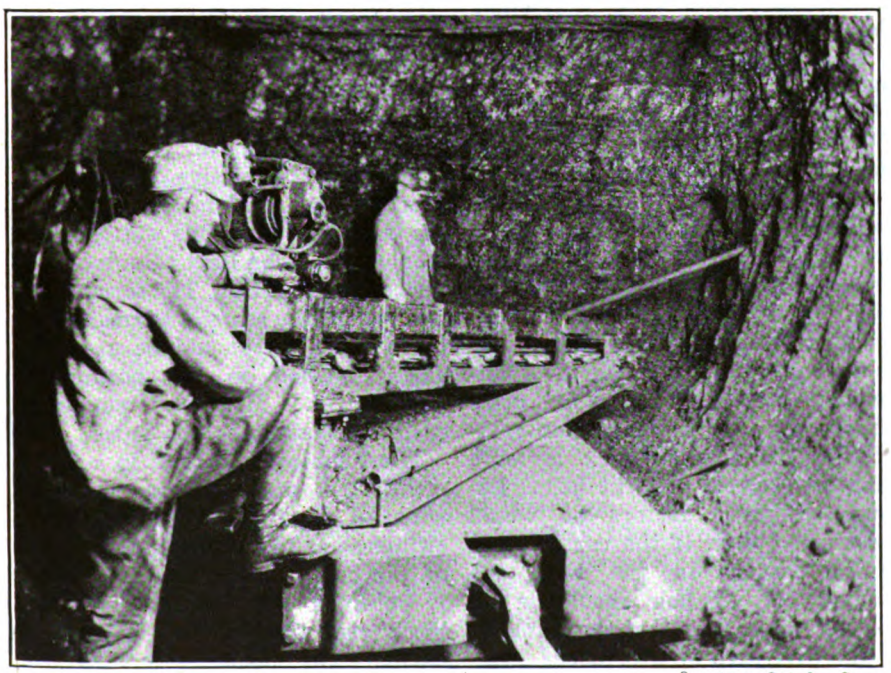
The cut is blasted in three stages. First, the bottom bench is shot down by three shots which are placed immediately under the bone parting and perpendicular to the face. The center shot is detonated first, this merely serving to spring the bench; then two rib shots are fired which break down the coal so well as to make loading by hand or mechanically quite easy.

These holes and all the others drilled higher in the seam are extended to the same depth, 7 ft. or 1 ft. beyond the back of the cut. All are given an equal charge. This consists of one stick of permissible set midway of the depth of the cut. Behind this single cartridge is an air cushion nearly 4 ft. long. In front of it is inserted the usual stemming which is loosely placed and not tamped at all except for the last 10 in. which is tamped solid. Having been thus shot down, the bottom bench is loaded out.

The next stage is to break down the bone parting, which is accomplished by three holes placed immediately over this bony layer. Having gobbed this material the final stage is completed by three similar boreholes which are drilled horizontal and near the top.

Snubbing Decreases Slack

In shooting the coal in the Pittsburgh seam, the practice of his company is to place two pop shots of ½ stick each with air-spacing in a 3-ft. hole which is started slightly above the mid-height of the seam and extended downward on about a 45-deg. angle. The bottom of this hole is within 5 to 6 in. of the kerf. These two shots snub the coal across the entire width of the place.



Two horizontal holes near the roof and along the ribs, which are extended about 1 ft. beyond the back of the cut, are air-space loaded by placing one to one and one-half sticks of permissible in each in the same manner as has been described for shooting the Freeport seam.

These methods of shooting have been in practice for about six months and have decreased the violence and shattering effect of the explosive greatly. They have lowered the proportion of ¾-in. slack in the mine product by 8 per cent.

Why Not Cut in Fireclay?

A talk on "Cutting in Fireclay Bottoms" was given by W. J. Freeman of the Fayette Realty & Development Co., of Indiana. He said loading machines have emphasized the possibilities from an economic and mining standpoint of cutting in clay bottoms rather than in the coal. Mr. Freeman wanted to know why the operator who had a thick bed had not found it advisable to follow the thin-coal operator in putting his kerf in the clay floor.

Not only does cutting of the clay bottoms decrease screenings, but it also makes it unnecessary to place the cut in the pyritic coal which

Courtesy, Coloder Co.

Machine That Snubs the Coal so as to Give a Wedge Kerf

This machine has been improvised from a breast machine. Set on a frame it cuts a sloping kerf that breaks down the coal and at the back intersects with the horizontal kerf. Thus a cut is made that looks like a saw cut in a tree after it has been trimmed by an axe. The cutter bar is fed forward mechanically and swung around as desired.

Digitized by Google

usually lies along the bottom. In many mines all over the country water is being sprayed over cutter bars to keep down the dust. The expense of this safety precaution would be eliminated by the practice which he advocates.

REQUIRES SPECIAL CHAIN

To be successful in this project the manufacturer must provide a special chain. That used for cutting coal will not work in clay. At the mine of his company in Nashville, Ill., a bone-clay band which occurs about 24 in. from the bottom is being cut. The machine used for this job is in all respects similar to a shortwall cutter except that the bar is mounted on the top of the machine instead of at the bottom. As the refuse band is fairly regular little trouble is experienced in keeping the cutter bar in it.

At first much difficulty was found in obtaining a chain for the job, that would stay in the band, for the latter is harder than the coal. The solution to the problem was finally found in an 11-position Sullivan chain, each lug of which holds two bits. This chain cuts the refuse so successfully that the machine runners now cut as many places in the band as they formerly did in the coal.

The screenings have been decreased thereby 10 to 12 per cent, and the coal can be better prepared at the face than was possible when cutting in the coal.

Mr. Freeman said that time and money are well spent in seeking a method to cut bands or clay bottoms in that the cost of hauling dirt to the surface is eliminated and waste material is left in the mine where it properly belongs. Though it took his company more than a year to solve the problem, it now feels that the money was indeed well spent. The adoption of the loading machine has brought the industry face to face with the need for new methods of cleaning and of keeping the coal clean.

KEEPS DIRT IN THE MINE

In his mine the practice of refuse cutting has decreased the proportion of ¾-in. screenings from 22 to 12½ per cent and lowered the quantity of refuse which is taken out of the coal at the washer by 50 per cent. It has increased the percentage of 2-in. lump to 75 per cent and made it possible to obtain 120 tons of coal with 25 lb. of powder. Before the change was made only 90 tons of coal was obtained with the consumption of that quantity of powder.

A discussion by John L. Clarkson, of the Clarkson Coal Mining Co., Illinois, dealt with his experience in cutting in the clay bottom. The mine where this practice prevails is working the Indiana No. 5 seam. When his company started to develop this bed it was questioned whether undercutting machines could be used.

Up to that time they had not been successfully applied to this seam in the region in which the mine is located because of a large quantity of sulphur in the coal near the bottom. To the best of his knowledge no one had made any extensive attempt at cutting in the clay which underlies this seam.

WANTS SMALLER CARTRIDGES

His company has continued this practice ever since and has fully demonstrated that the venture was well worth while. The cutting conditions vary from place to place, and bits, therefore, are changed with no regularity. The worst drawbacks are that of throwing back and handling the cuttings and the dense clouds of dust stirred up in cutting. The shoveling of the clay is expensive but the dust can be overcome by providing the machine runners with respirators. This dust, of course, adds to the safety of the mine, for it is pulverized rock and not fine coal.

Theodore Marvin, managing editor of *Explosives Engineer*, took exception to some of the remarks made by Mr. Nelson in his talk on cushion blasting. He objected chiefly to his advocacy of a cartridge of smaller diameter than is being generally used. The cartridge of smaller diameter costs more per pound, and its rate of detonation and its sensitiveness decreases with time more rapidly than with the larger cartridge. The smaller stick is more liable to produce a burnt hole. Because of these factors he would recommend that, if the cartridge is to lie loosely in the hole, the diameter of the hole should be increased rather than that the diameter of the cartridge be decreased.

Mr. Nelson replied that the use of a larger hole does not give the true cushion-blasting effect. He knew of no tests which had demonstrated that such a practice increases the efficiency of blasting. Replying to the charge that cartridges under 1¼ in. deteriorate rapidly with age, he cited an experience in which he used successfully 1⅜-in. cartridges which had been in storage in a magazine at one of the mines of his company for eight months.

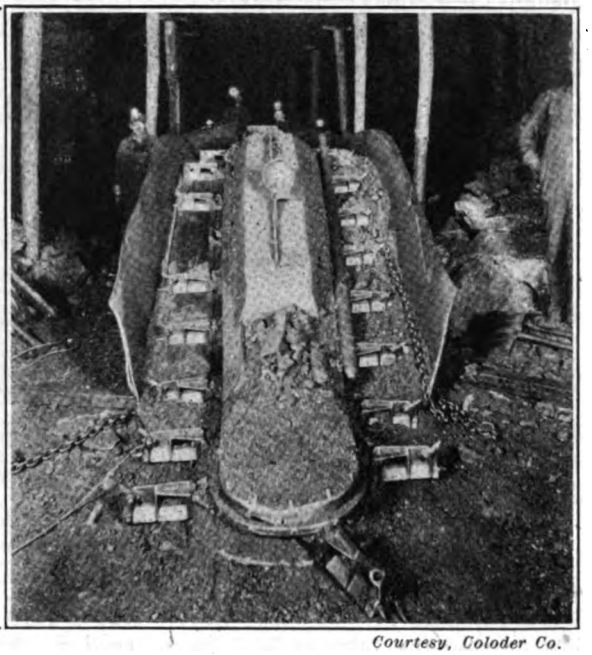
NELSON DOUBTS THE MINER

Mr. Lubelsky said that the manufacturer put forth a similar cry at each demand of the operator for a smaller cartridge beginning with the change from the 1¼-in. size. He makes the claim that in some instances the explosive in a cartridge of 1-in. diameter may be more sensitive than that in one of 1¼-in. He is not at all in sympathy with the 1¼-in. limit and claims that when the U. S. Bureau of Mines tests are correctly interpreted the limitation is not well grounded.

Someone asked Mr. Nelson whether he has had any experience with miners blasting by the cushion method. He said that his company employs shotfirers because miners cannot be relied upon to cushion their blasts correctly and because in general, it was not safe to leave the blasting in the hands of the miners. Where it is left to them the results are as varied as the methods they employ and these as varied as the miners themselves.

AIR SPACING IS SUGGESTED

Josiah Keely, of the Cabin Creek Consolidated Coal Co., asked why a center cutter in one of his mines in 7-ft. coal failed to decrease the quantity of explosive needed and shattered the coal more than when the face was not thus cut. Frank Dunbar and John Bart volunteered to answer this question. The former said that where the seam is burned to the top a topcutter should be used and where burned to the bottom an undercutter. Mr. Bart suggested cushion blasting as the cure.



Mr. Fenning said that, in a three-month test of a machine equipped with an elevated cutter bar which swings so as to cut an arc at the back of the cut, his company found that it obtained 10 per cent less 4-in. block coal than it did before the change was made. Mr. Clarkson suggested that a square cut at the same elevation be tried for the sake of making a comparison.

Mechanical Loading Saves Money for Many

Cost of Coal Lowered 40c. per Ton at Rock Springs—Drives 42 Ft. of Entry in Nine Hours—Duck-Bill Attachment Loads Coal on Shaking Conveyor

By Staff Correspondent

Courtesy, Coloder Co.

"TO make a success of mechanical loading we will have to discard traditions; the problem is 90 per cent management," said Eugene McAuliffe, president of the Union Pacific Coal Co., Rock Springs, Wyo., at the meeting held in the forenoon of Wednesday, at which he presided.

Geo. B. Pryde, vice-president and general manager of the Union Pacific Coal Co., talked in the place of A. W. Dickinson on "Mechanical Loaders That Have Operated Successfully at the Face and Their Operating Costs." He confined his remarks to a description of the experience of his company, which operates seventeen mines in the State of Wyoming.

The first loaders were installed in 1916 and now the company has at one operation thirty-eight Thew and twelve Joy machines, at another six Goodman scrapers and two Eickhoff conveyors and at a third three Eickhoffs. It is planning further installations of scraper loaders. Mr. Pryde stated that the company has had a marvelous success with the Eickhoff conveyors in driving narrow work.

The scraper loaders have a capacity of 3½ tons per trip. Consequently each scraper will load two cars on each return run. These scrapers operate in a section working the block system. At the first attempt a fall closed up the face, but the second trial of the system was quite successful, about 90 per cent of the timbers being recovered. This is important, for the posts cost $1 apiece.

Joy loaders are used to drive the lower bench of a 32-ft. seam, the top portion of which is later shot down and loaded by a Thew shovel. The average advance with Joy loading is 7 ft. per day, as compared with 1 ft. per day with hand loading. The type 4-BU Joy machines are loading an average of 90 tons each per day at a maintenance cost of 8 cents per ton.

Loads 342 Tons per Shift

The Thew shovels load an average of 175 tons each per day; and the scraper loaders on thirty-two consecutive working days averaged 342 tons per shift with a crew of fifteen men. Mr. Pryde also said that the scraper and Eickhoff loaders were producing coal for about 40c. per ton less than it could be produced by hand loading.

A time study of mechanical loading showed that of the total delays 60 per cent were administrative and 40 per cent due to repairs. The administrative delays include moving and other like items all of which, with experience, the mine officials should be able to shorten or eliminate.

H. C. McCullough, engineer, H. C. Frick Coke Co., Scottdale, Pa., read a paper on the "Shaking-Conveyor Loader and Its Use in Mining Coal." He described the system of loading progressively from one end of a long face toward the other, using a duckbill loading attachment with an automatic feeder at the end of a shaker conveyor. Rather than one long face, he proposed a number of faces of medium length operated in steps.

The paper was discussed by Mr. Pryde. He stated that in the Union Pacific mines, 42 ft. of entry, 12 ft. wide by 6 ft. high, has been driven in 9 hours by use of a loading attachment on an Eickhoff conveyor. The company has developed an automatic feeding attachment to the Eickhoff by which it has loaded 15 tons in six minutes.

This method was used on two faces, one on each side of the main entry; one face 165 ft. long and the other 135 ft., but the roof could not be held, so the company has now gone to 100-ft. faces in steps. When loading a long face with the automatic feeder attachment, about 13 ft. of the face must be loaded by hand in order to obtain room for starting the loader.

It has been found that the duckbill can more easily undermine the loose coal if the machine cuttings are spread over the floor before the coal is shot down. The original duck-bills used were 7 ft. high, but this has been reduced to 4 ft.

Sneaks Up Along Face

R. Y. Williams, of the Weston Dodson interests, in commenting on Mr. McCullough's paper, said that he liked the plan of loading a long face with the automatic attachment to the shaker conveyor because it reduces the roof overhang. At his company's mines heavy metal jacks are used,

The headpiece shows front view of loading machine at one of the Pocahontas Fuel Co.'s mines. As far as possible a clear path is maintained in front of the machine. Props are placed 3 ft. apart, but located so as to interfere as little as possible with the movement of the loader. The seam is about 10 ft. thick. Drawslate which varies from nothing to several feet is removed before the coal is loaded out in the pillar sections.

Scraper Loader Cleaning a Long Face in a Thin Seam

At last, the industry has boldly adventured with large scrapers that fill two cars in a single run. At one time the scraper was a thin coal proposition, going where men could scarcely crawl, but it did difficult rather than much work. Today, it will beat hand loading in any kind of seam.

thus moving the fulcrum back from the face.

First the company worked two blocks, one 300 ft. and another 350 ft. long, then it had to wait nine months for the development of other long faces. Now there are three 300-ft. faces and one of these has been going since April 21.

The first break came after an advance of 85 ft. and now the roof falls behind the jacks each day. This face is being worked with a Jeffrey conveyor, 300 ft. long. On the second of the three faces they expect to try an Eickhoff conveyor.

HAS 125 SCRAPER UNITS

Cadwallader Evans, Jr., general manager, of the Hudson Coal Co., said that his firm has 125 scraper loading units in operation every day, and that last year they loaded over 1,000,000 tons with their assistance. The company first tried longwall but could not control the roof, so went to chambers 125 ft. wide by 225 ft. long and abandoned pillar work.

Answering a question of Charles Enzian, chief engineer, Berwind-White Coal Mining Co., Windber, Pa., Mr. McAuliffe said that his company drives up the pitch with the Eickhoff loading attachment, but narrow work is advanced along the strike. He also stated that his firm is in some cases conveying coal up a 7 per cent grade with this equipment. This grade, however, is at the end where the trough is elevated to discharge into the mine car, the main part of the conveyor usually working in favor of the load.

W. L. McCoy, mine inspector, Bertha Consumers Co., Pittsburgh, read a paper on "Best Methods of Adapting Present Standard Mining Systems to Mechanical Loading." This emphasized the many factors which must be combated when mechanical loading is introduced in a mine. He asserts that it is impractical to draw pillars mechanically, for the reason that the noise of the machinery does not give the miner a chance to hear the warning noises of a working roof.

In discussing the paper, Sterling S. Lanier, Jr., Norton Coal Mining Co., Nortonville, Ky., said that his company has used Goodman scrapers, Joy loaders, and Jeffrey conveyors and Shortwaloders and was successful with all and made some savings. His firm has been particularly successful in driving narrow work with Shortwaloders and conveyors. In a recent test in driving 600 ft. of entry a saving of 33⅓ per cent over hand loading was effected. The average was five or six cuts per shift with five men in the crew.

Edwin H. Johnston, of the Coloder Co., Columbus, called attention to the fact that the fields having high wage scales are not necessarily the most active in the development of mechanical loading, and as proof, he cited the many successful installations in West Virginia and Kentucky.

The last paper of the morning meeting "Getting Mine Cars to and from Mechanical Loaders" was read by Charles Gottschalk, consulting engineer, of Evansville, Ind. He predicts that 290 tons per shift will be the average production of loading machines. Car-changing efficiency is a measure of the effectiveness of a loader and this efficiency can be greatly increased by proper track facilities and close attention to administrative details. Promotion of friendly rivalry between gangs is one of the best ways of increasing car-changing efficiency.

F. F. Jorgensen, consulting engineer, Superior Coal Co., Gillespie, Ill., said that he has had to change his ideas of mechanical-loading possibilities about once a month, and sometimes every day. For instance, he at one time had made up his mind that if the mine cars were not of 2½ tons or more capacity, they could not be loaded economically by mechanical means. This idea was shattered by his learning of certain mines having much smaller cars which were nevertheless effecting a saving by mechanical loading.

The large attendance at the morning session was duplicated at the meeting held in the afternoon, which would seem to indicate that the interest in mechanical loading is on the increase rather than on the wane as some operating men believe. The first speaker of the afternoon was Robert Wallace, superintendent of the Pocahontas Fuel Co., who read a paper on "Mechanical Loading in Pillar Work" as practiced in the mines of his company.

REPAIR COSTS 3C. A TON

During 1925 the Pocahontas Fuel Co. produced with twenty-five Colodders 1,709,132 net tons from seven mines. The cost of parts and labor for repairs last year was 3c. per ton and the power consumption 0.2 kw. per hr. The average daily loss of loading time per machine was 9.18 min.

This company finds that it can load pillar coal mechanically at a lower cost than room coal and therefore has increased the width of its room pillars. It has mined thus far more than four million tons mechanically without a single machine runner being fatally injured. The difference in cost between coal loaded by machine and that shoveled by hand is between 20 to 25c. in favor of the former. Mr. Wallace characterized the mechanical loader by saying that "you can send him back to work a double shift without danger of backtalk."

W. J. German led the discussion of Mr. Wallace's paper. He said that on several occasions individual machines have loaded 300 tons in 9 hours from pillars. Pillar coal can be loaded four to eight times as fast

Digitized by Google

by machine as by hand. N. G. Alford, consulting engineer, Pittsburgh, Pa., said that the roof in the mines where the Coloders are in operation is worse than any other he has seen in that part of the state.

Mr. Wallace explained that the roof immediately over the coal consists of drawslate which has a thickness varying from nothing to 3 ft. This must be taken down before the loader begins to load out a cut. He said that much timbering is eliminated by machine loading. Hand-loaders under similar conditions are sometimes compelled to reset timbers three to five times.

"Mechanical Loading in Rooms and Entries" was discussed by I. N. Bayless, superintendent of the Union Colliery Co., Dowell, Ill. A paper containing his remarks and additional information will appear in an early issue of this magazine.

He pointed out that a prerequisite of successful mechanical loading is education of the management as well as the workers in the new problems which will accompany mechanicalization. His company is satisfied with the results being attained mechanically. The machines are working successfully from an economic viewpoint in spite of the many disadvantages under which they have to operate in the Kathleen mine.

L. D. Smith, of the Chicago, Wilmington & Franklin Coal Co., opened the discussion of the subject introduced by Mr. Bayless. He indicated a few of the difficulties that must be considered by those who contemplate the installation of loading equipment. At shaft mines where the hoisting equipment is working at capacity, the loading machine will lower the output because less coal can be loaded into any given mine car by machine than by hand. With machine loaders more refuse will be loaded with the larger sizes of coal than the hand loader will put on the car, at least in mines where discipline prevails.

SAVED 204 MEN

J. G. Bart wanted to know how many men were employed in the Kathleen mine before and after mechanical loaders were introduced. Mr. Bayless stated that these machines have eliminated 204 men with no change in the daily output of the mine. In answer to another question Mr. Bayless said that all except the machine cutters are paid a flat day wage.

The machines installed in his mine work every day except when they break down, which is not often, and when they do it is generally from small defects which can be easily repaired. He has never anticipated that he could operate machines without some trouble, and he is of the opinion that several spare machines should be kept on hand. These loaders have increased the daily output per man on the payroll from 5.5 to 8.5 tons. The record output per man employed at his mine for one day is 11 tons.

In a paper on "Mechanical Loading of Top and Bottom Rock in Entries," A. C. Hohnke, superintendent, Russell Coal Mining Co., Clymer, Pa., said that the substantial savings which Myers-Whaley machines have effected in the taking of top and bottom rock, as indicated in his paper, are second in importance to the speed with which development can be advanced in thin seams where such brushing and bottom lifting are necessary. His paper will be published in a later issue.

MUCH WORK OR NONE

W. L. Householder, electrical engineer, Buffalo, Rochester & Pittsburgh Coal & Iron Co., related the experience of his company in the same kind of work. For five years that company has been using Myers-Whaley machines for taking rock and in some instances has realized savings in excess of those given by Mr. Hohnke.

In this work the cars must be low enough to enable the roadways to be extended in the coal at least 50 ft. before shooting the rock. The machine will not work to advantage where the rock is taken with each advance of one or two cuts. In such instances the cost of loading the rock may be twice that where the rock is loaded by hand. A machine should work at least one or two full shifts in a single place.

This machine showed up to great advantage in the driving of a rock tunnel, 1,200 ft. long, 7 ft. wide and 6 ft. high. A comparison of hand-loading methods with those in which machines were used showed a saving of $25 per yd. The upkeep cost of the machines in the mines of his company compares favorably with that given by Mr. Hohnke, which is 2.67c. per ton.

The experiences of the Berwind-White Coal Mining Co., Windber, Pa., with new methods of mining by long face advancing, and by long face retreating with conveyors in the former case, were described by Charles Enzian, chief engineer of that company. It has done much mining on long faces and finds that such methods give genuine promise of being practicable at its mines, so much so indeed that the organization is constantly thinking along these lines.

LONG FACE AND HEAVY COVER

In the places where long face retreating was tried roof conditions are difficult. The immediate strata over the Miller seam which was thus being mined are soft and friable. In places the roof will fall up to a rider 20 ft. above the coal. The coal is 39 in. thick and the cover varies in thickness from 600 to 700 ft.

The faces in the layout of long face retreating were 150 to 200 ft. in length. Pack walls, 15 ft. wide, were separated by spaces of equal width. The coal was shoveled by miners who were paid a task rate. This method has been abandoned, temporarily at least. The seam being worked has many rolls and clay veins.

Recently a system of long face retreating, upgrade, was started in the same seam with no saving as yet over the room-and-pillar system. In this work a 290-ft. face has been moved back a distance of 710 ft. The roof is supported principally by 10-ft. pack walls separated by 10-ft. spaces.

The cover over this place is heavier than that which was over the faces which were mined advancing. Though the cost of timbering and building pack walls in this work is not favorable, the company is getting a return in the form of experience.

SCRAPER LOADERS FAVORED

Conveyors are also being operated in 28-ft. rooms with 36-ft. pillars with a material increase in output per man. The average output per man per day by this method is 11 tons.

Mr. Enzian has great faith in the scraper loader and intimated that his company will shortly try a machine of this type in an attempt to find out how the roof will act in a suitable system.

His company has concluded that mechanical mining, at least in the mines of his district, must be accompanied by mechanical cleaning.

Face and Main Conveyors Are Receiving More Attention Than Ever Before

Can Be Used Even in Thin Coal and in Rooms—Dunbar Would Have Conveyor Work Full Shift—McAuliffe Believes Mines Should Produce Coal Night and Day to Outstrip Action of Roof

THURSDAY morning was devoted to "Underground Conveyors." A. C. Callen of the University of Illinois, acted as chairman. The viewpoint of the material-handling engineer was given by Nixon W. Elmer, consulting engineer, Quincy, Mass., in his talk "Inside Mine Conveyors."

He condemned the practice of selling conveyors on approval, saying that no manufacturer of a competitive non-patentable article can afford to spend much money in development work. The conveyor should be made to fit the mine rather than the mine to fit the conveyor.

BELT CONVEYORS ON MAIN ENTRY

Mr. Elmer pictured the coal mine of the future as one with little track, few locomotives and cars, and with belt conveyors on the main entry. The production per entry will be 600 to 800 tons per day. He is not so sure as to what will be the method at the face, but mentioned an instance where a caterpillar loader was operating along the face and loading the coal into a conveyor. Glen Southward, consulting engineer, of New York, in discussing the paper, agreed in general with Mr. Elmer's conclusions.

Frank Dunbar, general superintendent, Hillman Coal & Coke Co., Pittsburgh, said his company was using some conveyors, but would like to know how to reduce the time taken by the first two operations in the cycle, that is, (1) cutting and (2) drilling, shooting, timbering and cleaning-up slate. He would like to keep the conveyor working 80 per cent of the time instead of about 20 per cent as is now customary. The third part of the cycle, loading the coal on the conveyors, he considers the easiest part of the operation.

SHOULD WORK NIGHT AND DAY

Eugene McAuliffe, in commenting on the future of loading and conveying said that he believed that a loading machine should be a relatively small mobile unit. "If there is an industry on earth that should be operated 24 hr. per day, it is a coal mine," were his words in prefacing a remark regarding the present mine laws. He called attention to the fact that the forces of nature are working in a mine 24 hr. a day and outwitting those who worked only 8 hr. He predicted the time when in well-ventilated and face-sprinkled mines, even in those that are gaseous, shooting will be allowed at any hour, and yet the risk will be lessened by concentrated and continuous operation.

R. J. Smith, of Terre Haute, Ind., president of the Princeton Mining Co., said that efforts should be made to eliminate hand labor wherever possible; for instance, by shooting down the undercut coal onto a conveyor. He remarked that a small easily handled shearing machine was needed that would cut in any position at the face, possibly with a cutter bar resembling that of the old breast machine.

CONVEYORS IN LOW COAL

In the second paper of the morning session, "Room-and-Pillar Mining with Conveyors," R. A. Suppes, general superintendent, Knickerbocker Smokeless Coal Co., Johnstown, Pa., described in considerable detail his experience during fifteen months of operation in seams from 23 in. to 44 in. thick. Because of the rolls, faults, and other uncertainties of mining, he believes that in most instances the room-and-pillar method must be retained and that mechanicalization must be suited to fit this condition. The system at his mines is to drive rooms 35 ft. wide and about 250 ft. long, with 18-ft. pillars between them.

A sectional chain conveyor is used on the main roadway and a belt conveyor passes along the face. Ventilation is by a distributing fan with 12-in. flexible tubing. It is the practice to stop all machines for three minutes, at specified intervals, so that the men at work can listen for signs of roof action. Up to the present the conveyors have not been used for the removal of heading stumps or barrier pillars.

In the mining of somewhat over 55,000 tons the average output has been over 14 tons per man, including cutting, timbering, drilling, shooting, conveyor moving and like items.

EQUIPMENT COST PER ROOM

The total equipment investment per room, including the mining machine is $8,000. The mining cost, including 25 per cent depreciation on the equipment has been materially less than at neighboring mines in that district.

S. W. Blakeslee, superintendent, Pennsylvania Coal & Coke Corp., Ehrenfeld, Pa., in discussing the paper, stated that the tonnage per man reported by Mr. Suppes, is greater than is obtained by any method in that part of Pennsylvania so far as he knows.

WAY OF EARNING A LIVING

"Mining Plans for Different Types of Conveyors," by Heber Denman, president, Paris Purity Coal Co. Clarksville, Ark., was the last paper of the morning session. Mr. Denman described the face-conveyor panel-longwall method by which he has been operating for three years. It has ceased to be an experiment, but instead is now the company's "way of earning a living." The coal thickness runs from 18 to 24 in. and the product goes only to the domestic market. The roof is handled by the caving method, the breaks being produced by a single row of sand-pack, cast-iron jacks.

The loaders move the conveyor forward as a unit at the end of each shift. Mr. Denman doubts if face conveyors could be used successfully in thin coal where the roof is so bad that face timbering would necessitate moving a conveyor in short sections. He stated that there are now fifteen to twenty long-face conveyors in use in the Paris field.

Coal-Dust Explosion at Bruceton Mine Staged for Inspectors' Institute, May 13, 1926. Below —Initial Flame Emission. To Left—Flame and Smoke on Second Explosion.

Many Attest to Value Of Rock Dust

Jones, Jenkins and Osler Testify How It Saved Lives at Their Mines — Wet Coal Dust Explosive — Saturated Rock Dust Effective — Gas Still a Menace

By Staff Correspondent

"To quibble and argue in the face of scientific evidence which has been unqualifiedly supported by actual experience is to show such an utter disregard for mine safety as to entitle one to contempt," said A. C. Callen, professor of mining engineering of the University of Illinois, in a paper on "Proven Advantages of Rock Dusting," in opening the Thursday afternoon session.

He said that those who assigned him the topic evidently desired him to prove that rock dust will stop an explosion. In accord with this interpretation, he presented pertinent facts showing the effectiveness of rock dust and reviewed recent experiences which demonstrate that point.

"When an insurance company refuses to insure you because of high blood pressure, a bad heart or for other reasons, you begin at once to consider your case seriously. When an insurance company refuses you compensation insurance because your mine is considered too great a risk you should likewise consider your case seriously." In addition to recommending unqualifiedly the practice of rock dusting, Mr. Callen urged the use of every other practicable safety device. The session was conducted by Dr. J. J. Rutledge, chief inspector of Maryland, as chairman.

J. E. Jones, safety inspector of the Old Ben Coal Corporation, was scheduled to comment on the subject covered by Mr. Callen's paper, but being unable to attend, he sent a short paper which was read by N. G. Alford.

In his paper Mr. Jones stated that damp rock dust is by no means ineffective. The section in which the recent explosion in the Orient mine originated was throughout extremely wet. An inspection after the explosion showed that coking action began 100 ft. from the origin and continued for a distance of about 175 ft., extending, however, only 25 ft. beyond the inby extremity of the rock-dusted section of that entry.

The rock dust, like the section in which it was spread, was extremely wet; yet it extinguished the flame. On the other hand the coal dust at the dead end of this entry which had not been covered with inert material burned and deposited coke despite the fact that it also was wet water, therefore, neither prevented the rock dust from extinguishing the flame, nor rendered the raw coal dust at the face incombustible. Who shall doubt, therefore, that rock dust is more effective than water, either dry or wet?

Charles Enzian, chief engineer of the Berwind-White Coal Mining Co., read a paper in which he described the methods, and detailed the costs,

The explosion shown in the headpiece is that described in the last four paragraphs of page 734 of the May 20 issue of *Coal Age*. The shot from the cannon first ignited the dust between the cannon and the drift mouth and then later the dust behind the cannon. It was this last explosion that filled the valley with flame and smoke, making it an inferno. The dry material on the hillside caught fire and added evidence, if any were needed, of the scorching effect of the blast.

Digitized by Google

of rock dusting in the mines of his company. This paper will appear in a later issue of *Coal Age*.

Rock dusting saved the lives of all but seventeen of the 125 men in the mine during an explosion which occurred on June 8, 1925, in the No. 9 mine of the West Kentucky Coal Co., said T. E. Jenkins, the vice-president of that company. In 1917 he had noted that an explosion had been halted on a haulway by the finely ground sand which was lying in the roadway and that this same explosion had traveled some distance along a companion aircourse until it came to a shaft. This carried conviction to his mind, and in 1924 he took advantage of what he had learned and began rock dusting mines of his company.

Trough at Line Brattice

The general practice at the West Kentucky Coal Co's mines is to build barriers on aircourses at 300 ft. intervals and also to erect them at the outby end of each line brattice. His company pulverizes the rock dust that it uses in its workings at a cost of $4.60 per ton including the cost of sacking it and delivering it to the mines.

He said that he was in hearty accord with the recent decision of the Associated Companies, as recently promulgated. The companies announced that thereafter they would refuse to assume the explosion risk of any mine which is not rock dusted. He believed that this would do much to increase safety, for since the declaration was made several of the companies in his field had commenced the rock dusting of their mines.

Saved Men at Horning

That rock dust undoubtedly checked the propagation to wider limits of the explosion in the Horning mine was the opinion of George Osler, general manager of the Pittsburgh Terminal Coal Corporation. The information collected after this explosion, which led him to this belief and which he detailed at this session, has already appeared in *Coal Age*.

He believes that strict attention to rock dusting on haulways and in rooms to the face may make it unnecessary to apply inert matter on aircourses. He was convinced that of the two, the rock dusting of the haulways was the more important provision.

Mr. McAuliffe does not believe that the 9 mills per ton of coal mined which his company expends on rock dusting is in any way sufficient to afford adequate safety. To prove the sincerity of his belief he outlined the safety program which his company has adopted. He attacked the attitude of not a few operators who, having rock dusted, place almost entire reliance on that practice for freedom from explosions.

In his opinion, rock dusting is only a third line of defense. Ventilation and methods of keeping down coal dust must be given priority. Means should be taken or sought to stop the initiation rather than the propagation of an explosion.

Last year his company applied 1,200 tons of rock dust which cost $9 per ton at the mill. It spent altogether in the practice $27,000, excluding in that estimate the capital investment. In the last six months it installed 36 miles of water line. This is being used to wet down the coal dust at the face. Last year the company sunk five new air shafts to reduce the travel and decrease the friction of the mine air and to increase the volume of air delivered to the mines. His company is using gunite machines to make stoppings as leakproof as possible.

Many Diverse Opinions

John T. Ryan, general manager of the Mine Safety Appliances Co., presented to the meeting a complete and comprehensive compilation of the opinions of a wide group of men, in a paper on "Sealing Fires in Gaseous Mines," which he strengthened with his own conclusions. He gathered much of the information contained in this paper by sending far and wide a questionnaire of twenty-one questions to ninety men, of whom seventy-five responded.

It represents, therefore, the best opinion current as to what practices should be adopted in the fighting of mine fires. Though conditions from mine to mine vary somewhat, he pointed out that certain fundamentals are known which can be applied at all times. His paper will be published in a later issue.

Old-timers used to say, "when a fire breaks out, fight and fight till you can't fight no longer; then bottle her up and 'git' out, for the cork may blow off." This was the expression given by Charles H. Nesbitt, chief inspector of mines of Alabama, in a written discussion which was read by C. W. Nelson in the absence of the writer.

Mr. Nesbitt believes that every known means consistent with safety should be exhausted to extinguish the flame before sealing is considered. When a fire breaks out all employees with the exception of those whose services are needed should be immediately ordered to the surface.

When it has not already been done, that part of the mine in the vicinity of the fire should be thoroughly rock-dusted, washed down and made wet. Immediately after completing the temporary seals all men should leave the mine and stay out for twenty-four to forty-eight hours. This is necessary to avoid fatalities in an explosion which might occur within these limits of time.

Simultaneous Closing

E. J. Newbaker, general manager of the Berwind-White Coal Mining Co. would build doors as temporary fire seals, which when ready would be closed simultaneously. Mr. Ryan likewise is of the opinion that the intake and return should be sealed at about the same time. When this cannot be done the intake should be sealed first.

Installed in the Nemacolin mine of the Buckeye Coal Co. is perhaps more equipment for preventing and fighting fires than at any other plant in the world. Water lines, water cars under pressure, sand buckets and extinguishers of several types in adequate numbers are installed to extinguish the fire before it can gain headway. The story of this installation as given by W. Z. Price, assistant superintendent of the Buckeye Coal Co., in a paper on "Fire Protection Underground."

Ignore Small Shorts

In his paper Mr. Price stated that many automatic circuit breakers are installed in the Nemacolin mine. Mr. McAuliffe said that great care should be taken to see that all permanent track is well bonded as a means of eliminating that source of mine fires. He gave as his reason the occurrence of a fire in one of his mines. This was caused by the fall of a trolley wire on a new unbonded rail. Unfortunately the automatic circuit breaker in this instance failed to open.

Mr. Price declared that even where the rails are thoroughly bonded a similar condition might prevail, as the circuit breaker to carry the load must be set for such high amperages that the short might not draw sufficient current to operate the device.

Rigid Supports Near Face Help Bring Down Roof

Step-Face Longwall Next of Kin to Pillar Work on a Long Break Line—Woodson Describes Breaks in Roof Starting Back of Cut—Face Falls Said to Be Light

By Staff Correspondent

That rigid supports close to the face are necessary for the breaking of the mine roof, was an opinion frequently expressed and generally approved at the Friday morning session on "Roof Control and Mining Methods." At this meeting L. E. Young, general manager of the Union Colliery Co., of St. Louis, presided.

H. F. McCullough's paper on "Roof Control" pointed to the step-face system as the best solution of any departure from standard room-and-pillar methods. He stated that almost any attempt at working longwall without a gob pack is only an effort to work a long face without adequate means of controlling the roof.

Falls as a Form of Control

If the roof cannot be controlled, then it must be allowed to come down, and this is best accomplished by means of rigid supports at the break line which will prevent bending and produce a fracture at the coal face. The projecting corners of a step face furnish rigid supports, which move the general break line outward, allowing a reasonably free space behind the greater portion of each face.

Mr. McCullough called attention to the fact that the step-face system is in principle the same as drawing pillars on a pillar line. He showed how natural conditions can be met by varying the length of face, distance between steps, and the relative direction of the general break line. He described his company's first attempt in 7-ft. coal on a 300-ft. face. Cribs were used, but still there was enough deflection of the overhanging strata to allow the roof, at times, to fracture close to the face.

R. Y. Williams, consulting engineer, of Shenandoah, Pa., in discussing the paper said, that 90 per cent of mining today is in reality done by the step-face method, because this system corresponds to the robbing line in room-and-pillar workings.

He called attention to the fact that seldom, if ever, does the roof shear off immediately at the face. The falls at that point are light and usually extend but a short distance in an upward direction. An example of a conveyor digging itself out of the fall and of a mining machine and other equipment being reclaimed from under a mass of rock at the face were cited as proof that such falls are light.

The paper by E. F. Woodson, general superintendent of the Crowe Coal Co., Henrietta, Okla., was read by Mr. Burgess of the Republic Iron & Steel Co. The author described a recent attempt at working a face about 200 ft. long by conveyor mining in a bed 32 to 38 in. thick under a cover of 200 to 300 ft., with a good roof of blue shale. The plan was to set a row of break timbers close to the conveyor face so as to cave the area mined and relieve the weight.

After advancing the 200-ft. face about 150 ft. heavy roof breaks occurred after which a fall was obtained with every cut of coal. A fracture was formed at the back of the undercut, taking an angle of 60 to 70 deg. with the horizontal, and extending over the caved area.

Results Vary With Height

The break would always appear at the back of the cut as the mining machine crossed the face. Later the work had to be abandoned because of the heavy pressure which resulted from encountering a normal fault. He described in detail his observations and theory as to the bending and shearing action in the overburden.

Following this, Mr. Pryde read a discussion written by W. D. Brennan, general manager of the Phelps-Dodge Corporation, of Dawson, N. M. This detailed experience during the past year and a half, with long-face mining in coal from 4 ft. to 9 ft. thick, under overburden which in places attained a thickness of 1,500 to 2,000 ft. These faces were 150 to 400 ft. long. The breaks extended entirely to the surface.

In coal over 6½ ft. thick the results were disastrous, but where the bed was less than 6½ ft. thick the roof was successfully broken at a row of props 6½ ft. from the face. The practice followed was to remove all supports back of the break row in which four rows of props were always used so as to assure protection to the men and equipment. The opinion was expressed that longer faces resulting in a slower advance so as to give the roof more time to settle, might afford better results.

Seams Above Limit Methods

Dr. J. J. Rutledge commended the paper by Mr. Woodson, saying that the author had put into concrete form a likely theory of roof action. He called attention to the fact that in panel longwall the roof action is the reverse of that with true longwall advancing, and that the breaks should be obtained at rigid supports so as to relieve the face of weight.

Josiah Keeley, president of the Cabin Creek Consolidated Coal Co., Kayford, W. Va., was the third speaker. His subject was: "Control of Roof in the Eagle Seam." He opened by humorously describing the idosyncrasies of the No. 1 Gas or Big Eagle Seam. Pillar drawing in this measure results in cracks which extend to the top of the mountain, perhaps through 1,000 ft. of cover.

He said that little over 50 per cent of the coal is removed, principally because of the fear of disturbing the valuable beds above. The thick draw slate overlying the coal presents a real problem. This can be controlled only by complete lagging, which is, of course, out of the question.

The last paper of the morning, "Recent Developments in Roof Control," was read by W. C. Stratton, chief engineer of the United States Coal & Coke Co., Gary, W. Va. He described his company's endeavors to improve and cheapen the method of controlling the roof. One of these was by the use of a two-part crib with height adjustment accomplished by sliding one part upon the other at a suitable angle, the two portions

Digitized by Google

being held in position by a chain. The other device is a power-propelled metal jack.

One of the most interesting talks of the session was by Glen Knox, superintendent of the Gunn-Quealey Coal Co., Quealey, Wyo., who at the request of Eugene McAuliffe, reviewed his experience in longwall mining. The coal worked is 6 ft. to 6 ft. 3 in. thick, the roof a strong sandy shale and the cover about 500 ft. thick. The coal is free of partings and is shot down onto a heavy-duty conveyor, which is moved up tight against the face.

His company has already worked two continuous faces each 250 ft. long for a distance of 2,000 ft. Selected posts 8 to 10 in. in diameter are set 12 in. apart in one direction by 15 ft. in the other to form rigid break rows. Between these rows of selected posts ordinary props are set on 4 ft. centers.

If the roof does not break at every second cut or each 15 ft. of advance, work is stopped until the roof can be brought down. Cribs are sometimes used, but are employed only for the safety of the men and equipment. A new break row is set about 4 ft. from the face, or about 11 ft. from the back of the cut.

After the conveyor has been put in operation shooting is started at one end of the face and is continued along its entire length at one-minute intervals. About 10 per cent of the coal is loaded automatically by the conveyor and the remainder is shoveled by hand. Each loader handles 18½ to 19 tons per shift and the output per underground employee is 9 to 10 tons daily, which compares favorably with 5 tons which was the production before the adoption of the new system.

Without a single accident at the face, 175,000 tons have been mined. During the last year, the men have never failed to clean up a face each shift. Less lump coal is obtained than with the old system of mining.

At the start a face was lost by advancing a distance of 30 to 35 ft. before getting a break. Mr. Knox stated that the saving realized has been small. Timber cost is somewhat increased. The net saving in getting the coal into the cars is less than 15c. per ton. He said that they are now reclaiming more rail than is required for development and eventually they will have some to sell.

Erskine Ramsay described two successsfull longwall mines in Alabama. He also hinted at a new system of mechanical mining that he is working out and which he predicts will prove of great advantage under favorable conditions.

Carl Scholz, of Charleston, W. Va., said that so far, his company has failed to control the roof in wide places. However, it has one mine in which all production is from faces that are 60 to 80 ft. in length.

Better Track and Bigger Cars Are Advocated

Heavier Rails, Fixed Standards of Construction, Smaller Car Wheels and Greater Length of Cars All Urged—Paint Should Reduce Corrosion—Young Wants Double Trucks on Mine Cars

By Staff Correspondent

FRIDAY afternoon's session was devoted to a discussion of underground transportation. So busy had the exhibitors been during the week demonstrating and exhibiting their equipment to coal company officials to the number of at least 1,200, who milled around the exhibit spaces, that they were willing to close the show at noon. This they did. That was not the case, however, with about 150 operating men who desired expert information on the design, construction and maintenance of track and rolling stock. R. L. Kingsland, electrical engineer of the Consolidation Coal Co., presided.

"Track materials and layouts must be standardized to keep maintenance cost low and efficiency high," said A. A. Culp, consulting engineer of Birmingham, Ala. Track men will become more proficient in their work when track is standardized. Often so little is spent on the haulage system that other phases of mine operation suffer thereby to the extent that the unit cost of mining is higher than it should be.

Mr. Culp made a statement which should be at all times borne in mind: "No matter how good the condition of the track, if the layouts are not planned so as to minimize delays to other phases of the operation, the haulage system is not efficient."

He drew attention to the fact that as a short ruling grade will limit the tonnage of a train over a long haul, such abnormalities in grade should be in most cases corrected. When details are properly planned and executed the maintenance forces are lowered to a minimum without jeopardizing the efficiency of the track. Poorly laid rails and complementary equipment are torn up by passing trips as fast as they can be repaired.

Some years ago, the Lehigh Valley R.R. turned to the use of 136-lb. rail as an experiment, though it thought at the time that this section was much heavier than necessary. The rail has been in long enough use now to prove that not only are the track maintenance costs less, but that the yearly tonnage of rail renewals also is less.

In some mines the cost of track maintenance is as much as that on the best railroads, according to Fred C. Hohn, consulting engineer, Scranton, Pa. This unfortunate situation is due to the fact that makeshift and unsuitable materials are improperly installed, and then maintained in a haphazard manner with the result that their life is short, derailments are common and labor is wasted in patching. He read a paper on "Track Work, Details and Maintenance."

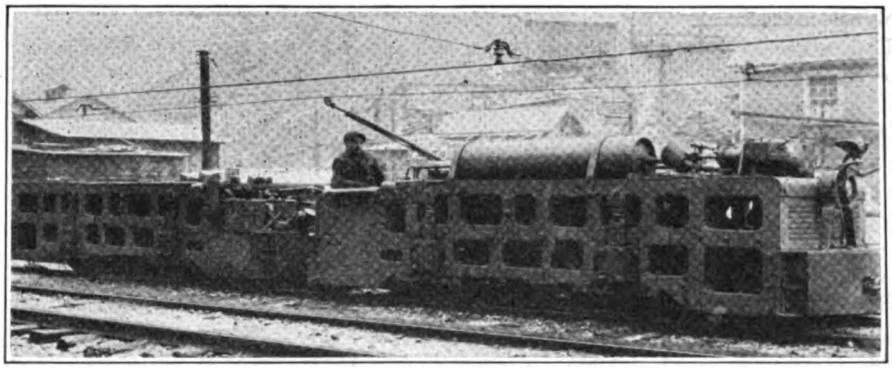
Clarence E. Watts, mechanical engineer of the Berwind-White Coal Mining Co., Windber, Pa., delivered a paper on the subject of, "Selecting a Mine Car Design." His attitude is that though great strides have been made in the design and construction of mine cars, not much progress can be noticed with respect to certain of its mechanical features. He feels that the last word has not nearly been reached in achieving the highest ratio between the dead weight of the car and its gross weight.

In his paper, Mr. Hohn objected to the practice of having bond holes

Digitized by Google

punched in rails before they left the mills. R. P. Hines wanted to know his objection, stating that it was cheaper to follow this practice than to do the drilling on the job. Mr. Hohn's chief objection is that the punch hole is irregular and therefore requires reaming.

Mr. Hohn also had said in his paper that he could not see the merit of steel ties for general use. George Hay, general manager of the Consolidation Coal Co., said that his company was experimenting in the use on main haulages of heavy steel ties under 60-lb. rails. The tie being used has a bearing surface of 7 in. and a top surface of 5 in.; it is ballasted with rock, and is held in line with braces which extend from the rib to the rail. He thinks that the steel tie is of particular value in the repair of rails, which have spread. Where they are used under switches, a floor of concrete is poured.



STEEL TIES CONCRETED

Mr. Johnson of the Bethlehem Steel Co., described a steel tie installation in a Michigan copper mine where concrete was utilized to hold and support the track along the entire length of the main haulway. Mr. Hohn said that in his experience steel ties in general use, and under heavy rails in particular will bend and tend to draw the rails together because the center of the tie is in contact with ballast material at a higher level.

W. D. Hockensmith, of Penn, Pa., pointed to current practices and tendencies in design which car manufacturers are now following. A change from the 16-in. wheel to the 14-in. wheel has been made to increase the capacity of the car by 5 to 8 cu.ft. with only a slight increase of tractive effort. He intimated that no brake should be designed so as to protrude beneath the axle. Where the brake gear extends beneath this point, it is generally out of order.

He stated that the steel-band brake is satisfactory for spotting mine cars, but is of no value for steadying trips on long hauls.

He urges wider use of the composite type mine car because it has proven to be best both from a practical and an economical standpoint. The cost is 15 to 20 per cent higher than the wood car of the same carrying capacity, and the weight in each case is about the same. In his opinion the width of a composite mine car can be increased to such an extent as to give 30 to 40 per cent greater capacity without sacrificing strength.

Two Fifteen-Ton Locomotives Operating in Tandem, Keystone, W. Va.

This heavy haulage equipment is being used on the main haul of the Keystone mine, operated by the Keystone Coal & Coke Co. The motors in each unit are adapted for a locomotive weighing 20 tons.

Steel sides of mine cars will last at least twelve years. The Steel Corporation has found by experience that the average life of wood cars is five years. After that time they have to be rebuilt. Contrary to common belief, the bodies of steel cars are not much weakened by rust which attacks the outside and not the inside of the plates. Mr. Hockensmith would recommend therefore that oil or paint be applied to the outside surface, perhaps by the use of a spray gun.

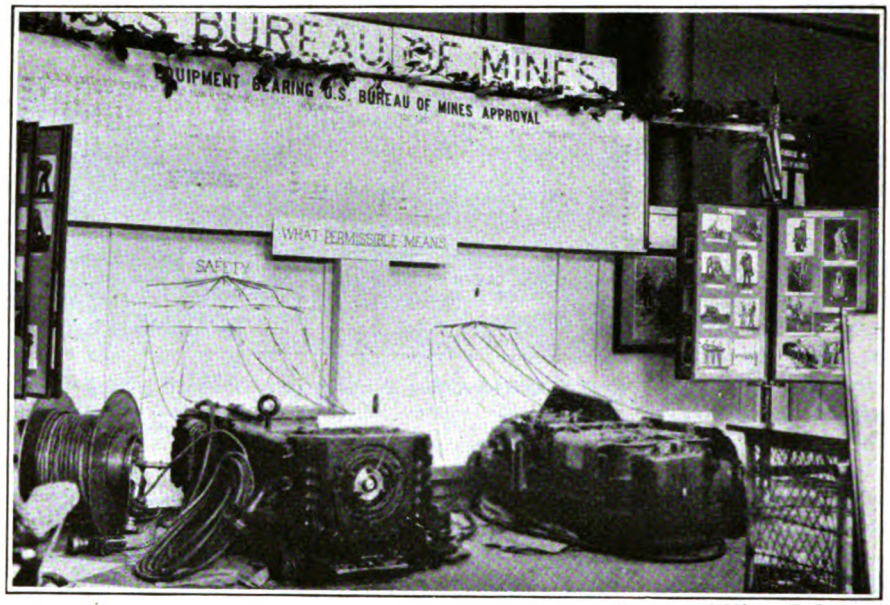
The mechanical loaders now in use require a clearance of 14 to 18 in. between the top of the mine car and the mine roof. Many operators are considering the possibilities of mechanical loading as applied to their properties. Mr. Hockensmith urged them to consider the requirements of the mechanical loader when having cars built for hand-loading purposes.

LONGER MINE CARS

According to him, the mine car will be increased in length. Inasmuch as 16-ft. mine locomotives are being used successfully, he sees no reason why the mine car should not be longer where conditions require higher capacity than that can be obtained with current proportions. He feels that a bottom could be built strong enough to take care of the additional overhang of a longer mine car. He has no doubt but that a 16-ft. car on a 6-ft. wheel base would work with entire satisfaction, providing the track curves were made longer.

Much is yet to be learned about features of design and construction which will give the same strength to the mine car and at the same time lighten its dead weight. He sees no reason why the 3 to 1 ratio between the capacity and dead weight which is being obtained in railroad cars could not at least be approximated in mine cars to the extent that the latter would carry as much as two and one-half times their dead weight.

He is building for outside tram purposes at a certain mine a 40-ton car, one end of which will be equipped with a hand brake and the other end with an air brake.



Dr. L. E. Young, of St. Louis, is confident that the idea of double trucks on mine cars is practicable and in the future may have to be adopted where the hauls are long. Little encouragement from others was forthcoming to strengthen him in this belief. Nevertheless he remained as ever "from Missouri."

DISPATCHING METHODS

The Consolidation Coal Co. employs two distinct methods of controlling underground haulage. In closed-light, gaseous mines traffic is regulated through a motor boss. In such of its mines as are equipped exclusively with permissible equipment no telephones are installed. In its open-light mines, transportation is governed by telephones and a dispatcher. A detailed account of these two methods was described by J. B. Hicks, electrical engineer of the Consolidation Coal Co., in a paper on "Dispatching for Long Haulage."

The subject of this paper was discussed by T. G. Fear, general superintendent of the Inland Collieries Co., Indianola, Pa. He said that if he should ever decide that the use of a telephone in a gaseous mine was dangerous practice, he would at the same time make a decision to take out all electrical equipment. The mine which he is operating produces normally about 3,100 tons of coal per day. This tonage is hauled over a distance of one and one-half miles by two 15-ton locomotives.

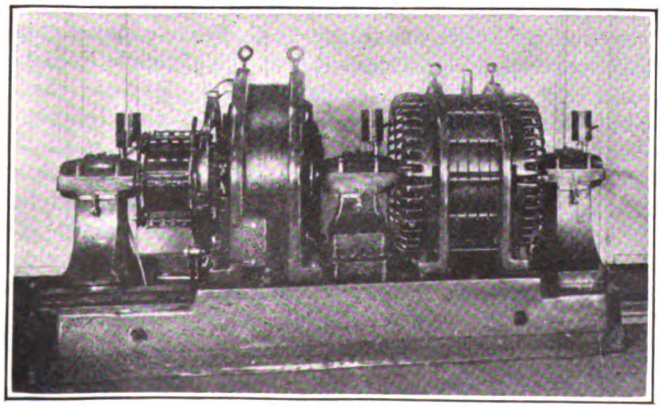
Bureau of Mines Exhibit

Many Exhibitors Show New Equipment At Cincinnati

Ninety-Two Separate Booths Exhibit New Suggestions for Cutting Cost and Increasing Safety—Trend Strong for Greater Use of Power—More Mechanical Loading Devices Shown Than Ever

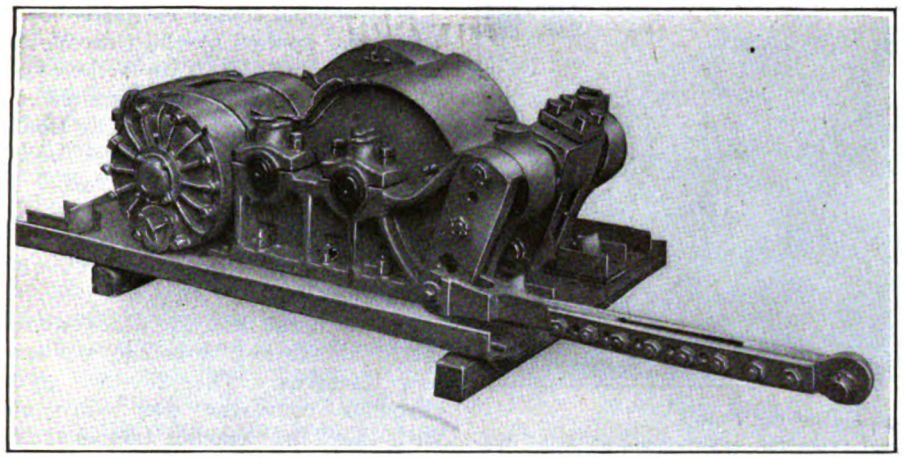


By Frank H. Kneeland
Associate Editor, *Coal Age*

EACH SUCCEEDING year seems to show a growth and improvement in the exhibition of mining equipment held in conjunction with the meeting of the American Mining Congress. One needs only to study these exhibits carefully to see the present and future trends of the industry. This year face conveying, power drilling and shoveling were much in evidence. It is not, however, the intention here to enumerate the various exhibits, interesting though they were, but rather to recount some of the new devices, each capable of doing its bit toward easing the labor or cheapening the cost of coal production. These ran a wide gamut of usefulness, ranging all the way from pump controls to shotfiring devices. Just as the visitor to the show came upon these various pieces of new equipment in no particular order or arrangement, so no attempt will here be made to place the descriptions in any premeditated sequence.

Simplicity and compactness, two highly desirable features, were embodied in the new automatic substation exhibited by the Ridgway Dynamo & Engine Co. The control apparatus, with the exception of the direct-current breaker and its supervisory relays, was made by the Cutler-Hammer Mfg. Co. and was concentrated on two panels. Only one voltage was employed for operating the magnetic switches and relays.

The direct-current breaker is that manufactured by the Automatic Reclosing Circuit Breaker Co. This substation was unique in that it was the product of three companies, each a specialist in its particular field. The Ridgway synchronous motor-generator set of the exhibit is characterized by abundant copper, by the "Ridgway" compensating winding of the generator, and by provision for easy alignment of the motor and generator frames. Adjusting bolts are provided which make it convenient to raise or lower the frames or shift them laterally on the base. Although the motor-generator on exhibit ran at 1,200 r.p.m. the same automatic switchboard is used with the 900-r.p.m. machines.



The automatic reclosing circuit breaker, which is the new type KSA, has a number of new features. The most important of these are: Solid contacts instead of laminated, a magnetic blowout and a laminated frame. The blowout is designed for maximum effectiveness even at low current values. The contact pressure has been greatly increased which results in an operating temperature

Motor-Generator Set

This constitutes part of the automatic substation described in the right column of this page. The switchboard is not visible in the picture. The bearing relays and some automatic equipment are plainly shown.

Engine That Gives Differential Shaking Motion to Conveyor

This side-drive engine, which is intended for actuating the Mavor & Coulson conveyor, is one of three types available. It operates at 65 strokes per minute. The motor and controller are of the explosion-proof type and the design is rugged and simple throughout.

considerably below the limits permissible on a solid-contact device.

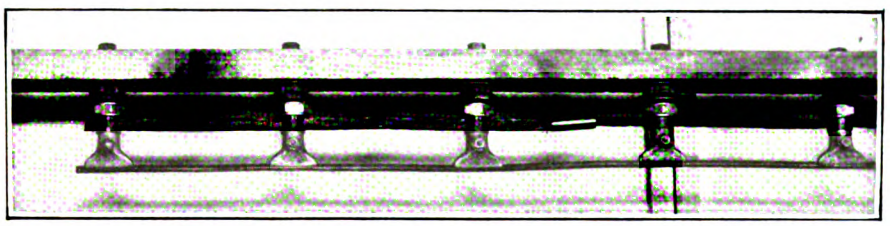
The laminated frame of the breaker speeds up its operation and reduces the actuating current required. Another feature is the use of a rolling-ball contactor which delays the insertion of resistance in the holding coil circuit, until the breaker has had plenty of time to seat itself.

The C. H. McCullough Engineering Co., of Pittsburgh, Pa., had on exhibit a driving engine and two sections of the Mavor & Coulson shaker-trough conveyor, which is made in Glasgow, Scotland. The engine is compact, and appears to have that ample ruggedness and simplicity which is necessary for duty in a mine.

The motor and controller are of the inclosed type approved in Europe for use in gassy mines. The armature is fitted with grease-packed ball bearings. The bronze sleeve bearings are oiled by the wick system from an oil cellar, the covers for which instead of being held in place by ordinary nuts, are each secured by a single lever nut requiring no wrench. Gears and the wearing portions of the shafts are case-hardened.

The 9-ft. trough sections exhibited were 20½ in. wide. The standard sections, which are made of lighter gage steel than the drive section, weigh only slightly over 100 lb. each. Two men can easily handle one of these.

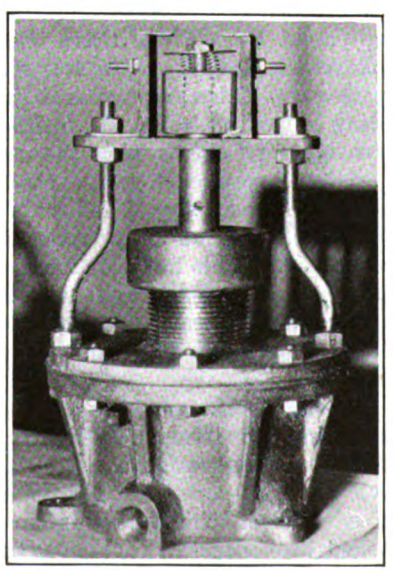
The conveyor is designed to operate at 65 strokes per minute, and on a level course, 360 ft. of 20½-in. trough is the maximum to be driven from one engine. The tonnage rating on the level, when using a 9 to 10-in. stroke is 30 to 70 tons, and when using a 6¾-in. stroke 28 to 40 tons per hour. Ratings are naturally somewhat higher for grades in favor of the load.



Another exhibit of the McCullough company showed an EMB drawn alloy-steel continuous locomotive resistance built in one section with a side frame shaped to suit the available space in a certain type of locomotive. This design makes the complete resistor nearly jointless so far as the elements are concerned and leaves only external connections to be made on the job.

"Insta" control for centrifugal pumps, the "Rogers" feeder-wire clamp, and a new "Curtis" valve were among the new features of the exhibit of the Dravo-Doyle Co., of Pittsburgh, Pa. The purpose of the "Insta" control is to shut down a centrifugal pump if for any reason the water is lost. It consists of an anti-acid bronze body containing a differential plunger which operates an electrical contact. The only pipe connections necessary are two ½-in. lines to the sides of the discharge-line check valve.

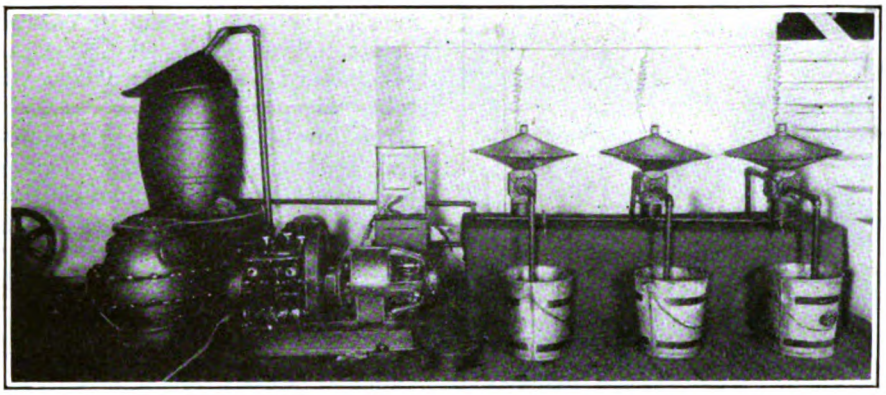
The Rogers feeder-wire clamp is interposed between the hanger and the trolley clamp. It is adjustable to take several sizes of wire. The smaller size will take cable up to 500,000 circ. mil capacity. Perhaps one of the most important advantages of the clamp is that in case of a slate fall, the loosened feeder can be tightened without disturbing the trolley wire.



The Curtis valve now has two distinct features; automatic suction control and automatic pump control. Both are combined in one unit. The suction control does the work of a pump man by automatically opening and closing the several suction lines from a pump as the various sumps served by it fill up and are emptied.

This valve with the new electrical contact arrangement in the top makes mine gathering pumps completely automatic. It operates as follows: By means of the electrical contact in the top of the valve, which is a built-in feature, and may be connected in multiple where more than one valve is installed in connection with a given pump the time of operation of the pump will coincide exactly with the water conditions encountered. When all of the places have been drained the pump automatically stops and remains inactive until sufficient water has ac-

Rogers Feed Wire Clamp Holds and Connects Trolley and Feeder Cable



This is another of the several devices of a similar nature and for a like purpose that have been put upon the market recently. This clamp holds both trolley and feeder cable from one support and forms a connection between them.

Insta Pump Control

This device is intended to control the operation of centrifugal pumps. It is of simple design and built of acid-resisting bronze. Its only connections are two ½-in. pipes that come from either side of the discharge-line check valve.

Digitized by Google

Curtis Valves Controlling Gathering Pump

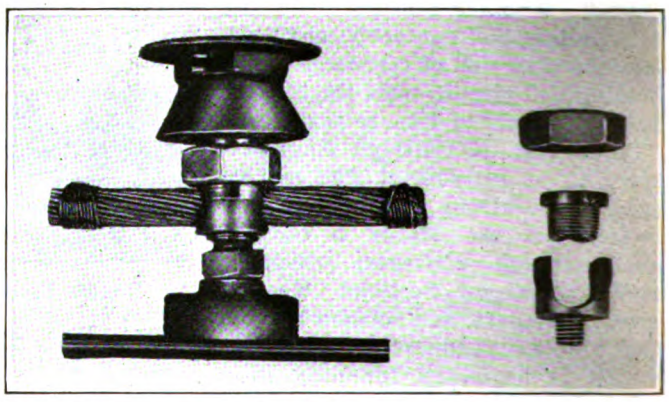
These valves are now fitted with an electrical connection which adds much to their utility. The pump station may now be made almost as truly automatic as the substation, as the pump will operate only when and as long as there is water to be pumped.

cumulated to make it necessary to pump out one or more of the branch suction lines. The electrical contact then starts the pump, which remains in operation until this water has been removed, when the machine is again shut down. It has been found that many of the pumps used in mines operate at only 10 to 20 per cent efficiency. During much of the time they merely waste power. By means of this contactor, which is built into the valve, this excess power loss has been eliminated. At the same time this device insures reliability of operation.

This firm also exhibited in combination with the Bureau of Mines, the first government-approved mine pump for use in gaseous workings. This unit has been tested by the Bureau and permits have been issued to the manufacturer for both 550 and 250 volt machines.

Six new developments were noted at the booth of the Electric Railway Equipment Co. First, there was a trolley-wire splicer with staggered set screws, this arrangement providing space so that an ordinary wrench can be used. Thus the usual special socket wrench is not needed.

The next was the "No-Loss" expansion bolt for hanging trolley and feeder wire. This has a double, ½-in. pitch thread and the end is slotted so that the bolt can be screwed out of the hole with a spanner socket wrench.

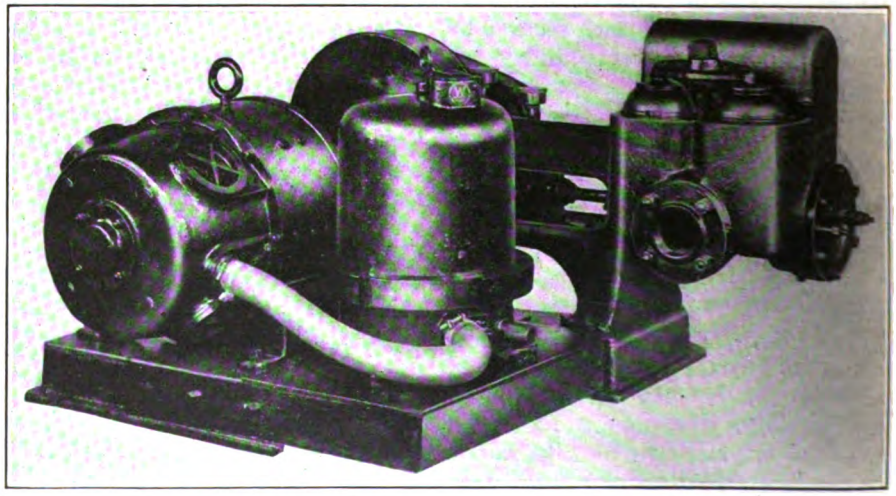


Another development is the triple-duty sure-grip clamp. Cast integral with the compression ring of this device is a set-screw lug for holding a feeder wire. The feeder is simply hooked into place and fastened by a set screw. The three functions of the clamp are to support the trolley wire, support the feeder wire, and to connect the feeder and trolley at each hanger.

A mining-machine cable nip is another new item of this company's line. This has a solderless connection in the handle, with a plug connector on the side as well as on the nip end.

Another item is an improved sectionalizing insulator switch. This has a double blade, and a double hanger support. There was also on exhibit a double feeder clamp which provides for carrying two feeders of any size, or a trolley and a feeder, at the same level, but 6 in. apart.

Triple Duty Clamp

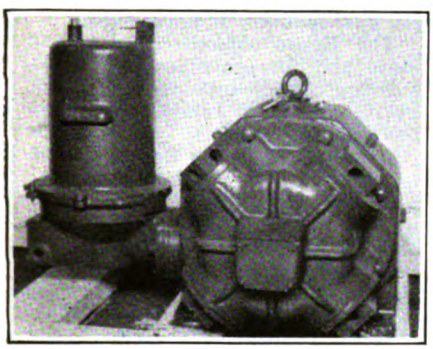


Trolley and feeder cable hanger combined. It is simple in construction, holds both conductors, either of which may be tightened without disturbing the other. It also joins them electrically.

A steel-mold copper electrode bond was being applied by the Una Welding & Bonding Co. This is the type CBM, "Metmold." The terminal is held securely in proper welding position by driving the mold-fitted bond head onto the base of the rail. A reduction of accessories, quick installation and contact to both base and web of the rail are secured by the new design.

The General Electric Co.'s automatic substation embodied several new features. The 200-kw. synchronous converter was equipped with the TB-8 bearing temperature relay which uses mercury contacts operated from a rod extending into the bearing where the temperature element is concentrated. The starting and running contactors now have demountable arc chutes in place of the hinged type. This facilitates inspection.

On the main control board, several dash-pot relays have been replaced by the more positive induction type, and the starting protective timing relay is motor-driven. Phase-failure protection is now accomplished by a current phase-balance relay of the induction type instead of by two tem-



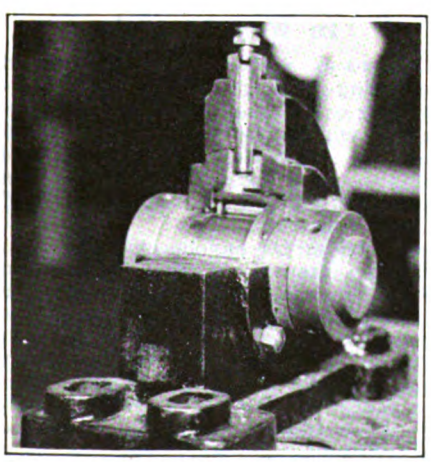
A Permissible Pump Unit Approved by Bureau of Mines

It consists of the gathering pump, the motor that drives it and the control device. All electrical equipment is inclosed and explosion-proof.

Digitized by Google

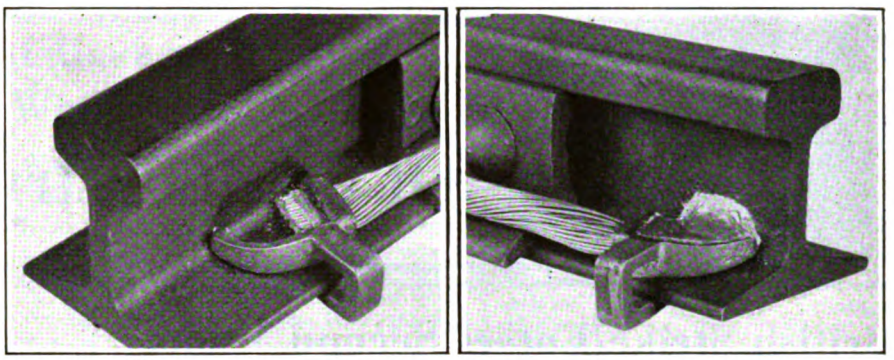
perature relays. Also the old plunger-bellows type of alternating-current relay has been replaced by the type IA induction relay.

Among the electrical instruments shown were the new type CP-4 and CP-5 graphic portable meters and a type D-7 polyphase watthour meter equipped with potential indicating lamps. Each of the graphic meters has self-contained resistance units, a non-spillable and quick-removable ink well, potential change switch, quick-opening back giving ready access to the meter element and inking mechanism, a knurled nut for locking the apparatus for transportation, also a hinged clock and chart element, all of which add to the ruggedness or convenience of the instrument.



General Utility Motor

This motor and its control equipment is entirely inclosed and forms a unit within itself with no flexible connections between the two elements. It is intended primarily for driving pumps in gassy places.



Line Shaft Bearing

This bearing is split so that the shaft to be supported may be laid into it. It is so proportioned that it will fit any standard shaft hanger.

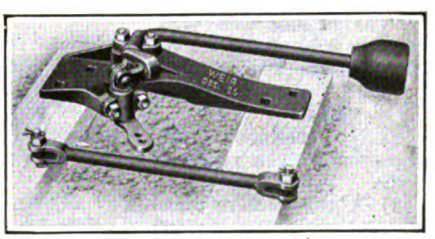
Roller Bearing Pillow Block

Ordinary cold-rolled shafting can be used with this pillow block. It is so constructed as to prevent longitudinal movement and the shaft does not require turning down.

Steel-Mold Bond Terminal Said to Be Rapid in Application

The terminals of this stranded copper bond are so made that they may be driven over the flange of the rail where they form molds for the deposition of molten copper. Bonds of this kind can be applied, so it is claimed, with greater rapidity than those that have to be clamped in position before they can be welded.

As its name implies, the potential indicating feature of the D-7 watthour meter provides a visible means of knowing that potential circuits of the meters are not open. Flashlight lamps rated at 3½ volts are operated at one volt from a few turns of transformer winding, which is added to the meter elements.



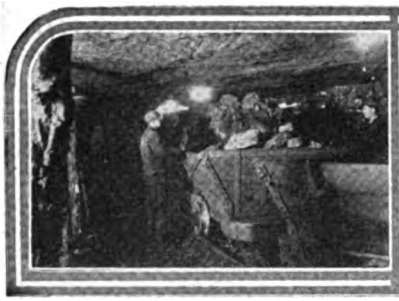
Another exhibit of this company was its new general utility motor for use in the mines and designed primarily for driving pumps. This is a direct-current machine of 5 hp. and 1,200 r.p.m. The controller is attached directly to the motor, making a unit with no flexible connection between these two elements. This machine is protected from overload by a thermal relay, which, if tripped out, can be reset by a push rod without dismantling the machine. The motor may be thrown directly across the line, and although designed primarily for driving gathering pumps it will doubtless find favor for actuating other machinery, such as face conveyors and the like.

This company also showed a 6-ton permissible storage-battery locomotive that has been approved by the Bureau of Mines. The particular unit exhibited has been operated for nearly a year in the Warden mine of the Pittsburgh Coal Co.

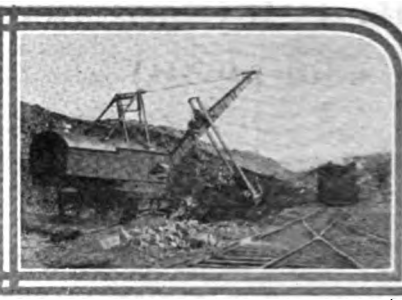
For Any Standard Hanger

The Hyatt Roller Bearing Co., of Newark, N. J., exhibited a line-shaft bearing built to fit any standard shaft hanger. The construction of this bearing is extremely simple, consisting of two parts held together by four bolts. The roller cages also are split so that the entire bearing may be put in place without disturbing the shaft assembly.

This firm also showed a roller-bearing pillow block built along the same general lines. In this block the inner race is slipped over the shaft and held in place longitudinally between two collars that are clamped to it upon either side of the block. It is thus unnecessary to turn the shaft down in any way, and the block is made to fit commercial cold-rolled shafting of diameters ranging from $1\frac{7}{16}$ to $5\frac{7}{16}$ in. A thrust collar within the block resists any tendency of the shaft toward longitudinal movement.



Parallel-Throw Switch Stand



Malleable iron and steel parts only are used in the construction of this switch throw. It is a notable fact that there has been a measurable decrease in the accident rate at mines that have made parallel-throw stands their standard.

The Weir Kilby Corporation showed a new parallel ground switch throw stand. The base of this stand is a single casting of malleable iron, all other parts being forgings. The reverse crank of the throw lever is provided with a ball-and-socket joint which actuates the throw arm. The connecting rod may either be solid or fitted with a spring. This stand is self-locking in either position of the points; but with the spring rod cars may be passed through the switch. The chief advantages as claimed by the makers are that the switch stand is low and may be set at a point remote from the track, the throw is parallel, a rest is provided at each side, all the parts are accessible, repairs may be readily made and the device has great durability.

News Of the Industry

British Strike Enters Second Month With Both Sides Outwardly Unmoved; Informal Efforts for Accord Continue

The British coal strike enters its second month with the tie-up in production complete and with neither mine owners nor mine workers offering any new formulas for peace.

Officially neither side has receded from the positions taken when they rejected Premier Baldwin's settlement program. Unofficially, however, efforts are being made to find a platform upon which both sides can stand.

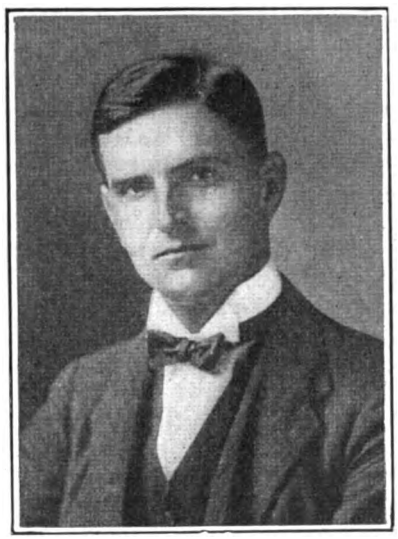
The leadership in this movement has been taken by F. B. Varley, M.P., a member of the executive committee of the Miners' Federation. Mr. Varley's plan calls for mutual concessions. Mr. Varley suggests:

(1) A reduction of 8½ per cent in wages to the end of the year, instead of the 10 per cent included in the Baldwin proposals.

(2) No profits to the owners until wages have been restored to pre-strike levels.

(3) A government subsidy of £6,000,000, instead of the £3,000,000 offered by the Premier.

(4) Immedate wage adjustments by the National Wages Board to be set up, instead of postponing action until December.



Frank Hodges, secretary of the Miners' International Federation, is another one who has come forward with a plan. Mr. Hodges calls for a general reorganization of the industry. He favors increasing the working day from seven to seven and one-half hours and a five-year extension of the wage agreement of 1924.

New coal regulations issued by the goverment last Thursday cut the allowance to domestic consumers from 100 lb. weekly to 50 lb. Lights for display and advertising signs have been prohibited to save coal. Industries in general are beginning to feel the pinch of the fuel shortage. Only a few furnaces are in blast. Several large Sheffield cutlery plants are down. Most of the pottery plants have been closed again. Railway service is being further curtailed.

Stamp Urges Restrictions

Sweeping restriction of the coal-mining area and a reduction in the number of mines in Great Britain were urged as the only solution of the British coal problem by Sir Josiah Stamp, chairman of the executive committee of the London, Midland & Scottish R.R., and a member of the Dawes commission, in an address before the British Empire Chamber of Commerce at New York on May 27.

"Before the war," he said, "the [British] coal production in peak years was about 280,000,000 tons going into export trade, enough to make all the difference between that kind of prosperity that existed before war and the depression in unemployment today. A large number of mines of very great age are operating on, what we should say in economic language, the margin of profitability. They cannot hope to succeed in competition with mines

Frank Hodges

under a modern equipment. The geolocial formation and the half dozen other conditions preclude that, and, if you could cut out of the producing area many of those mines and some 200,000 men, then it is quite clear that the remaining mines would produce enough coal to satisfy the market today under such conditions as would enable the present wages to be paid on an economic basis without loss.

"It is obvious that you cannot negotiate for a wage agreement for a state of affairs in the industry as the industry will be when it is reconstructed, because it will take three or four years at least for the things to be done that are required, and at least three or four years for them to have their full effect in profitability to the industry. You have, therefore, an interim period during which that state of affairs is being brought about by common agreement. That is the period for which you have to negotiate, and with the dissensions that exist within the mining association I cannot conceive that it is possible to negotiate for that interim period without a lapse of time—say four or five months."

No Change in Situation On Coal Legislation

The legislative situation at Washington as it affects the bills introduced in Congress to regulate the coal industry is unchanged.

The House committee on interstate and foreign commerce, considering the bill introduced May 17 by its chairman, James S. Parker, has made no report.

In the Senate, the Copeland bill is listed with the major legislative proposals pending before the upper house. The Republican steering committee, which is expected to map out the program for the remainder of the session, has taken no action.

With the continued delay, opinion grows that no bill will pass either branch of Congress before adjournment. The most uncertain factor, however, is the date of adjournment. The longer Congress is in session the greater will be the opportunity to press for consideration of coal regulation.

Studdard Heads New District In West Virginia

James L. Studdard has been named as acting president of District 31, comprising counties in northern West Virginia, which was recently established by the international executive board of the union. C. F. Davis has been appointed acting secretary-treasurer of the new district.

In making the announcement, Van A. Bittner, international representative in West Virginia, said: "There is only one task confronting us and that is the complete establishment of our union in this field. It is a great task, but with the splendid spirit of unionism displayed in the future that you have displayed in the past, we will demonstrate our ability to thoroughly unionize every mine in District 31. This condition will be made a living fact by that co-operation and assistance which knows no defeat."

British Coal Situation Intensifies Complexity of World Markets; Fuel Economy, Oil and Water Power Spread

By Paul Wooton
Washington Correspondent of *Coal Age*

That the serious depression which underlies the British coal situation is reflected in the United States and in other coal-producing countries is apparent from studies being made in Washington of the situation. There is enough competition between coal produced in the several countries of the world to influence the price level in each country.

To find the key to this world situation it has been necessary to examine the broad features of supply and demand of coal in the world market. In comparing present conditions with those existing in 1913—the last year before the war—two great tendencies are clear. One is the worldwide interest in fuel economy, which has tended to reduce the demand. The other is the competition of other sources of heat and power.

It has been found difficult to reduce to figures the effects of fuel economy. It is known, however, that the high prices and the shortages caused by the war turned the attention of engineers to fuel economy in a much more determined way than ever before. This was particularly true among the electric utilities. It became the great test of operating efficiency. The route to rapid promotion for the aspiring engineer was through the boiler room.

Railroads Reduce Consumption

Out of this movement there are certain places where savings in fuel can be reduced to figures. In the United States the consumption of locomotive fuel in the freight service has decreased 18 per cent per unit of work done. In the passenger service the decrease has been 13 per cent. All of this saving has taken place since the war.

Improvement in blast-furnace operation and in coking practice have cut by 9 per cent the consumption of coke and coal per ton of pig iron. The savings of gas and tar and other byproducts of present coking methods have reduced the consumption of heat by metallurgical industries by an additional 10 per cent. The electrical utilities have shown even a greater decrease. The pounds of coal per kilowatt hour have been reduced 34 per cent since the war. Figures from Great Britain are hard to get, but those available show the same trend.

At the same time that fuel economy has been reducing the demand, other competitors of coal have been taking away a part of the market. Before the war the world demand for coal increased with surprising regularity at the rate of about 40,000,000 tons per year. Since the war there have been only three years in which the 1913 output was reached. Production in 1925 was 1,368,000,000 tons, which shows an apparent increase over 1913, when 1,342,000,000 tons was produced. Most of the 1925 increase, however, came from German lignite. The world production of bituminous coal alone, since the war, never has reached the 1913 level. On a B.t.u. basis the world output for 1925 was not quite equal to that of 1913.

While the demand for coal has stopped growing the production of its competitors has increased at a faster rate than before 1913. Water power has doubled since 1913 and the production of petroleum has much more than doubled. The increase in water power since 1913 is equivalent to 66,000,000 tons of coal per year. The increase in oil and gas is equivalent to 172,000,000 tons per year.

Coal Recedes in Position

Putting it in another way, the contribution of coal and of its competitors to the world's supply of energy may be expressed as follows:

	Per Cent 1913	Per Cent 1925
Coal	89	76
Oil and gas	7	16
Water power	4	8
Total	100	100

Before the war coal absolutely dominated the world's energy supply. It now supplies 76 per cent of that demand. This arrested growth has been all the more difficult for the industry because it had accustomed itself to a steadily expanding market. Even the British industry was growing. Coal production in Germany and in the United States was expanding very rapidly, while in some of the outlying new countries, of which South Africa is an example, the rate of growth surpassed that of the United States. The industry not only was accustomed to an increase in demand but capacity has continued to increase even though the demand has not. In the United States this increase in capacity has been enormous. The same is true in the outlying countries, when expressed in percentage and not in tons.

The plight of coal is worldwide. For that reason the solution being worked out in Great Britain is being followed very carefully by the government's coal specialists in Washington.

Deplores Perennial Strife In Coal Industry

Much of the unrest in the United States may be attributed to the lack of co-operation between people whose interests certainly lie in harmonious understanding, yet appear to be in eternal strife, according to a statement made May 12 at the annual convention of the Maryland Bankers' Association in Atlantic City by George Decamp, of the Federal Reserve Bank of Cleveland.

"The coal industry," Mr. Decamp said, "is a specific example in this regard. It would seem that we may look forward annually to disputes concerning wage adjustments, ending in strife which apparently benefits neither miner nor operator and in which the public is generally greatly inconvenienced.

"It is a sad commentary on American business that some workable plan had not been developed to bring about better co-operation between these warring elements."

Burns Bros. Earnings Jump

Official figures of earnings for the fiscal year ended March 31, 1926, of Burns Brothers, New York City, show net sales of $29,049,655, against $27,287,472 in the previous fiscal year. Net profit totaled $2,420,779, against $1,271,902 the year before. The net profit for the last fiscal year was equal to $15.17 a share on the 97,365 shares of Class A stock and $7.17 a share on the 97,367 shares of Class B common stock. This compares with $10.22 a share on Class A and $2.22 a share on Class B in 1925.

Are British Coal Mines Efficient?

Wide World Photo.

Boiler Room in a New British Colliery

This boiler room is at the Snowdown Colliery, Nonington, near Dover, Kent, England. It is one of two plants owned by Pearson & Dorman Long, Ltd. It will be noticed that coal is still being stoked by hand at this brand new plant. We are told that the British mines are hindered by the besetting conditions of earlier operation, but here, in Kent, are new mines. Will the old traditions ever be overcome?

Promising Program Arranged For N. C. A. Convention

"Big doings" are promised coal men who visit Chicago to attend the annual convention of the National Coal Association to be held at the Drake Hotel, June 9, 10 and 11. Operators from all parts of the country are expected to be present and, according to Harry L. Gandy, executive secretary of the association, and D. H. Pape, assistant to Mr. Gandy, the program will be one of the most interesting ever prepared for the bituminous coal industry.

The following addresses are scheduled:

"Research and Its Value to the Coal Industry," by Walter Barnum, president, Pacific Coast Co.

"Hunting for the Elements Produced by Low-Temperature Distillation," by Russell B. Cooper, National Coal Association graduate research fellow, Carnegie Institute of Technology.

"Questions Arising From the Disposal of Mine Waters," by Richard D. Leitch, associate chemical engineer, U. S. Bureau of Mines, Pittsburgh, Pa.

"The Human Element in Safety Work," by P. H. Penna, secretary-treasurer, Indiana Bituminous Coal Operators' Association.

"Reducing Hazards in the Mining of Coal," by J. William Wetter, general manager, Madeira, Hill & Co., Phillipsburg, Pa.

"One Way of Teaching a Miner to Protect Himself," by R. E. Howe, vice-president, Climax Caol Co., and secretary of Southern Appalachian Coal Operators' Association, Knoxville, Tenn.

"Keeping the Cost of Compensation Insurance to the Minimum" (with a motion picture film, "The Story of Rock-Dusting"), by J. T. Rupli, superintendent, compensation department, Chicago, Wilmington & Franklin Coal Co., Chicago.

"Centralized Accident Reports—Their Advantages and Benefits," by W. A. Ellison, general manager, Southern Harlan Coal Co., and president of the Harlan County Coal Operators' Association, Harlan, Ky.

"Have Statistics Any Value to the Coal Industry?" by C. E. Bockus, president, Clinchfield Coal Corporation, Dante, Va.

"Coal Salesmanship," by Ralph Knode, vice-president, General Coal Co., Philadelphia, Pa.

"Will Oil Compete With Coal or Will Coal Compete With Oil?" by J. G. Puterbaugh, president, McAlester Fuel Co., McAlester, Okla.

"Efforts on Behalf of Bituminous Coal Industry in Federal Tax Matters," by R. C. Tway, president, R. C. Tway Coal Co., Louisville, Ky.

"Legislative Proposals Now Before Congress Affecting Coal," by W. H. Cunningham, secretary, West Virginia Coal Association.

The annual dinner will be held at 7 p.m., June 10, in the ballroom of the Drake Hotel. Judge H. B. Lindsay, of Knoxville, Tenn., will preside as toastmaster.

Railroads to Spend Heavily For Betterments

Capital expenditures for new rolling stock and other improvements authorized by Class 1 railroads this year up to April 1 total $822,000,000, according to a report by the Bureau of Railway Economics of the American Railway Association. The Bureau estimates that the total capital expenditures for the year 1926 will run between $750,000,000 and $800,000,000.

Capital expenditures made during the first three months this year for equipment amounted to $74,900,000, a decrease of $22,800,000 compared with similar expenditures for the first three months last year. Capital expenditures, for locomotives, however, amounted to $18,300,000, an increase of $5,600,000 over the same period in 1925, although decreases, compared with the first quarter last year, were reported in capital expenditures for freight and passenger cars.

For roadway and structures, capital expenditures for the first three months this year were $90,800,000, an increase of $19,200,000 compared with the first three months last year.

Midwest Dealers Reorganize And Hold Annual Meeting

When members of the Mid-West Retail Coal Association gathered in Kansas City, Mo., May 26, for a two days convention, they were met by a "cease and desist" order from the Federal Trade Commission, effective that day (see *Coal Age*, May 27, page 772). The association immediately disbanded, but, as individuals, the members reorganized as the Missouri Valley Retail Coal Merchants' Association, and continued the program interrupted by the order.

The new association elected James P. Andriano, of the Todd-Sunshine Coal Co., St. Joseph, Mo., president, and W. R. Feuquay, also of St. Joseph, executive secretary. Ray D. Kelly, of Springfield, Mo., was president of the disbanded Mid-West Association.

The program May 26 included these talks: "Credit, Cash or Cash Discount—Which?" by W. A. Storrs of the W. A. Storrs Ice & Coal Co., Hannibal, Mo.; "The Association, Its Policies and Opportunities," by W. R. Feuquay, of St. Joseph; "Clinkers—Their Effect on the Furnace," by L. W. Millis, of the Security Stove Co., Kansas City; "Newspaper Advertising," by K. C. Richmond, advertising manager of the Albert Silk Co., Topeka; "How to Fire That Furnace," by A. Bement, of the Saline County Coal Corporation, Chicago.

At a dinner dance that night, James T. Bradley, of the Commerce Trust Co., Kansas City, Mo., discussed "The Value of Organization," and C. W. Morris, of the Western Railways committee on public relations, Chicago, discussed "Transportation."

The second day of the convention, Albert Silk of Topeka, talked on "Know Your Costs"; J. C. Dennis of the Howe Scale Co., Kansas City, Mo., had as his subject "Scales and Their Care"; V. McDaniel of the V. McDaniel Fuel Co., Kansas City, discussed "How to Hold That Customer," and L. B. Clough, managing director of the Chamber of Commerce, St. Joseph, answered the question of "Why an Organization?"

The convention was attended by two hundred retail coal dealers of the Southwest.

Anthracite Produced in 1925, by Regions

(Compiled by U. S. Bureau of Mines)

Short-Circuits Ventilation, Saves 62 Lives in Fire At Mount Lookout Mine

The lives of sixty-two employees at the Mount Lookout Mine of the Temple Coal Co., in the borough of Exeter, sixteen miles south of Scranton, were saved on May 27 through the heroism of their foreman, Thomas Hislop. For five and a half hours they were hemmed in by dense clouds of smoke and flame from a burning building underground and blazing timbers, but were kept alive in an airway one mile from the shaft because Hislop, aided by four miners, including his son, Robert, 22 years old, had perfected a temporary system in a short time that completely short-circuited the regular mine ventilation system and swung the air currents so that the fire was not fanned by air being pumped into the shaft and at the same time fresh air was sent into that part of the mine where the sixty-two men were instructed to remain until rescued.

Only the resourcefulness of Hislop saved the men from suffocation, William P. Jennings, president of the Temple company, and S. C. Curtis, state mine inspector, declared. Had not Hislop shut off the air current the smoke and fumes from the burning timber and the fireboss shanty would have gone into the workings and smothered all.

The fire broke out soon after 8 a.m., around a shanty in the Pittston vein, 300 ft. below the surface, according to company officials, and the flames spread so quickly that sixty-two men were cut off at their places one mile from the shaft.

The sixty-two workers were trapped in the 11-ft. or surface seam of the mine when a fire started in the first aid hospital about 600 ft. from the shaft., and rapidly spread to the timbering along the seam, pouring clouds of smoke in the direction of the workers.

Hislop, who was among the fire fighters, volunteered to skirt around the flames toward the men through a return airway. Upon reaching the furthest end of the rapidly moving fire he closed the main doors and short-circuited the ventilation back through the airway, cutting off and checking the flames. Rather than return through the airway to safety he elected to push through to where the frantic workers were huddled.

Resourceful Foreman Who Saved 62

Thomas Hislop, age 51, mine foreman of Temple Anthracite Coal Co., whose presence of mind saved lives of 62 miners in fire in Mount Lookout Mine, Wyoming, Pa., on May 27.

Once with the men he reassured them, explaining that it would be but a matter of a few hours before the flames would be extinguished and they could leave the workings in safety. The fire burned for more than four hours. It was extinguished by two streams of water pumped by Exeter and Wyoming (Pa.) fire companies in lines dropped down the shaft.

The cause of the fire has not been ascertained. One version has it that a naked-flame lamp left in a footman's shanty at the landing tipped over and started the blaze.

Thomas Hislop will be recommended to the Carnegie Hero Commission for recognition and award. W. P. Jennings, of Scranton, Pa., president of the Temple Anthracite company, who led the fire fighters in the threatened area, will present Hislop's name.

Lake Cargo Hearing July 20

The Lake Cargo Coal Rate Case, Docket 15007, has been set for hearing July 20, 1926, at 10 a.m., at the Marlborough-Blenheim Hotel, Atlantic City, N. J., before Commissioner Hall and Assistant Chief Examiner Gerry of the Interstate Commerce Commission.

Official Leads Volunteer Rescue Workers

W. P. Jennings (with pipe in mouth), president of the Temple Anthracite Coal Co., who led rescue workers in fighting Mount Lookout mine fire, Wyoming, Pa., on May 27, surrounded by volunteer aids. George F. Gallagher, superintendent of the Lehigh Valley Coal Co., right foreground, who assisted in work.

Wholesalers Hold Convention In Toledo Next Week

The American Wholesale Coal Association will hold its tenth annual convention at the Hotel Secor, Toledo, Ohio, June 7-9. Business sessions will be held in the mornings. The afternoons will be given over to a golf tournament.

The business session on June 7 will be devoted to the presentation of official and committee reports. On June 8 the convention will hear addresses by Ira C. Cochran, commissioner of the organization; Joseph Harrington, combustion engineer, who will speak on "The Use of Pulverized Fuel," and Owen Meredith Fox, executive vice-president, Chicago Coal Merchants' Association, who will discuss "Retailer and Wholesaler Co-operation Toward the Establishment of a Fuel Research Institute."

Noah H. Swayne, 2d, of Philadelphia, will be the toastmaster at the annual association banquet on Tuesday evening. The principal speaker will be Senator James E. Watson, of Indiana. The program for the final business session includes the election of officers and the reports of the resolutions and trade relations committees.

Predicts Bright Future for Texas Coal Trade

The future of the coal business in Texas is bright, said D. M. Faulkner, of Dallas, at the annual meeting of the Retail Coal Dealers' Association of Texas, held at the Baker Hotel, Dallas, May 18 and 19. Lower prices may be expected, he said, due to the passing of trouble with Oklahoma miners, which, he declared, resulted in the diminution of union influence in that region. The year 1926 will be better than the year 1925 and by the year 1928 unusual prosperity may obtain, he said. Fuel oil, he declared will be largely removed from troubling the coal industry. Elijah Coles, past president, deplored the small attendance at the meeting and urged increasing the membership.

A number of timely topics were included in the addresses and a question box brought out interesting discussion of pressing trade problems. Wastage of coal between mine and retail yards was declared to be one of the gravest of the dealers' problems. They declared in favor of requiring railroads to weigh cars of coal free of charge at the point of destination rather than at the mine. Speakers for this measure declared that such a practice would cause railroad employees to exercise greater diligence to prevent both loss by leakage and theft by trespassers.

The convention unanimously indorsed a resolution asking that retailers be permitted three days' free time instead of two days for unloading shipments of coal.

Hugh L. Wallace, Fort Worth, was elected president and McAlester, Okla., was chosen as the 1927 meeting place. Other officers elected were Tillman Bibb, Fort Worth, second vice-president; Bruner R. Penniman, Dallas, third vice-president, and Clarence R. Goldman, Dallas, re-elected secretary-treasurer.

Pierce Defends Quality and Sizing of Anthracite

Daniel T. Pierce, vice-chairman of the Anthracite Operators' Conference, in a statement May 31, took strong exception to the charge made by Representative Hamilton Fish that anthracite operators were "selling standard quality of coal, such as chestnut or buckwheat, mixed with a large proportion of inferior grades, and often containing from 20 to 30 per cent non-combustible substance."

"The industry resents such statements," said Mr. Pierce. "The industry does not follow the practice of adulterating its product. On the contrary, it uses every care and employs every known means of removing foreign material from anthracite.

"Statements made from time to time that the anthracite industry has cut down the standard sizing of coal are not true. Partly due to non-observance of established practices during the war, there grew up certain variations in the sizing of anthracite which, once the emergency was over, caused unfavorable comment. To cure this and to establish definite standards by which dealers and consumers could test anthracite, the operators agreed, in March, 1925, upon uniform sizing for egg, stove and chestnut coal and the allowable percentages of impurities."

The only change made from former practice, according to Mr. Pierce, was in connection with chestnut, where an extra allowance was made for 5 per cent undersize due to unavoidable breakage. However, Mr. Pierce added, since the strike ended in February, no operator's output had contained the maximum undersize or impurities permitted under the adopted standards.

To determine just what percentage of degradation occurs between the mine and the consumer, the operators will begin the first of next week a series of tests which will cover each step of the operation of delivering the fuel. There will be the usual test for size and purity at the mine. Another test for size will be made at the New Jersey docks when the coal arrives, still another is to be made when the coal has been loaded on the barges, another when it is delivered in the retail dealer's bins and a final test when the coal is on the truck ready for delivery to the consumer.

Summer Coal Mining Course At State College

A five weeks' summer course in practical coal mining will be instituted soon by the School of Mines and Metallurgy of Pennsylvania State College, State College, Pa. The course, which will begin June 21, is free to all men about anthracite or bituminous coal mines, practical miners, firebosses and mine foremen especially being invited.

The first week will be devoted to the following subjects: Mine safety, 44 hours, for men not having Bureau of Mines certificates; teacher training or mining subjects, 30 hours, and renewal of Bureau of Mines certificates, 14 hours, for men who already have such certificates.

During the last four weeks, for those preparing for state examinations, the studies embraced will be as follows: Mining law, 20 hours; mine gases, 12 hours; mine timbering, 6 hours; blue print and map reading, 10 hours; mine management, 6 hours; mine ventilation, 12 hours; safety lamps and gas detectors, 10 hours; mining methods and machines, 6 hours; mine fires and explosives, 6 hours; mechanical equipment, 10 hours; explosives, 6 hours; electives, 10 hours; conference and review, 38 hours.

Men qualified for advanced work are privileged to take optional subjects from the above and in addition the following: Mine ventilation calculations, 12 hours; mine mechanics, 6 hours; drawing and mapping, 20 hours; electricity, 14 hours; ventilation laboratory and fan testing, 20 hours; surveying, 50 hours; use of explosives, 5 hours; geology of coal, 5 hours.

Prominent mining men will speak on special mining subjects, moving pictures of operations will be shown and the Bureau of Mines safety car will be on hand during the first two weeks of the course. Further information about the course may be obtained by addressing E. A. Holbrook, dean of the School of Mines and Metallurgy, State College, Pa.

The state Department of Mines announces that examinations for bituminous mine foremen and firebosses will be held at State College on July 21, 22 and 23, at the close of this course. The department also reports that it hopes to be able to announce similar examinations open to men from the anthracite field.

To Ally 500 Trade Bodies Against Snooping

With a view to combating interference of the government with the normal processes of legitimate business, members of the American Supply & Machinery Manufacturers' Association, at their annual convention at the Hotel Statler, St. Louis, May 18-20, authorized a committee to take up with the more than 500 organized trade bodies in the United States a proposal to hold a meeting to "consider ways and means of bringing forcibly to the attention of Congress the necessity of amending the Sherman and other so-called anti-trust laws so that business can function fearlessly along legitimate and sensible lines."

The executive committee of the association was instructed to assist the special committee, headed by Dixon C. Williams, Chicago Nipple Mfg. Co., in its efforts to unite these trade associations into a concrete body with a definite aim. At the same time a sum not to exceed $500 was appropriated to defray the organization's portion of the total expenses of the centralized campaign against governmental "snooping" in purely business channels.

Engineering Foundation Lays Plans for Research

The quarterly meeting of the Engineering Foundation was held on May 19, members and guests gathering for dinner at the Union League Club, New York. Edward Dean Adams, John Fritz medalist 1926, was guest of honor.

Financial assistance was granted to two research projects requested by the American Institute of Mining and Metallurgical Engineers and the American Institute of Electrical Engineers. The sum of $4,000 a year for three years was granted for research in blast furnace slags by Professor R. S. McCaffery, University of Wisconsin. The sum of $5,000 a year for two years was granted for research in electrical insulation by Professor J. B. Whitehead, Johns Hopkins University.

Adams Makes Gift to Foundation

On behalf of the endowment committee W. L. Saunders announced that a contribution of $100,000 has been made to the Foundation by Edward Dean Adams. In response to an appropriate resolution Mr. Adams was elected an honorary member for life in recognition of his service as vice-chairman of the Engineering Foundation for the past ten years.

Addresses were made by Dr. John A. Mathews, president of the Crucible Steel Co. of America, on "Present Tendencies in Engineering Materials," and by Prof. Richard S. McCaffery on "Research in Iron Blast Furnace Slags." Dr. Mathews paid his respects to the present tendencies toward standardization in engineering materials through written specifications which are often practically useless. He deplored the necessity of "manufacturing down to a specification rather than up to an ideal." Unless specifications offer an advantage to both the maker and the buyer and contribute to public welfare they often are bars to progress. Dr. Mathews stated that metallurgy is rapidly becoming a branch of physical chemistry and cited alloy steels resistant to corrosion and high temperatures as examples of scientific efforts to meet engineering demands.

Begin Study of Production In Relation to Safety

Active work has been started on the American Engineering Council's study of the relationship of safety and production. The work is being directed by A. R. Berresford, executive vice-president of the Nizer Corporation, of Detroit. The study is to cover ten basic industries as follows: Iron and steel, steam railroads, cement, mining, woodworking, metal trades, paper and pulp, textiles, electric utilities, and building construction. The field work is to be completed by Sept. 1. Data will be gathered from some 2,000 plants. Records showing the accident frequency rate and its bearing on the rate of production will be studied over as long a period as new records are available. In addition a specific study will be made to determine what occurs incidental to the loss of man hours, machine hours and curtailed production.

Digitized by Google

Equipment Makers Organize To Promote Fuel Economy

A number of representative manufacturers of equipment for the more efficient burning of small sizes of anthracite, particularly for users of large quantities and where plants can be installed or altered, if necessary, at less expense than for the use of oil or other substitutes, have formed an association with the following officers: W. D. Craven, Pyramid Iron Products Co., president; F. B. Williams, Graybar Electric Co., vice-president; J. B. Nicols, American Blower Co., treasurer; F. B. James, New York *Commercial*, secretary.

The new organization is intended to promote efforts for fuel economy, which have been widely discussed since the anthracite strike. These discussions have resulted in the recommendation of increased use of buckwheat by both large and small consumers of anthracite, either as a mixture with other sizes or alone.

The anthracite operators have promised co-operation in order to insure a dependable supply at reasonable prices. Retailers also are giving assurance of willingness to do their part in moving the smaller sizes, which will insure a sufficiency of the larger sizes and tend to keep prices at an even level as well as prevent economic waste.

N. & W. and Virginian Protest Proposed Ban on Merger

Twelve exceptions to the proposed report of Haskell O. Davis, an Interstate Commerce Commission examiner, turning down the application of the Norfolk & Western Ry. to acquire control of the Virginian Ry. are set forth in a brief filed with the Commission by the Norfolk & Western last week.

Because of the principles involved, the Norfolk & Western asked permission to present oral arguments in support of its contention and to do so before the full commission.

The Virginian Ry. also has filed a brief with the Commission taking exception to the tentative recommendation against the merger.

A considerable portion of the examiner's report regarding financial phases of the Virginian's operations were disputed in the brief, which added that it was difficult to ascertain from the record what weight had been given these findings by the examiner in reaching the conclusion that the lease would be against the public interest.

Fayette Institute Outgrows Present Facilities

The Fayette County (W. Va.) Mining Institute held its sixth annual dinner at the Loup Creek Y. M. C. A., in Mount Hope, W. Va., May 8, with over five hundred members and guests present.

Short addresses were made by J. J. Rutledge, Chief Engineer of the Maryland Bureau of Mines; R. M. Lambie, Chief of the West Virginia Department of Mines; Dr. C. E. Jones, dean of the College of Engineering of the University of West Virginia; L. C. Hudson, former instructor in West Virginia University but now Director of Mining Extension in Maryland; C. E. Lawall, professor of mining engineering and Director of Mining Extension of West Virginia University, and Adam Crawford, Assistant Director. The speech-making was closed by Robert Lilly, president of the institute, who stated that the organization had grown so large in membership and enthusiastic in spirit that the opening of the next term would see all present accommodations outgrown and that the time had come to look forward to obtaining quarters of their own.

R. J. Holmes, as announcer, introduced each speaker to the audience, and acted as a sort of roving chairman.

Labor Well Cared For and Contented, Says Gary

"It may and should be said that employers in the United States generally stand for fair and liberal treatment of employees," said Judge Elbert H. Gary, chairman of the board, United States Steel Corporation, speaking of labor conditions, at the meeting of the American Iron & Steel Institute, at the Hotel Commodore, New York, on May 21. "They believe in the open shop, which permits a man to work whenever and wherever he is disposed and can agree with the employer. They insist labor should always receive proper and adequate compensation, depending on the financial ability of the employer and the results of the business. . . .

"We do not believe he [the employee] should be entitled to a voice in the management of the employer's property or business unless he has a pecuniary interest and corresponding responsibility.

"It may truthfully be said that labor generally in the United States is well cared for and is contented. In some lines or places it is overpaid; in some instances perhaps underpaid, though it is hoped and believed such cases, if any exist, are exceptional and will be rectified."

Railroads Make Big Strides In Fuel Economy

Direct purchases of fuel during 1925 by Class 1 railroads of the United States totaled $459,465,341, 2.6 per cent less than in 1924 and considerably less than in 1923. The railroads in 1925 bought 129,325,480 tons of bituminous coal, an increase of 2.3 per cent compared with 1924 although freight traffic in 1925 was approximately 6 per cent greater. Purchases of bituminous coal in 1925, however, fell 16.5 per cent under 1923 while freight traffic compared with two years ago was practically the same, measured in net ton miles. In 1925 the roads purchased approximately 28 per cent of the total output of bituminous coal as well as about 20 per cent of the fuel-oil output.

Due to improved locomotives and other factors, the railroads of this country are operating their freight trains with the greatest efficiency in the use of fuel ever attained, and this is reflected in the reports on fuel consumption. In 1925 an average of 159 lb. of fuel was required to haul 1,000 tons of freight and equipment, excluding locomotive and tender, a distance of one mile. This was a decrease of 11 lb. from that for 1924 and 24 lb. under 1923, and was the lowest average ever attained since the compilation of reports by the Bureau of Railway Economics began, in 1920.

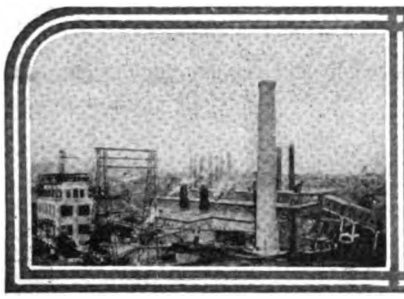
In 1925 more fuel oil was purchased than in 1924 by 6.9 per cent, but the total cost was greater by 22.3 per cent.

Traffic News

Recommendations and Decisions Announced by I. C. C.

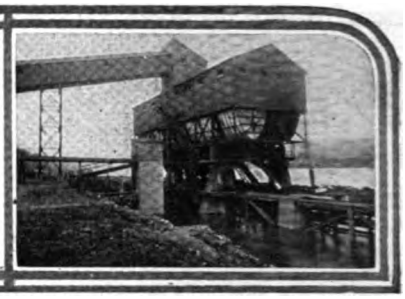
The Strouds Creek & Muddlety R.R. filed a complaint with the Interstate Commerce Commission in Washington, D. C., on May 29, against the Baltimore & Ohio R.R. alleging that the division of the coal-carrying rate is not sufficient to make it profitable. The Strouds Creek & Muddlety R.R. extends from Delphi to Allensdale, in Nicholas county, W. Va., and taps rich fields of smokeless and semi-anthracite coal.

The complaint of the Fentress Coal Co. alleging unreasonable rates on coal from Tennessee points of origin to points in Iowa, should be dismissed, Examiner Jewell has recommended to the Interstate Commerce Commission.



A basis for the establishment of freight rates on lignite from North Dakota points of origin to points in Minnesota and South Dakota has been recommended to the Interstate Commerce Commission by Examiner Harris Fleming.

Examiner Fuller of the Interstate Commerce Commission has recommended a new schedule of rates on anthracite from mines on the Delaware & Hudson R.R. and on bituminous coal from the Clearfield, Westmoreland and Pittsburgh districts, to Willsboro, N. Y. He also recommends reparation to cover excessive charges in the past. Examiner Boat recommends the dismissal of the complaint alleging unreasonable rates on bituminous coal from Herrin, Ill., to points in Michigan. He recommends the refunding of certain overcharges in connection with these rates.



Condemns Proposed Reductions

Proposed reductions in rates on coal from Springfield and Riverton, Ill., to Keokuk, Iowa; Hannibal, Mo., and related points have been disallowed by the Interstate Commerce Commission in *Bituminous Coal to Iowa, Illinois and Missouri*. The proposed reductions were an attempt upon the part of the Alton and Wabash railroads to meet rates established by the Burlington at Keokuk in conformity to the Commission's decision in *Illinois Coal Cases*, 62 I.C.C. 741. The Wabash and Alton rates would have destroyed the differential adjustment prescribed in that decision.

News Items From Field and Trade

ALABAMA

Shift Convict Leasing Probe.—The grand jury which has been probing Alabama's convict leasing system suddenly shifted its investigation recently to Banner Mine, where an inquiry into a mutiny two years ago was halted by Gov. W. W. Brandon. The decision to start a new inquiry at Banner Mine is regarded as an indication that the jury is determined to bring the leasing system to an end by its revelations.

New Washery Starts.—The Porter Coal Co. has placed in operation its newly completed washery at Porter mine, near Palos. The company has made a large outlay at this operation recently in order to increase production and improve preparation. The mine is owned and operated by W. C. Adams and E. J. Rowe, Birmingham.

New Premier Slope?—It is understood that the Premier Coal Co., operating the Mossboro mine, at Helena, Shelby County, is contemplating the opening of another slope at that point.

Southern Seeks New Line.—The Southern Railway Co. has asked permission of the Interstate Commerce Commission for authority to acquire the portion of the Ensley Southern R.R. branching from its line at Parrish, Ala., and serving the Gorgas mine of the Southeastern Coal Co., the Stith Coal Co. and other operations in Walker County. The line has been in receivership for a year or more. The main line extending from Ensley, Ala., to Port of Birmingham, was acquired recently by the Port of Birmingham Corporation to be operated by the Inland Waterways Corporation as a connecting link between Birmingham and the Warrior River barge service.

The Neill Coal Co. has opened a slope mine on the Southern Ry. near Coalburg on property leased from the Sloss-Sheffield Steel & Iron Co.

ARKANSAS

Jailed for Violating Injunction. — Lindsey Hedgepeth, of Dardanelle, Yell County, was sentenced to six months in jail and assessed all costs of prosecution by Judge Trieber in U. S. District Court at Little Rock last week for violation of an injunction restraining union miners from interfering with property or employees of the Bernice Anthracite Coal Co.'s mines at Russellville. Hedgepeth was charged with contempt of court in having intimidated two negro miners as they were approaching the mines. Lack of evidence against Will Martin, charged with having intimidated miners at a railroad station at Russellville, resulted in the court finding him not guilty. The injunction which Hedgepeth is alleged to have violated was issued by Judge Trieber last September following labor disturbances at the coal mines in Russellville in connection with a strike of union miners.

CALIFORNIA

Form $10,000,000 Coal Company.—The Mt. Shasta Coal Co. has filed articles of incorporation with a capitalization of $10,000,000 for the purpose of mining coal in Shasta County. For several months extensive development work has been carried on along Clover Creek and Oak Run, twenty-five miles northeast of Redding. Reports from time to time have told of ledges having been cut into up to as high as 14 ft. in thickness. Three different coal development camps have been maintained. Five miles of power line were built to furnish power. The company now controls more than 15,000 acres in the central part of Shasta County in what is known as the Oak Run and Round Mountain districts. The directors of the corporation are Charles A. Dickey, of San Francisco; H. C. Morris, of Oakland, a director of the American Bank; S. E. Biddle, of Piedmont, president of the new First National Bank of Oakland; A. P. Cross, Los Angeles capitalist; John A. McCandless, sugar and tractor magnate of Honolulu; A. F. Hockenbeamer, of Berkeley, vice-president of the Pacific Gas & Electric Co.; Harry H. Fair, president of Peirce, Fair & Co., fiscal agents; R. Ferbeck, of San Francisco; E. L. Dow, San Francisco capitalist and head of River Garden Farms, and John L. McNab, attorney, of San Francisco.

COLORADO

April Output Increases. — Colorado mines produced 805,729 tons of coal during April, an increase of 112,132 tons over March, according to the monthly report of James Dalrymple, state coal mine inspector. Total output for the first four months of 1926 was 3,430,619 tons, compared with 3,500,421 tons in the corresponding period of 1925.

The Black Diamond Fuel Co. has been incorporated to take over the mine of that name east of Boulder and to produce and sell its coal. W. W. Morgan is president of the new company; F. W. Thurman, who has been associated with him in the management of the Crackerjack mine at Marshall for eleven years, is secretary-treasurer, and Jim Bertotti, who was associated with the company from whom the Black Diamond was purchased, is vice-president of the new company. Tom Hilton is superintendent.

Cuts Wages to 1917 Level.—The Vickers Coal Co., Trinidad, notified the state Industrial Commission last week that it was reducing the wages of its men at the Aguilar mine to the 1917 scale. The company said it took this action to place its wage scale on the basis of mines operating in the same district. About forty men are affected.

To Sell National Fuel Co.—Sale of the National Fuel Co., Denver, now in the hands of a receiver, has been authorized by District Judge George F. Dunklee, who signed a decree granting the International Trust Co., as trustee, foreclosure under a deed of trust and a judgment against the fuel concern for $1,464,375.01. H. Van Mater, receiver for the National Fuel Co., was instructed by the court to give nine weeks' notice of the sale of the property at public auction at 511 Colorado Building at noon on a date to be fixed by Van Mater. The receiver also was instructed not to accept any bid under $400,000. The trust company was the holder of a mortgage on property of the fuel company, given to secure a $2,000,000 bond issue. The fuel company owns property and lands in Denver, Boulder, Weld and Las Animas counties.

INDIANA

State Gets Coal Cheaper.—Awards recently made by the state Joint Purchasing Committee on coal for the coming year for various state institutions are substantially less than expiring contract prices. For instance, where the state last year paid $1.73 a ton for screenings, the price under the new award is $1.54. Successful bidders were the Jackson Hill Coal & Coke Co., White Ash Coal Co., Patoka Coal Co. and Ogle Coal Co., all of Indianapolis; Walter Bledsoe & Co., Terre Haute; J. H. Scott Coal Co., Vincennes; Ayshire Coal Co., Oakland City; Tildesley Coal Co., Cincinnati, Ohio; Madison Coal & Supply Co., Madison, and Brazil Coal Co., Brazil. The contract will cover about 300,000 tons during the year.

Electric Road Scheme Revised.—The proposition to build an electric line from Owensboro, Ky., to Elnora, Ind., through the coal fields of Warrick, Pike, Daviess and Green counties in Indiana, has been revived. It is said that English capitalists are back of the move. The Interstate Commerce Commission refused to sanction the building of the road several months ago, but

Digitized by Google

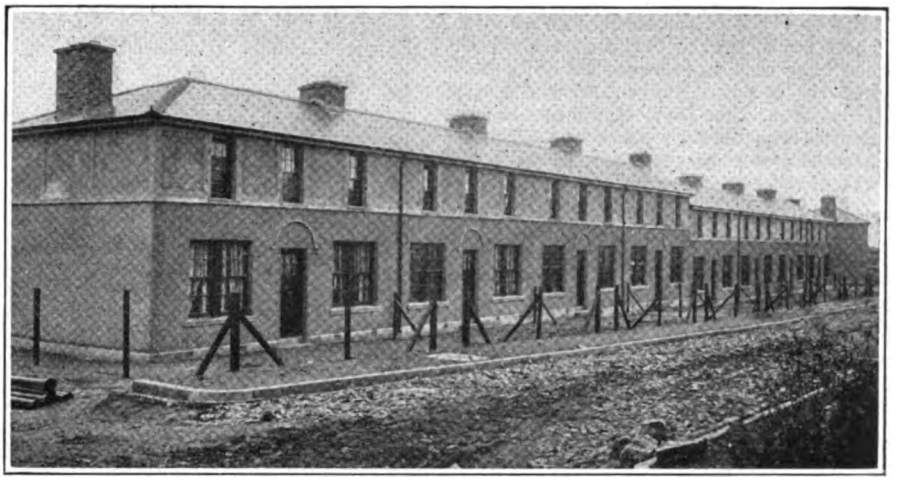
steps will be taken, it is said, to have the petition reconsidered. The company proposes to bridge the Ohio River near Rockport. It is said the aim of the company is to develop coal fields in southern Indiana.

Indiana coal fields are now operating at greater capacity than at the same period last year, according to William Mitch, secretary-treasurer of District No. 11. He said that indications pointed to normal production schedules during the summer months. About 70 per cent of the mines in Indiana are said to be in operation at the present time.

KENTUCKY

To Improve Russell Yard.—Railroad officials of Columbus have been advised that the Chesapeake & Ohio Ry. will spend approximately $500,000 in reconstructing the yards at Russell, Ky., which is across the river from Portsmouth, Ohio. The improvement is to facilitate the movement of coal from West Virginia mines to the lakes. The coal is shipped through Columbus over the Norfolk & Western Ry., going north to the Toledo docks over the Hocking Valley Ry. Additional automatic devices will be installed in order to speed up the movement of coal.

Construction work on the new $700,000 electric power plant to be erected by the Kentucky Electric Power Co. at Nortonville is scheduled to start soon. The Norton Coal Co.'s mines at Nortonville will be supplied with power from this plant, it has been announced.



Storm King Mine Sold.—The C. L. Ryley Coal Co., of Lexington, has acquired the property of the Storm King Mining Co., of New York, located in Perry County. The property is located three miles east of Hazard on the Louisville & Nashville Ry. and includes the Storm King mine and more than 200 acres of land. The mine has a daily output of 400 tons. The purchaser paid $100,000.

Arnold Mine Suspends.—The West Kentucky Coal Co. has suspended operation of its Arnold mine, at Earlington, temporarily because of unfavorable market conditions. The suspension will continue for about three weeks. About 250 men are employed at the Arnold mine and they will be distributed among the other mines of the company.

PENNSYLVANIA

P. & R. C. & I. Has Deficit.—A net loss of $4,115,567, after depreciation, depletion, interest and taxes, is reported for the year ended Dec. 31, 1925, by the Philadelphia & Reading Coal & Iron Co. and subsidiaries. This is in contrast with a net income of $1,020,593, or the equivalent of 72c. a share earned on 1,400,000 shares in 1924. Coal sales in 1925 totaled $70,623,106 against $83,511,650 the year before. Other income was $320,498, against $612,406. Production costs, general expenses, etc., were $69,674,064, against $77,641,497; depreciation and depletion, $1,218,091, against $1,504,503; federal and local taxes, $2,498,504, against $2,346,771, and interest, $1,668,512, against $1,610,092.

Constitutionality of the anthracite tax law is involved in the case of the Commonwealth vs. the Hudson Coal Co., argued last week before the Pennsylvania Supreme Court at Harrisburg. The case was carried to the state's highest tribunal on appeal from a decision of the Dauphin County Court of Common Pleas which held that the company should pay the state the sum of $43,350 in taxes.

Houses at the Newtownkelly Mine, in Northern Ireland

Substantial work has been done by Sir Samuel Kelly at his new colliery in Ulster. Note the curbs on both sides of the street. The mine is at Coalisland, Tyrone, not far from Lough Neagh, the largest body of inland water in Ireland.

During the present spring thirty-seven mining companies of Pennsylvania planted more than 1,565,000 trees on their property. These trees will produce mine timbers, ties and props in from 25 to 40 years. The state Department of Forests and Waters has announced that up to the present time the mining companies of Pennsylvania have planted more than 8,383,000 forest trees supplied from the state nurseries.

Proctor Mine Deserts Union.—Proctor mine, located at Force, has resumed operations on the 1917 scale, adding another mine to the list of those that have deserted the union rate.

Randolph Disaster Due to Dynamite.—After hearing the testimony of almost a score of witnesses during a period of five hours, the coroner's jury convened to inquire into the cause of the fatal accident at the Randolph colliery, Port Carbon, on May 6, in which five men lost their lives, returned a verdict finding that the men met their death as a result of an explosion of dynamite. Mine Inspector Brennan testified that he visited the mine on March 18 and found gas and gave instructions regarding changes in ventilation to eliminate the trouble. The company had the changes under way when the explosion occurred. The inquest was conducted by Coroner K. M. Schultz at his office in Port Carbon.

As a reward for long and faithful service in the mines of the Pittsburgh Coal Co., 24 miners have been placed on the pension list by favorable action on their applications by the advisory committee governing the pension fund of the company. This makes a total of 246 miners on the pension roll. More than $45,000 is required to fulfill the pension payments for one year.

Supreme Court Allows Bell Appeal.—John A. Bell, Pittsburgh banker and coal operator, has been granted an appeal by the state Supreme Court of Pennsylvania from his conviction last fall on a charge of embezzling more than $600,000 of the funds of the defunct Carnegie Trust Co., of which he was president. The appeal is being taken on a constitutional point relating to the statute of limitations. Bell's counsel contended that the statute of limitations of four years should have governed his indictment under the act of 1878. The Superior Court declared that the act was unconstitutional. The law had been on the statute books of Pennsylvania for nearly 50 years without its constitutionality having been tried before the higher courts. The case will be argued before the next session of the state supreme court in Pittsburgh.

Poland Fire Loss $40,000.—Fire at the Poland coal plant of the Maple-Sterling Coal Co., in Greene County, May 25 destroyed two tipples, two coal bins, two dumps, three motors and the entire conveying and loading system, with a total estimated loss of $40,000. Origin of the flames is as yet undetermined. The flames were first discovered by John Barney, clerk of the coal company's commissary. With the aid of other men about the plant he succeeded in saving the main tipple. The plant will be rebuilt immediately, officials of the company say.

The Snowdon Coke Co. has completed the erection of coke crushing and screening equipment at its plant near Brownsville, Fayette County, and is trying it out.

WEST VIRGINIA

The Wilhelmina Collieries Co. has changed its name to the Morningside Land Co., and the Talbott Chambers Coal Co., a foreign corporation, will hereafter be known as the Dragon Coal Co.

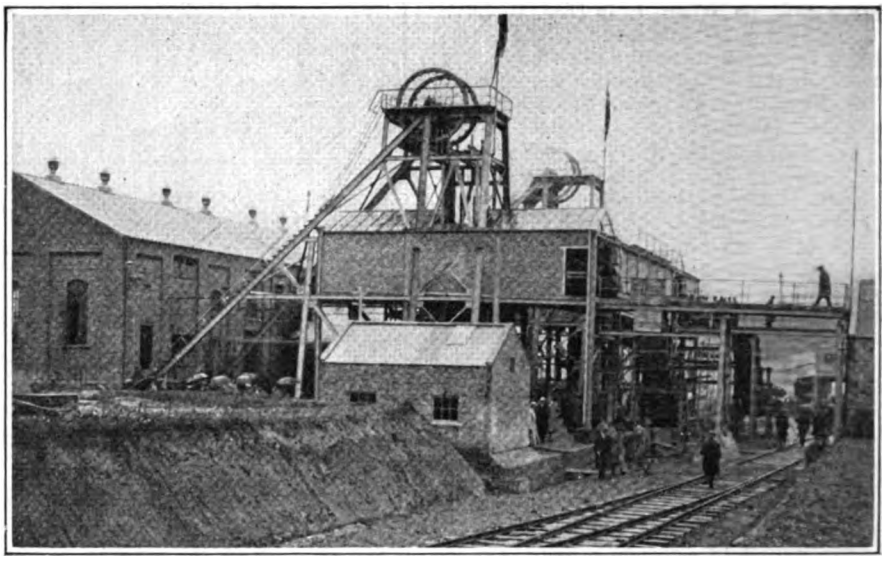
The Buckeye Coal Mining Co. has filed a certificate of dissolution with the Secretary of State of West Virginia, and the **Vester Coal Co.** has been dissolved by deed of sale.

Since beginning to operate its No. 1

Digitized by Google

mine in the Scotts Run field on an open-shop basis the Gilbert-Davis Coal Co. has been able to increase its daily loadings to a point above 14 cars a day. This was the last company in the Scotts Run field to cease operating its plants under an agreement with the union.

By foreclosure proceedings in Cincinnati on May 15, it is announced, the Otto Marmet Coal & Mining Co., of Raymond City, Putnam County, W. Va., obtained a clear title to its property, which was sold several years ago to J. C. McKinley, of Wheeling, who went into bankruptcy some time ago. Mortgages against the property totaled $1,250,000. The property consists of several mines at Raymond City, steamboats, barges, wharfs and coal yards in Cincinnati. The company proposes making some extensive improvements, according to reports.



Judge Birk S. Strathers, of the Harrison County Circuit Court, has been asked to appoint a receiver for the Francois Coal Co., operating a mine at Norwood, in Harrison County; the Anna May mine, in Monongalia County, and the Vincent mine, in Marion County. The petition was made in the suit of the Clarksburg Trust Co., trustee, and John A. McNichol, president of the coal company, brought for the purpose of getting a court order for the sale of the property and at the same time have a receiver appointed to operate the mines but with authority to borrow not more than $20,000. Indebtedness of the company is approximately $180,000, it is said.

More Houses for Nelson Fuel.—The Nelson Fuel Co., Leslie, Greenbrier County, will soon start the erection of 50 new houses at its plant, which is located along the Sewell Valley Ry. It probably will require 60 days to do the work and about $50,000, it is reported, will be expended. The Sewell seam is mined there.

New Babcock Plant.—The Babcock Coal & Lumber Co., Cliff Top, Fayette County, is erecting a wooden tipple with shaker screens, loading booms and conveyor lines. The tipple will have a capacity of 1,500 tons daily. The plant is located along the Chesapeake & Ohio Ry. and will be completed in 90 days. The Sewell seam is mined there.

Safety Day Committee Named.—In preparation for the observance of Safety Day, to be held Aug. 31. Robert M. Lambie, chief of the state Department of Mines, who is acting as chairman, has named the following committee on general arrangements: Archie Forbes, Lundale; Clyde McDowell, Thomas; J. V. Berry, Bethlehem Mines Corp., Johnstown, Pa.; T. J. McParland, Gary; Vitus Kleir, Gary: G. L. Wilson, Minden; Edgar Blackwell, Scarbro; C. J. Flippen, Kingston: James Gatherum, American Rolling Mills Co., Middletown, Ohio; W. A. Eads, Fordson Coal Co., Stone, Ky., and W. H. Forbes, U. S. Bureau of Mines, Huntington. It is planned to hold a state first-aid and mine-rescue contest on Aug. 31. Huntington probably will be selected, but this has not been definitely decided.

Rock-Dusting Spreads Rapidly.—A year ago there were only the No. 2 and the No. 12 mines of the Boone County Coal Corporation, at Sharpless, were thoroughly rock-dusted. A year later finds 30 mines owned and operated by twenty-two companies as being rock-dusted—seven in the Panhandle district, five in the Pocahontas field, four in the New River field, two in the Logan field, two in Boone County and one in the Thacker field.

Newtownkelly Mine, in Ulster, Which Sir Samuel Kelly Owns

This mine at last reports was still operating, and Sir Samuel Kelly declared that he did not anticipate that the men would refuse to work or that the railroad would fail to give it service. The administrative area, known as Northern Ireland, like the Irish Free State, is free of the strike fever.

Plan Road to Untapped Field.—The Chesapeake & Ohio and the New York Central railroads will co-operate in buliding a 39-mile connecting line between branches of the two railroads through several counties of West Virginia rich in coal and timber hitherto inaccessible. A charter has been applied for at Charleston by the Nicholas, Fayette & Greenbrier R.R., capitalized at $8,000,000. The incorporators are equally divided between the New York Central and the Chesapeake & Ohio. The charter calls for the construction of a railroad from Swiss, in Nicholas County, the terminus of the Kanawha & Michigan, which is a subsidiary of the Central lines, to a point near Rainelle in Greenbrier County, on the Sewell Valley R.R., which in turn connects with the main line of the C. & O. at Meadow River.

Sale of the property of the Otto Marmet Coal Co. in West Virginia to Otto Reeselin, for $75,000, as authorized by the District Court for the southern district of West Virginia, has been approved in an ancillary decree handed down by the federal court at Cincinnati. The suit against the company was brought by the Fourth Central Trust Co. of Cincinnati and the property sold at Charleston under order of the U. S. Court there.

CANADA

Denies Seeking Subsidy.—"We have never, at any time, approached Mr. McCrea, or any other member of the Provincial Government, on the subject of a subsidy for the further development of anthracite at Larchwood, Ont.," said Albert Slade, secretary-treasurer of the British-Colonial Mines Co., in Toronto, commenting on a statement to the effect that the Minister had denied promising such a subsidy.

New Kay Moor Tipple Completed.—A new steel four-track tipple, among the best along New River, has been completed at Kay Moor No. 1 mine of the New River & Pocahontas Consolidated Coal Co. It has a capacity of 250 tons of coal an hour, and an output of 900 tons a day is now being handled. This mine, which was formerly owned by the Low Moor Iron Co., was purchased a little over a year ago by the New River & Pocahontas Consolidated Coal Co., which is the operating company in West Virginia for the Berwind-White Coal Mining Co., of Philadelphia.

Foreman "Exams" Announced.—The West Virginia Department of Mines announces examinations for mine foremen and firebosses as follows: Mechanical Hall, West Virginia University, Morgantown, July 26; Central School Building, Elkins, July 29; high school building, Welch, Aug. 9; high school building, Williamson, Aug. 12; Junior High School Building, Beckley, Aug. 16; Central Junior High School Building, Charleston, Aug. 19; high school building, Logan, Aug. 26, and high school building, Wheeling, Sept. 2.

Ontario Still Seeks Alberta Coal.—At a meeting on May 21 of the Ontario committee on coal, composed of mayors and other officials of a number of Ontario cities and towns, attended by producers and dealers of Ontario and Alberta, a sub-committee was appointed to inquire into the possibility of making a temporary arrangement for bringing a supply of Alberta coal eastward immediately. Premier J. E. Brownlee, of Alberta, will be assured of every assistance in any plan he proposes to obtain a lower freight rate on coal moving eastward. So far the determination of Sir Henry Thornton, president of the Canadian National Rys., to maintain the $9 rate remains unchanged.

Digitized by Google

Among the Coal Men

Robert Grant, who for several years has been president of the New England Coal & Coke Co. and the New England Fuel & Transportation Co., with headquarters at Boston, has also been elected president of the Mystic Steamship Co. and of the new Mystic Iron Works.

Duncan C. Kennedy, secretary of the Kanawha Coal Operators' Association accompanied by his wife and daughter, will sail on June 26 on the "Transylvania" for a two months' trip abroad. They will visit England, Scotland, France, Switzerland, Belgium, Holland and Germany.

Dr. W. S. Blaisdell, an Allegheny Valley coal operator, residing at Punxsutawney, Pa., is in the Clifton Springs (N. Y.) sanitarium, suffering from intestinal trouble. He is much improved, however, and expects to be at home within two or three weeks.

Lee Long, vice-president of the Clinchfield Coal Corporation, Dante, Va., has been elected president of the Virginia Coal Operators' Association. The new vice-president is **Webb J. Willits**, president of the Norton Coal Co., Norton, Va. C. B. Neal, also of Norton, was re-elected secretary-treasurer at the recent annual meeting held there.

L. E. Young, general manager of the Union Colliery Co., of Dowell, Ill., has been elected president of the Apollo Club of St. Louis. This is one of the highest class vocal organizations in the Middle West.

A. H. Crane, secretary-treasurer of the West Virginia Coal & Coke Co.; **J. Blaine Moore**, chief accountant, of Fairmont, W. Va., and **C. C. Campbell**, auditor, of Omar, W. Va., were in Cincinnati, May 10 to 12 conferring with W. M. Wilshire relative to moving general headquarters of the company there

Kirby Thomas is examining coal properties in Butler and Armstrong Counties, Pennsylvania.

Dr. T. D. Scales, who for many years was heavily interested in the John Bull coal mine and the Erie Canal coal mine, near Boonville, Ind., is now engaged in banking on a large scale. He is president of the Farmers and Merchants National Bank at Boonville; president of the Newburgh State Bank at Newburgh; vice-president of the City National Bank at Boonville and director of the Citizens' National Bank at Evansville, Ind.

J. G. Julian, who for many years was associated in the development of the coal industry in Evansville and other southern Indiana towns, has been engaged as manager of the Luhring Investment Co. at Evansville, Ind., and will help promote real estate in that city.

Robert Z. Virgin, editor of the *Coal Trade Bulletin*, Pittsburgh, Pa., until it suspended publication recently, and former assistant director of the mining extension department of West Virginia University, Morgantown, has joined the sales force of the Koehler Manufacturing Co., Pittsburgh, which manufactures the Wheat super-electric cap lamps for miners.

L. T. Putman, for some years assistant to the general superintendent of the Old Ben Coal Corporation at Christopher, Ill., has been transferred to the company's newly purchased properties in West Virginia.

Photo by Underwood & Underwood.

Charles O'Neill

O'Neill Succeeds Clark.—When the executive committee of the Association of Bituminous Coal Operators of Central Pennsylvania met at Altoona on May 17, B. M. Clark, of Indiana, Pa., resigned as president, and Charles O'Neill, of Altoona, was elected in his place. The association deals with the wage scale for the Central Pennsylvania Coal Producers' Association, of which Mr. Clark is president and Mr. O'Neill secretary. The two bodies will hold their annual meeting June 8.

S. A. Bacon, of London, England, connected with D. L. Flack & Sons Co., Ltd., London, coal wholesalers, visited the mines of the New River Coal Co. in southern West Virginia on May 13.

Charles Fox, of Terre Haute, Ind., former secretary of District No. 11, United Mine Workers, and one of the most popular members of organized labor in Indiana, has been elected chairman of the Vigo County Democratic Committee. Mr. Fox at one time was president of the Indiana Federation of Labor and during the Goodrich administration was appointed a member of the state Industrial Board.

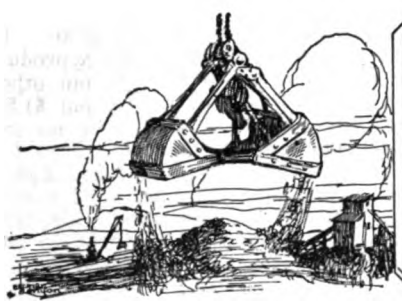
John Griffen, formerly assistant fuel engineer to the Lehigh Coal & Navigation Co., at Lansford, Pa., and later fuel engineer to the Hudson Coal Co., making tests on the burning of pulverized anthracite in stationary boilers and investigating the reclaiming of fine coal from breaker slush, after eight years spent installing equipment for such reclamation on behalf of the Dorr Co., has become sales engineer of the American Rheolaveur Co., of Wilkes-Barre, Pa.

Dr. Henry Mace Payne has been appointed consulting engineer and geologist to the Gulf, Mobile & Northern R.R. Dr. Payne will retain his connection as consulting engineer to the American Mining Congress, but has discontinued his office at 300 Madison Ave., New York City.

Clyde G. Brehm, of Uniontown, Pa., master mechanic and in charge of safety work at the coal and coke plants of the Oliver & Snyder Steel Co., has been appointed assistant general superintendent.

Charles H. Hinsey, of Uniontown, Pa., has been appointed general superintendent of the Oliver & Snyder Steel Co.'s coal and coke plants (Oliver Nos. 1, 2 and 3), near Uniontown, to succeed John H. Lane, who died last January. For many years Mr. Hinsey has been chief engineer of these properties, and shortly before Mr. Lane's decease he also was made assistant general superintendent.

George W. Hay has been appointed general manager of operations of the Consolidation Coal Co., with headquarters at Fairmont, W. Va.



P. J. Walsh, of Uniontown, Pa., has resigned the position of general superintendent of the Guy C. Corrado interests, with headquarters at Connellsville, Pa., and a number of small coal and coke plants scattered throughout the Connellsville coke region. Most of these plants have been closed down since the settlement of the anthracite strike, so that the position will not be filled at present. Mr. Walsh has not yet made any other connection.

William T. Payne, president of the East Boston Coal Co., Kingston, Pa., has been chosen chairman of the board of directors of Burns Bros., New York City, in succession to the late S. M. Williams. Mr. Payne, who also is vice-president of the Second National Bank of Wilkes-Barre, Pa., has been acting chairman.

Obituary

Albert Kemmerer Cosgrove, vice-president of the Cosgrove-Meehan Coal Corporation, of Johnstown, Pa., died in the Homeopathic Hospital, Pittsburgh, on May 25. He was stricken with pneumonia while on business in Pittsburgh. Mr. Cosgrove was born in Cambria County, Pennsylvania, Dec. 24, 1890. He was graduated from Lehigh University in 1913 with the degree of mining engineer. He entered the coal business with his brothers under the firm name of Cosgrove & Co., and for a time was located in Philadelphia, in charge of the offices there. He later was made vice-president of the Cosgrove-Meehan corporation and moved to Johnstown. He is survived by his mother, one sister and two brothers, George D. Cosgrove, of the Grazier Supply Co., of Johnstown, and John C. Cosgrove, chairman of the Cosgrove-Meehan corporation. The body was taken to Johnstown for interment.

Production And the Market

Bituminous Coal Market Tone Firmer, Aided by British Strike and Heavy Lake Movement

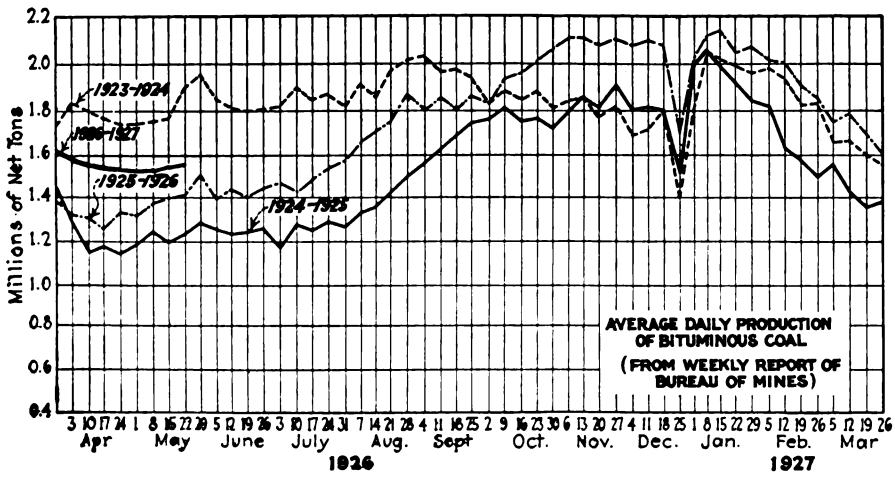
The bituminous coal trade of the country enters the new month with its technical and actual market position improved. The chief factor in this betterment, of course, has been the steady flow of coal to the lakes. Although the season was slow in starting, the weekly movement now tops the 1,000,000-ton mark. This diversion of tonnage from all-rail channels has had a direct beneficial influence upon a large part of the Appalachian Region and indirectly has helped other fields.

A secondary favorable factor has been the prolongation of the British strike. To the speculative element in the industry the reaction, both in prices and in the volume of buying, has been disappointingly feeble. Nevertheless, there has been a moderate increase in foreign orders and an expansion in bunker trade. This has contributed to a healthier undertone in the Atlantic seaboard markets.

Production as a whole also has been cut closer to actual consumer demand. During the week ended May 22 the total bituminous output was estimated by the Bureau of Mines at 9,295,000 net tons—or 4,000 tons less than during the preceding week. Production rates recorded in those two weeks marked the first increase in output in a month. The increase, however, falls far short of equaling the weekly lake dumpings, which totaled 1,256,679 tons of cargo and 55,161 tons of vessel fuel for the week ended May 30.

Spot Prices Stronger

These favorable factors are reflected in an unevenly distributed increase in spot quotations. *Coal Age* Index of spot bituminous prices on May 31 was 160 and the corresponding price was $1.94. A week earlier the figures were 157 and $1.89, respectively. Eastern and southern slack prices were higher and there was a stronger tone to pool quotations along the Atlantic seaboard. Illinois and Indiana figures were unchanged. The price situation at the Head of the Lakes and in Colorado and Utah was unsettled.



The Central Competitive Field probably is the hardest hit in the present struggle for business. Ohio, except for a few mines in the Pomeroy Bend district and operations with direct dock connections, is out of the lake picture. Non-union tonnage is growing in western and central Pennsylvania, but profits are not keeping pace with the increases.

Anthracite Decline Accelerated

Current weekly anthracite output is now making clear the justification for the complaints as to market conditions voiced in the hard-coal trade for some time back. During the week ended May 22 the estimated output dropped to 1,750,000 tons. Part of this decline, it is true, was attributable to time lost by the miners in voting and electioneering for Governor Pinchot. Consumer demand, however, will not absorb full-time production.

The larger companies have been able to move their tonnage of domestic sizes through the regular channels of trade. It is freely admitted, however, that these companies soon must look for new business unless the market improves. Nominal premiums are the best that average independent shipper can command and there are some who are ready to make concessions to move tonnage. Steam sizes, except barley, drag.

The Connellsville coke trade is dull. Production during the third week in May showed a small increase, but spot quotations on standard furnace and foundry grades, though nominally unchanged, were softer.

Estimates of Production

(Net Tons)

	1925	1926
BITUMINOUS		
May 8	8,277,000	9,039,000
May 15 (a)	8,350,000	9,299,000

Middle Western Coals Weak

Neither steam nor domestic orders for Illinois and Indiana coals brightened the outlook in the Chicago market last week. There were some operators who favored raising the price on 6-in. lump 10 or 25c. on June 1, but the majority did not believe buying conditions would support such a move. Eastern quotations, on the other hand, are stronger —largely because of shipments to the lakes.

Potential overproduction and the inroads of non-union coal, rather than a decline in general industrial activity, explain the weak market for steam grades in the Middle West. Offerings from the strip pits also help depress prices on shaft-mined coal. In southern Illinois screenings and small nut sizes find a readier market than other offerings. The Duquoin and Jackson County fields are running less steady than southern Illinois proper.

The Mt. Olive group is in worse shape than the Jackson-Duquoin operations. In the Standard field the same unsatisfactory conditions of weeks' standing still prevail. All fields report accumulations of unbilled loads of large sizes. Many mines are compelled to crush coal to take care of screenings contracts. Local domestic demand is slow in both Chicago and St. Louis. Country trade, too, is backward.

Kentucky Improves Position

Moderate improvement marks the course of the Kentucky markets. The lake trade is absorbing increasing quantities of eastern Kentucky coal and there is some demand from Georgia and the Carolinas. Western Kentucky is picking up scattered orders for small screened coal in the South. The greater part of the western production, however, is moving northward.

The comparative scarcity and high prices commanded by screenings during recent weeks have strengthened the demand for mine-run. Eastern Kentucky slack is bringing $1.10@$1.25 and western Kentucky, $1@$1.25. Western Kentucky mine-run is $1@$1.40. In the eastern part of the state byproduct mine-run brings up to $1.65, but other grades range between $1.25 and $1.50. Prices on prepared coals show no important changes.

The docks at the Head of the Lakes have been kept busy unloading cargoes since the opening of navigation. The first week the movement got under way 67 vessels were unloaded; the second week, 48, and the most recent week for which figures are available, 65 cargoes, including 6 of anthracite. Dock interests now estimate that they will need 10,000,000 tons of bituminous coal this season and approximately 900,000 tons of anthracite.

Dock Price Situation Unsettled

Dock prices are badly unsettled. Concessions running up to 75c. have been reported on Youghiogheny, Hocking and splint lump. Pocahontas lump and egg are $7, and stove is $6.75. As a result of the decline in spot quotations many large industrial consumers refuse to

renew contracts. Current movement of coal off the docks also is falling.

Trade at the Twin Cities is normal, but economies in fuel consumption and shifts in manufacturing enterprise have reduced the total demand. Prices on all-rail coal for steam and domestic purposes are well maintained. Local trade at Milwaukee is quiet. The docks, however, are working at a rapid rate to take care of the cargoes coming from the lower ports. Anthracite receipts are increasing.

Southwestern operations are marking time. Kansas mines are selling little but screenings. Early orders for threshing coal are the only bright spot in the Oklahoma situation. There has been little tonnage mined in Arkansas since the new coal year opened, but operators in that state are laying plans to push sales of storage coal this month.

West Drives for Storage Orders

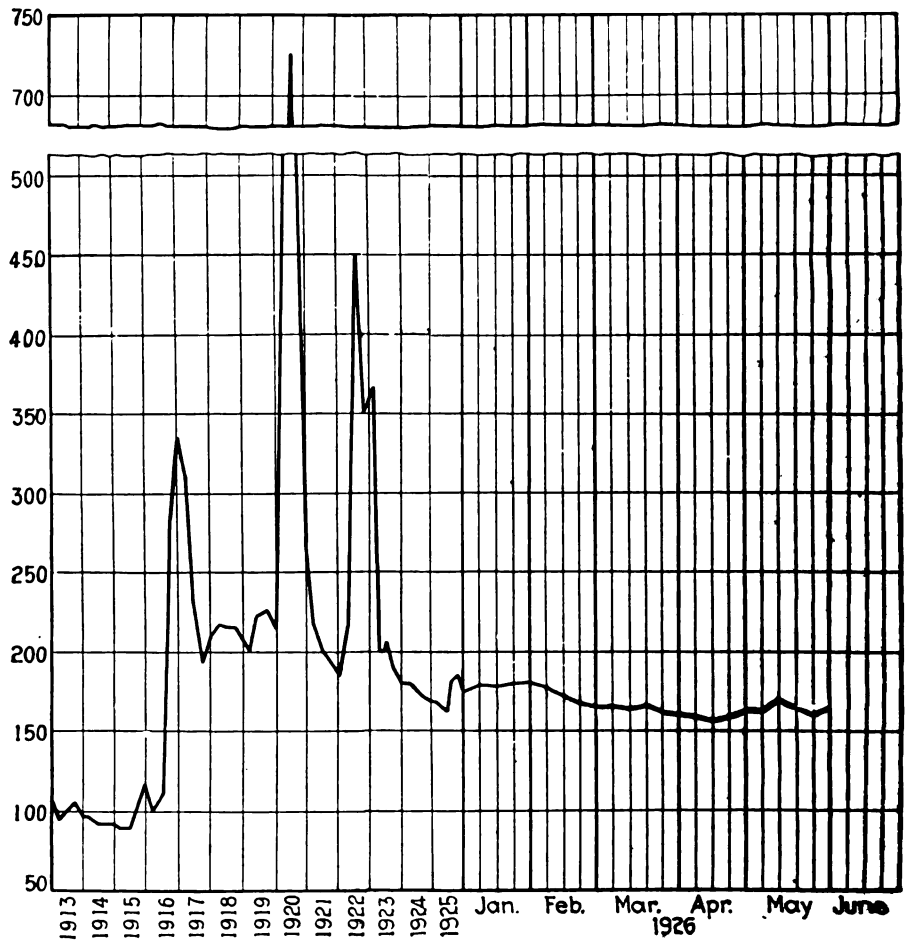
Utah operators are staging an energetic drive for summer storage orders on domestic lump. Coal is being offered to the householder at Salt Lake City for $6.45@$7, as against an earlier price of $9. Consumers are making some response to these inducements, but are not working the retail distributors to death filling orders. Two C. O. D. retail companies which have not met these prices are urging buyers to ignore the storage rates on the ground that there will be no increase in their prices next winter.

How long this price drive will last is uncertain. It was started, it is reported by the insistent demands of the smelters and other large industrial users for more slack coal. As a result of the low lump prices, there has been a substantial reduction in the number of "no bills," which two weeks ago had passed the 1,000-car mark.

Storage prices have been less successful in stimulating demand in Colorado. As a matter of fact, production has been declining. Steam sizes are going for what the market will bring. Effective June 1, Walsenburg-Canon City lump was quoted at $4.75; nut, $4.50; chestnut, $3; Trinidad lump, nut and fancy chestnut, $2.95; Crested Butte bituminous lump, $4.75; nut, $4.50. Crested Butte anthracite is $6.75 to $8.25, depending on size. Kemmerer-Rock Springs domestic sizes are $3.50, mines; steam coal, $1@$1.30.

Cincinnati Market Stronger

On the whole, the market at Cincinnati was slightly stronger last week, despite some congestion in lake movement. High-volatile producers were heartened by the announcement that the Island Creek Coal Co. schedules for June would show advances. This company is now asking $2.50 for 6-in. lump, $2.25 for 3-in. lump, $2 for egg and 1¼-in. coal. One or two other large West Virginia operators already have followed suit and several Hazard shippers have advanced their price on block to $2.30. High-volatile slack is stronger and mine-run maintains its position.



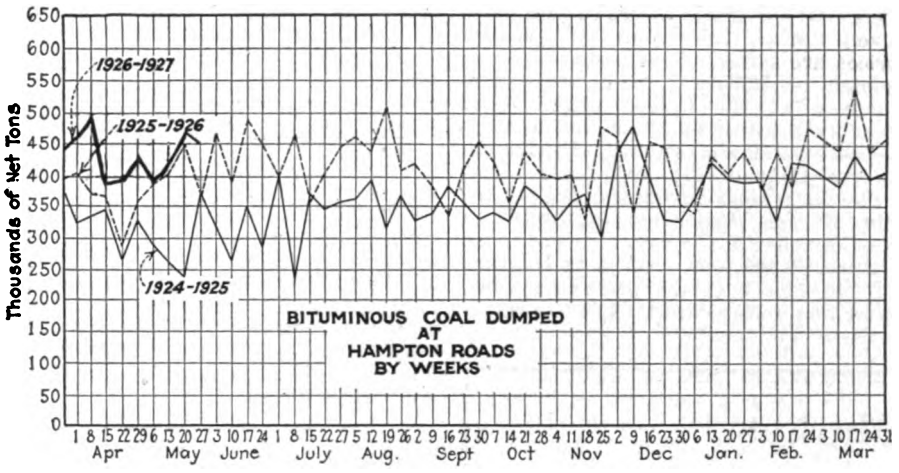
Pocahontas producers will endeavor to hold to the $3 price on lump throughout June. The same price is asked for egg; stove is $2.50, and nut, $2.25. The standard circular price on mine-run is $2, but spot sales have been made at 15@25c. under that figure. Slack is the weakest member of the low-volatile family.

During the week ended last Saturday 14,864 carloads of coal were moved through the Cincinnati gateway. This total, which was an increase of 306 cars over the preceding week, including 4,654 loads en route to Toledo and Sandusky for lake shipment. There also was a slight increase in the number of empties sent to the mines.

Lake Embargo Hits Columbus

Another embargo on lake coal to Toledo and Sandusky, placed early last week, reacted unfavorably upon the Columbus market. Prompt modification of the Toledo embargo relieved the situation somewhat, but enough track coal was offered at concessions to worry the Columbus coal men. Aside from screenings, the all-rail industrial market is dull and featureless. Little domestic tonnage is moving. Southern Ohio production is between 15 and 18 per cent of capacity.

Northern Ohio is no better off than the central and southern parts of the



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	May 31	May 24	May 17	May 10	June 1	June 2
Index	160	157	159	161	162	169
Weighted average price	$1.94	$1.89	$1.93	$1.95	$1.96	$2.04

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Week ended May 16, 1925.....	984,916	155,630

	Surplus Cars — All Cars	Coal Cars	Car Shortages — All Cars	Coal Cars
May 15, 1926..	259,699	90,295	.....	.....
May 8, 1926..	270,385	105,108	.....	.....
May 14, 1925..	330,433	141,258	.....	.....

state. Slack quotations in the Cleveland market are up 5 to 10c. Stripping operations are holding their own against non-union competition for steam business, but the shaft mines are waging a losing battle.

During the week ended May 15 the No. 8 field produced approximately 188,000 tons, or about 26 per cent of capacity. This was 22,000 tons less than during the preceding week and 28,000 tons under the figure for a year ago. Except in the case of mines with close dock affiliations, Ohio is shipping little coal to the lakes.

Pittsburgh Non-Union Output Grows

There is a slow but persistent gain in commercial non-union production in the Pittsburgh district. The strength of the union output in that field lies in the captive mines. General demand for coal shows no improvement. The Connellsville region is selling only a small quantity of coal in the steam market. Its business in gas and byproduct coals is less than normal.

Central Pennsylvania conditions show little change. During the week ended May 22 the district loaded 12,887 cars, as compared with 12,965 cars the week preceding. Pool 1 coal is quoted at $2.50@$2.75; pool 71, $2.30@$2.50; pool 9, $2.10@$2.25; pool 10, $1.75@$1.95; pools 11 and 18, $1.60@$1.65.

An increase in the quantity of unsold coal on tracks has further dampened the sodden spirits of the Buffalo bituminous trade. Nominal mine quotations, however, are: Youghiogheny gas lump, $2.15@$2.35; Pittsburgh and No. 8 steam lump, $1.65@$1.85; gas or steam slack, $1.30@$1.50; Allegheny Valley mine-run, $1.50@$1.75. Cambria County mine-run is $2@$2.25; Indiana County mine-run, $2.10, and lump, $2.85.

Export Demand Relieves Piers

There now is enough export demand to relieve Hampton Roads shippers of heavy accumulations of coal at the piers, but this has had little effect upon spot prices for New England delivery. Quotations on Navy Standard coal at the Southern piers have oscillated between $4.50@$4.65 and $4.65@$4.85. On cars at Boston and Providence an effort has been made to establish a $5.60 basis for future business, but some September tonnage has been closed at $5.40.

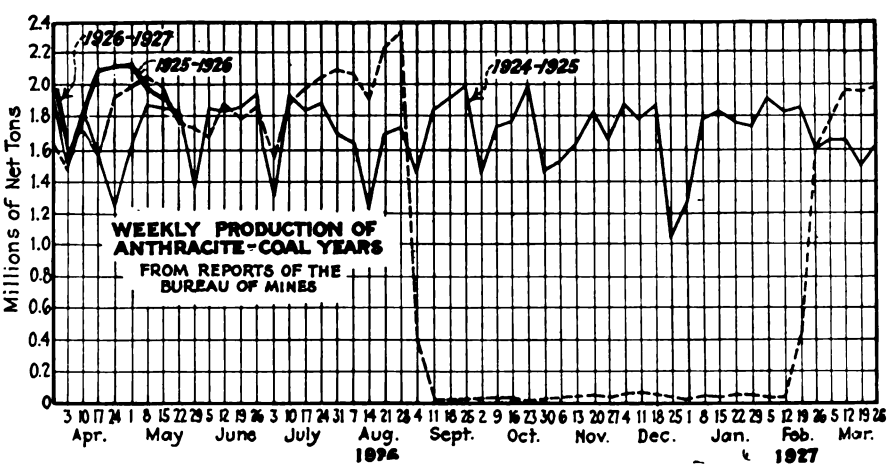
The course of the trade during June is highly problematical. There is no domestic support for a strong market. As soon as the British strike is over, renewed dullness and lower prices are forecast. Current buying is on a hand-to-mouth basis. There is, however, a slightly more optimistic feeling in industrial circles, but nothing to warrant belief in a booming demand for coal.

The all-rail situation on central Pennsylvania offerings is unchanged. There is little general spot buying. Most of the movement is restricted to the usual narrow strip of territory not far east of the Connecticut River.

Seaboard Watches British Situation

New York, Philadelphia and Baltimore find it more cheering to speculate on export prospects than to contemplate bituminous demand at home. Some charters have been closed since the British strike began, bunkering activity has increased and there is more inquiry from prospective foreign buyers. In the New York market dumpings have been steady, but consumers are not buying freely.

Industrial purchasers placing business with Philadelphia houses are making no move to increase their stockpiles. Producers are hoping that the railroads will place contracts before long. In the spot market the most active feature is gas slack, but there have been no sharp advances in prices. Competition for business is too keen at Baltimore to worry purchasing agents over prices, quantity or quality.



While there has been a gradual slowing down in the Birmingham district, the underlying situation is sound. There is no overproduction of high-grade coals and little surplus of less favored grades. Contract orders are absorbing the bulk of the steam-coal output. The limited quantity of high-grade domestic tonnage offered on the spot market finds a ready sale; medium and lower grades are sluggish. Foundry coke is firm at $6@$6.50, ovens. There is a fair demand for egg coke at $5 and nut at $3.50.

Company Anthracite Steady

The New York market reports a steady but unhurried movement of company anthracite. Most of the tonnage is going to old customers, but, unless the situation changes, it will not be long before some of the companies will be able to take on business from other sources. Except for occasional sales of straight stove at 10@15c. above company circular, independent shippers are unable to sell the larger sizes at a premium. Barley is the only steam size showing any strength.

At Philadelphia, on the other hand, backward consumer buying has slowed up the movement of both company and independent domestic coal. Pea is the only size which maintains any great strength. The disposition of nut threatens to assume the proportions of a real problem. Further reductions in premiums are resorted to by independents to move coal, but buyers show little interest in anything above company circulars. There is a surplus of all steam sizes. The Baltimore anthracite trade still marks time.

Buffalo demand for anthracite and for anthracite substitutes is quiet. Ice conditions outside the harbor still interfere with the free movement of lake tonnage. Loadings for the week totaled 52,900 net tons, of which 22,100 tons cleared for Superior and Duluth, 20,500 tons for Milwaukee, 6,800 tons for Chicago and 3,500 tons for Racine. Vessel rates will be the same as last year, viz., 90c. to Racine, 55@60c. to Chicago, 50c.

Digitized by Google

to Milwaukee and 40c. to Duluth and Superior.

Canadian Demand Maintained

Although more moderate weather has taken the edge off household demand for hard coal at Toronto, retail deliveries are being kept up by fill-up orders for next winter. Coke, too, is in good demand. Welsh anthracite also finds a ready sale. The bituminous market is quiet. Retail prices are: Anthracite stove, $15.75; egg and nut, $15.25; pea, $12.50; coke, $12.50.

The outlook for spot coke in the Connellsville region grows progressively darker. Movement is light and prices are softer, Spot furnace coke is quoted at $2.85@$3, with very little tonnage at the higher price. Spot foundry holds at $4@$4.50, but there is no real volume of buying. Production in the Connellsville and Lower Connellsville regions during the week ended May 22 was 155,450 tons, according to the Connellsville *Courier*. Furnace oven output, 90,840 tons, showed an increase of 140 tons over the preceding week. Merchant oven output, 64,610 tons, increased 440 tons.

Foreign Market And Export News

British Coal Subsidy Hit German Export Trade

March returns for Germany show rising imports and declining exports. The explanation given in German mining circles is that the British subsidy has enabled importers to offer British coal at prices at or slightly below even the recently reduced German summer season prices. At the same time it is reported that in markets outside of Germany competition from British coal has become considerably keener. In several reports it is noted for the first time that Dutch coal is coming into evidence on foreign markets.

German imports and exports in the first quarter of the current year are set out in the accompanying table. The corresponding figures for 1913 are added for comparison.

Coal Imports by Germany

		January to March 1926 Metric Tons	January to March 1913 Metric Tons
Bituminous		1,231,546	2,177,843
Coke		12,708	139,996
Brown Coal		426,155	1,732,519
Patent Fuel:	Bituminous	579	6,231
	Brown Coal	33,189	35,693

Coal Exports from Germany

Bituminous		3,563,332	8,460,214
Coke		1,220,243	1,698,747
Brown Coal		8,130	19,730
Patent Fuel:	Bituminous	329,444	613,621
	Brown Coal	220,599	261,972

As the deadlock between Germany and Poland concerning exports from Polish Upper Silesia continues, Great Britain is now practically Germany's chief supplier of foreign coal. In districts reached by water British coal enjoys an advantage in price over German coal and a number of consumers, chiefly gas works, give it preference on account of quality. This preference is so marked that a sharp differential in favor of German coal would be needed to eliminate British coal from German markets. So far the German syndicates have not been able to establish such a differential. But some sort of working arrangement between German and British mining interests is ultimately expected as an outcome of the British crisis.

In exports a broadening of the German foreign market is noticeable in spite of the slight drop of the total. This decrease is due chiefly to reduced shipments to certain European countries, principally France, which gets most of her German coal on reparation account. (Reparation coal is not included in the export returns). The wide span which is still separating the present volume of foreign coal business from that of 1913 is caused in the main by the loss of business in the case of a few Europeaen countries, notably that of Austria-Hungary, Russia and Switzerland.

Belgian Market Stronger

Brussels, Belgium, May 20.—Some improvement has taken place in the Belgian coal market since the first of the month. The full force of the British strike, however, has not yet been felt. There are still many consumers who refuse to augment their coal stocks. When these buyers enter the market it is felt that a shortage will be inevitable and that prices will advance sharply.

French Prices Advanced

Paris, France, May 20.—Prices in the Nord and Pas-de-Calais were increased May 16 to cover the advances in wage rates which went into effect at that time. The new schedules raise the price on raw smalls and on screened and unscreened industrial coals 10 fr. per ton; washed coals, 11 to 13 fr.; ovoids, 10 fr.; briquets, 12 fr.; coke, 15 fr.; domestic coals, 20 fr.

Demands for higher wages are pending in other districts and there seems to be no doubt that increases will be granted. Collieries in the Center and the South already have anticipated this move by increasing prices 10 to 15 fr.

Demand for French coals is naturally more active as a result of the British strike. The government also is facilitating the entrance of non-reparation coals.

April imports of coal into France totaled 1,571,105 metric tons; coke, 436,827 tons; patent fuel, 73,966 tons. During the same month this country exported 386,400 tons of coal, 31,311 tons of coke and 15,642 tons of patent fuel. Germany and Great Britain were the chief sources of coal imports; Germany, Belgium-Luxemburg and Holland, of coke; Great Britain, Belgium-Luxemburg and Germany, of patent fuel.

May End Australian Strike

The sympathetic strike of coal miners and engine drivers called in Australia probably will experience an early settlement, according to a recent cable to the Department of Commerce at Washington. The relief funds are exhausted and the miners are anxious to return to work. The unions are permitting coal shipments to the Broken Hill Steel Works, one of the important Australian mills.

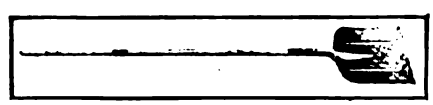
New Equipment

Shovel Cleans Back of Kerf, Aiding Fall of Coal

Bugdust from the undercut made by a mining machine heretofore has been removed in a more or less desultory and haphazard manner by means of hoes, shovels, scrapers and the like, equipment in the majority of cases but ill-adapted to the work in hand. The need for an efficient tool for this purpose became so great that the Pittsburgh Shovel Co., 1832 Oliver Bldg., Pittsburgh, Pa., has developed and placed on the market the special shovel shown in the accompanying illustrations. This tool is capable of removing

Clean the Kerf and Save Powder



This scraper's shovel has a broad flat blade and a long handle with an almost negligible lift. It can be thrust clear to the back of any ordinary undercut, removing all the bugdust and leaving the kerf in the best possible condition for shooting. No undercut attains its maximum possible efficiency unless it is thoroughly cleaned out.

practically all bugdust from a kerf, leaving the undercut in the most effective possible condition for blasting.

The blade of this shovel is of special design and shape, built of high-carbon steel, 14⅛ in. wide and 16 in. long. The handle is of selected second-growth Northern ash, 6 ft. long, the total length of the finished shovel being 7 ft. 2 in. The lift is extremely low—almost but not quite negligible. This permits the tool to be thrust to the extreme rear of the undercut.

The following advantages are claimed for this shovel by the manufacturers: All bugdust can be easily and quickly removed from an undercut; one-third less explosive is required to bring down the coal; a larger percentage of lump is produced; cleaner coal containing less slate, ash and fine material is obtained. Safety is greatly increased through the removal of dangerous fines, and the safety provisions of the state laws are effectively carried out. This results in lower insurance premiums because of total bugdust removal. All of these advantages are made possible because men will willingly and thoroughly remove all bugdust from an undercut when this can be done with the ease resultant upon the use of a tool suited to the purpose.

Many mining officials regularly assure themselves that the working faces are being undercut in an efficient and workmanlike manner, yet forfeit many of the advantages realizable from such undercutting by not making sure that the cuts are thoroughly cleaned out. A machine kerf is narrow at best; to attain its fullest possibilities it should be entirely unobstructed.

Shovel that Gets in Under

It is a peculiarity of human nature that men will do willingly and thoroughly that which is easy, but are likely to shirk if the task in hand is hard. The special blade, long handle and low lift of this tool admirably adapt it to removing the bugdust to the extreme rear of the undercut and, what is perhaps equally important, they make this operation easy.

Electric Heater Makes Sand Flow Freely from Pipe

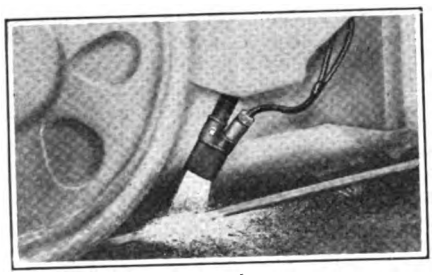
In order to eliminate the uncertainty and danger incident to clogging of a locomotive's sand pipe from water or freezing, the Crawford Machinery Co., Bessemer Building, Pittsburgh, Pa., is marketing the safety electric sander shown in the accompanying illustration. This simple device assures a dry and unobstructed end on the sanding pipe and a dependable flow of sand at all times.

As is well known, dry sand will not flow from the end of a wet pipe without some of it sticking to the interior surface. This decreases the effective delivery area, and if it becomes cumulative, as is frequently the case, the entire cross-section of the pipe may be effectively clogged. Many accidents and much delay to traffic have occurred on railroads, street-car lines, and on mine and industrial roads generally from this cause.

Electric Heating Averts Clogging

After long study and experimentation, a railroad locomotive engineer who, during his 32 years of active service, encountered many difficult trips, because of the clogging or freezing of the sand pipe on the engine, devised the equipment here shown. In construction this device is extremely simple. It may be attached to the end of the sand pipe nearest the rail and is heated electrically. By this means it is possible to drive moisture out of the pipe, keep it out, and positively avoid clogging.

This electric sander is fastened to the lower end of the sand pipe next to the rail. If rubber hose is used at this point it is removed and the pipe extended so as to permit proper attachment. The sleeve of the sander is slipped over the end of the pipe and made fast by heavy set screws and lock nuts.



The necessary wire connections to any convenient source of electrical sup-

Digitized by Google

ply are easily made and are readily accessible for inspection. The function of the device is to keep the delivery orifice dry, and thus to permit of a flow of sand thereby assuring adequate traction and maximum adhesion for braking whenever this is needed.

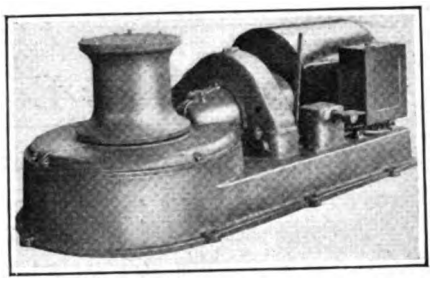
Should the end of the sand pipe be submerged in water, the sander will immediately respond as soon as the device rises above the surface of the liquid. The heat generated by the passage of current is sufficient to dry the end of the pipe in a few seconds. It is thus positively effective in operation, and may be applied to any sand pipe on any type of locomotive or street car.

Mine locomotives thus equipped are able to handle trips on heavy grades with greater efficiency and with perfect confidence on the part of the motorman, as moisture in the mines or water through which the machine may be

Sander with Electric Heater in Operation

This device consists of an electrically heated orifice or nozzle that may be slipped over and fastened to the end of the sand pipe. This will effectively dry out the pipe and permit an unobstructed flow of sand within a few seconds after total submergence in water.

compelled to pass will not in any manner clog the sand pipe.



Many motormen have been badly injured and some have been killed in trying to release sand from clogged pipes while the trip was running away on a heavy grade. As a rule the motorman has no recourse when he is unable to release sand on a wet or slippery rail.

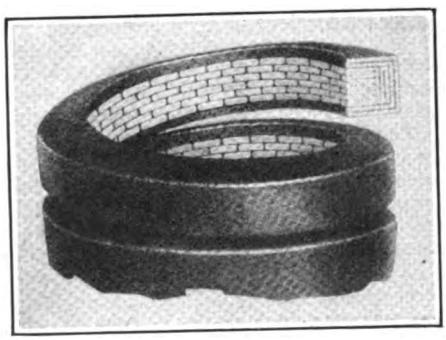
Electric Capstan Pulls Cars

In the accompanying illustration may be seen the improved electric capstan car puller designed and manufactured by the Clyde Iron Works, of Duluth, Minn. In this machine a vertical winch head, or capstan, is bolted direct to a rugged bevel gear which is driven by an electric motor through two sets of intermediate gears and a bevel pinion.

The unit is said to be of exceptionally sturdy construction, having all parts totally inclosed and covered with a semi-steel housing so as to be dust- and weatherproof. This is a valuable detail of construction, as a car puller is exposed to the elements at all seasons of the year. The capstan head is fitted with renewable bronze bushings.

All the gears are of steel, except the intermediate gear, which is semi-steel, and the motor pinion, which is of Bakelite Micarta, making operation practically noiseless. The frame is so constructed that all gears run in a bath of oil, insuring perfect lubrication. An Alemite greasing system is provided throughout. A hand-operated pawl for

Despite Rail Conditions, Places Cars Wherever Desired



Fitted with electric motors wound for any desired current, these machines are said to form reliable units for spotting or respotting coal cars under the tipple or material cars elsewhere.

holding the load when the capstan is stationary also is furnished. The operation is controlled by a push button arranged for foot control. Over-load and low-voltage protection is provided.

These car pullers are built in three sizes, having line pulls of 3,000, 6,000 and 10,000 lb. at a speed of approximately 40 ft. per minute. They are equipped with 5-, 10-, and 15-hp. motors respectively for the available current.

New Metal-Filled Packing

A type of metal-filled packing designed for use on piston and valve rods and other services where high steam pressures are encountered has been brought out recently by the Garlock Packing Co. of Palmyra, N. Y. It has a wearing surface of soft metal inclosed on three sides by a covering of asbestos and rubber. The metal filler in the channel of the packing is of special design and is perforated and cut to fit the various sizes of rod. The design of the filler is such that it tends to hold a large percentage of lubricant and to make the sections or studs seal one another against the pressure.

Metal Filled High-Pressure Packing

Within the channel of the packing is a specially perforated and cut metal filler that is porous and capable of holding much lubricant. This packing, therefore, is capable of being used without other lubrication for a long time.

New Companies

Rosedale Fuel Co., Fairmont, W. Va., recently was organized with a capital of $1,000,000, by C. H. Humphreys, Charles E. Hawker and R. S. Waller, all of Fairmont, and James E. Gaskins and Robert D. Bradford, both of Morgantown, W. Va.

The Magnolia Coal Co., Poteau, Okla., with a capital of $15,000, has been incorporated by William F. Faither, Paris, Ark., and Joe R. Edelmann, Poteau.

The Vermillion Coal Co., of Charleston, W. Va., was organized recently with George E. Merryman, Charleston, president; J. P. Bess, Orgas, vice-president, and H. N. Greenlee, Charleston, secretary and treasurer. The company recently acquired the mine of the late A. E. Moore, of Charleston, which is located on the Chesapeake & Ohio Ry. at Orgas, Boone County. The Cedar Grove seam is being worked there.

The Kimbolton Co-operative Coal & Mining Co., Kimbolton, Ohio, has been chartered with a capital of $10,000 to mine and sell coal on the co-operative plan. Incorporators are: James Hardwidge, Joseph Latchic, Everett Rose, John S. Dobransky and John B. Dobransky.

The Roach Creek Coal Mines, Inc., Cincinnati, Ohio, has been chartered with a capital of 10,000 shares of stock, no par value, to operate mines and deal in coal. The incorporators are Loyal S. Martin, Bernard J. Giliday, W. M. Mance, Anna F. Watts and Ruth McConnell.

The Hilltop Coal Co., Crooksville, Ohio, has been incorporated with a capital of $50,000 to mine coal in the Crooksville field. Incorporators are Frank Sample and Charles Sample, of Saltillo, and Ruth Wall, Mary Detenbeck and C. F. Ribble, of Zanesville, Ohio.

The Canada Process Fuel Co., Ltd., of Halifax, N. S., has obtained papers of incorporation for the purpose of mining coal and kindred mineral products, with a capital of $1,000,000, by William Marshall Rogers, Henry Poole MacKeen, Joseph Patrick, Connolly, and others, of Halifax.

A charter has been granted to the **Maywood Coal Co.**, Laville, Boone County, W. Va., with a capitalization of $10,000. The incorporators are C. L. Burns, C. L. Milligan, E. R. Milligan and W. M. Erwin, all of Laville, and N. E. Milligan, of St. Albans.

The Ideal Fourth Vein Coal Co. has been incorporated at Jasonville, Ind., with a capital stock of $25,000 to do a general coal mining business. The incorporators are Vaughn Daugherty, Sam Harrison, Oscar Lafoon, Ross Bond and Charles Stewart.

A charter was issued recently to the **Raleigh-Wyoming Mining Co.**, of Charleston, W. Va., with a capitalization of $50,000. The incorporators are W. G. MacCorkle, T. L. Johnson, J. M. Britton, Y. Riffe and T. S. Clark, all of Charleston.

The Minot Colliery Co. has been incorporated in Minot, N. D., with a capital stock of $50,000, and will manufacture briquets. John Nedreloe, L. J. Wood and J. A. Verzott are interested.

The Big Run Coal & Clay Co. has been incorporated in Ashland, Ky., with a capital of $313,000, by C. A. Coleman, John R. Means and S. F. Hoge.

W. H. Bowater, Inc., has removed its offices to the Whitehall Building, 17 Battery Place, New York City.

and double capacity with the
Y Type Separator

The industry is fast taking advantage of the greater efficiency and lower cost of investment and operation of the American Y Type Pneumatic Coal Separator.

This new Y Type Separator not only has twice the capacity of the older type, but also handles increased range of sizes.

Coal Mine Officials are cordially invited to investigate results obtained in the many American Pneumatic Separator Plants installed throughout the country. We'll be glad to make arrangements for a complete commercial test and demonstration. Get in touch with us.

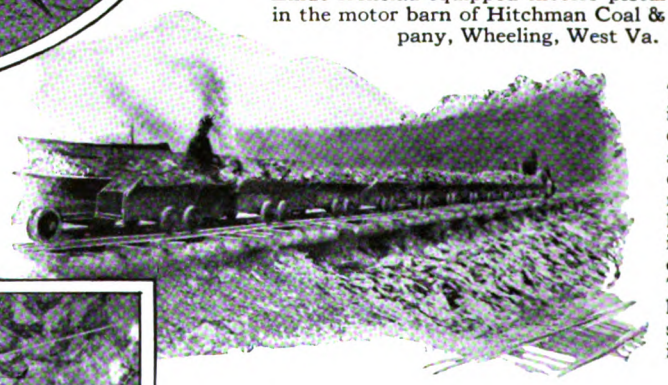
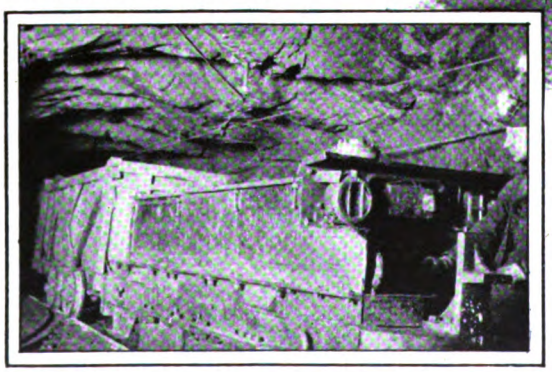
The more cars that pass under this tipple each day the more profit the mine makes. Yet those cars can be loaded with coal no faster than the mine's haulage system can bring that coal to the surface. That is why it is so important that you use Exide-Ironclad Batteries in your haulage motors—they make a good haulage system even more efficient.

Efficient

ON CHARGE *as well as* IN ACTION





If you've never seen an Exide-Ironclad Battery on charge, you've a pleasant surprise in store. It takes current in quickly, easily and with little waste. The Exide-Ironclad-equipped motors pictured here are in the motor barn of Hitchman Coal & Coke Company, Wheeling, West Va.

There won't be any waiting for these empties at the face, for the motor is powered by an Exide-Ironclad, and the great speed of this battery hustles the cars in and the loads out with no delays. Furthermore, the speed of this battery holds up well all day long.

The last trip of the day is out, bringing with it extra cars of rock and all the miners that could crowd on the motor. Yet the motor has power to spare, for it has an Exide-Ironclad in the battery box. This battery always has extra power in reserve when extra power is needed.

Rugged as the rock roof above is the battery in this motor. That battery is an Exide-Ironclad, built by a company that has been making storage batteries for thirty-eight years. Is it any wonder that an Exide-Ironclad stays on the job year after year without needing repair?

Next Week's National Coal Association Issue

Coal Age has Sydney A. Hale covering the National Coal Association Meeting at Chicago. Next week the issue will be largely devoted to the meeting and to the various articles that were delivered there.

The National Coal Association deals with some of the most vital problems of the coal industry, and the program which it has prepared on this occasion touches those vital matters in their most important phases. Engineering problems are fundamental, but so also are those which appertain to the direction of business and of industry.

Coal Age, as usual, will cover the meeting adequately, as you will note when you open next week's issue.

Bet on Bulldog

—to meet mining conditions

YOU never saw a bulldog falter, no matter what the number or ferocity of his antagonists. His make-up is such that he has no need to fear them. O-B Bulldog Clamps are built the same way. The necessary stuff is in them to meet and survive the worst of conditions met with in mining service.

O-B Bulldog Trolley Clamp

A sturdy clamp, with self-opening jaws, that offers no obstruction to wheel passage—on straight track or on curves. Made of hot-dip galvanized O-B Flecto Iron.

O-B Bulldog Cable Clamp

The same clamping principle as the Bulldog Trolley Clamps. Sling jaw holds the feeder cable while it is being strung, then the smaller jaw clamps it securely and relieves strain from dead-end points.

Holding Down the Peaks

IN MINING and other plants that operate on purchased current, peak loads carry a strong penalizing charge. The monthly peak thus has almost as much influence on the power bill as does the actual consumption of current. The high points, or excessive demands, therefore, should be avoided by all means possible.

Certain industries that have a highly fluctuating load and a peak that can be foretold with a fair degree of accuracy have found it advantageous to install internal combustion engines of the Diesel type that can be started promptly and which will shoulder the load in excess of a certain predetermined quantity.

At the mines the maximum demand usually develops about 8 a.m. and begins to fall off sometime before noon. At some operations a secondary peak makes its appearance at about 3 p.m. and subsides within about an hour. In both of these cases an auxiliary source of power could be advantageously employed to keep the demand upon the central station within reasonable bounds, or such that heavy demand charges would be avoided.

In addition to its use in alleviating or lessening the demand charge, and which results in some industrial cases in savings sufficient to pay for the equipment in from 3 to 4 years, such a unit would always be available as a standby in case of power failure on the line. A unit of this kind can be started quickly and should logically be made of such power as to be capable of operating the fan and material hoist in case of emergency. It would thus serve as a standby as well as an auxiliary.

It would probably be quite possible to so arrange a unit of this kind that it could be started and stopped automatically. It would thus come into operation whenever the load reached a certain predetermined amount and would be stopped when the load had fallen to some other pre-established lower level. Such an arrangement would not only prove ideal from the standpoint of peak-load avoidance, but would furnish a ready source of energy in case of power failure or on idle days.

Evading Acid

FOR MANY of his pump-, pipe- and screen-corrosion troubles the mine manager can largely blame himself because he has not learned as yet how to protect from the pollution of water that he has to remove from the mine. If he creates a storage place for water in the mine he will do well to remove all slack and loose coal before turning in the water, because the slack inevitably contains a quantity of pyrite which oxidation in the presence of water will turn to iron hydrate and sulphuric acid.

The tendency today is to limit electric load peaks by shifting the pumping load to the night and to arrange immense storage spaces against floods, but if the old rooms are full of slack there will be increased cost in the repair of all pumps and pipes. Too often the rooms chosen for such storage have been abandoned for years and cannot safely be cleaned, and the water has to be dammed back to such a height, in order to reach all parts of the territory, that it rises high on the coal and procures acid from the ribs.

Where it is possible it is best from an acidity standpoint to pump water in a single lift thus reducing its opportunity to take up acid along its path.

"Eating Their Heads Off"

TO MANY MINING executives the words "obsolete" and "worn out" appear to be synonymous. This may or may not be the case, but probably in the majority of instances equipment, tools and appliances become obsolete long before they are worn out. In any good museum may be seen numerous articles that are, to all intents and purposes, exactly as serviceable today as when they were first constructed hundreds or possibly thousands of years ago. A stone mace, for instance, might crack a skull just as efficiently now as in the days of the Pharaohs, but who would think of attempting to rout a burglar from his home with such a weapon when he has every reason to believe that that intruding individual will be armed with a modern automatic pistol?

One of the chief reasons why this country has forged ahead of its competitors in manufacturing is because it has consistently and persistently thrown perfectly good machinery on the scrap heap. Thus a manufacturing lathe might be capable of lasting for 20, 30 or even 50 years and do just as good and accurate work at the end of that period as at the beginning. At the termination of the first decade, however, the probabilities are that such marked improvements will have been made in the design of machines of this kind that one that is 10 years old can be operated only at a loss. In other words it would be far cheaper to sell the old, albeit perfectly serviceable machine, for junk and buy a new one than to continue its operation.

And what is true of such machines as lathes in a manufacturing plant often is true of production machinery at the coal mine. During the past few years such improvements have been made in boilers and power-generating machinery in general, that many pieces of equipment that were installed only a comparatively short time ago and were at their installation justly considered efficient, are today obsolete in the sense that it would be cheaper to scrap them and install newer and more up-to-date apparatus. The ever-increasing consumption of energy resulting from the mechanization of mining processes formerly performed by the muscles of men or animals makes this only the more advisable.

Digitized by Google

The sickle and flail are unquestionably just as efficient agricultural implements today as they ever were but they are seldom used because they cannot compete with the self-binder and the threshing machine. Cheap as these devices are, because of the muscular energy that must be expended in their use, they are obsolete and discarded. Although just as efficient as ever were they to be used today they would, figuratively, "eat their heads off." The same is true of many other pieces of equipment in all industry, mining included, which, because of the onward march of progress, have gone, are going, or are doomed to go the same road.

Because of this obsolescence, therefore, every progressive mining official may with wisdom periodically ask himself the question: "How much longer can I afford to operate this or that particular piece of equipment?" If the conditions and possibilities involved are carefully weighed some executive might be surprised at the proportion of his equipment that would find its way to the scrap heap to be replaced by newer and more efficient machines. Many an old engine, boiler, coal cutter and the like, although in perfectly good condition and capable of rendering years of service, is in reality "eating its head off."

Stronger Than Statutes

THE ORGANIC ACT creating the Bureau of Mines gives that agency of the federal government no mandatory powers over the operation of the coal mines of the country. In the light of the Supreme Court ruling that mining is not interstate commerce, any attempt to vest such authority in the Bureau would be open to challenge on constitutional grounds. And yet, in certain directions, the Bureau of Mines exercises a control more potent than probably would be possible under a specific statutory grant of authority.

The Bureau of Mines determines what explosives may be used with safety. It pronounces judgment upon this and that type of equipment. In the course of its studies to make the mining of coal a less hazardous occupation, it condemns this practice and sets the seal of approval upon that—and its recommendations are written into the laws of certain coal-producing states. Even where state laws are silent upon the practices indorsed by the Bureau, there are few operating officials of coal-producing companies who care or dare to run counter to the seasoned opinion of the Bureau's staff.

Whence comes this power? How is the Bureau of Mines, lacking authority itself, able to establish and maintain its control? Public opinion is the answer. As an independent, non-political, technically-trained organization, the Bureau of Mines has enlisted public confidence in its work. Because of that public confidence, its leadership in the safety movement is unquestioned. Manufacturers of explosives and mining machinery strive for its indorsement. State mine inspectors, coal-operating officials and their subordinates seek to keep within the lines of the Bureau's recommendations as a sure protection against public censure in the case of accidents.

No one will deny that the industry is better for this co-operation. Voluntary in its inception, public opinion makes that co-operation more compelling, more binding, more effective than direct Congressional mandate. The success which has attended the Bureau's endeavors ought to impress itself upon our national law-makers. Industry, too, will be blind to its own best interests if it does not recognize the value of massing public opinion in its favor by showing a willingness to co-operate in voluntary movements for industrial betterment. The industry which is backed by public opinion need fear no threats of repressive regulation.

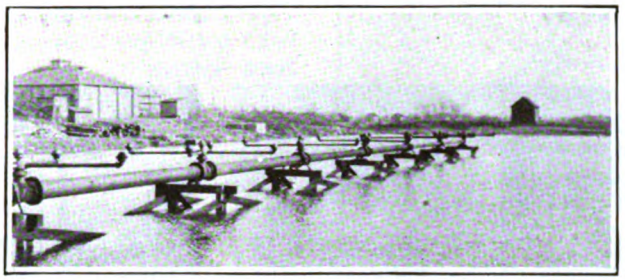
Roof Control

NO ONE CAN fail to realize that the study of roof action and control always will be troubled by elements of uncertainty but that is true of kindred studies. The kinetics of beam and plate action under stress is none too clearly understood, though the study has in years past made wonderful progress. The analysis of roofs and girders is hedged with assumptions which we know are too often incorrect. Nevertheless they afford solutions that are indicative of the true conditions and therefore are of value if not wholly reliable. Despite assumptions and uncertainty the stresses in dams are also calculated.

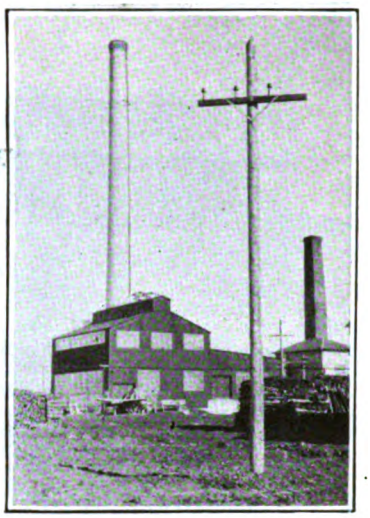
But with all the difficulties apparent and hidden in the problems involved, engineers have not hesitated to theorize, and the results are so much better than guesses that no one would design a bridge, a dam or a girder or place a beam without them.

The problems of the roof are greater, but theories, mathematical studies and tests are of more value than vague surmises. Erratic conclusions that may be readily proved fallacies are the necessary outcome of not sitting down resolutely to make certain assumptions and argue mathematically from them.

We shall find that the roof is not what the assumptions would make it; we shall discover that there are exceptions where the measures slide readily on each other or are badly creviced, or faulted, or subjected to preliminary strains, thus confounding our theories.



Our trouble is that we declare that a solution of the problem is impossible and refuse to attempt it. Yet when we begin to operate we assume not merely the conditions on which a solution of the problem might be approximated but the final result. We make not one or two assumptions but several and those less nearly correct than those we have refused to make.



One assumption that lies at the basis of all reasoning regarding the roof is that it is a monolith except for two main layers that lie above and below the central mass respectively. The bottom layer is the drawslate, the top layer, the surface material. Now, it is to be admitted that there are often uncertainties as to the monolithic character of the mid-roof, but our trouble is to break a strong roof, not a weak one, so if we assume that the mid roof is integral we get a safety factor, which is what we sometimes need.

In any event by assuming a monolithic structure we make a start. We discuss, at least, one type of roof; in the parlance of the street "we get down to cases." Later we can take up the exceptions. Meantime we clarify our ideas. Our study of roof action today is altogether too nebulous. One man has a good roof, another a bad roof and what is meant by good or bad no one knows. There are different kinds of goodness and badness and a good roof at one time is a bad roof at another. Such vague terms cannot profit anyone. Only analysis will afford an adequate terminology.

Three Illinois Mines Generate Their Own Power

Install Three Water-Tube Boilers Each Capable of Producing 700 Hp. and Two 1,872 Kva. Generators Driven by Direct-Connected Condensing Steam Turbines

By E. Steck
Mine Equipment and Service Bureau,
Chicago, Ill.

E. Steck

THE Indiana & Illinois Coal Corporation operates a mine at Nokomis, having a capacity of 6,000 tons, and two at Witt, one with a capacity of 3,500 tons, and the other with a capacity of 2,500 tons per day. These mines are known as Nos. 10, 14 and 12 respectively. No. 10 mine is completely electrified and purchases power from a central station. Nos. 14 and 12 purchase power for operating motor-generator sets, for underground electrical equipment and generate their own steam for hoisting and miscellaneous use.

The boiler plants are typical old-style mine plants, using mostly 150-hp. return-tubular boiler, with no attempt at consistent engineering layout for boilers, piping, water treatment, buildings or coal and ash handling. Naturally the quantity of coal burned is excessive and the costs of maintenance and operation are heavy.

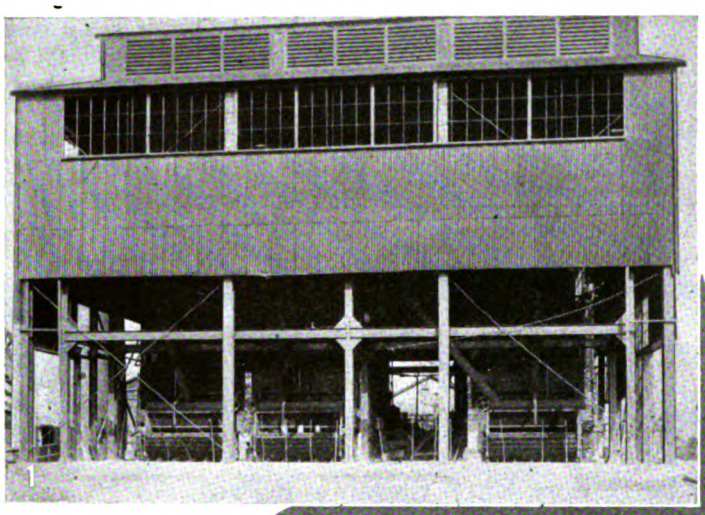
The cost of purchased power for No. 10 mine became especially burdensome, due partly to the mine only working part time during the last few years. In 1923, the coal company used 1,655,400 kw.-hr. at a net cost of $56,837 or a charge of 3.43c. per kw.-hr. That year the run was irregular and power consumption low.

A study was made as to the cost of power, part purchased and part generated, and also what would be the cost of producing it at the company's own central station. The investigation showed that a large saving would be effected by the company building its own central station and abandoning its boiler plants at mines Nos. 12 and 14. In view of the future development of the properties and the present operating conditions, it was decided to locate the plant at mine No. 12 and to transmit power to mines Nos. 14 and 10, a distance of approximately 10 miles.

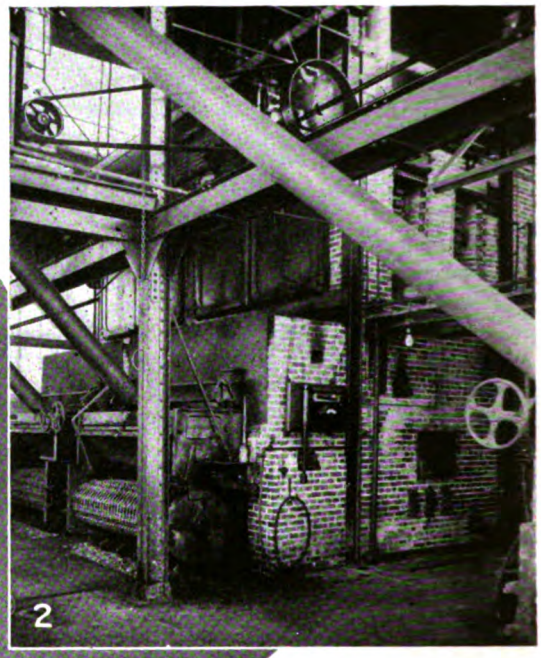
Steam for No. 12 mine will be supplied by the new plant, but at mine No. 14 there still remains a steam hoist which must be electrified before that boiler plant can be shut down. Labor released at mines Nos. 12 and 14 will be more than sufficient to operate the new plant. Little more coal will be burned at the new power plant to operate all three mines than was used formerly at mines Nos. 12 and 14 alone.

A track hopper near the shaft of mine No. 12 takes screenings direct from the tipple or from a hopper-bottom car from one of the other mines in case No. 12 is shut down and by means of a reciprocating feeder delivers it to a belt conveyor which discharges into a screw conveyor over the coal bunker. The coal bunker is made of steel and has a capacity of approximately 125 tons. From the bunker the coal is delivered by swinging spouts to hoppers that feed the chain grates.

Adequate Indicating Equipment Used

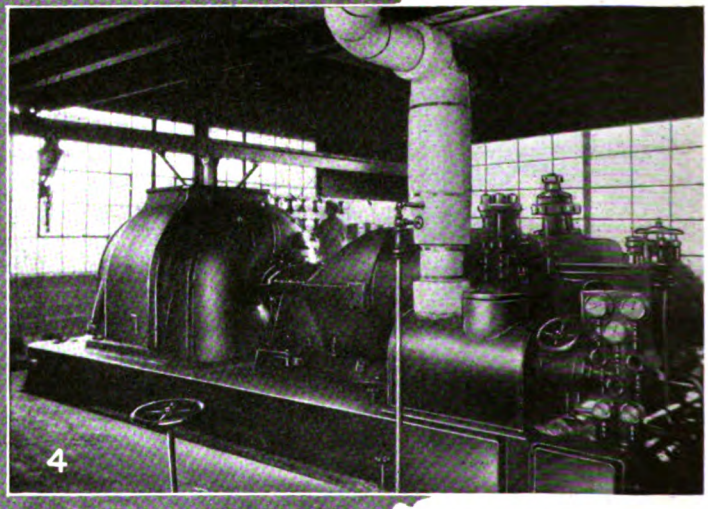


Three water-tube boilers having normal capacity of 353 hp. and maximum capacity of 700 hp. each have been installed, each having two drums 36 in. in diameter and 21 ft. 9 in. long and 175 straight tubes of 4 in. diameter and 18 ft. long. The boilers are equipped with flow meters, carbon-dioxide recorders, draft gages, pyrometers and regulators for the feed water and dampers. Steam is generated at 175 lb. and delivered to the header with 100 deg. of superheat.



From the chain grates the ashes are discharged into concrete hoppers and thence into ash cars under the boiler-room floor. These are drawn out and emptied on the mine property.

A water-softening plant was erected, consisting of



The headpiece shows scenes at the Witt power house. On the left is the conveyor for transporting coal from the track hopper to the coal bunkers in the boiler room. In the center is the spray pond, and the third illustration is of the boiler room and turbine house, the latter being on the extreme right.

Scenes in the Boiler House of the Indiana & Illinois Coal Corporation

(1) Front of boilers before building was finished. (2) Spray pond. (3) Aisle between boilers. (4) Turbines. (5) Pumps. (6) Turbine foundations and condensers.

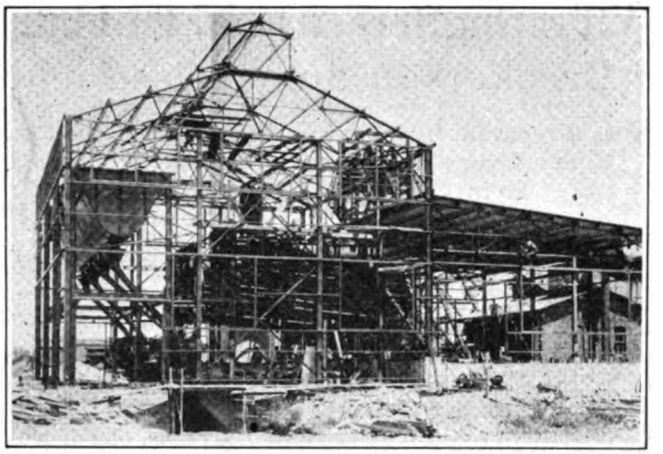
Digitized by Google

a feed-water heater, filtering and chemical tank, supply pumps and a meter proportioner which supplies a fixed proportion of chemical to the water, no matter what the demands are on the plant.

Two boiler-feed pumps, 10x6x12-in. duplex, equipped with pump governors are located in the condenser room basement under the water-softening plant thus giving them a considerable suction head. The exhaust steam from the pumps, exciter turbine and air ejector is used for heating the feed water in the water-softening plant.

An air compressor, electrically driven, is installed for operating boiler-tube cleaners and air tools and for cleaning the electrical equipment.

The chimney 202 ft. 6 in. high is made of re-inforced concrete and lined with radial brick for a distance of 50 ft. with an inside diameter at the base of 11 ft. 5 in. and at the top of 8 ft.



The prime movers consists of two 1,875-kva., 3-phase, 60-cycle, 2,400-volt generators driven by direct-connected condensing steam turbines operating on 175-lb. steam pressure and 100 deg. superheat. A 35-kw. turbine-driven exciter is furnished to supply excitation to the two turbo-generators and to supply power for the station lights in case of emergency. Additional space is povided in the turbine room for a smaller unit to be installed later to take care of the night and idle-day load. Both condensers are of the jet type, one being equipped with a two-stage steam-air ejector, and the other with an air pump.

Abundant Water Supply Is Provided

A pond is located near the power house which is used for both boiler-feed water and for operating the condensers. Water from the pond is taken by gravity through a concrete basing with removable screen and settling chamber to cold wells in the condenser room, whence the condensers lift it by short suction lines. A pipe line is run from the washhouse tank for priming the condensers. The discharge water from the condensers is taken back to the opposite end of the pond from the intake water to a concrete basin which overflows into the pond. The pond level is below the condenser discharge so that little power is taken by the discharge. A centrifugal pump is located at the afore-mentioned basin which is connected to the spray system for cooling the water. This cooling system is independent of the condenser discharge which permits operating the sprays in the summertime at night when the turbines are shut down and shutting them down in the winter time when they are not needed.

The switchboard consists of two generator panels, one exciter, two 2,300-volt feeders, and one 440-volt distributing panel. The generators and feeders are supplied with recording wattmeters which record the power delivered by each generator and furnished to each mine. Each generator panel is supplied with an alternating- and a direct-current ammeter, an alternating voltmeter, an indicating wattmeter and a non-automatic oil switch. The 2,300-volt circuits each have an oil circuit breaker and recording wattmeter. Both turbines have motor-driven synchronizers, with control switches on their respective generator panels. On a swinging bracket is a synchroscope and a power-factor meter.

A bank of three 75-kva., 2,300/440-volt transformers is used to supply power to the motors in use at the power plant such as condenser drives, compressors, pumps, conveyors, etc.

Witt Power House in Process of Erection

Bunkers, boilers and ash pit can be seen to the left of the illustration. The boilers have a maximum aggregate capacity of 2,100 hp., the normal capacity being 1,059 hp.

Mine No. 14, which is less than a mile away, is operated by a 2,300-volt transmission line, and No. 10, which is about 9 miles distant, by a 23,000-volt line. For operating No. 10 mine there are two transformer substations, delta-star connected, each consisting of three 667-kva. transformers, one at the generating end, and the other at the receiving end. Each transformer station is equipped with high- and low-tension disconnecting switches, air-brake switches, lightning arresters, high-tension expulsion fuses and choke coils.

The engine room for a height of 3 ft. and the boiler room for a height of 7 ft. above the ground level is constructed of reinforced concrete, and the remainder of the building is steel-frame construction and sided with asbestos-covered corrugated-steel siding. Steel window sash is used with wire-ribbed glass in the lower sashes, plain glass being used in the upper windows. The water-softening plant is built of reinforced concrete up to floor level, the upper part being of concrete block with steel sash. The turbine foundations are built entirely of reinforced concrete. The plant, except the brick work in the chimney and boilers, was built by men at one time connected with the coal company.

Savings Will Depend on Running Time

The cost per kilowatt-hour for generating power at the new plant depends on many elements entering into the cost, that is, the efficiency and care with which the plant is operated, the cost of repairs and depreciation and the working time of the mine. In making a comparison with the purchased power, it should be remembered that the plant will not only replace this power but will furnish steam to Mine No. 12, which will abandon its power plant and eventually supply additional electric power to Mine No. 14, which will also shut down its boiler plant.

Making no allowance for savings in maintenance, coal and labor in these old plants, the new power station will show a reduction in the power costs of from $20,000 to $50,000 per year over purchased power, depending on the running time of the mines. This saving is greatly increased by shutting down the old steam plants, so that this new power plant will pay for itself in from three to six years. After the plant has paid for itself, the cost of producing power will be further decreased. The plant was designed, built and put into service in 1925 by the Mine Equipment & Service Bureau, of Chicago, Ill.

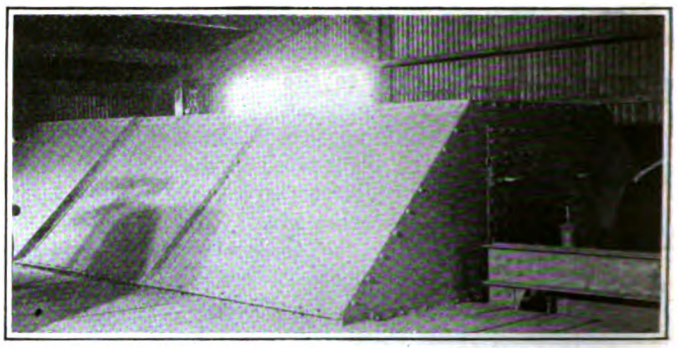
Vibrating Screens and Tumbling Breakers in Smokeless Field

Pea Prepared by Passing Slack, One Inch and Under, Over a Vibratory Screen—Rock Cleaved from Coal by Mechanical Means

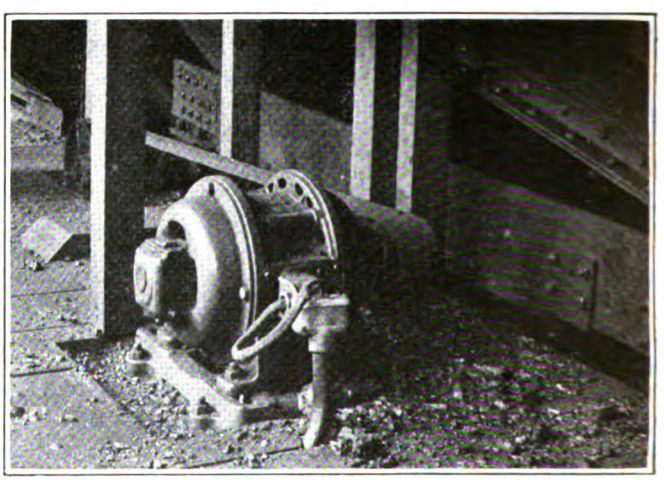
DURING the past winter a substantial market developed for bituminous coal of pea size, especially for smokeless fuels. With proper equipment low-volatile coal of this grade can be utilized as successfully for domestic heating as for steam raising.



At the new tipple of the Crozer Coal & Coke Co., Elkhorn, W. Va., pea coal from the Pocahontas No. 3 bed is prepared over Hum-mer electric screens, one of which is shown in the accompanying illustration. The installation in this tipple consists of two single-deck screens, each 6 ft. long and 4 ft. wide. These are placed in tandem on a slope of 30 deg. The screen unit thus formed takes a feed varying in size from nothing to 1 in. From this it separates all coal over ½ in. It is capable of handling this material at a maximum rate of 25 tons per hour. The tipple is provided with facilities for loading upon only four tracks, and accordingly pea coal is elevated to a 220-ton bin, which holds a day's supply.

At the mine of the Upland Coal & Coke Co., adjoining the property of the Crozer company and operating under the same management, the tipple is likewise equipped for the preparation of pea from Pocahontas No. 3 coal. At this plant, however, a 4x6-ft. Arms vibrating screen with ½-in. perforations is used for this purpose. This screen is horizontal and is supported from below. It receives its feed from a Marcus reciprocating screen, which prepares the larger sizes. The pea coal which passes over this Arms screen, as well as the slack going through it, is sent by chutes to railroad cars direct.

Tandem Vibrating-Screen Unit Removes Fines



This shows the fine-coal screens in the Crozer tipple. The tandem unit, which is electrically driven, separates coal less than ½ in. in size from the slack screened out by a preliminary process. The capacity of this unit is approximately 25 tons per hour. The screen is set on a 30-deg. slope.

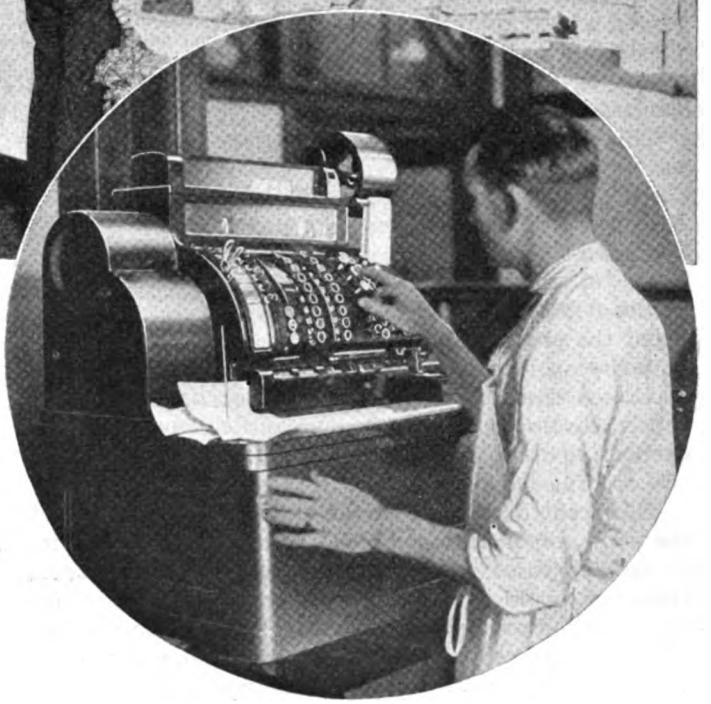
Tumbling Coal Breaker in Upland Tipple

Within the housing is a 9x11-ft. breaker which separates good coal from adhering but worthless bone and slate. Lumps composed of these two materials rejected from the picking table are fed to this machine. This saves the pickers from wasting time in cleaving the coal by hand from the bone.

Both of these tipples are equipped with Bradford breakers, which separate the high-quality lump coal from the bone and rock adhering to it. This machine handles the reject from the picking tables. A bone binder sometimes attaining a thickness of 3 in. occurs slightly above the middle of the coal bed. It is not the practice in these mines or throughout the adjoining fields to separate this bone from the coal at the working face. In the past it has been customary to lift lumps of combined coal and bone from the picking tables and cleave off as much good coal as time would permit. As a result of this practice much coal, as well as bone,

Vibrating Screen, Upland Coal & Coke Co's Tipple

This screen is horizontal and is installed under the main reciprocating screen. Over it ½x1-in. pea coal is prepared. It is driven by a 3-hp. motor.



was relegated to the dump. The time consumed in cleaving the bone by hand seriously lessens the ability of the pickers employed on the tables to prepare a large tonnage daily.

The practice now followed at the picking tables of these companies is to cleave off only the coal that separates readily from the bone. The residue or lumps of combined coal and bone which cannot be readily separated are fed into the Bradford breakers. These machines convert the coal into slack and reject the bone. The Crozer tipple is equipped with a 9x14-ft. breaker having a capacity of 50 tons per hour, and the Upland tipple has a breaker 9x11 ft. in dimensions.

F. FRASER MACWILLIAM'S name was incorrectly given as F. Fraser Williams on page 707 of the issue of May 20.

Company Store Run by Better Business Methods Lowers Costs and Gives Improved Service

Good Salaries Paid to Really Competent Men Who Know How to Turn Stocks Rapidly and Free from Spoilage

By Louis Spilman
Editor, *Industrial Retail Stores*,
New York City

BUSINESS IS business and welfare work is welfare work, but when a combination of the two results is good for both—that is a paradox. This, however, has been the result of the gradual development by coal-mining companies of retail stores to serve their employees. At the start, coal-mining companies were forced into the retail mercantile business in order to supply their employees with the necessities of life. This was due to the isolation of the mines and to the reluctance of independent capital to invest in stores located in these communities.

These early retail units, which were termed "commissaries," were not in any way progressive stores, but merely units that carried such items of food and clothing as were necessary to meet the general demand of the miners and other employees. As the managers of these commissaries were not experienced in store operation, the usual result was a tremendous overstock of inferior goods which were sold at high prices.

COMPETITION DOES NOT HINDER

The profit which accrued from the enterprise, nevertheless, was sufficient to call the attention of the mine operators to the fact that a large revenue could be secured through this division of their business. With competition developing, however, due to the rapid rise of the mail-order house, the building of a great system of hard roads, the growth of bus systems and the wider distribution of automobiles, thus giving access to larger cities, coal operators were face to face with the proposition of making one of two decisions: They must either end their mercantile operations and permit independent capital to care for the demand, or they must re-organize their stores on modern, progressive principles of merchandising, which would enable them to meet any competition offered.

The headpiece shows the butcher's shop at the Lynch store of the United Supply Co., a subsidiary of the United States Steel Corporation, Lynch, Ky.

Digitized by Google

The decision in most instances has been to develop the stores, and it has been found, that, as the commissary has given way to the modern retail unit, managed by an experienced personnel, stocked on a scientific basis and merchandised in the most approved and modern system, not only was the service to the employee better, the prices offered much lower and the qualities presented higher, but the net profits to the company itself were as great, or in most cases, even greater. As a thorough realization of the advantages to be gained by operating retail stores on modern principles became apparent, increased opportunities for the development of the stores were given.

Perhaps the greatest single step forward has been the absolute divorce of the mercantile enterprise from coal production. In Pennsylvania, this was made necessary some forty or fifty years ago, when the state passed a law prohibiting the operation of retail stores by industrial organizations.

This law is, of course, not necessary now so far as the coal industry is concerned, for there has been no recent evidence of the existence of the evils that brought about the passing of the early law. Today we find the majority of the coal companies in every state have separated these two functions, law or no law; either separately incorporating a mercantile department or conducting it as a distinct and independent section of the existing business.

The profit derived from the store, however, was not the only consideration which prompted the operators to develop these retail merchandise establishments to their present high standard. Labor, at certain periods, such as, for example, during the World War, became extremely scarce and the actual wage alone was not the sole consideration which caused the workman to become a permanent fixture in a particular community. During such times it was necessary to create within the laborer confidence in the company for which he worked and to surround him with an environment that tended to create contentment and satisfaction.

As the miner, or members of his family, visited the store daily, the company found that its largest opportunity to create confidence and to spread contentment was to give a square deal at the store. The prices and qualities had to be such that they would bear a favorable comparison to those offered by competing stores in nearby towns.

FIGURES OF OTHER COMPANIES AS GUIDE

This development in the store field has brought many problems to executives of coal companies. What should the investment be in merchandise? What should the cost of business be? What should the net profit be, if any? How many store employees should there be? What convenient system of credit for company employees can be utilized? What percentage of the total mine payroll should a company expect to be spent at the store? These are a few of the questions that have confronted the coal-company executive, since he began to realize the importance of a store to the satisfactory operation of a mine.

The only fair way to arrive at a conclusion on any of these questions is to find out how some of the successful coal-company merchandise units are operating and what their figures are. Let us turn first to the largest operators of coal-community stores in the United States, the Union and the United Supply Co., with headquarters at Pittsburgh, Pa., which operate seventy-one stores in Pennsylvania, West Virginia and Kentucky, in communities established by the H. C. Frick Coke Co. and the United States Coal & Coke Co.

The Union Supply Co. was incorporated as a separate organization in 1882, and the United Supply Co. was incorporated in 1902. The headquarters for both these groups is the same, and J. W. Anawalt is president of both corporations. The general offices are at Pittsburgh, where in addition to Mr. Anawalt, are the other general executives of the companies, including Frank Walton, general purchasing agent.

The Union Supply Co. operates sixty stores and has its general store headquarters at Uniontown, Pa., with C. L. Steiner in charge as general store superintendent. The United Supply Co. operates eleven stores, among which is the remarkable unit at Lynch, Ky., under the store management of John C. Howard. The general store headquarters for the United Supply Co. is at Gary, W. Va., where Claude Boughner serves as general store superintendent.

For the purposes of this survey, the two companies are considered together, and, as they are really under one executive jurisdiction, this can be done satisfactorily.

When you come face to face with the fact that this organization, only one of the many merchandising organizations developed during the past few years to serve coal-mining communities, has an average of 900

IN preparing this article for *Coal Age*, Mr. Spilman surveyed 101 coal-community stores located in various sections of the country. Here are some of the outstanding results of his survey:

Number of stores surveyed	101
Average store stock carried	$21,837.21
Average annual sales	$164,797.91
Average turnover	7.5 times
Average number of store employees	11
Average per cent of company pay roll spent at store	32.62
Average business other than company employees	9.4
Average salary of manager per month	$205.95
Average cost of doing business	13.95 per cent
Of this	
The average salary cost was	9.5 per cent
The average delivery cost was	1.07 per cent
The average rental cost was	0.83 per cent
The average advertising cost was	0.23 per cent

The rest of the 13.95 per cent is distributed in lesser amounts over a varied number of items.

Company Store of Island Creek Coal Co., Holden, Logan County, W. Va.

The coal company has its offices in this building. The superintendent's house is on the hill to the left. Stores are unloaded from the railroad, the Chesapeake & Ohio, on the right. Note the paved streets. It is an easy run from Holden to Logan, but the Holden store holds its own nevertheless.

Digitized by Google

employees, carries an average stock investment of over a million and a half dollars, and does an annual retail business of around twelve million dollars, you begin to understand why this branch of coal-mining company activities has taken on such an important aspect; anyway that's what the Union and United Supply companies are doing.

ONE THIRD DO A CASH BUSINESS

About 30 per cent of this business is for outright cash. The remainder is done on charge accounts extended to employees of the coal companies, who assign their earnings as collateral. Most of the business, of course, is done with the coal-company employees, but some of the stores, such as the one at Lynch, Ky., draw as much as 10 per cent of their business from people of the adjacent countryside, who are in no way connected with the coal company.

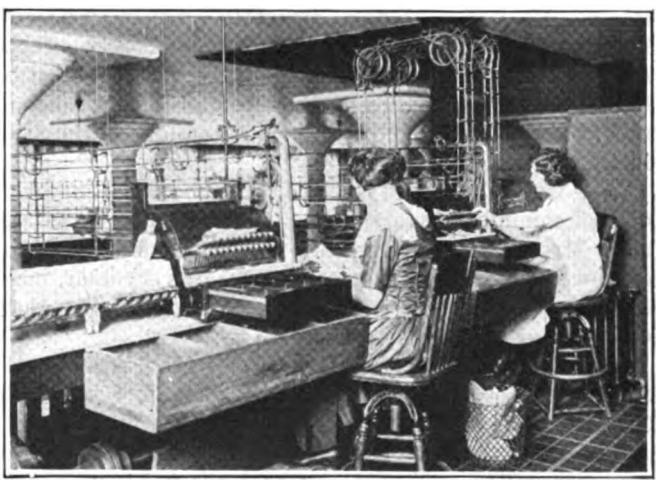
As to the matter of expense, the Union and United Supply companies made figures that would challenge many nation-wide chain-store organizations to equal. It costs them 15 per cent to do business and 10.37 per cent of this goes for salaries and wages. Their supplies cost them 2.5 per cent and delivery 1.2 per cent. They have discovered that to operate successful stores they must offer a fair wage to the store manager. Hence, the average salary paid Union and United Supply companies' store managers is $235 a month. In addition to the actual cash salary, the manager is, of course, given a discount on his merchandise and enjoys extremely low rent.

Grocery Department of an Illinois Mine Store

Over the counter may be seen the cash-carrier system. Order and neatness is the rule of the store. New goods, well displayed kept clean and moving. What a contrast to the older days!

Some coal-company executive will say, "Yes, all these things are very well for an organization of such size, but our company is small. We can have but one store, so there is little chance for us to compete with the nearby city stores or to expect to offer our employees any particular inducement as to price or assortment through our merchandise department."

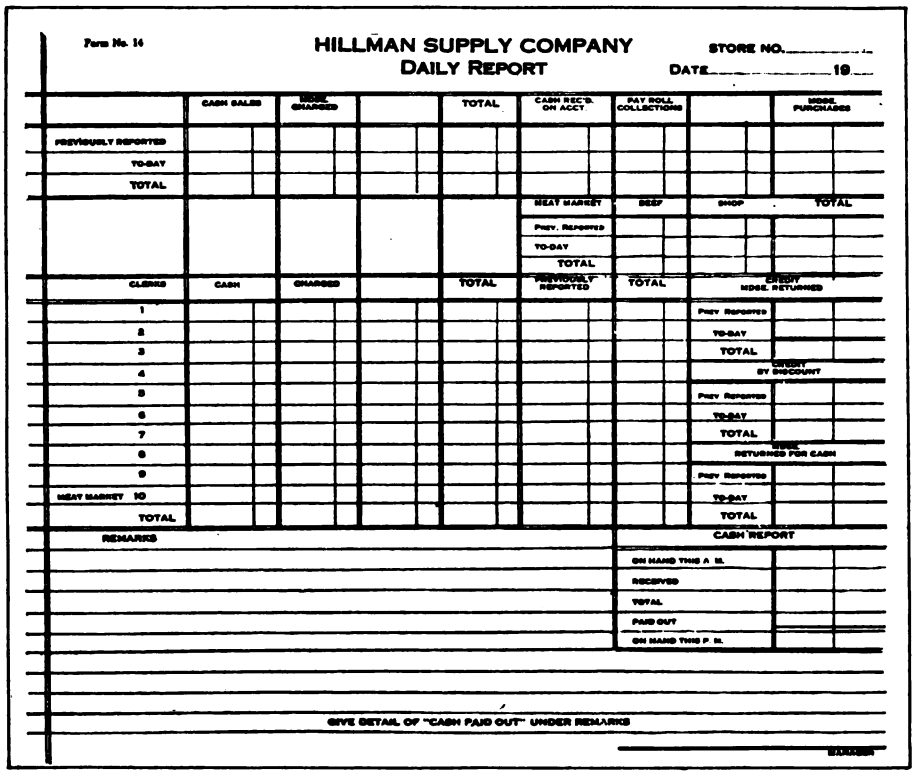
All we have to do is to turn to the Garden Coal Co., at Tazewell, Va. This company has one store, carrying an average stock of $8,500 and doing about $100,000 business a year, which is an excellent turnover indeed. They have four store employees. Twenty per cent of their business is outright cash, and the remainder is done on credit extended to employees of the coal company. About 15 per cent of their total business is done with people other than Garden Coal Co. employees.



Another of Lynch's Store Departments—This for Hardware

Show cases give an opportunity to tempt trade. The spick-and-span appearance has its value not only in making sales but in forbidding the keeping of dead stock. With no place to put it, every one tries not to get stock that will not sell.

The two outstanding facts about the operation of the Garden Coal Co.'s store that disprove what may be said about the single-unit operation, are these: (1) 42 per cent of the total payroll of the Garden Coal Co. is spent through the store, so evidently, the employees are well satisfied with the type of service, quality and assortment of merchandise and the fairness of the prices. (2) It costs the Garden Coal Co. just 6.19 per cent to do business, showing that the overhead of the small store does not necessarily eat it up. In fact, R. O. Van Dyke, secretary-treasurer of the Garden Coal Co., says that the officials of the company look on their store with great favor, in reference to net profit, as well as to the service rendered company employees.



Many companies find it necessary to operate three, four or five stores for the benefit of their men. In West Virginia are two examples of coal companies of this kind; the Lillybrook Coal Co., at Lillybrook and the Kanawha & Hocking Coal Co., at Longacre. The Lillybrook Coal Co. operates three stores and carries about $100,000 worth of stock, and does a business of about a million dollars. Its cost of doing that business is 9 per cent of the gross turnover. Fifty to fifty-five per cent of the coal company's payroll is spent at the store and 20 per cent of its business is done in cash. Figures to be proud of indeed!

Cash-Carrier System at United States Coal & Coke Co. Store, Lynch, Ky.

This building is fitted up like a city department store with every facility for display and for operation. The cash-carrier system shown above saves steps and makes it possible to keep a record of every transaction as made.

How the Hilman Supply Co. Keeps Track of Day's Sales

This enables the manager to see how much every clerk has sold both for cash and on charge accounts; also to keep account of returned merchandise whether charged or sold for cash.

The Kanawha & Hocking Coal Co. has four stores. It carries about $80,000 worth of stock in these stores, and during the first nine months of last year did just a wee bit under a half million dollars' worth of business. Its cost of doing business was 9.4 per cent. This company departs from the prevailing method of compensating store managers, in that it pays an average monthly salary of $160 and gives, in addition to this, 5 per cent of the net profits made by the store. Both the Lillybrook Coal Co. and the Kanawha & Hocking Coal Co. issue metal checks to the miners for use at the store as a convenient method of supervising credit.

Leaving the eastern and central fields in order to get an even broader outlook on store activities in coal communities, let us examine the records made by the Union Pacific Coal Co., which operates six stores with headquarters at Rock Springs, Wyo. E. R. Jefferis, manager of stores for this company, says that it is his endeavor to maintain the standards for efficient operation recommended by the outstanding authorities in the merchandise field.

"We realize that the isolated location of the majority of coal community stores is no longer a business asset," says Mr. Jefferis. "Instead, the automobile and the catalog have brought competition to our very door, making it absolutely essential that we offer quality merchandise at competitive prices."

The Union Pacific Coal Co. carries from $200,000 to $225,000 stock and does a business of from $900,000 to $1,110,000 each year, employing about fifty men.

The average salary paid the store managers is $230 a month. The cost of doing business is about 15 per cent, 7 per cent of which is for salaries and wages, including delivery costs. Twenty per cent of the business done is for outright cash, and the issuance of coupon books as a medium of credit, cares for the remainder. Approximately 25 per cent of the Union Pacific Coal Co. payroll is spent through the store.

On the Pacific Coast, the Pacific Coast Coal Co., employing union labor exclusively, operates four successful stores. They carry a little less than $100,000 worth of stock and last year did $558,156 worth of business.

E. F. DeGrandpre, manager of miscellaneous operations for the Pacific Coast Coal Co., supervises the store developments and maintains an efficient and concise survey of the store activities. Its figures are exact in every instance and are given here in detail. For instance, the company knows that 13.9 per cent of its business is for cash. It knows that 3 per cent of the business is done with people not connected with the coal company in any way whatsoever, and that the rest of the business is done through the medium of credit, as represented by coupon books issued in denominations of $2, $5 and $10, charged to the customer's account. It knows that 25.24 per cent of the Pacific Coast Coal Co. payroll is spent at the store, which is a fair percentage.

The cost of doing business is 14.34 per cent, and this is less than it was ten or twenty years ago. Mr. DeGranpre attributes this decrease to four causes: Improved methods of handling, increased volume of business, greater experience, and the standardization of merchandise. Its cost of doing business is so well divided that it is given in its entirety in Table I.

Table I—Distribution of Operating Costs, Pacific Coast Coal Co.

	Expenses Chargeable to	Per Cent of Business Transacted
A.	Salaries (excluding driver)	7.82
B.	Deliveries	1.38
C.	Fuel	0.22
D.	Store supplies and expenses	1.30
E.	Coupon books	0.11
F.	Repairs and renewals of buildings	0.51
G.	Losses	0.09
H.	Other expenses	0.05
I.	Depreciation of buildings	0.44
J.	Manager of stores and clerks	0.53
K.	Insurance	0.19
L.	General office salaries and expenses	0.75
M.	Taxes	0.30
N.	Rent	0.65
	Total	14.34

The item of rent is given as 0.65 per cent. No rent is paid as the company owns its own building, this figure merely being the amount set aside as a return on the investment in the building.

The investment required in merchandise, equipment and buildings to conduct the coal-community stores merits the close attention of the coal-company executive to the problems with which the stores are confronted. Just glance at these figures on the company-store business: There are about 7,500 of them in the country, distributed through coal and metal mining, lumbering and general industrial communities; they serve a population of seventeen million; they employ 100,000 people; and in bulk of business done the stores rank high in the retail distribution field.

Other Exhibits at Mining Congress Exposition

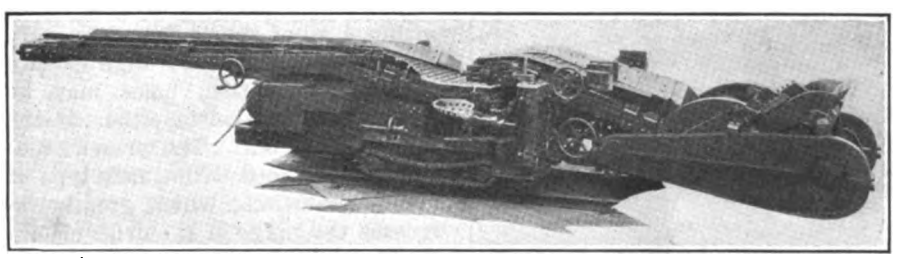
Shaking-Screen Family Has Enlarged During Year Past — Car Height Being Lowered to Meet Shovel Needs—Powder Men Seek to Meet Stray-Current Menace—Gas Detector—Drills and New Bonds

By Frank H. Kneeland
Associate Editor, *Coal Age*

NEAR THE entrance to the exhibition hall the Roberts & Schaefer Co. of Chicago had on exhibition its new Arms shaking screen. This consists of two decks of screen cloth mounted on wooden frames and supported at one end by the driving eccentrics and on the other by short rocker arms. As ordinarily used this screen is inclined at an agle of from 3 to 5 deg.

Shaker Screen

Two decks of screen cloth are superimposed in the Arms screen. The eccentric driving head is fitted with ball bearings. The motion imparted facilitates screening action.

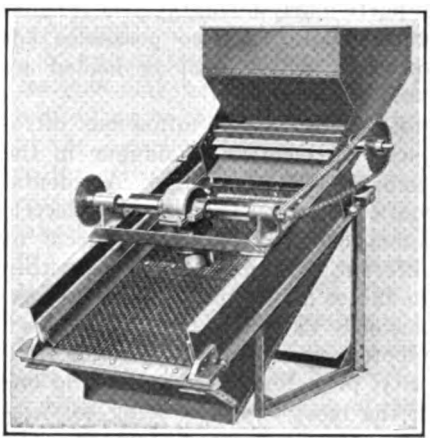


Because of the peculiar motion imparted to the screening surfaces this device is said to be highly effective and capable of breaking up a bed of material and agitating it uniformly so as to permit the undersize to pass through. The head is mounted on ball bearings and the machine operates at approximately 500 r.p.m. requiring from 3 to 5 hp. to drive it.

When installed in conjunction with air-cleaning plants, this screen provides a conveying action which helps to distribute the coal to the required points. When double decked an opportunity is afforded for providing the lower deck with the finer mesh of screen cloth, thus multiplying the screen area for the fine sizes, or those requiring the most screening surface.

Out in the "side show" tent in the rear of the building the Myers-Whaley Co. of Knoxville, Tenn., had one of its new 2-25 shovels in operation. The first machine of this type was put to work last September in a mine in Pennsylvania where it has been successfully employed in entry work ever since. The machine shown in Cincinnati was the second one of this kind ever built.

It is 39 in. high overall from the rail. This is the traveling height and for operation the machine requires 42 in. for the proper discharge of the shovel. It weighs 13,000 lb. It can be equipped for any track gage, from 20 in. upward. Its length is 23 ft. 10 in., width overall 5 ft., including the operator's platform, or 4 ft. 6 in. when this platform is removed. The shovel cleans up a space 17 ft. in width. A 15-hp. motor is employed for driving this machine and its capacity is 34 cu.ft. of loose material per minute.

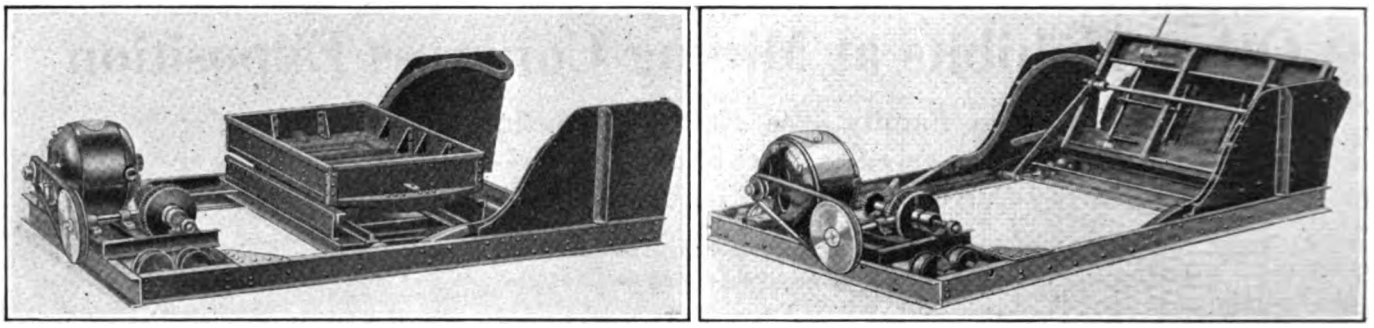


Several changes from previous designs have been embodied in this machine. Thus the motor drive is through a triple roller chain operating in a closed case. The drive to the rear conveyor is by a spline shaft with universal joints instead of by means of a long chain. Naturally other changes have been made but these are the most important.

With This Loading Machine Only Low Headroom Is Required

This shovel is the second of its model ever built. It will operate in a headroom of only 3½ ft. and may be traversed in 3 in. less space. Several refinements in design over previous types have been incorporated in its construction.

Especially for treating the smaller sizes of coal vibrating screens are being extensively employed in place of the older and better known shaker screens. The Kanawha Manufacturing Co. of Charleston, W. Va., exhibited its new Kanawha Vibrator,



Vibration Assures Effectiveness

Either a belt or direct connection to a motor may be employed for driving this Kanawha vibrator. The inclination of the screen surface and the speed of the drive may be varied to suit local requirements or to afford maximum capacity.

which it is claimed may be successfully used for screening any material that will pass through a wire cloth. It is particularly suited to the smaller sizes of coal, either wet or dry and ranging in size from 1½ in. downward.

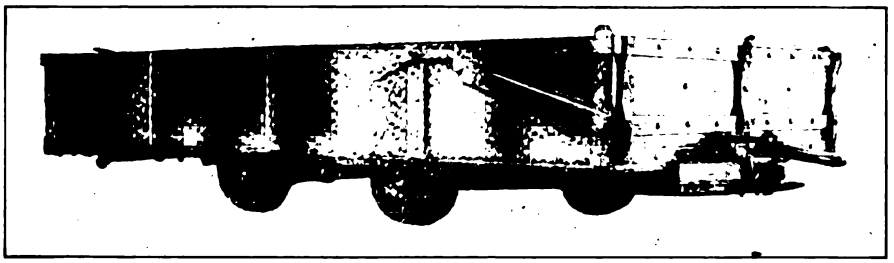
This firm also exhibited a model of its sidehill dump intended for refuse disposal. This device is a self-contained unit capable of discharging any type of car, but particularly adapted to those having "solid ends" such as are normally discharged in a rotary dump. As may be seen in the accompanying illustration, the car in its extreme position is several feet to the side of the refuse track. It is thus unnecessary to move this dump frequently and when a move

Digitized by Google

Any Kind of Car Can Be Dumped by This Mechanism Which Is Made for Sidehill Refuse Disposal

Although any kind or type of car may be handled by it, it is primarily intended for dumping those having solid bodies. The car is turned almost completely over and as it is moved several feet transversely the dump need be transfered only infrequently, making it possible to keep the track nearer the body of the rock pile where the grade is easy to maintain and where there is less likelihood that a sudden slide will take the dump and the track down the hill. The trouble with the dumping of rock is that track and dump have to be taken onto the uncertain ground at the edge of the rock pile necessitating frequent regrading, and the placing of rock by hand. This disadvantages is obviated by this mechanism which is well away from the pile's edge.

becomes imperative the frame may be skidded to its new position in a short time.

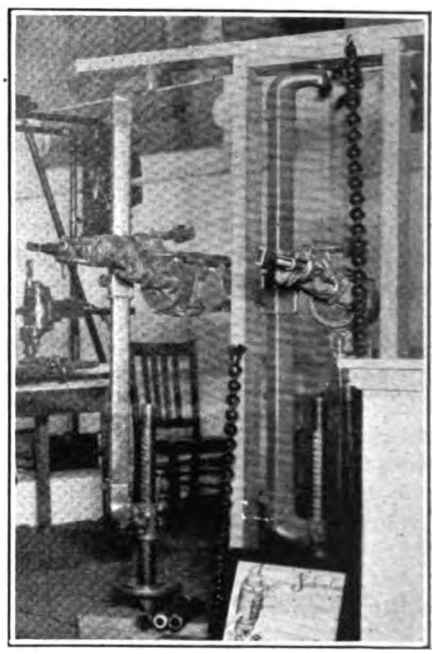


Low cars are becoming the vogue. The Watt Mining Car Wheel Co. of Barnesville, Ohio, exhibited a car of this kind that was designed primarily to secure large capacity and low height. Though this type of car is particularly advantageous for machine loading it also possesses advantages where coal is loaded by hand shovel.

Electrification of mines has introduced an element of danger in the shape of stray currents. Accidental contact between the wires of electric detonators and any two objects of different electrical potentials within the mines may cause a premature explosion. Various schemes have been adopted for overcoming this difficulty, probably the simplest and one of the most effective being to twist the ends of the wires together. The Hercules Powder Co. of Wilmington, Del., however, has introduced a spring clip spanning the ends of the wires. This makes a positive contact between these two conductors beyond the insulation. When short circuited in this way tests with a 550-volt power line have fused the wires at the point where they were connected by the clip without setting off the cap. It is claimed that this clip affords positive protection from stray currents. It may be removed with the fingers leaving the wires clean and straight ready for use.

Many operators consider the old flame safety lamp as constituting a possible source of danger. To overcome this difficulty and at the same time obtain results comparable to those afforded by it, the Concordia Electric Co., of Pittsburgh, Pa., is introducing a new gas indicator. This device depends for its operation upon the power of a platinum sponge to absorb inflammable gas. The detector is equipped with a small 2-volt dry-electrode battery.

When the current is so regulated that the wire upon which the spongy platinum is deposited will just glow perceptibly in pure air, it will be found that when placed in a mixture of air and gas this wire will be heated to redness. Its glow will increase as the relative proportion of combustible gas to air increases and when a 10-per cent admixture is attained the wire will become white hot.

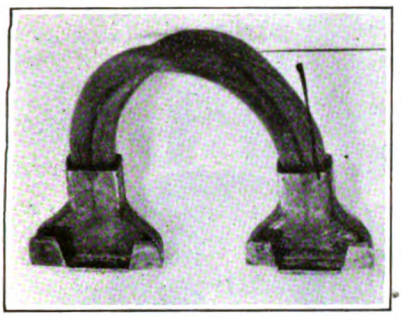


This device measures 5¾x2¾x2 in. and weighs approximately 2 lb. 2 oz. It is claimed that it constitutes a convenient, reliable and accurate means for determining the gas content of mine air without the use of a flame of any kind. Furthermore, tests may be made with it by almost anyone, the skill required being small compared with that necessary for the manipulation of a safety lamp.

Car Is Low, Wide, Strong and of Large Capacity

This car was designed primarily for machine loading, but is excellently adapted to hand-loading as well. It stands only 28 in. above the rail and is over 6 ft. wide inside, so that shoveling into it is easy and its capacity is large even though no chunking is done.

The Chicago Pneumatic Tool Co. showed an improved type of post drill. The improvement consists of the provision of a movable footpiece with both a ratchet and a screw adjustment. The footpiece or tube is of hydraulic pipe with notches fitting a pawl. Inside this pipe is a screw provided with a hand wheel—or in this case a "foot wheel." This improvement permits drilling holes within 4 in. of the roof or floor. By digging the fixed spur slightly into the top or bottom, holes may be drilled within 2 in. of either of the cap or foot rock. The present machine is provided with a new type of reversible switch, which greatly increases the range of the drill. Holes may be drilled at any angle.



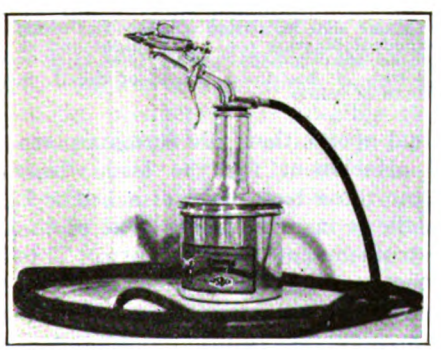
Improved Post Drill

Improvements on this machine consist of the top and bottom spurs and the switch controlling the motor. The arrangement is such that holes may be drilled within 2 in. of either top or bottom.

The Penn Machine Co. showed a new type of short stranded bond intended for installation under the

Digitized by Google

flange of the rail. An angle bar is placed on one side of the rail and a fishplate on the other. The hooks of the bond terminals are slipped over

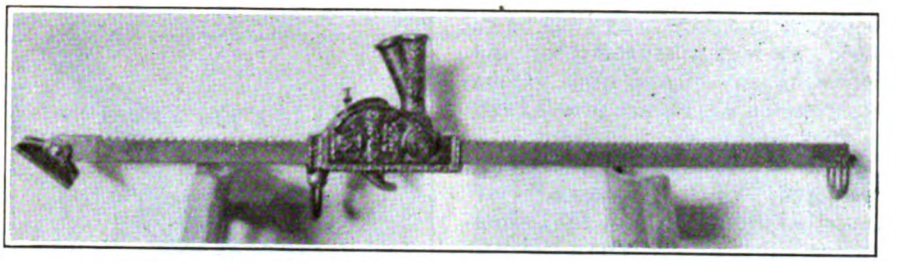


Short Rail Bond for Welding to Rail

When in place this bond is comple ely protected from injury. The terminals may be pushed over the flange of the rail and form a mold for the copper weld. Application is thus easy and rapid, and the bond is entirely below the rail out of harm's way.

the edge of the flanges on the fishplate side and pushed or driven to place. This holds the bond in position while it is being welded to the rail. As may be readily seen this bond is thoroughly protected, being entirely below the rail flange and out of harm's way.

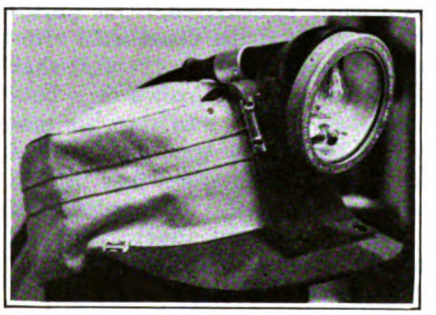
Templeton, Kenly & Co., Ltd., of Chicago, exhibited a type of jack for pulling mine timbers. This machine was designed originally for telephone use, that is, for tilting or moving poles. Inasmuch as it may be used for pulling quite as readily as pushing, however, it makes an excellent post puller. For this purpose, it is anchored at one end and a chain from the post to be pulled is hooked



Handy Paint Spray Gun

This gun holds 1 qt. of paint but larger sizes may be obtained. With this outfit a man can cover several times as much surface as he is able to cover without its aid. Furthermore the paint is shot to place and intricate surfaces are little if any harder to paint than plain ones.

to the jack head which is then traversed along the ratchet bar.



Painting at the average coal mine requires periodic attention. The Simons Paint Spray Gun Co., exhibited a small paint gun that should find favor at the larger mines at least. This new gun consists of an aluminum container of 1 qt. capacity

Puller Suited to Use in Recovery of Mine Posts Under Pressure

Designed primarily for telephone work, for the lifting or tilting of poles, this jack is finding application as a post puller within the mines. For this purpose it is amply strong yet light enough to be readily carried from place to place.

provided with a friction top to which the spray nozzle is attached. After filling, it is only necessary to give the top a few light taps with the hand to fasten the cover firmly in place. Air for this gun is supplied by a small compressor driven by a ½ hp. motor that may be attached to any light socket. The compressor and air tank or receiver may both be mounted on a hand truck that can be readily moved anywhere. It is claimed that with the aid of this machine a man will cover from 6 to 8 times as much area as he would be able to cover by hand methods.

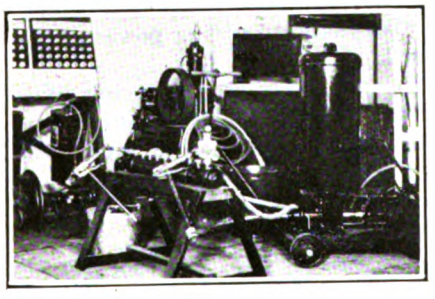
More Comfortable Cap Lamp

Note the bracket by which it is attached to the cap. The lamp has a less leverage upon the wearer's head and is held more firmly than usual.

The Koehler Mfg. Co. showed its improved Super-Wheat lamp. This lamp like its predecessor is provided with two bulbs, but one is of higher power than the other and affords much more light than the lamp it replaces. The most recent improvement, however, consists in the bracket by which the reflector is fastened to the cap. As will be observed this bracket is shorter than the old one and is stiffened by means of ribs or corrugations that are rolled into the metal. This makes the lamp much firmer on the cap and reduces its leverage on the head of the wearer. Incidentally, the illustration shown was made from a photograph taken by the light of another lamp of the same kind as that photographed. This well demonstrates the light-giving power of the new lamp.

In one of the accompanying illustrations may be seen the new composite type of car built and exhibited by the American Car & Foundry Co., in the construction of which are incorporated several details that decrease its weight and lengthen its life. Thus the drawbar is a plate or strap that is forged in a U-shape and inverted with the opening of the U flanged outward forming a bearing for the edge of the floor planks.

Under the outer edges of these planks are the flanges of the bottom plates. These floor plates extend first outward, then upward the thickness of the planks, then outward to the sides of the car where they are again flanged upward affording connection to the side boards. In cross-section each plate is thus a Z terminating at one end in an L. With the belts and other ironing an extremely rigid construction is afforded. All iron work is riveted and the planks are bolted in place. Any



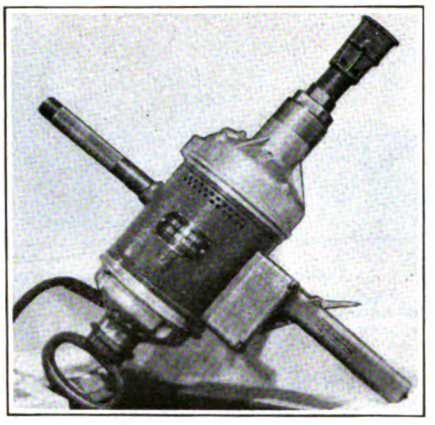
Low Car of Large Capacity Suited for Mechanical Loading

Small height above the rail, large capacity and ease of repair are the cardinal virtues claimed for this car of composite construction. To decrease the necessary headroom the wheels are let into the car floor and housings over them forged into the plates.

Digitized by Google

woodwork that fails may thus be replaced without disturbing or disconnecting any of the irons. Housings over the wheels are pressed into the floor plates.

Greasing cars has always been considered a kind of "necessary evil" about the mines. One of the accompanying illustrations shows the new grease gun exhibited by the Lincoln Steel & Forge Co. This machine is small in size and may be used either as a piece of portable equipment or installed permanently. The outfit consists of a motor-driven air compressor, an air receiver, a grease tank, the gun proper, the delivery hose and the nozzle. The grease reservoir on the gun holds 50 lb. of grease and the machine is arranged to discharge a predetermined weight of this lubricant each time the nozzle trigger is pulled. Ordinarily about ¼ to ½ lb. of grease is thus delivered under pressure. The nozzle may be



Power Car Greaser

A ½-hp. motor will drive this machine. The grease tank will hold 50 lb. of lubricant which is forced into the bearings under heavy pressure.

of several types, the latest being one that needs only to be pushed against the grease plug of the wheel and held there as the grease is discharged.

The Simplex Wire & Cable Co., of Boston, Mass., exhibited its new selenium-rubber covered cable. This is a mechanically strong rubber covering which the company claims will wear 50 per cent longer than any compounds it formerly marketed. It is called a 60 per cent selenium-rubber armor, meaning that it contains 60 per cent pure rubber. Selenium is peculiar in that it is a non-conductor of electricity in the dark, but a conductor in the light. It is sometimes called a non-metallic metal. It costs about $2 per pound as against 4c. for sulphur.

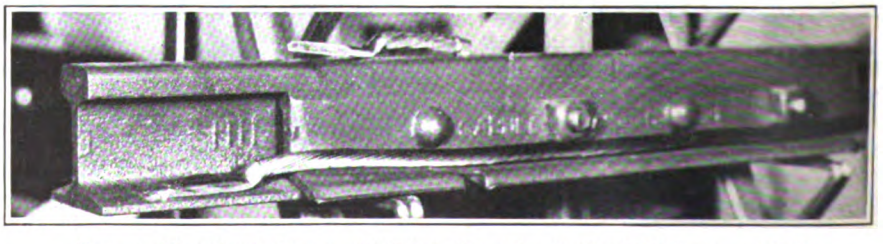
The Cincinnati Electric Tool Co.'s shothole drill exhibited at this show has been provided with a new automatic switch so arranged that release of the trigger stops the machine. This drill weighs 48 lb. and operates on direct current at 250 volts. The new switch is of the quick

Electric Drill for Shotholes

The switch on the right hand grip of this drill was completed just before the Cincinnati exposition. It is so arranged that release of the trigger stops the drill—a valuable safety measure.

make-and-break type so arranged as to be kicked out as soon as pressure of the hand is removed. One objection to power drills fitted with ordinary switches has been the fact that a switch had to be thrown or a button pushed in order to stop the machine. The result was that serious accidents sometimes occurred in case the auger struck a hard substance. In such a case the auger remained stationary and the machine itself revolved twisting up the lead cable and sometimes the operator as well before power could be shut off. The new switch obviates this difficulty and tends towards safety.

The Electric Railway Improvement Co., showed a copper terminal bond that can be laid in place and copper-welded to the rail without the aid of a form or mold. This is done by means of a special copper electrode, which is a pure copper rod covered with a coating of carbon and silicon, which greatly reduces the tendency of the metal traversing the arc to fly or splutter and makes it possible to weld the terminal to the rail without a mold or form. In practice the two terminals are laid on the two rails and held in place usually by the workman's knee instead of being clamped rigidly in position.

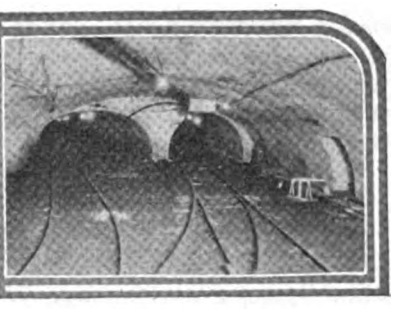


E. I. du Pont de Nemours & Co., showed a small single-shot blasting machine. The body of this device is about 1½ in. in diameter and 5½ in. long and weighs approximately 2 lb. It is fitted inside with a small spring-actuated magneto. A suitable ter-

A Single-Shot Blasting Machine

This little machine which may be hung on the belt by means of the swiveling ear at its top furnishes a ready means for firing one shot at a time which is the usual method of blasting coal. It is light and so durable that nobody knows how long it will last. It has the approval of the U. S. Bureau of Mines.

minal upon either side forms a place of attachment for the lead wires. After these have been attached a T handle is inserted in the head of the instrument and given a turn. This actuates a spring, which in turn, drives a small magneto generating enough current to discharge a single cap, igniter or electric squib. This machine has been approved for safety, reliability and durability by the Bureau of Mines.



Copper Terminal, Copper-Welded, Can Be Applied Without a Mold

The welding electrode is said to be so made that the molten metal carried by the arc does not splash and splutter in the usual manner. Hence, this bond can be welded in place while being held against the rail by the welder's knee.

Underground Operation

Is the Finest Coal Dust as Hazardous as That Which Is Coarser?

Certain Laboratory Experiments Show That Dust of 15 to 25 Microns Diameter Gives on Ignition Greater Pressures than Coarser or Finer Dusts

Mining engineers have been disposed to regard coal dust as becoming progressively more dangerous as it becomes finer. The U. S. Bureau of Mines has quite generally supported this point of view. And, indeed, it seems almost ill-advised to question the conclusion, because, once questioned, there may be many who will fail to appreciate the fact that though the finest of the coal dust may be relatively less dangerous than that which is coarser it may nevertheless be true that the most dangerous coal dust is that which still may be regarded as exceedingly fine.

PEAK OF EXPLOSIBILITY

Apparently the most explosive coal dust has a diameter somewhere between 15 and 25 microns. Now a micron is 0.001 millimeter. Consequently the dust which is 0.015 to 0.025 millimeter, or about 0.006 to 0.01 in. in diameter is possibly the most explosive of any. Such dust might quite rightfully be termed very fine, in fact impalpable. To get an idea of the size of the particles from 102 to 169 would go side by side and yet only occupy a linear inch. To cover a square inch, imagining them exactly square, 10,332 to 28,674 would be required. As they may be of any shape the square inch would not be entirely occupied by the particles even then.

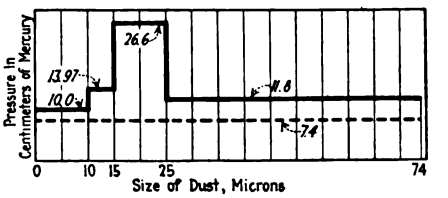
Say Craig M. Bouton and J. H. Hayner in bulletin 22 published by the Carnegie Institute of Technology, the U. S. Bureau of Mines and the Mining & Metallurgical Advisory Boards conjointly, entitled "Rate of Combustion of Coal Dust Particles: Part II—Effect of Particle Size Upon Pressure Increase Attending Flammation of Coal Dust" (price 50c.):

"It has been generally accepted that the explosibility of coal increases as the fineness of the dust is increased. Early tests conducted by the U. S. Bureau of Mines, in which the portions of a ground dust caught on 20-, 40-, 60-, 80- and 100-mesh sieves, respectively, were subjected to identical tests for explosibility in a large steel gallery, demonstrated the accuracy of this statement for the range of sizes tested.

"Clement and Scholl concluded that 'the finer the dust the greater is its flammability,' and supported their assertion by photographs of the flames produced by the ignition of suspensions of four different sizes of one dust. The same order of explosibility has been shown in tests in the Experimental Mine of the Bureau of Mines."

FINEST DUST NOT THE WORST

This bulletin describes experiments planned to obtain a quantitative relationship between the fineness of dust and its tendency to flare up when suspended as a cloud and ignited at some point. The experiments gave the unexpected result that flammability does not increase indefinitely with fineness but seems to reach a maximum, and then fall off or at least remain constant, as the fineness of the dust is still further increased.



"This result, of course, cannot at this stage be held as valid except for the authors' own experimental conditions. Until further analysis of the various factors which enter into the procedure for obtaining the fine sizes of dust and into the method of testing for flammability, little more can be done than report the methods and results and indicate what seem to the authors to be the probable reasons for the apparent anomaly. In the meantime, experiments are being continued for the purpose of evaluating the various possibilities.

"It may be stated, however, that three possibilities—two chemical and one physical—are being considered in relation to this peculiar reluctance of very fine suspended dust to flame.

"First, it may be a property of coal that, when pulverized, the very fine dust is of a somewhat different chemical nature from the coarser dust, because of a greater friability of some constituents than of others.

"Second, the process of elutriation which suspends the dust in air for long periods, may result in a greater degree of oxidation of the finest particles than of the coarser sizes.

"Third, the very fine dust may tend to agglomerate or form groups of particles so that a cloud of this dust may actually be less completely dispersed in air than a coarser dust."

Shows Relation of Size of Dust to Explosive Violence

For each size in microns is plotted the average pressure in centimeters of mercury for all the tests made on the flammation of Pocahontas coal in the test recorded in Table II. The fact that the mixture of sizes from 9 to 74 microns gives a low result suggests that the mixing of sizes deadens the explosion.

"ELUTRIATION" BY AIR

Perhaps something should be said as to "elutriation." As used by the authors it is the segregation of certain sizes of coal dust by air. Of course, the finer sizes of coal dust cannot be separated by screens. It was observed that with Pittsburgh coal the fixed carbon increases as the fineness increases and the volatile content and ash decrease.

This decrease in the ash and volatile content with increased fineness was not unexpected, because the constituent of coal known variously as fusain, coal charcoal or mother of

Digitized by Google

coal is extremely friable and of low volatile and ash content and would tend to accumulate in the finest portion of the coal. "On the other hand, the bony and slaty particles are more resistant to pulverization."

"The excess of ash in the coarsest fraction is, probably, also attributable to the presence of the hard mineral pyrite, a supposition which is strengthened by the similar distribution of sulphur." The oxygen is higher in the fractions than in the unsized coal, but emphasis should not be placed on that fact, for the oxygen determination, being by difference, is the most subject of any to errors.

Table I—Analysis of Coal-Dust Samples, Per Cent

Size (Microns)	Fixed Carbon	Volatile	Ash	H	C	N	O	S	Calories per Kg.

15–25	27.0	27.6
25–74	9.7	14.0

Reasonably Consistent

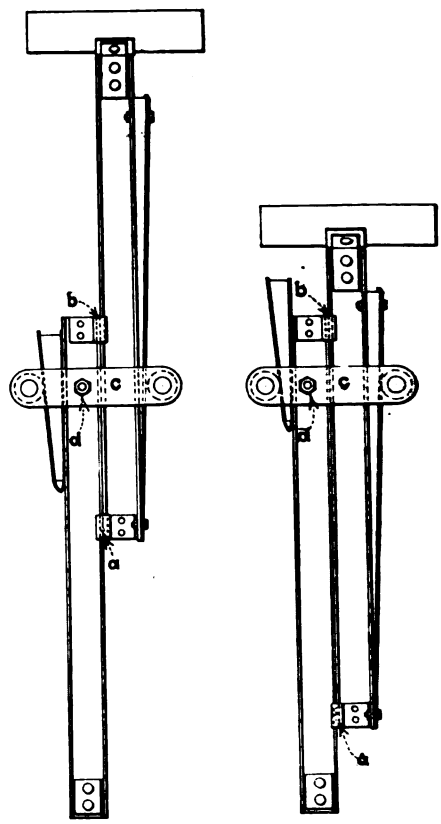
It might be well to give the last of the series of tests on Pocahontas coal, thus exhibiting the degree of consistency of the results and the nature of them. It is noticeable that the 15- to 25-micron coal gives the greater pressure on flammation. The dust from 25 to 74 microns in diameter gives a distinctly lower pressure—only half as great as that of dust of diameters ranging from 15 to 25 microns—and that is true also of the dust ranging from 0 to 10 microns in diameter. The figures given in this series of tests for Pocahontas coal have been averaged for each size and plotted so as to make the relation of the values more obvious. This the bulletin does not do, possibly because there is some slight possibility that such a graph might be misleading as not giving the values for any given size but for the range of sizes. If we knew what the values for any particular size actually were the graph might be somewhat different.

Slowly Yields Under Weight Like Wood Prop

Roof support always is a perplexing problem in mining work. Steel and concrete timbering for many years have gradually been taking the place of many of the less permanent wood posts and sets formerly employed. In either of these materials 3-piece sets may be readily constructed, but the simple steel mine prop appears to be far more difficult to fashion.

Hails from the Sarre

In the Sarre region, Charles Gascard, a well known mining engineer, has devised and put into use the prop shown in the accompanying illustration, which is taken from the *Colliery Guardian*. This shows the prop both extended and collapsed. In construction this prop is extremely simple, being composed of two similar pieces of H-beam clipped together so they can slide one upon the other by means of the clips *a* and *b*. Near the upper end of the bottom section and encircling both pieces is a yoke, *c*, which is fastened to this section of the prop by means of a bolt, *d*, that passes through a slot in the yoke. Along one side of the upper section is fastened a long tapering wood wedge faced with strap iron. A shorter and blunter wood wedge is driven between the yoke and the lower section of the prop. This binds and locks the two parts together securely. If desired, a wood cap piece will afford the needed cushioning effect in the manner shown.



Yields Better Than Wood

When properly set in the manner just described this prop takes weight in exactly the same manner as a wood post under similar conditions. Whereas a wood prop would crush, however, the two parts of this prop slide slightly past each other. This action, however, because of the relative proportions of the two wedges, can take place only under extreme pressure. The prop will continue to support the roof until it has been telescoped in this way for almost 50 per cent of its length.

All mining men will readily appreciate the advantages of such a prop. Sudden falls are avoided, the prop itself lasts indefinitely, actual collapse of the roof is extremely rare and, in most cases, as soon as the superincumbent strata start to "work," movement of the two prop parts upon each other is accompanied by considerable noise, giving ample warning of roof conditions.

Knock Out Wedge; Use Again

This prop has been made in lengths ranging from 2½ to 13 ft. It was first put into practical use in 1918 and has now been tried in many mines and under widely varying conditions. It is asserted that no roof supports of this kind have been broken or bent in service. Nor have they fallen down when in use. As they are withdrawn by merely knocking out the blunt wedge they can be used over and over again. It is difficult to give actual comparative costs or savings, but it has been estimated that they pay for themselves in one year's use and thereafter return about 80 per cent of their cost yearly.

Takes Great Weight Without Failure

This shows the Sarre pit prop both extended and collapsed. Ready adjustment to height between wide limits, high resistance to collapse and great durability are the chief advantages of this new steel post.

News Of the Industry

Wholesalers Want Positive Policy Instead of One of Negation Only; Statistics, Said One, May Cure All

Toledo, Ohio, June 8.—Determination of the stand to be taken on National Legislation came to the front this morning as the biggest problem confronting the American Wholesale Coal Association which opened its tenth annual convention at the Hotel Secor yesterday. Ira C. Cochran, commissioner, brought the problem home when he announced that a motion to place the Copeland bill before the Senate Monday had been defeated by only two votes.

Mr. Cochran made this statement in the course of a review of the legislative situation. There were, he said, three schools of thought on the question. One group opposed all legislation as dangerous and unwarranted. This position was supported by a line of resolutions adopted at preceding conventions. A second group found nothing objectionable in the Parker bill now before the House Committee on Interstate and Foreign Commerce. A third group agreed that the Parker bill itself was harmless but opposed it because it would establish a precedent for more drastic legislation in the future.

How Regulation Grows

The development of the present railroad regulation from a seemingly innocuous beginning and the manner in which supervision of the packing house industry had been extended, said Mr. Cochran, showed that the fears of the third group were not wholly groundless. Other amplifications of government power also made clear the danger of making a start. At the same time the speaker placed little confidence in constitutional objections pointing out that regulation had been enforced in many other cases where there was no apparent specific grant of authority to Congress.

The commissioner devoted some time to discussing the position of the Department of Commerce on the legislation now pending. He read a number of extracts from the testimony of Secretary Hoover before the House Committee, in which Mr. Hoover had favored a suspension of Congressional activity in order to give the coal industry a chance to work out its own salvation. The so-called Hoover amendments to the Parker bill made, he said, at the request of the committee, were improvements upon the original draft.

Dr. Allan H. Willetts, National Coal Association, expressed the hope that the statistical work undertaken in a modest way by the bituminous operators would make legislation unnecessary. The National Coal Association, he stated, was unalterably opposed to any Congressional action at this time.

In the general discussion that followed, many members wanted to know what appeals could be made to Congress to forestall legislation. Some of those objecting to regulation, nevertheless, held it would be improper to ask senators to vote against bringing up the Copeland bill for discussion. Mr. Cochran pointed out that a constructive attitude was needed, that the industry could not hope to defeat the organized movement in favor of regulation by a consistently negative policy. Formulation of a definite statement of the association's position will be left to the Committee on Resolutions which reports tomorrow.

Following the formal opening of the convention with an address of welcome by Fred J. Merry, mayor of the city, and a gracefully worded response by George M. Dexter, of New York, past president of the association, the delegates settled down to a consideration of the reports of the officers and committees. President Harry warned the organization th industry was facing the mos period in its history. The said, a real effort, foste minority of domestic cor northern New York and Ne to put the coal business i ernmental strait-jacket.

Senate Refuses To Consider Copeland Bill

Senator Copeland of New York made an ineffectual effort June 7 to get his coal bill before the Senate on a motion to allow consideration of his bill for a period not to exceed two hours. The vote was 43 to 25. Thus the motion failed by the narrowest of margins to receive the two-thirds vote required for a special order of business. As this is written, June 8, the New York Senator is trying to bring his bill before the Senate in a way which will require only a majority vote for its consideration.

The Copeland bill provides for compulsory fact finding, authorizes the President to set up an emergency coal board and to declare operative the fuel distribution act of 1922, with an amendment providing that the Interstate Commerce Commission must comply with recommendations of the fuel distributor.

Digitized by Google

act fuel-oil propaganda. The association, he said, was now studying proposals of finance corporations to finance deferred payments on domestic coal and would report to the Association thereon at a later date.

E. M. Platt, of Chicago, discussed the efforts of the Western members of the organization to induce the railroads to grant more liberal reconsignment and diversion rules. He cited the practices of the anthracite carriers at Chicago. These rules had been extended to Detroit. Tariffs which would again curtail the Detroit privileges, he announced, had recently been disallowed by the Interstate Commerce Commission.

The Chair appointed Leonard F. Leighton, Carbon Coal and Coke Co., Boston, Mass.; E. M. Platt, Platt & Brahm, Chicago, and George M. Kearns, Kearns Coal Co., Cincinnati, Ohio, as a committee on resolutions. Seth Morton, W. G. Morton Coal Co., Albany, New York; George M. Dexter, Dexter-Carpenter Coal Co., New York; Ira Bixler, Bixler Coal & Coke Co., Pittsburgh, Pa., and Fred Legg, Logan & Kanawha Coal Co., Cincinnati, were named as the committee on nominations.

Pulverized Coal

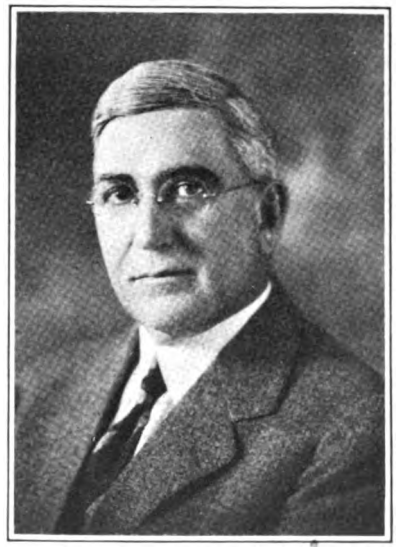
Joseph Harrington, consulting engineer, Grindle Fuel Equipment Co., addressed the convention this morning on "The Use of Pulverized Fuel." While all the technical problems have not been solved powdered coal is gaining ground in steam-generation. In 1920 the boiler capacity using pulverized coal was 40,000 hp. In 1924 the horsepower had increased to 210,000. Actual consumption now approximates 5,000,000 tons annually as compared with 8,000,000 in cement plants where powdered coal has been used in cement burning for many years. Before long he predicted consumption for steam generation would exceed that for cement burning.

Mr. Harrington's paper provoked lively discussion by coal men interested in selling to plants using powdered coal. The ash content, he said, was more important in running up the cost of pulverization than in affecting combustion. The highest type of underfeed stoker installation with clinker grinders but eliminating economizers and preheaters would give an overall efficiency of 82 per cent as compared with 87 per cent in a pulverized fuel installation. Control of the fine ash blown out of the stack still baffled the engineers.

Owen Meredith Fox, executive vice-president, Chicago Coal Merchants Association, was the last formal speaker of the session. His subject was retail and wholesale co-operation in the establishment of a fuel research institute.

This evening the annual banquet will be held at the Chamber of Commerce. Noah H. Swayne II, of Philadelphia, past president, will be the toastmaster. Edwin Morrow, ex-governor of Kentucky and member of the defunct railway labor board, will be the principal speaker, substituting for Senator Watson of Indiana.

Tomorrow morning the Association will consider the report of the Resolutions Committee and elect officers. G. H. Merryweather, vice-president, is talked of for president.



Move to End British Strike

Another move to end the British coal strike, now in its sixth week, was made a few days ago when Evan Williams, representing the mine owners, invited Herbert Smith, president of the Miners' Federation, to meet him informally at an early date. At the time the invitation was extended, Mr. Smith was in Brussels, attending a meeting of the Miners' International. Announcement was made on Saturday that the executives of the Miners' Federation would consider the invitation at a meeting on June 8.

No official announcement of the terms of discussion proposed by the mine owners has been made. Unofficial reports indicate that the operators are ready to abandon their demand for an immediate reduction in wages, but will insist on a longer working day. It is also understood that they may propose a small joint committee, with an independent chairman, to reconsider the entire mining question.

The Cannock Chase operators have offered to pay 1924 wages if the men will work eight hours.

Comment in advance of the meeting of the miners was pessimistic. On June 7, A. J. Cook, secretary of the Miners' Federation, stated that the miners' executive committee would probably agree on the day following to accept the invitation of the coal operators to a preliminary conference regarding the strike.

F. C. Hohn

Who addressed the Coal Mine Officials' Convention at Cincinnati on "Trackwork, Details and Maintenance." Mr. Hohn graduated from Purdue University in the School of Engineering and entered the service of the Baltimore & Ohio R.R. shortly afterwards. He continued in railroad maintenance and construction work until he entered railroad valuation work as chief of field parties with the Kansas City Southern Ry. Later he was with the Delaware & Hudson R.R. Co. in a similar capacity, becoming in 1917 division engineer of that company. In 1919 he had charge of mine and railroad track maintenance and construction for the Hudson Coal Co. He is now engaged in appraisal and consulting work.

Miners Overpowered in Mine of Alpha Cement Company

Within four hours after they had entered the mine of the Alpha Portland Cement Co. at Ironton, Ohio, the last of the eighty miners who had been overcome by a mysterious gas were rescued alive. The miners entered the mine at 7 a.m. and, on reaching the workings off the main shaft, 576 ft. underground, began to lose consciousness. Those nearest the shaft dragged themselves to the cage and were hoisted to safety, where they spread the alarm. Workers with rescue equipment worked continuously until everyone in the crew had been brought to the surface. From all that can be ascertained coal was not being mined at this shaft. According to reports, officials of the company denied that the strange gas which caused the miners to collapse on their way to their work was either blackdamp or methane.

Pennsylvania Coal & Coke Deficit Drops

A deficit of $56,963 for April is reported by the Pennsylvania Coal & Coke Co. and its subsidiaries. This is after charges, ordinary taxes, depreciation and depletion, but before federal taxes, and compared with a deficit for the same month last year of $62,648. For the first four months of this year the company reports a deficit of $77,170, against a deficit of $221,333 in the same period of 1925.

The final report on earnings for 1925 showed a deficit of $467,532, as against a deficit of $425,324 in the preceding year. In its preliminary report, published Jan. 27, the deficit was fixed at $461,294, as against $428,376. Net sales were $5,652,013, as compared with $5,959,582 in 1924. Other income reached $250,824, against $180,279 in 1924. Expenses, depreciation and depletion totaled $6,370,369, as against $6,565,095 in the preceding year. No provision is shown for federal taxes in either year.

Total assets for 1925 were $13,079,923 and total liabilities $12,271,296. Cash was $267,180; accounts and notes receivable, $761,068; United States Government securities, $120,950; inventories, $79,868; and coal on hand, $89,445. Of the current liabilities accounts payable were $457,800, while accrued interest and taxes reached $57,200.

Authorized to Continue Rates

The Interstate Commerce Commission on June 4 authorized nine railroads in the East to continue to charge rates on anthracite transportation from Pennsylvania to certain New England points without observing the long and short haul provisions of the Transportation Act.

The applications were not concerned with petitions for continuance of the emergency rates effective during the anthracite suspension.

Feared That Stiff Stand of Operators May Speed Unfavorable Legislation

By Paul Wooton
Washington Correspondent of *Coal Age*

Opposition from coal operators to legislation providing for even an emergency mediation board has occasioned surprise among members of the House Committee on Interstate and Foreign Commerce. The committee is engaged in an effort to frame a bill that is satisfactory to a majority of its members. It is recognized that there is legitimate objection to arbitration, but some of the members fail to see how, in the event of a deadlock, there can be legitimate objection to mediation. The attitude of the operators has given rise to the thought that they may be planning a finish fight with the union and that they recognize a mediation board would interfere with such a program.

Some members of the committee have gained the impression that a part of the operators, at least, are much opposed to investing the President with any emergency powers for fear that it might spoil an opportunity to break the union—a purpose with which the committee is not in sympathy. As such an effort doubtless would mean a six months' suspension, at least, the non-union operators are viewing the alleged plan with satisfaction, it is suspected.

Some coal men have declared that the Department of Commerce proposed several changes in the original Parker bill, and that these changes have been embodied in the revised bill; that Secretary Hoover, though he said he was agreeable to a postponement of the consideration of legislative action until the next session of Congress so as to give the unionized section of the bituminous industry a chance to set up its machinery of mediation, nevertheless failed to make a request to the committee to let the matter rest until the next session.

What Some Have Alleged

They allege that a list of witnesses to be heard by the committee was given to the committee by the Department of Commerce and that an employee of the Department, the former secretary of the U. S. Coal Commission conferred with Representative Hamilton Fish of New York before the latter, one of the leading proponents of legislation, testified before the committee.

These reflections on Secretary Hoover are not clearly understood in view of his efforts against regulation of the industry. At the Department it is denied that anyone there advised on the drafting of the original Parker bill, which is a softening of the measure prepared by Senator Copeland. It is admitted that the bill as originally introduced was referred to the Department where alterations and additions were made to the bill to comply with the request, made while Mr. Hoover was testifying before the committee, that he put his suggestions in legislative language. Suggestions which had the effect of making the bill much less stringent were accepted by Chairman Parker and incorporated in his revised bill.

After Mr. Hoover had urged that consideration of legislation be suspended, to see if the industry itself could not set up mediation machinery and provide fundamental facts, the Association's unfriendly statement is expected to increase the determination in the committee to bring out legislation. In addition it has created the impression that the operators are bending their efforts to prevent legislation at any cost and that many of the producers are hoping for a strike. The fact that the Association does not hasten to attempt the development of a mediation plan and a system of fact-finding to cover all the production instead of the thirty per cent in the Association, also is expected to stimulate those who are demanding legislation.

What Congress Might Do

The thought also is expressed that, should there be a suspension next April of sufficient duration to demoralize business and to cause serious public inconvenience, Congress then would not be satisfied with "an emergency mediation board, an emergency authority to the Interstate Commerce Commission in coal distribution and, in failure of provision by the industry, a more effective service as to primary facts."

The least that might be expected under such circumstances would be the early enactment of the recommendations of the Harding Coal Commission, which constitute regulation with a vengence as compared with the regulation-free suggestions to be enacted only after failure of the industry to provide the safeguards for itself.

Eight Research Fellowships At Carnegie Tech

Eight research fellowships will be available in connection with the program of mining and metallurgical research at the Carnegie Institute of Technology for next year. According to the announcement, the fellowships are open to graduates of colleges, universities and technical schools who are properly qualified to undertake research investigations, and will be awarded for a ten months' period beginning Aug. 16, 1926.

Most of the research work will be conducted in the laboratories of the Pittsburgh station of the U. S. Bureau of Mines, adjacent to the campus. The subjects for investigation, as in the past, will be selected by two advisory boards composed of metallurgists, mining engineers, chemists and coal operators. At the end of the period of study, the results of the investigations, it is announced, will be published jointly by the Carnegie Institute of Technology, the Bureau of Mines, and the Advisory Boards.

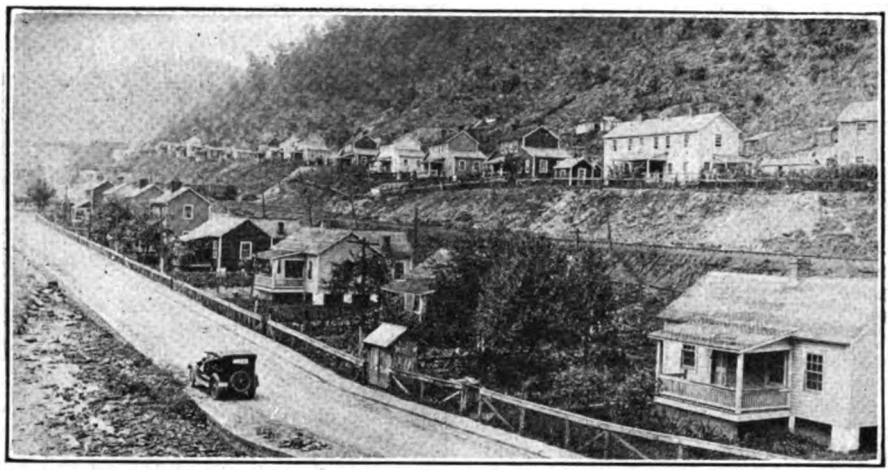
Predicts "Cultural Wage" Instead of Living Pay

"Industry is approaching rapidly toward a new objective in this country," said Owen D. Young, chairman of the General Electric Co., speaking at the tenth annual meeting of the National Industrial Conference in the Hotel Astor, New York City, last week. "The 'cultural wage,' as compared to the old ideal of a 'living wage,' is what I refer to.

"By cultural wage I mean that which will enable a workman to develop his intellect, so that he will be in a position to take advantage of all opportunities offered by this country. When the time comes there will be equal opportunity for all men in the United States."

Mr. Young does not feel that industry will be less profitable because of the cultural wage. "Industry may become even more profitable, and industry should be profitable," he said.

"I have no sympathy for indictment of profits. They are the motive power of industry, and why deny it or apologize for it? I notice that when a governmental investigation of industry is being made the investigators always pick on the ones who are making profits. I think it ought to be the other way around, for when industries are making money it follows that they are also delivering a service people are willing to pay for."



Bittner Wins Rehearing of Charge of Contempt

The West Virginia Supreme Court of Appeals on June 3 granted Van A. Bittner, chief international representative of the United Mine Workers in northern West Virginia a rehearing on the charge of contempt of court. The rehearing will come up at the September term of the Supreme Court. The case was first heard in that court on a writ of error on March 9, and was dismissed on the ground that the court had no jurisdiction.

Bittner was sentenced to serve six months in jail on a charge of contempt toward an injunction granted by Judge I. Grant Lazelle of Morgantown, in the Monongalia Circuit Court. In an address in Farmington and later at a mass meeting in Fairmont, Bittner is charged with having flaunted the court's order in an attack on injunctions.

Points made by Attorney Thomas C. Townsend, attorney for Bittner were as follows: That the evidence did not show that Bittner had notice of the injunction and did not prove any contempt; that the Supreme Court in its former opinions did not recognize the distinctions between civil and criminal contempts and that "the defense, if any, was a constructive criminal contempt and under the statute entitled to have the charge reviewed."

County Road in a Mountainous Mining Town of Pocahontas Region

Good roads, prosperity and the automobile go together. This shows the concrete road and sidewalk along the headwaters of Sand Lick leading into the town of Filbert in McDowell County, W. Va.

Seek Modified Metric System, Failing Real Thing

Other legislative proposals intended to bring about increased use of the metric system of weights and measures having failed, bills now have been introduced in the Senate and in the House proposing that the Department of Commerce be authorized "to establish commodity quantity units for general use in merchandising after 1935, standardizing the yard to the meter, the quart to the liter, and the pound to 500 grams, decimally divided."

The legislation, which was introduced in the Senate by Mr. Gillett, of Massachusetts, and in the House by Mr. Britten, of Illinois, carries a preamble pointing out that "the Constitution of the United States of America provides in Sec. 8, Par. 5, that Congress has the power to fix the standards of weights and measures"; that there now exists a lack of uniformity in the weights and measures of the United States," and, that "these are not standardized with the weights and measures used by the vast majority of nations of the world."

It was stated at the committee on coinage, weights and measures of the House that the committee would give no consideration to the measure at this session. In the Senate the bill was referred to the commerce committee, instead of the manufactures committee, to which such legislation has been referred before. As the commerce committee is one of the busiest of the Senate it is believed that no time could be found thus late in the session to consider the metric bill.

Development of Explosives Outlined in Lecture

Sir Frederick Nathan, K.B.E., chairman of the Explosives in Mines Research Committee of the Safety in Mines Research Board of England, spoke on "Mining Explosives" recently in the third of a series of six lectures on "Some Problems in the Mining Industry" given at the University of Sheffield, England, under the auspices of the Department of Mining.

Reviewing the history of explosives in general, the history of their adoption in mining, and finally the history of permissible explosives, Sir Frederick said the present methods of testing explosives for permissibility were only empirical and did not always reproduce the conditions met with in a mine. One of the difficulties encountered was the production of atmospheres of constant explosibility and ease of ignition. The greatest difficulty, that of obtaining an adequate supply of pure methane, was now being overcome at the Rotherham testing station by producing it from wood pulp by fermentation.

The fact that an explosive was on the permissible list, said Sir Frederick, was not a guarantee that it would not cause ignition of an inflammable atmosphere. It merely certified that the explosive was safe in comparison with other explosives. No explosive is safe. The objects of present research are to produce explosives which are less liable to produce ignitions of explosive atmospheres than existing explosives and which would bring the coal down in a manner similar to or better than blasting powder. With that object in view, fundamental research is being carried out on both the inflammable mixtures and the explosives.

Number and Annual Output of Soft-Coal Mines in the United States in 1924, by Classes[a]

Exclusive of Wagon Mines

State	Class 1, Producing Over 200,000 Net Tons: No.	Per Cent of Total Mines	Per Cent of State Output	Class 2, Producing 100,000-200,000 Net Tons: No.	Per Cent of Total Mines	Per Cent of State Output	Class 3, Producing 50,000-100,000 Net Tons: No.	Per Cent of Total Mines	Per Cent of State Output	Class 4, Producing 10,000-50,000 Net Tons: No.	Per Cent of Total Mines	Per Cent of State Output	Class 5, Producing Less Than 10,000 Net Tons: No.	Per Cent of Total Mines	Per Cent of State Output	No. of Mines	State Output (Net Tons)

a Note that the coal statistics of the Geological Survey for a given year include only the mines that had an output in that year. Many mines tha 1923 produced no coal in 1924; moreover, many of the mines that did produce in 1924 worked for a short time only. The number of active mines c size in North Dakota was 144 in 1923 and 132 in 1924.
b Includes also loaders and shotfirers.
c Billings, Dunn, Golden Valley and Oliver.
Statistics issued by U. S. Bureau of Mines.

130 Mine Workers Die From Accidents in April; Month's Death Rate Low

Accidents at coal mines in the United States during April, 1926, according to reports received by the U. S. Bureau of Mines from state mine inspectors, caused the death of 130 men; 101 occurring in bituminous mines and 29 in anthracite mines. The death rate per million tons of coal mined during the month was 2.69, based on a production of 48,296,000 tons, as compared with 3.90 for April, 1925, based on an output of 40,994,000 tons. The rate for bituminous coal alone was 2.52, with a production of 40,079,000 tons, and that for anthracite was 3.53 and a tonnage of 8,127,000, as compared with 3.53 and 5.62, respectively, for April of last year, with a production of 33,702,000 and 7,292,000 tons.

During the first four months of 1926, 814 men lost their lives from accidents in the coal-mining industry. The production of coal in this period was 205,718,000 tons, showing a death rate of 3.96 as against 4.14 for the same four months in 1925.

Accident Rates, United States, with Causes

	Year 1925	Jan.-Apr. 1925	Jan.-Apr. 1926
All causes	3.811	4.144	3.957
Falls of roof and coal	1.842	1.946	1.774
Haulage	.615	.603	.631
Gas or dust explosions	.590	.666	1.001
Explosives	.174	.226	.127
Electricity	.144	.142	.112

No major disasters occurred in April but there were seven in the preceding months of 1926, which caused the loss of 190 lives. There were 4 major disasters causing the death of 96 men during January to April in 1925. The fatality rates based exclusively on these figures were 0.924 and 0.504 for the four-month period in 1926 and 1925.

Considering accidents by principal causes for the period January to April, a reduction is noted in the per-million-ton fatality rates in all of the principal classes of accidents except those caused by gas or dust explosions, which showed a marked increase. All of the major disasters thus far in 1926 have been caused by explosions. The comparative rates for the principal causes of accidents were as set forth in the accompanying table.

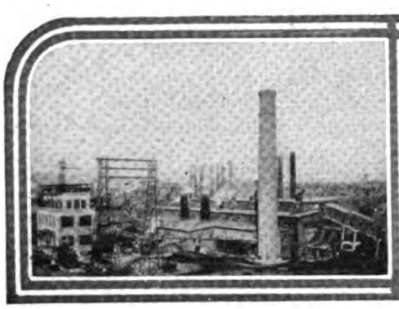
Brotherhood Mining Company Elects Officers

At the board of directors' meeting of the Coal River Collieries Co., owned and controlled by the Brotherhood of Locomotive Engineers, held in Huntington, W. Va., on June 1, J. T. Dunigan was re-elected president. Other officers elected were: First vice-president, T. C. Songer, Ashland, Ky.; second vice-president, N. J. Burns, Wilkes-Barre, Pa.; secretary-treasurer, G. G. Huffman, Cleveland, Ohio; and assistant secretary-treasurer, J. Rex Cooper. E. C. Glass of Huntington, W. Va., was named as chairman of the board of directors and the executive committeemen chosen included Messrs. Dunigan, Glass and Huffman. E. C. Sandberg of Charleston, W. Va., was chosen superintendent of the company's Boone County holdings.

World Conference at Pittsburgh to Stud Better Uses f

An international conference will be held at the Carnegie of Technology in Pittsburgh of November, 1926, accordi announcement of plans now vised by Dr. Thomas S. Baker, of the Institution.

Several prominent scientists many, France and England h or will be invited to participa discussions, according to Baker's plans, and in additio will be presented by a numbe ing American engineers and representing the latest disco connection with the distillatio its byproducts, new methods ducing energy from coal, etc.



Some of the topics that receiving the consideration dent Baker and his associates cussion during the conference low temperature carbonization generation of power at th domestic use of coke, and wat vs. coal energy.

Dwellings and Garages in West Virginia Mining Town

Mining today is one of the best paid callings known and the miner dema receives better housing than most other people. Note the dwellings in the ba and the garages—row on row—in the foreground. This is part of the village of McDowell County, West Virginia, the No. 4 property of the United States Coal &

News Items From Field and Trade

ALABAMA

Install Big Conveyor Belt.—The Brookside-Pratt Mining Co. is installing a conveyor belt at its new Warrior River opening for conveying the coal from inside the mine to the tipple. Deister concentrating tables are also being installed. Other improvements are being made with a view to largely increasing production and improvement in the quality of the product.

COLORADO

Frank L. Bishop has resigned as receiver for the Routt-Pinnacle Coal Co. and L. B. Bromfield has been appointed by Judge Dunklee of the District Court to succeed him.

ILLINOIS

Groveland Takes New Quarters.—The Groveland Coal Mining Co. has removed its office from the Straus Building in Chicago to Suite 708 Bell Building. The company also has opened an office in the new Stark Building, Louisville, Ky., in charge of R. W. Hunter, vice-president, directing Kentucky operations.

The Bush Mining Co., a subsidiary of the Missouri Pacific R.R., is about to start sinking a new mine between Bush and Elkville. The mine, it is said, will be of large capacity and will be located almost exactly on the Jackson-Williamson county line.

Extensive Stripping Planned.—Representatives of the Union Electrical Coal Co., of Danville, have been exercising options on coal lands in the vicinity of Duquoin for the past month and have already paid out about $100,000 to farmers in the vicinity on what will ultimately be a million-dollar deal if all options are exercised, as it is presumed they will be. The options and plans which have been completed foreshadow the opening of one of the largest strip mines in the world within the next 18 months. The company will remove approximately 40,000,000 tons from the acreage now under lease and employ from 275 to 300 men.

Dullness Shrouds Herrin.—After operating almost steadily for fifteen years, Mine A, of the Chicago, Wilmington & Franklin Coal Co., at Herrin, closed down indefinitely on May 29. One mine in the Herrin district, owned by the Jeffrey Coal & Mining Co., is working now. Mine A, which employs in the neighborhood of 740 men, probably will reopen later in the summer.

Examiners' Itinerary.—A. D. Lewis, of Springfield, Director of the Department of Mines and Minerals of Illinois, announces the following June itinerary of the Illinois Miners' Examining Board: West Frankfort, 10th; Duquoin, 11th; Centralia, 12th; Litchfield, 14th; Springfield, 15th; Taylorville, 16th; Danville, 17th; La Salle, 18th, and Peoria, 19th.

Coal Roads Merge.—The Illinois Commerce Commission on June 2 authorized the Missouri Pacific RR. to purchase all of the outstanding capital stock of the Marion & Eastern RR. Co. for $190,000. It is believed that the taking over by the Missouri Pacific of this coal road will result in the re-opening of several coal mines along the Marion & Eastern. The direct connection through the Missouri Pacific System to the markets of the Central West should prove beneficial to the mines.

The New National mine at Belleville, Ill., reopened on June 3. It employs 150 workers. The reopening is in anticipation of a late Summer demand for coal.

More Stripping Forecast.—Approximately 10,000 acres of farm land west and southwest of Duquoin, Ill., have been purchased by the United Electric Company of Danville, Ill. and New York. The company is said to have paid more than $150,000 for 1,400 acres of the land and it is expected that the entire acreage will cost $1,000,000 or more. The company will strip the coal. The acreage embraces 40,000,000 tons.

The Binzel mine at Farmington, was sold May 20 at bankrupt sale and brought only $12,922. It is said to be questionable whether the United States court would approve the sale.

The closing down of Wasson coal mine No. 1 east of Harrisburg, Ill., has been followed by the opening of Wasson mine No. 2 just west of Carrier Mills. This mine has been closed for about two years.

The main offices of the Brewerton Coal Company was removed June 1 from Lincoln, Ill., to Chicago. This company operates mines at Lincoln, Springfield and in southern Illinois, with branch offices at Kansas City and Chicago. The Central Illinois mines have become the smallest part of the Brewerton enterprises and the main offices will in the future be maintained in Chicago. Most of the staff in the Lincoln office is removing to Chicago, as is also W. A. Brewerton.

The Peabody No. 6 mine, at Springfield, hoisted 4,727 tons of coal, May 26, breaking the record in the Springfield sub-district.

IOWA

The Rock Island Railroad is erecting a new coaling station at Washington, at a cost of $50,000.

KANSAS

Blame Blast on Sparks from Pump.—Inspectors attribute the explosion which killed four men in the Cigaret mine near Cherokee, on May 14, to the ignition of gas by sparks from the brushes of an electric pump in operation at the bottom of the pit. The mine was partly wrecked March 13 by a gas explosion. The four men killed May 14 were pumping out the mine preparatory to making repairs to permit the resumption of digging. The mine was being opened by D. W. Bash, of Joplin, Mo., operating as the Lightning Creek Coal Co.

Shovel Mine to Open Soon.—Operation of the new steam-shovel mine of the Kelly-Carter Coal Co. on what is known as the No. 9 lease of the Sheridan Coal Co., a mile north of Mulberry, is scheduled to begin July 15. The company has bought a large shovel, which was installed a year ago at the mine of the Superior Coal Co., a mile east of Weir. The 35-B type loader is on the ground and a loading tipple is being erected. The tipple will be electrically operated. The plant is near the Kansas City Southern R.R. and has a tract of 135 acres of 3-ft. coal with a 20 to 25-ft. overburden. When in full operation it will have a daily production of 600 tons.

The Kansas state Commission of Forestry, Fish and Game has given approval for a 400-acre fish and game preserve five miles north of Pittsburg on land cut up by coal stripping operations. This is part of the state program for reforestation and fish and game protection adopted by the last legislature at the instance of the Izaak Walton League. Pittsburg business men and other citizens are buying the land from the Pittsburg & Cherokee Coal & Mining Co. to present it to the state. It is thought this may be the beginning of a system of preserves in which the ponds formed in old strip pits can be linked together and stocked with fish, while the land can be beautified with trees and shrubbery.

KENTUCKY

The Beaver Coal Mining Co. has been organized to take over the operation of the Blackburn Coal Co., Alphoretta. The company has 200 acres under development at present, and more available land. The daily output of the company is 250 tons.

The Asher Coal Mining Co. will issue $850,000 bonds to retire $285,500 of

Digitized by Google

5 per cent first mortgage bonds of the company and approximately $800,000 *floating* debt and to complete the purchase of 16,000 acres of land located in Clay and Leslie counties.

Incendiary fire is believed to have been responsible for the loss of stables, *mules*, powder house and about fifty kegs of powder at the Rhea Coal Co. plant, seven miles from Madisonville, on May 24, at an early hour in the morning.

Begin Work on River Control.—Work is well under way on a new combination power dam and river-stage control at Louisville, which it is said will insure boating stages between Louisville and Cincinnati, to bring coal down as far as Louisville. The dam is being built jointly by the government and the Louisville Hydro Electric Co.

Twenty-eight cases in equity involving titles to coal, oil and timber lands in eastern Kentucky are before the session of the Federal District Court at Catlettsburg, which started work on May 24, under Federal Judge Cochran.

Long Litigation Ended. — Litigation which has been in progress for over a year to determine the control of the Carr's Fork Coal Co., of Perry County, came to an end May 26, when Judge Hurley approved an entry dismissing an injunction suit brought by Harry E. Bullock, of Lexington, and L. H. Stone, of Cincinnati, to prevent B. Kemp Littlepage from selling certain stock of the Wallin's Creek Coal Co., of which Littlepage was the liquidating agent. There is a long story connected with the manner in which this became a balance of power between the opposing factions in the Carr's Fork Coal Co., and while Littlepage was dickering with members of the factions they composed their differences and found means by which the company could proceed. The Carr's Fork company is a $1,000,000 concern.

Two residences belonging to the Lee Land Coal Co., Island, were destroyed in a $50,000 fire about the middle of May.

Takes Over Blackburn Mines.—The Beaver Coal Mining Co., Ashland, of which E. W. Smith is secretary and treasurer, has taken over the operation of the mines of the Blackburn Coal Co., Alphoretta, and has 200 acres under development at present, with daily output of 250 tons.

Plans Big Bond Issue.—The Asher Coal Mining Co., Lexington, of which T. J. Asher is president, is reported to be about to issue bonds for $850,000, with which to retire outstanding bonds, clean up floating debt and purchase 16,500 acres of coal land in Clay and Leslie counties.

Three thousand acres of mineral land in Hopkins County has been leased by the Hopkins County Mineral & Mining Co. and will be developed in the near future, according to announcements from company officials. Mineral specimens are being analyzed and reports on the quantitative values of the mineral deposits are expected in the near future. Lessors of the property are J. D. Mitchell and J. F. Montgomery, both of Providence, Ky.; and Louis Corberger, Colorado mining man.

In the Federal Court at Louisville Judge Charles I. Dawson has taken under submission testimony in the Federal Government tax case against J. W. Lam, Greenville, Ky., last surviving stockholder of the Hillside Coal Co., for $20,017.54 in income taxes alleged to be due for the years 1916, 1917 and 1918. The company was liquidated in 1919, but assets alleged to have been recovered by Lam from the company are the basis of the suit.

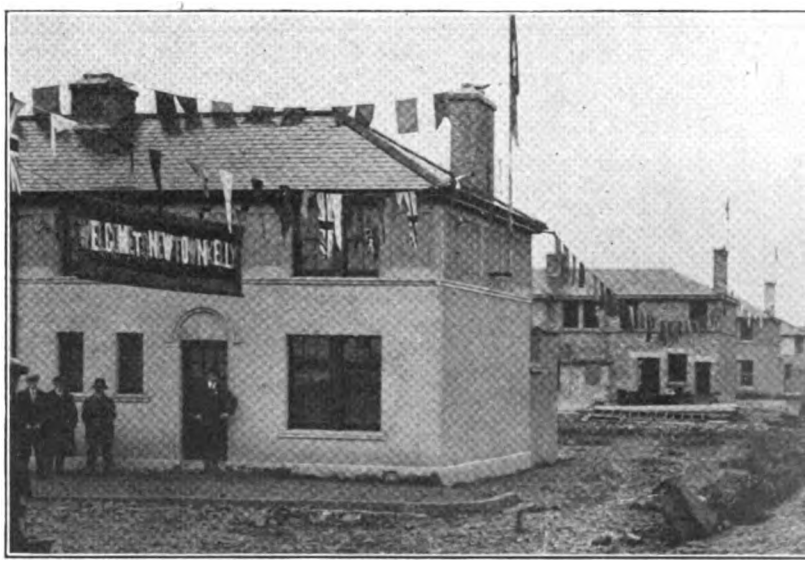
Strike Declared.—The first labor trouble in western Kentucky for some time is that of 350 miners and workmen of the Norton Mining Co., Nortonville, Ky., who declared a strike on June 2, because of a controversy regarding working conditions. The company is controlled by the Monroe-Warrior Coal & Coke Co. interests of Alabama.

The Louisville & Nashville R.R. Co., has announced the letting of additional equipment contracts totaling $2,400,784, making $11,100,784 contracted on new equipment since December. Included in the contracts are thirty-two locomotives, of which twenty-four are big Mikado freight types, for heavy hauling.

MARYLAND

Strike Preparations?—The Jones & Laughlin Steel Corporation, it is understood, will establish a large coal reserve on Neville Island. The last time the company established a coal reserve was during the strike of 1922. The move may represent only a desire to have a sufficient supply of coal on hand, especially as the company consumes more coal now in additional ovens at its by-product plants, but in various circles there are references now and then to the possibility of a strike of the union mines next year. According to local coal men, a glimpse of the coal pile of the United States Steel Corporation at Wilson, near Clairton works would almost lend the belief that there is enough coal stored there to sup country. Incidentally, the ste pany mines of the district are al

The Chesapeake & Ohio ca Maryland, will remain idle for t year, according to the Canal Co., which operates the canal. no coal business—that's the caus



The Board of Awards of Ba has announced the placing of c for 60,000 tons of semi-bitumin 4,400 tons of anthracite to ta of municipal department needs year. The price of this coal gated $347,000. The head of reau of Standards stated that the new contract anthracite w the city 40c. per ton more th paid under old contracts. The no advance in the price of th bituminous coal delivered in lots from the mines.

MINNESOTA

Exchange Has Tenth Birthda Twin City Coal Exchange, comp independent dealers, celebrated it anniversary May 25 with a di the St. Paul Athletic Club. Th ing was in the nature of a cele over the outcome of a laws cently tried before the U. S. Court of Appeals requiring railr pay full price for coal lost in J. R. Hartzell was the p speaker.

Concrete Replaces Wood Pie Clarkson Coal & Dock Co. has a a contract for the building of of concrete piers and sheet pilin dock at Duluth to replace wood struction. The work will be co within a month and is estima cost $25,000.

Ford Control Complete.—Th interests are now sole owners dock property of the bankrupt S Coal Dock Co. at Duluth. Th Motor Co. acquired the mortgag of the defunct company and by $80,000 to the receivers to co

A Street Corner in Newtownkelly, Coalisland, Tyrone County

Decorated for a festival. Newtownkelly is a "captive mine" like most of the this country, for Sir Samuel Kelly, the owner, is interested in a large coasti serving ports in the British Isles. Each house has a parlor, kitchenette, sculler bedrooms, bath and washboiler.

terest, and $130,000 to the Brownhoist Co. of Cleveland who built the bridges at the time the dock was remodelel three years ago, it now has complete control. There was no opposition to the sale. It is understood that the Ford interests plan many improvements in the dock during this season.

Incorporates Dock Company.—The St. Louis Dock Co., a United States Steel Corporation subsidiary, has been incorporated to operate the coal dock of the Duluth, Missabe & Northern R.R. That dock will continue to be used to store and handle bituminous coal for the use of the Minnesota Steel Co. and the Universal Portland Cement Co. at Duluth and the Oliver Iron Mining Co. and the Duluth, Missabe & Northern R.R., Steel Corporation subsidiaries.

Receivers Appointed.—Receivers were named last week in Minneapolis, in the federal court for the Flour City Fuel & Transfer Co., one of the large independent retail concerns of the city. The receivers were P. F. Herrly, of the Pittsburgh & Ashland Coal Co. and J. D. Eckstrum, of the Flour City company. The action was brought by the Pittsburgh & Ashland Co. which declares the property to be worth $1,000,000 and the accounts due to be $750,000. The application was made at the request of a creditors' committee. The action was not contested by the coal company.

MISSOURI

The name of the Midland Coke & Iron Co., of St. Louis, has been changed to the St. Louis Coke & Iron Co. The name was changed in order to avoid conflicting with a company of a similar name.

NEW JERSEY

The Halden-Kelley Coal Co., Inc., of Clearfield, Pa., has moved its Eastern office to the new Military Park Building, Newark, N. J. This office is in charge of Mr. Halden, president of the company, who will supervise the purchasing for the three retail yards of the company and also for wholesale distribution.

NEW YORK

The str. "Harvey J. Kendall," of the George Hall fleet, Ogdensburg, which sank in 20 ft. of water in the St. Lawrence last fall, has just been raised and will be refitted for re-entering the coal and general trade. She has a wood hull of 500 tons capacity and was built in 1892.

OHIO

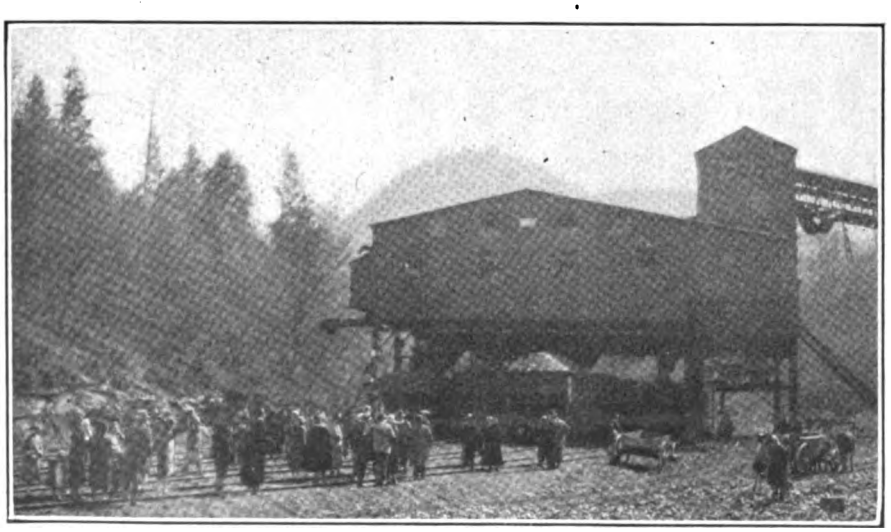
Will Ask for Coal Bids.—The City Council of Hamilton, Ohio, has authorized Service Director G. C. Mitchell to advertise for bids for 20,000 tons of West Virginia or Kentucky mine-run or screenings for the municipal light plant and the water works departments. The Board of Education of Hamilton will open bids June 17 for 2,000 tons of bituminous lump, egg or mine-run and 2,000 tons of smokeless lump, egg or mine-run for the Hamilton schools, to be delivered at the various buildings. Charles F. Holdefer is clerk of the board.

The Wheeler Coal & Coke Co., Columbus, recently chartered with a capital of $50,000, has been organized by the election of W. E. Wheeler, president and manager; C. E. Wheeler, vice-president, and E. A. Wheeler, secretary and treasurer. The company formerly operated as a partnership and does a general jobbing business. Negotiations are in progress to take over a mine in the Blue Creek district of the Kanawha field in West Virginia. The company has the sale of the output of several other Kanawha district mines.

The annual report of the Cincinnati Operating Committee of the American Railway Association credits this city with being one of the largest soft-coal centers in the United States. Last year the railroads delivered a total of 638,701 car loads of coal at Cincinnati. Of this amount, 104,147 was consigned for further shipment to the Great Lakes. The C. & O. delivered 313,314 loads of coal, the L. & N. 292,519, the Norfolk & Western 27,164 and the Southern 5,704 car loads. Over 900,000 empty freight cars were received in 1925.

The Cincinnati Coal Exchange is negotiating with Station WSAI, operated by the U. S. Playing Card Co. in that city, for the broadcasting of ten weekly messages to householders emphasizing the urgency of stocking coal during the summer. The geological story of coal also will be told. Those on the committee of arrangements for this feature are Calvin Holmes, Armour A. Sizer, W. J. Magee, Burke H. Keeney, Jim Reilley, George Kearns and the president, Nolan L. Mahan.

Included in the last pay of the miners of the Lorain Coal & Dock Co. in eastern Ohio, was a statement from R. L. Wildermuth which contained the following: "Every ton of lake coal sold in 1925 resulted in a loss to this company. We cannot afford to continue this policy and as a result we feel it our duty to notify our employees that our contracts for lake tonnage have been lost and the business has gone to West Virginia." The company has three mines down, and two others that are still working, are expected to go down soon.



Ohio Men Refuse Cut.—It is reported that the West Wheeling Coal Co., of which Henry Johnson is general manage, offered its miners in the Bridgeport district a proposition entailing a 20-per cent cut in wages to reopen the mines, but the proposal was turned down. Many of the men are said to have gone to southern West Virginia, where the wage rate is even lower than the 20-per cent cut would have meant from the Jacksonville scale.

Retailers Plan Open Meeting.—The Columbus Retail Coal Merchants' Credit Association, composed of the leading dealers of the city, has arranged for an open meeting June 7, and operators and jobbers of Columbus have been invited to attend. The association has now established permanent headquarters in the Chamber of Commerce Building with Ernest E. Althoff in charge as secretary and manager of the credit bureau. Steps are being taken to work in co-operation with the credit bureau of the Columbus Retail Merchants' Association.

Columbus Awards School Contracts.—The Columbus Board of Education has awarded contracts for 15,000 tons of Hocking lump, delivered at the various school buildings at $3.94 per ton. At the same time the Colonial Coal Co. was given a contract for 2,000 tons of West Virginia nut, pea and slack at $3.58 per ton. The total amount involved in the two contracts is $66,260.

PENNSYLVANIA

Fined for Mining Law Violation.—Charged with carrying cigarettes into the Edenborn mine, William Jackson, a negro, was arrested and committed to the Fayette County jail on oath of State Mine Inspector Edward E. Good. He was later released under a $200 bail.

Watching a Run for Their Money

Some of the stockholders of the Coal River Collieries Co. watching coal being loaded at the four-track tipple of No. 4 mine near Seth, W. Va. The coal is carried down the mountainside on an apron conveyor. On the annual inspection trip certain of the stockholder saw that "coal" was used to surface the roads. Later they learned that this "coal" was refuse.

Mine Exams in July.—In co-operation with the Carnegie Institute of Technology a special examination for firebosses, assistant mine foremen and mine foremen will be held by the Pennsylvania Department of Mines on July 12, 13 and 14, at the Pittsburgh educational institution. The dates will be of special convenience to the students in the Carnegie Tech summer course in coal mining, which ends on July 10. but any coal miner who feels qualified may take the tests.

Second Terminal Mine Closes.—The Pittsburgh Terminal Coal Corporation has closed down No. 2 mine, near Charleroi, indefinitely, 400 workers having been notified to remove their tools. The company, which received considerable recognition due to its ability to operate seven mines full for nearly two years on the Jacksonville scale while the other mines of the district, including those of the Pittsburgh Coal Co., were being shut down or had already been closed, has felt a slackening in business this spring. The company also has another mine down at Avella. The shutdown of No. 2 mine will enable the other five mines of the company to operate at a better rate.

Harris Retires Quietly. — Harry K. Harris, associate engineer in the Scranton bureau of mine caves and surface support, is reported to have resigned May 1 to manage a coal company in Tamaqua. Mr. Harris' retirement came to light about a week ago. William H. Rolles, of North Scranton, has been named successor to Mr. Harris. Mr. Harris was for many years a colliery superintendent for the Glen Alden Coal Co.

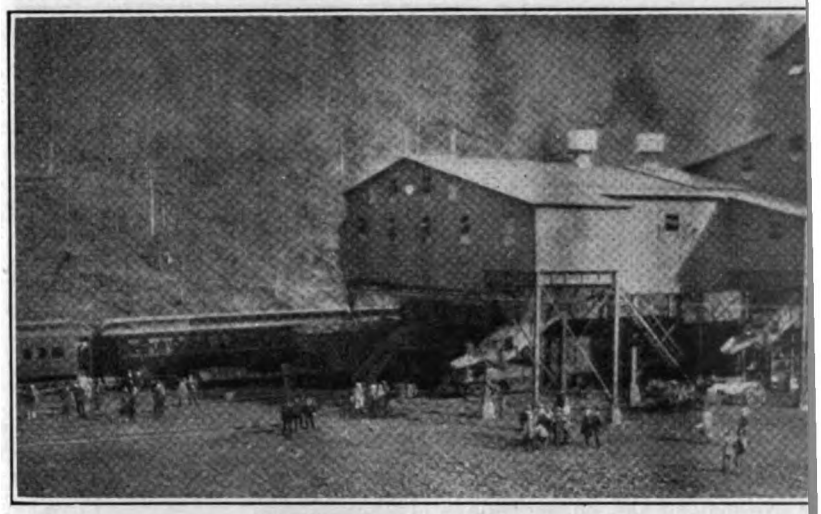
WEST VIRGINIA

New coal companies organized in West Virginia in April, including one non-resident coal corporation, had an aggregate capital stock of $3,600,000, the non-resident company being the largest of the group. In the list of new concerns were the **Allen Coal Mining Co.**, of Williamson, capitalized at $25,000; **Silver Creek Mining Co.**, of Welch, $300,000; **Kanawha Block Coal Co.**, 200 shares of no par value; **Grant Coal Co.**, of Fairmont, $450,000; **Stramer Fuel Co.**, of Charleston, $25,000; **Gulf Run Smokeless Coal Co.**, of Clarksburg, $300,000, and the **Superior Fuels Co.**, of Steubenville, Ohio, capitalized at $2,500,000.

It is reported that negotiations are again under way for a consolidation of a score or more of bituminous producers in non-union fields of West Virginia and Kentucky. Interests identified with Island Creek, Hardy Coal and Pond Creek have been approached in regard to a proposed consolidation. Strong efforts are being made to persuade Island Creek to enter such a merger.

The Melsh Coal Co., organized under the laws of Maryland, and with principal office at Hagerstown, Md., has been authorized to transact business in West Virginia.

Chafin Seeks Parole.—Don Chafin, former sheriff of Logan County, who figured in the labor troubles of that coal field, and who is now in the federal penitentiary in Atlanta, Ga., for violation of the prohibition laws, has paid his fine in full. Chafin had refused to pay the fine and appealed the case, but lost it. Settlement with the government was necessary because of his application to the federal parole board. Judge George W. McClintic sentenced him to serve two years in the penitentiary and fined him $10,000, which with costs in the trial brought the total up to $11,400. He was taken to prison eight months ago.



C. M. Moderwell & Co., of Chicago, has filed a certificate of withdrawal with the Secretary of State of West Virginia.

Mines along the Monongah Division of the Baltimore & Ohio R.R. in the Fairmont region loaded 294,100 tons of coal during the third week of May, an average of 980 cars a day, the highest record made since February.

The Clarksburg District Mining Institute held a meeting in Traction Hall, Clarksburg, May 22, after which it adjourned for the summer. The next meeting will be held the fourth Saturday night in September.

Property of Victor S. Veazey, of Fayetteville, formerly engaged in the coal mining business in Fayette County, recently was sold at public auction for $29,000. The residence at Fayetteville, acquired about six years ago, went to the New River & Pocahontas Consolidated Coal Co. for $21,000. The equipment at Veazey mine, near Glen Jean, was sold for $150 to a Mr. Turner, who is operating the mine.

The Gulf Run Smokeless Coal Co., Centralia, has 10,000 acres of land which it will develop.

Boarding the Special at No. 4 Mine

Stockholders of the Coal River Collieries Co. were taken on a special tra Huntington to inspect their three West Virginia mines. These mines are locate Kanawha field on the Big Coal River branch of the Chesapeake & Ohio Ry. Ea is equipped with a modern steel tipple. The company's production during 19 J. T. Dunigan as president and general manager was 632,189 tons, which is 303,(more than the total output during the past five years.

CANADA

Coke Output Declines.—Production of byproduct and gashouse coke in Canada during April amounted to 149,357 tons, a decrease of 2 per cent from the March total, but an increase of 14 per cent or 17,873 tons over April, 1925. Cumulative production for the first four months of 1926 was 623,549 tons, as against 474,085 tons last year. I of coke in April were 51,146 t against 102,485 tons in March. I were 3,673 tons, compared wit tons in the preceding month. A consumption of coke in Cana April was 196,830 tons, compar 249,633 tons in March and 162,5 in April of last year.

Dunsmuir Development Spr Canadian Collieries (Dunsmuir has announced that a 5-ft. s high-grade coal has been discov Timberland, and work has been on a seven-mile line from Lad Vancouver Island, to develo property. Geological conditio said to be similar to those wh best coal on the island has been Where the seam first was uncov was 12 ft. thick, but 5 ft. is giv conservative average. The p will be thoroughly explored diamond drill. Topographical tions are said to be well suited development of a colliery. T covery was made by George Sm employee of the Timberland co which owns extensive logging li the north of Ladysmith.

Telkwa Opens New Seam.— Collieries has opened a new s coal 9½ ft. thick, one mile fart Goat Creek than its existing slo present the coal is delivered by road to Telkwa, on the Grand Pacific Ry., now part of the Ca National system, but, later, th pany purposes to construct a sp necting the mine with the r Most of the coal is shipped to Rupert.

An Alberta syndicate has sta develop the Sir Sanford Flemi William Merritt leases, at Ant near Banff, on the Canadian Ry.'s main line, which have be for about a quarter of a century syndicate has secured 300 acres land from the Canadian Cement C coal is said to verge on an ant and some of it found on the old is said to be still in excellent co

Among the Coal Men

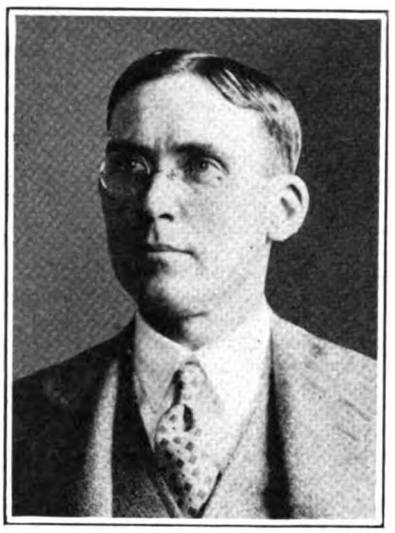
P. C. Thomas succeeds H. M. Bertolet as divisional superintendent of the New River & Pocahontas Consolidated Coal Co. Mr. Thomas was associated with the New River Co. for many years but more recently has been identified with Winding Gulf operations. For the time being Mr. Thomas will have his headquarters at Charleston, but it is possible that later his office will be moved to Fayetteville where the company has purchased the Veazey property.

In taking over the duties of divisional superintendent Mr. Thomas relieves Mr. Newhall of the Philadelphia office of the company who has been in charge temporarily since the retirement of Mr. Bertolet.

John Stafford has been appointed Chief Inspector of Coal Mines by the Government of Queensland, Australia. The son of one of the pioneers of the coal-mining industry in Ipswich, the principal coal district of that state, Mr. Stafford has been continuously connected with coal mines since his youth, working his way from mine worker to the position of manager, and subsequently to that of government inspector. For some years he was superintendent of state coal mines, and was appointed Chief Inspector on the passing of a revised Act of Parliament dealing with the coal branch of the mining industry of Queensland.

Dr. T. D. Scales, of Boonville, Ind., who formerly operated the large John Bull and Erie Canal coal mines, in Warrick County, has been appointed on a committee by the Boonville Business Men's Association to help bring new manufacturing enterprises to Boonville.

W. J. Rainey, Inc., has announced the appointment of **D. D. Dodge**, of Lonaconing, Md., in the Georges Creek field, as general superintendent of its eight large coal and coke operations in the Connellsville coke region, to succeed John Sincock, who resigned a couple of months ago. Mr. Dodge has taken up his new duties. Robert Woods, Jr., of Uniontown, assistant general superintendent, will continue in that position.



Otto Herres, assistant manager of the United States Fuel Co., Salt Lake City, has been elected chairman of the Utah section of the American Institute of Mining and Metallurgical Engineers. Mr. Herres is a mining engineer by profession and has served in Carbon County as a coal mine superintendent.

T. J. Thomas has been elected president of the Valier Coal Co., operating at Valier, Ill. This company is a subsidiary of the Burlington railway.

P. C. Thomas was appointed general superintendent of the New River division of the New River & Pocahontas Consolidated Coal Co. on June 1.

Edmund Ewing has been appointed superintendent of the Yolande and Connellsville mines of the Yolande Coal & Coke Co., succeeding E. L. Elliott, who died recently. Mr. Ewing served as superintendent of the Bessie mine division of the Sloss-Sheffield Steel & Iron Co. for about four years; later going with the Alabama Co., where he was asistant to J. E. Strong, operating vice-president of that company, at the time of its merger with the Sloss-Sheffield Company.

Erle Ormsby, president of the Donk Brothers Coal Co., has been elected president of the Downtown Lions' Club of St. Louis, Mo.

John D. A. Morrow

The new vice-president in charge of sales of the Pittsburgh Coal Co. assumed the duties of his new post on May 1. He has had a long and picturesque career in the coal industry, having been successively executive secretary of the National Coal Association, founder and president of the Morrow-Callahan Coal Co. and vice-president of the Joy Machine Co.

Andrew K. McKee, one of the best known anthracite men in Philadelphia, has resigned as vice-president in charge of retail sales, of the George B. Newton Coal Co. Mr. McKee's first connection in the trade was in a partnership known as McKee & Cox. Later Mr. McKee became the sole owner of the business developing an extensive retail trade under the name of McKee & Co. at 22nd St. & Allegheny Ave., which became one of the leading units of the Newton combination when it was formed in 1912. Mr. McKee has announced no definite plans for the future.

Vincent G. Thomas, of Johns Brothers, has been elected president of the Hampton Roads Coal Association, to succeed Oscar B. Ferebee, of Nottingham & Wrenn, who served two years. Herbert L. Wright, of Wright Coal & Wood Co., was elected vice-president and S. Harold Ferebee, of Norfolk Coal & Ice Co., was elected secretary and treasurer.

M. L. Hutchins, of the Byproducts Sales Co., and **Mr. Mayo**, of the Ford Motor Co., recently spent several days going over the Ford coal properties in Kentucky and West Virginia. So far, they said, no successor had been chosen to fill the position of general director held by the late Abner Lunsford.

Obituary

Lawrence Huntington Starkweather, of the O'Gara Coal Co., Chicago died in the Johns Hopkins Hospital at Baltimore, Md. on Sunday, May 30. Mr. Starkweather was born in Chicago in 1891. He was educated in private schools and at the University of Chicago. At the outbreak of the World War he repeatedly tried to enlist in both the Army and Navy, but was unable to, so finally went into government service in the U. S. Department of Justice, Bureau of Investigation, where he served with a distinguished record.

In 1919 C. M. Moderwell, receiver for the O'Gara Coal Co. appointed Mr. Starkweather to represent the O'Gara Coal Co. in the northern Illinois and Wisconsin territory. Last Fall Mr. Starkweather's health began to fail, and he was operated on at St. Luke's Hospital in Chicago. This Spring it was decided that another operation was necessary, so Mr. Starkweather went on to Johns Hopkins Hospital at Baltimore, but died before the operation took place.

Edgar Lee Elliott, age 56, for the past eight years superintendent for the Yolande Coal & Coke Co., at Yolande, Tuscaloosa County, died May 28 of pneumonina after a short illness. Mr. Elliott was connected with the Hills Creek Coal Co. and a number of other mining operations before going with the Yolande company, where he had been employed for the past ten years. Mr. Elliott also had charge of the Connellsville mine of Yolande company, which was rehabilitated and placed in operation the early part of this year.

Traffic News

Increased Schedule Approved

The Public Service Commission of New York has approved a new schedule of the New York Central & Hudson R.R. (east) on coke breeze and coke dust in carloads of a minimum weight in open cars of 50,000 lb. (except that when car is loaded to full visible or cubical capacity the actual weight will apply but not less than 35,000 lb.) and when in box or stock cars 40,000 lb. This schedule applies from Buffalo, East Buffalo and Harriet to stations between Mertensia and Pittsford inclusive and sets a rate of $1.51 per net ton (a reduction on prior rates.) The schedule also provides that the rate to stations between East Williamson and Hannibal, inclusive, Metcalf Furniss, Oswego to Liverpool inclusive, Central Square, Brewerton and Clay shall be $2.27 (an increase of 1c.) per net ton, effective June 30, 1926.

The New York Public Service Commission has approved new rates of the New York, Ontario & Western R.R. on coke, coke breeze and coke dust from Utica to Clinton and New Hartford, $1.13; reduction 13c. per net ton—effective June 22, 1926.

Production And the Market

Bituminous Index Sags Somewhat but Conditio In Kentucky and Ohio are Favorable

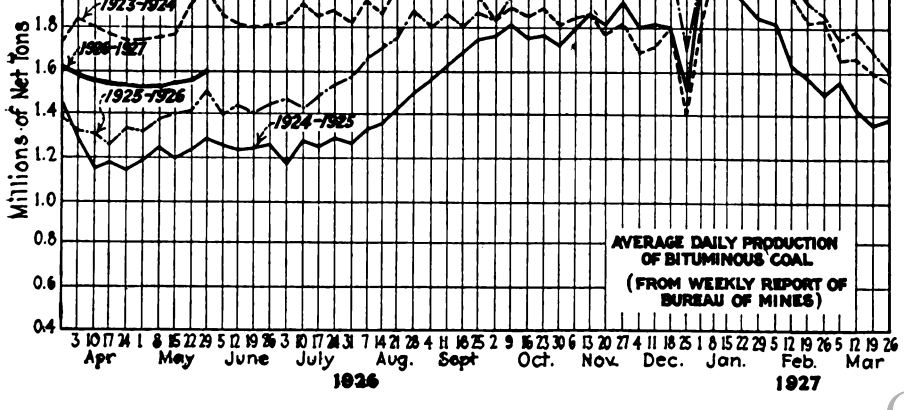
Indications for a firmer market are not so readily visible as they were last week. Certain sections of the country have not responded to the improved condition, notably the Pennsylvania bituminous regions, Alabama and the Head of the Lakes. In the latter a severe price-cutting is bringing as a penalty, slow business, for the buyer is waiting to see whether he cannot get a still lower price. In Cincinnati and points served by eastern Kentucky coals the recent gains have been maintained. Ohio markets have been helped by the removal of the lake embargoes but are still unstable.

Production during the week ended May 29 improved considerably over that of the previous week and is not far below the average for the year, though that average has been unusually high. The calendar year to date has shown a production per day of 1,771,000 tons, whereas the average daily production for the week ending May 29 was no less than 1,611,000 tons. A year ago the daily tonnage for the week was only 1,508,000. The lake dumpings continue large though not nearly so great as those of the previous week. The lake movement is stimulating production in the fields which are able to take advantage of it. For the week ending June 6 the cargo dumpings on Lake Erie aggregated 1,089,342 tons, and bunker fuel totalled 52,445 tons.

Price Lower Than Last Week's

Coal Age Index of spot bituminous prices on June 7 was 157, the corresponding price being $1.90. Thus the index has declined 3 points and the price 4c. from the figures of May 31. These, however, are better values than were obtained in the week ending May 26.

An unsettling condition in Indiana and Illinois is the ability of the strip-pit mine to cut prices 50c. to $1 below the shaft mines and so to take the business from them. These strip pits can work full tim have no difficulty in moving all their sizes.



The demand for slack is more nearly equal t output than before, but both strip and shaft min crushing larger coal to take care of their scree contracts, the sale for lump not sufficing to provi needed slack.

In Illinois, co-operative mining is again cutting the business of those operators who must pay the and cannot ask their mine workers to make good losses. Utah is working more steadily. In co distinction to the Head of the Lakes, the Utah fields are finding that price cutting has stimulated ness and are now working 70 per cent of normal time capacity.

Complaints are heard about the hard-coal marke in fact it cannot be expected to maintain itself thr out the coal year. However, in the week of May 2 estimated production was 2,088,000 tons as ag 1,681,000 in the same week of the previous year a against 1,750,000 tons in the previous week. sizes are only in fair demand and all the other size somewhat except barley.

The dullness in the Connellsville coke market is definitely to be recorded in a decline in price. The for spot shipment has sagged 10c. a ton, and thi cline will probably have its effect on third-quart second-half contracts.

Production in the Connellsville and Lower Con ville region the fourth week in May showed a dec of 5,340 tons from furnace ovens and 70 tons merchant ovens. The total production for the week 150,040 tons.

Estimates of Production

(Net Tons)

	1925	19
BITUMINOUS		
May 15	8,350,000	9,29
May 22 (a)	8,451,000	9,28
May 29 (b)	8,141,000	9,66
Daily average	1,508,000	1,61

Mid West Still Stagnant

Reports from the Middle West are not cheerful, though strip-pit mines in southern Illinois seem to be working practically full time, and like some of the shaft mines are crushing coal to take care of their screening contracts. At the shaft mines lump, egg and No. 1 nut are hard to move, but at the strip plants everything seems to go well because of the price.

This time of the year is always an off-season with the retailers in the Middle West, because neither will the public stock coal for house-heating nor the farmer buy it for threshing purposes. When the Franklin County operators decided not to raise their quotations as of June 1 they made an exceedingly wise move, because a raise could not be maintained in the face of the existing conditions. The West Virginia and eastern Kentucky operators, who raised their prices, would not be able to maintain them were it not for the fact that they have a dumping ground for their coal at the lake loading ports.

In the Jackson County and Duquoin field, two mines that are working are getting about three days a week. In the Mount Olive field railroad tonnage continues good, and the mines find it difficult to take care of steam sizes without crushing.

In the Standard field the co-operative mines are getting the business. Some of the mines without railroad contracts run from one to five days a week. Steam coal is in fairly good demand but at low prices.

St. Louis Buys Sparingly

At St. Louis a little cheap coal for tenement storage as well as other storage of the cheapest kind is going in but it is so small that it doesn't count. Dealers report anthracite tonnage as falling off perhaps one-half and smokeless is dropping off while coke is not as active as it might be. Indiana strip-pit mines are making prices anywhere from 50c. to $1 a ton below those quoted for coal from shaft operations in the Duquoin and Carterville fields.

No Arkansas coal is coming in. West Kentucky also is just at present selling some steam coal in this market.

Kentucky Maintains Position

The Kentucky fields are maintaining their recent gains. Running time has improved slightly in the eastern part of the state, where the lake and Southeastern markets are broadening. The movement of western Kentucky coal west and northwest is substantial for this time of the year. That section also enjoys some scattered business in the South.

The price situation is firm. Except for an inconsequential break on a small tonnage of eastern Kentucky slack, which sold down to $1.05, the general range of quotations is unchanged. It is becoming increasingly difficult, however, to pick up mine-run at the minimum price.

Eastern Kentucky 4-in. block is $1.75 @$2.25; lump, egg and nut, $1.75@$2;

Current Quotations—Spot Prices, Bituminous Coal—Net Tons, F.O.B. Mines

Low-Volatile, Eastern	Market Quoted	June 8 1925	May 24 1926	May 31 1926	June 7 1926†

slack, $1.10@$1.25; mine-run, $1.25@$1.50. Some mine-run still is quoted at $1.65, but little business is done on that basis. Western Kentucky 6-in. block is $1.65@$1.85; lump and egg, $1.40@$1.65; nut, $1.35@$1.50; mine-run, $1@$1.40; screenings, $1@$1.25.

Dock Prices Demoralized

The price war at the Head of the Lakes grows more bitter. At the outset only three companies were involved, but the other docks have been forced to cut prices in self defense. Pocahontas lump, held at $7 a fortnight ago, has sold at $4.50. Youghiogheny screenings are offered as low as $3.75.

Industrial consumers are indifferent to contract renewals while this price war lasts. Buying for current needs, however, holds up. Retail purchases are light, and consumers again are showing apathy on the question of summer storage of anthracite. Receipts from the lower ports have declined, but the movement is fairly heavy. The most recent weekly report shows 50 cargoes, including 4 of anthracite, unloaded, and 21 cargoes en route.

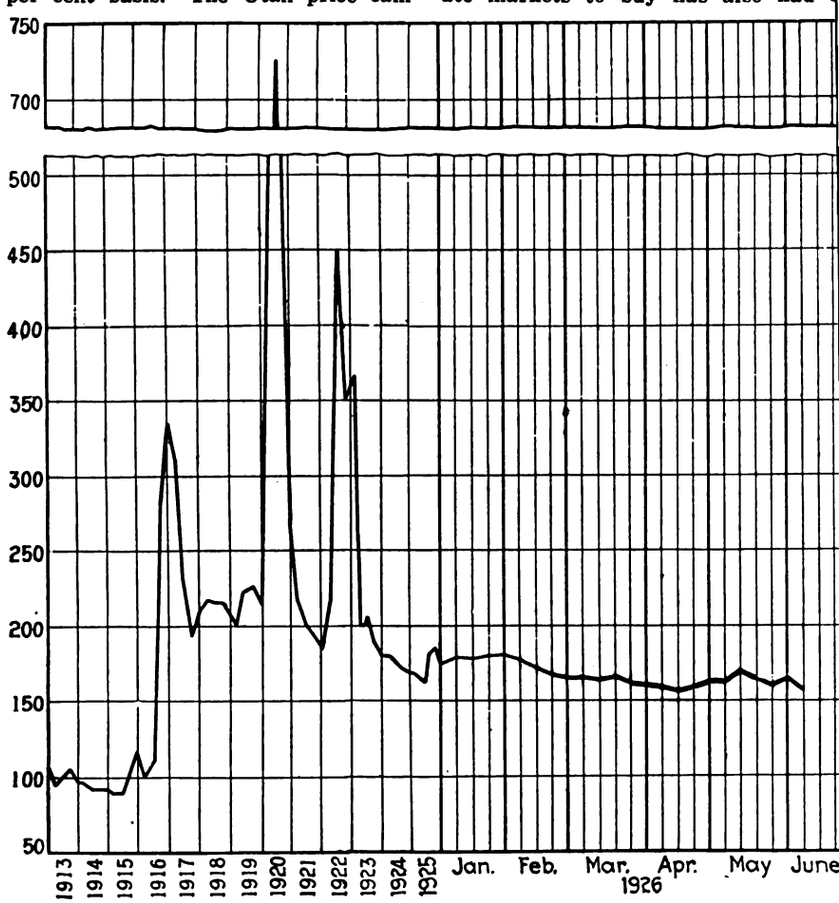
Waiting to Reach Bottom

Buyers at St. Paul and Minneapolis are delaying their orders, some in the hope that the freight rate from southern Illinois and Indiana to the Northwest will be revised by the courts if the case is reopened as is hoped. However, conditions seem better this Spring than in a number of years. Southern Illinois lump is $2.60 per ton at the mine, Central Illinois $2.25 and western Kentucky $1.75.

Receipts of bituminous coal at Milwaukee from Lake Erie shipping ports are heavy—702,220 tons up to June 3, as against 493,260 tons received up to the same date last year. Anthracite is away behind last year's record, but is coming in more freely now. The receipts up to June 3 total 101,000 tons. Last year during the same time 239,055 tons were received.

Stove-size Pocahontas has been cut $1 a ton, and egg and lump 75c. The prices now are $9.75 for stove, $10 for egg and $10.25 for lump, spouted, and an extra charge of 75c. when carried to the bins.

Arkansas More Active



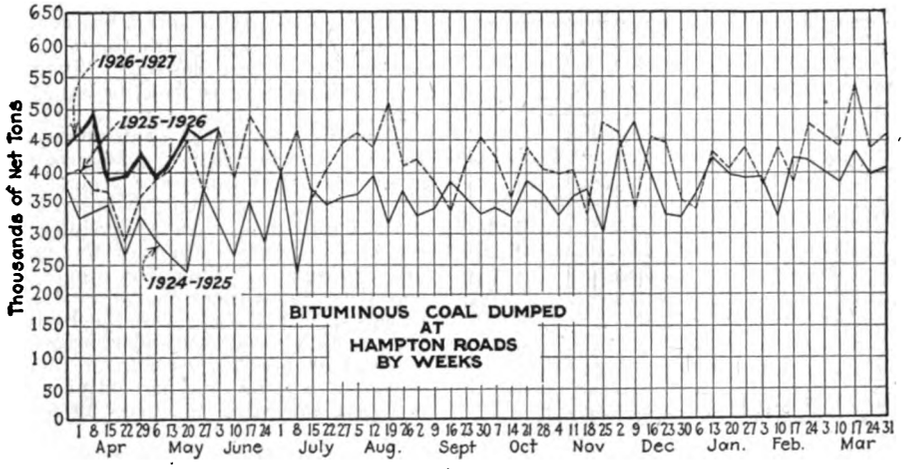
Storage orders for Arkansas semi-anthracite increased sharply during the last week of May and there was an overflow into the first few days of June. Householders were anxious to get coal booked before retail prices advanced. Threshing orders for Kansas coal also are heavier. Storage buying, however, has not yet reached substantial proportions, but an early gain in that direction is expected.

The Colorado market is sluggish with no assurance of any early improvement. Producers and distributers have been scouring the territory for business, but the results of their efforts have been disappointing. Prices are unchanged. The Colorado field is operating on a 50-per cent basis. The Utah price campaign for domestic business has boost buying above last year's figures, h not to the extent desired. Wyomi prepared grades are holding at $3.5 slack is $1.50.

Working time at the Utah mines as result of the big reduction in prices larger sizes, has jumped to around fo days a week, and about 70 per cent normal full-time capacity, taking t state as a whole. Some of the min are working full time, but others a operating about three days a week. R tailers are stocking up to the limit their ability, financial and storage. price of $7 and $6.50 c.o.d. for lump seems to warrant buying activity se ing that the price has been $9 for long.

Prices Hold at Cincinnati

Prices have moved up a step on th market and from the advances ma there has been little or no waverin Tidewater inquiries and even sales ha been stronger than for months pa this being true of both high and lo volatile. Lake buying has been liber and, with the lifting of the emba goes against Sandusky, which for time disconcerted things, this fact has been of supreme importance. T disposition of Chicago and intermed ate markets to buy has also had



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1916				1925	192
	June 7	May 31	May 24	May 17	June 2	June
Index	157	160	157	159	161	17
Weighted average price	$1.90	$1.94	$1.89	$1.93	$1.95	$2.

This diagram shows the relative, not the actual, prices on fourteen coals, represent tive of nearly 90 per cent of the bituminous output of the United States, weighted fir with respect to the proportions each of slack, prepared and run-of-mine normally shipp and second, with respect to the tonnage of each normally produced. The average th obtained was compared with the average for the twelve months ended June, 1914, as 1 after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," pu lished by the Geological Survey and the War Industries Board.

Digitized by Google

influence as has the booking of orders for later delivery to Iowa and the northwest.

The spot market on low-volatile lump has been especially bright, the circulars, it seems, have undershot the mark on this, some spot coal selling up to $3.25 with several of the standard producers of Pocahontas and premium New River asking that price. The egg failed to move above the $3 mark but mine run stiffened to $2 and is firm at that figure.

Smokeless screenings are still weak. Some have been sold up to $1.50 but the general range of the market is $1.25-$1.35.

Greater betterment, however, has been shown in the high-volatile market. With one large Logan County producer leading the way, the West Virginians have moved up all their prices. Thacker lump is selling at $2.25 and so is some of the Kanawhas. Run of mine is in much better demand and the general price on the steam is $1.35 and up. Some poor coal can still be picked up around $1.25 but it takes a bargain hunter to find it. No move has yet been made by the retailers here to advance prices.

Ohio Markets Unstable

Spot prices at Columbus are less erratic, following the lifting of the lake embargoes, but the market still lacks stability. General industrial buying is confined to immediate requirements, and some consumers are going into their storage piles. Utility and railroad consumption is on a satisfactory scale. Many railroad contracts, however, still hang fire. Domestic trade is possibly a little above the average as school buying helps to swell the total volume.

The lake movement is benefitting the Ohio fields in an indirect manner by making the competition with West Virginia and Kentucky for all-rail orders less keen. Nevertheless, output in the southern Ohio districts is only about 18 per cent of normal, and much of this tonnage is going to the railroads.

Eastern Ohio Ships More

Eastern Ohio is shipping a little Lake coal and this is reflected in a slight increase in output. During the week ended May 29 the No. 8 district produced 205,000 tons or a little less than 30 per cent of capacity, which was 17,000 tons over the preceding week but 1,000 tons more than a year ago. Pocahontas lump is quoted at $3 a ton, f.o.b. mines and some dealers are said to be buying and storing it.

Pittsburgh Outlook Darker

Notwithstanding the increase in the commercial production of non-union coal in the Pittsburgh district, the market situation is less attractive than it was earlier in the season. Prices are not quotably changed, but the undertone is weaker. The difficulties surrounding the sale of coal in this market multiply with the passing weeks.

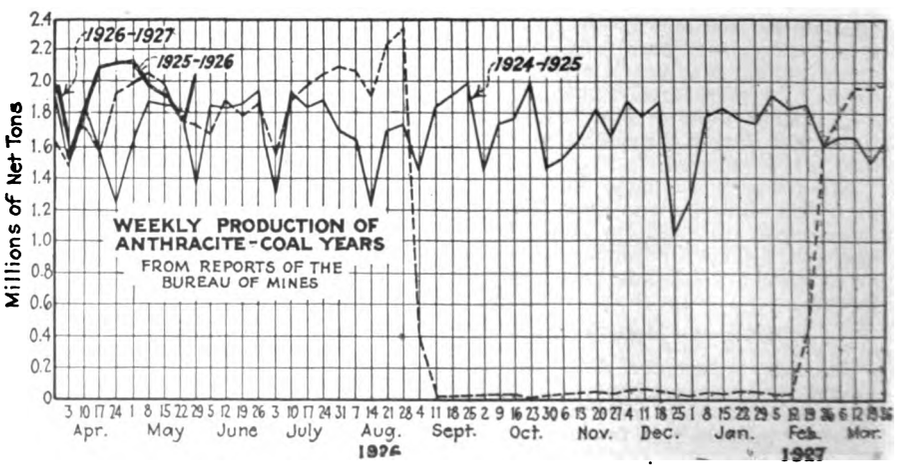
Central Pennsylvania also complains. May shipments from that district were approximately 2,000 cars less than the total for the preceding month. Only one-third of the 1,256 mines in this field are working and only 55 of this number are running six days a week. The bulk of the railroad buying is on the open market. Prices are weaker. Pool 1 is $2.35@$2.50; pools 9 and 71, $2.25@$2.40; pool 10, $1.90@$2.15; pool 11, $1.65@$1.90; pool 18, $1.60@$1.80.

Nominal quotations in the Buffalo market are unchanged, but there is a stronger tone to slack. Business generally, however, is dull. Some of the wholesalers have dipped into anthracite to keep their organizations busy. With independent prices down to or below company schedules, there is little chance for a big turnover in this trade.

New England Unstimulated

The steam-coal market in New England drags along without material change. Not even the tonnage requisitioned in place of British output is sufficient to provide any real stimulus, and spot prices on Hampton Roads coals are actually lower than a week ago. There is no buying of any moment in the coastwise trade and among the industries there is only mild interest in current prices. There is perhaps a better business undertone than a month ago, but not yet is this translated into any noticeable increase in manufacturing.

Pocahontas and New River of Navy standard grade could be purchased a day or two ago at $4.40, with occasional sales at $4.50 and $4.55. Accumulations are less than has heretofore seemed habitual, but from this it is never safe to predict that any organized curtailment is in effect.



For inland delivery the course of prices the past week has been much the same. Quotations have wavered with fresh arrivals, and in nearly every case where factors have their own facilities the wharves are piled high with storage coal.

New York Market Quiet

The New York bituminous market is quiet. Industrial consumption, however, is heavy, but buyers show no interest in accumulating new reserves. On the favorable side of the situation are the increase in the number of inquiries from foreign buyers and the disappearance of distress tonnage at the tidewater piers.

Philadelphia, too, is marking time. The optimists, however, think they see evidence of a slowly awakening interest on the part of consumers and here and there a customer has ordered a little more than his current requirements. Demand for slack, particularly from the cement mills, is strong. Prices, nevertheless, are stationary. Some in the trade believe that the quietness among local industrial users is due to the slowing down of the building trades, which this year are not as active as last.

With production keeping ahead of demand, Baltimore factors find nothing in the current domestic situation to invoke enthusiasm. Export possibilities flowing out of the British strike offer more comfort. Bunker business has increased, and more cargoes have been loaded for foreign consignment. This demand, however, has not been strong enough to bolster up prices on coal for home consumption. Prices are, therefore, approximately the same despite this foreign demand, which, although perceptible is not brisk.

Birmingham Market Featureless

The Birmingham market has settled down to a quiet, featureless position. Spot orders and inquiries are less than at any time previous this year. It becomes harder to move the medium and lower-grade coals. In a few cases, the railroads have reduced their weekly quotas, but the contract market as a whole holds up well and there are even a few straggling renewals on industrial business reported. The metallurgical coke market is fairly active. Domestic coke is quiet. Movement of domestic coal also is slowing down.

Anthracite Begins to Lag

Chestnut is the most backward of the larger anthracite sizes on the New York market at the present time. Egg also shows a tendency to drag. Stove, on the other hand, seems to be in fairly good demand. Movement from retail yards to the consumers' bins also keeps up. Circular prices were not changed on June 1. Buckwheat is a drug, rice is almost as bad; barley is the most active of the steam sizes.

The Philadelphia anthracite trade is less favorably situated. Company schedules are maintained, but independents no longer make any pretense that they can maintain their premiums. Some of the individual shippers are now soliciting business at company circulars and the others are glad if they can get 10@30c. over those figures. Retail buying reflects the disinclination of the householder to store coal before July or August. The steam trade is sluggish. There has been no change at Baltimore.

Shipments Have Declined

Lake shipments of anthracite from Buffalo during the week ended June 3 totaled 66,600 net tons. Of this quantity, 24,500 tons were cleared for Milwaukee; 16,000 tons for Duluth and Superior; 13,500 tons for Chicago; 6,600 tons for Green Bay and 6,000 tons for Sheboygan. The total loadings up to June 1 were 256,600 tons, as compared with 684,434 tons for the corresponding period a year ago.

Spot Coke Drops a Dime

Spot prices on Connellsville furnace coke broke 10c. last week, when the minimum dropped to $2.75 and small lots could be bought at $2.90. Spot foundry coke holds to the $4@$4.50 level, but there is practically no business to be had. The break in spot furnace prices probably will affect third quarter and second half contracts and force them below the $3 basis. Production in the Connellsville and Lower Connellsville fields during the week ended May 29 totaled 150,040 tons, according to the Connellsville *Courier*. Furnace-oven output dropped 5,340 tons and merchant-oven production declined 70 tons.

Average Daily Coke Output Declines Further in April

Production of byproduct coke in April showed a falling off of 175,000 net tons compared with that in March, according to the U. S. Bureau of Mines. This was not solely due to the shorter month, for there was a general slowing down of operations to about 88 per cent of capacity, causing a decrease in the daily rate of output. The total tonnage for April was 3,602,000, with an average daily production of 120,000 net tons; comparable figures for March were 3,777,000 tons and 122,000 tons, respectively. During April the plants operated at 91 per cent of capacity. Eighty-one plants are now in existence, 75 of them active in April. One new plant began production during the month.

Beehive coke continues its downward trend, with an estimated production of 981,000 net tons in April. This was 177,000 tons, or 15 per cent, lower than in March, which, in turn, had an outp that was 17 per cent less than that February.

Output from all the coke plants w 4,583,000 tons, 79 per cent from the b product ovens and 21 per cent fro beehive ovens.

Output of Byproduct and Beehive Col in the United States by Months*

(In Thousands of Net Tons)

	By-product Coke	Bee-hive Coke	To
1923 monthly average...	3,133	1,615	4,7
1924 monthly average...	2,833	806	3,6
1925 monthly average...	3,332	893	4,2
January, 1926.....	3,804	1,381	5,1
February, 1926.....	3,500	1,402	4,9
March, 1926.....	3,777	1,158	4,9
April, 1926.....	3,602	981	4,5

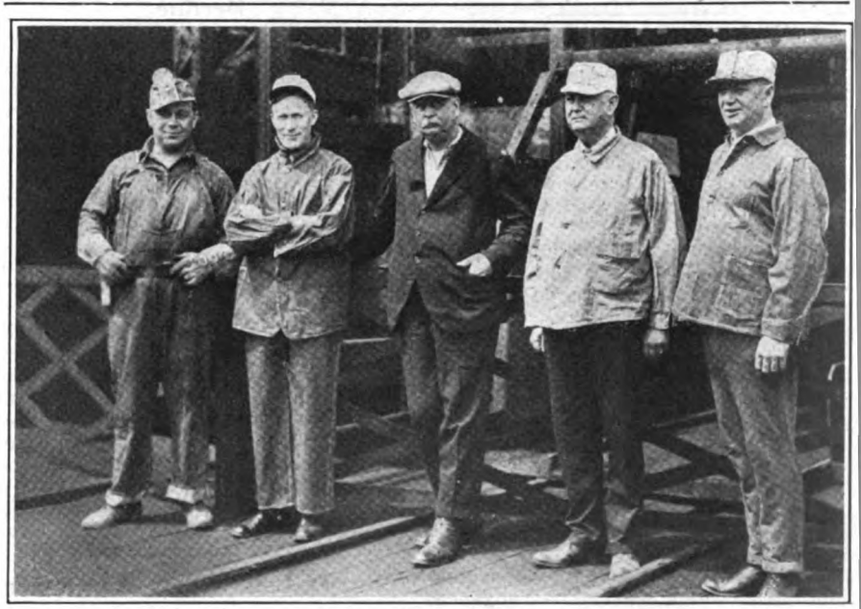
* Excludes screenings and breeze.

Coal consumed in beehive and by product coke plants in April totale 6,723,000 tons; 5,176,000 tons at by product plants and 1,547,000 tons a beehive plants. This was 529,000 ton less than was used for this purpose i March.

Estimated Monthly Consumption of Coal in Manufacture of Coke

(In Thousands of Net Tons)

	By-product Ovens	Beehive Ovens	Tota Coa
1923 monthly average...	4,523	2,507	7,03
1924 monthly average...	4,060	1,272	5,33
1925 monthly average...	4,787	1,371	6,15
January, 1926.....	5,466	2,178	7,64
February, 1926.....	5,029	2,212	7,24
March, 1926.....	5,426	1,826	7,25
April, 1926.....	5,176	1,547	6,72



Of the total output of byproduct coke during April, 2,982,000 tons, or 82.8 per cent, was made in plants associated with iron furnaces, and 620,000 tons, or 17.2 per cent, was made at merchant or other plants.

British Operators Visit New Orient

Apparently the suspension of coal mining in Great Britain afforded F. B. Richards, of the Woodall Duckham Co., and John Bingley, of the Bolsover Collieries Co., an opportunity to study coal mining in America. The above snapshot was taken May 19 as the party was about to step on the cage of the auxiliary shaft to be lowered into Orient No. 2 mine of the Chicago, Wilmington & Franklin Coal Co., West Frankfort, Ill. From left to right are Albert Mitchell, St. Louis; F. B. Richards; John Bingley; Jos. Louis general superintendent of the Chicago, Wilmington & Franklin Coal Co., Benton, Ill., and M. C. Mitchell, manager of the St. Louis branch of the Sullivan Machinery Co.

Foreign Market And Export News

French Production Heavy

Paris, France.—The British strike is causing maximum production of coal in France. May output is estimated to be less than that of April, however, because of several holidays.

Imports from Great Britain are negligible, while those from Belgium and Germany, particularly the Ruhr district, have increased sharply and it is believed that the receipts from that district will probably increase further as import restriction freeing German fuels have been temporarily waived, although not officially lifted. Consumers of both domestic and industrial fuels continue to pyramid orders for stocks, fearing a shortage and further depreciation of the franc, but deliveries are impossible on these supplementary orders.

Prices for French coals are up by ten to twelve per cent since May 1, but are still below the level which the French consider necessary for profitable purchase of American coals. If the strike continues, sharper price increases are expected in France. Sales of Ruhr coal on the west coast and at Rouen are heavy, quotations at Rouen on mine run being 135 fr. per ton, which price has not been changed since May 1. Washed pea coal is 160 fr. per ton, an increase of 23 fr. since May 1. No English quotations are being offered for these ports. French mine-run is priced around 150 fr. at Rouen. French coal is now used for bunkering, including the English Channel ports.

Belgian Prices Rising

Coal prices are increasing rapidly and mine owners are unable to accept all orders, says a cable from Brussels, to the Department of Commerce. The low franc exchange eliminates foreign competition and partly explains the good demand from France, Switzerland and the Netherlands.

April production of coal in Belgium totaled 1,984,000 metric tons as compared with 2,132,890 in March and 1,894,470 tons in February. Stocks at mineheads amount to 1,290,000 metric tons.

A five per cent wage increase, effective June 1, has occurred in the metallurgical and coal industries.

Dutch Market Active

England is now out of the Dutch market as an exporter and is purchasing in limited quantities, says a cable report from The Hague to Washington. The Dutch market has advanced as a result of the English strike. Westphalian gas flame was quoted at 12 guilders ($4.824); foundry coke, 16 guilders ($6.432) and bunkers, 13.50 guilders ($5.427) c.i.f. Rotterdam.

Dutch coal production in March was 760,000 metric tons, a new high record. Exports in April were 452,000 tons compared with 423,321 in February. Of the amount exported in April Belgium took 135,000 tons.

Imports in April were 680,000 metric tons, compared with 428,176 in March and 754,605 in February. Of the April imports, Germany furnished 548,000 tons and England, 111,000 tons. In February Germany supplied 630,496 tons and England, 104,727 tons.

German Output Larger

Berlin, Germany—Coal production in May will show an increase, without overtime, to meet increased demands resulting from the British coal strike, April production was 10,000,000 metric tons, compared with 11,400,000 in March and 10,500,000 tons in February. Lignite production in April was 10,000,000 tons, compared with 11,800,000 tons in March and 11,115,385 tons in February, while coke production was 2,000,000 tons in April compared with 2,485,291 in March and 1,984,765 tons in February.

Ruhr stocks decreased from 8,500,000 tons at the close of April to 8,200,000 tons at the end of May. The Ruhr stocks are mostly fine coal and coke while the export demand is for gas and bunkers or the decrease would have been greater. Prices are unchanged and movements normal.

Spanish Output Shows Slight Decline

Spanish coal production in 1925 amounted to 6,252,000 metric tons. Bituminous output was 5,559,000 tons, of that total, while the remainder was divided between anthracite and lignite. The quantity of anthracite and lignite mined slightly exceeds that brought to the surface in 1924. The increase, however, is outweighed by the decline in bituminous production.

The royal decree recently enacted by the Spanish government in an effort to improve conditions in the Spanish coal mining industry has resulted in considerable optimism. The Spanish fleet and a few of the industries controlled by the Spanish government which heretofore have been using British coal have commenced, it is said, to use the Spanish product, thus permitting the Asturian mine operators to dispose of the stocks that they had on hand for some time.

Soviet Coal Fields Improving

Coal production in the Soviet Union for the first half of the current Soviet fiscal year, Oct. 1 to April 1, showed an increase of 44.4 per cent over the same period of last year, according to a bulletin received by the Russian Information Bureau at Washington, D. C. The output was 12,410,000 metric tons, as compared with 8,596,000 tons. The advance in production was carried out as planned in accordance with domestic requirements and the growing exports to Italy and other countries. Production was at 91 per cent of the rate for 1913.

Much new equipment, purchased in the United States, Germany and England, is being installed in the Soviet coal fields. During the current year upwards of $40,000,000 will be expended on re-equipment and extensions. Of 180 cutting machines being installed in the Don Basin, 140 were purchased in the United States. During the summer thirteen large new shafts will be opened in the Don Basin.

Coming Meetings

American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Illinois Mining Institute. Annual summer meeting on steamer "Cape Girardeau," leaving St. Louis, Mo., June 24 and returning June 26. Secretary, Frank F. Tirre, Central National Bank Bldg., St. Louis, Mo.

American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

Illinois and Wisconsin Retail Coal Dealers' Association. Thirty-first annual convention, Highland Hotel, Lake Delavan, Wis., June 28-30. Managing Director, N. H. Kendall, Great Northern Hotel, Chicago, Ill.

Fifth International First-Aid and Mine-Rescue Contest, San Francisco, Calif., during the first week of September, 1926, under the auspices of the Bureau of Mines, Department of Commerce.

Coal Mining Institute of America. Annual meeting, Chamber of Commerce, Pittsburgh, Pa., Dec. 8, 9 and 10. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

New Companies

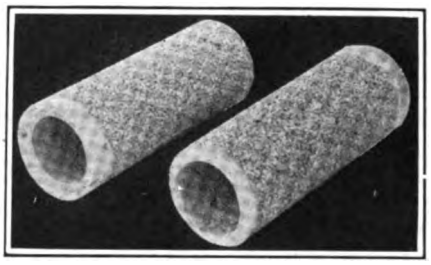
A new coal company has been organized in Wheeling, W. Va., to be known as the Kanawha Block Coal Co., with the following incorporators: John D. Thomas, of Charleston, W. Va.; Cecil H. Riggs, W. C. Gardner and Joseph Styche, of Wheeling, and H. O. Walls, of Martins Ferry, Ohio. The company has 200 shares of stock of no par value. The company's offices are in the Wheeling Steel Corporation Building, at Wheeling. The officers of the firm have not as yet been selected. The company owns coal lands in the Kanawha district about twenty miles from Charleston.

The Federal Fuel Corp. has been chartered in Louisville, Ky., by F. N. Meadows, H. K. Lawrence and others.

The Cliff Nelson Coal Co., Toledo, Ohio, has been chartered with a capital of $10,000 to mine and sell coal. Operations will be started in the southern Ohio field. The incorporators are Clifford F. Bechtel, Nels I. Gustafson, William H. Murphy, T. R. Jones and George S. Moss.

The Marcum Horse Creek Coal Co. was incorporated in Hima, Ky., recently by W. W. Marcum, Ray Price and others.

The Home Coal Co., Hillsville, Ill., was incorporated April 1 to operate a mine at that town.



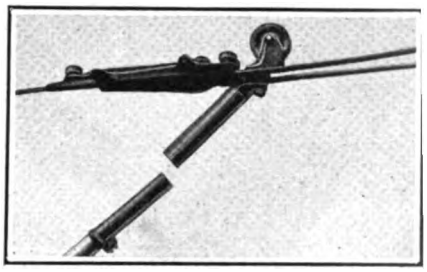
New Equipment

Water Enters Pipe Freely From All Sides

In the accompanying illustration may be seen the Rapid Drainage Pipe manufactured by the Walker Cement Products Co., of Little Ferry, N. J. This pipe, or tile, which originated in Europe, is made of crushed rock and cement. These materials are so mixed and forced together as to afford great strength yet afford a porous wall through which water may enter from all sides.

One of the big problems in drains that must resist the action of frost is to provide for the admission of the water that is to be carried away. Unglazed drain tile permits the entrance of water, but freezing shatters it. Glazed sewer pipe is unaffected by frost but its walls are impervious to water. This new product is said to combine the good qualities of both these drains, permitting the ready passage of water through its walls and yet being unaffected by freezing.

This new product has been applied extensively in difficult municipal and railroad drainage problems and excellent results are said to have been obtained. It will be particularly advantageous for draining sites where a high rate of permeation or influx as well as immunity from the effects of freezing are requisites. It is at present manufactured with internal diameters of 3½, 5½ and 8 in. and in 18-in. lengths. The ends are made male and female cones so that tight joints are assured. Tree roots are said to penetrate this tile only with great difficulty.



Water Enters Pores of Pipe; Frost Does Not Harm It

These tile are made of crushed rock and cement. The interstices between the aggregates are thus sufficiently open to admit water freely from all sides. Because of the indestructible character of the materials used, however, frost is said to have little or no effect upon them.

Pull Releases Wheel Without Breaking Pole

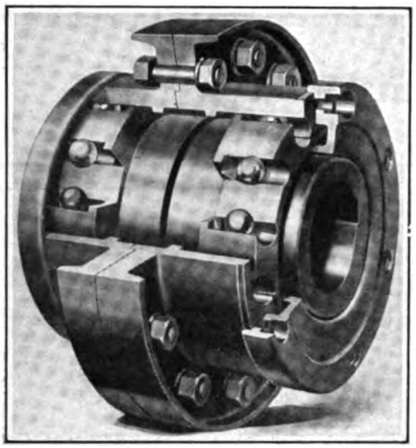
Broken trolley poles are a source of danger and delay. When a wheel comes off the wire, it may not only catch in a frog and tear down the wire, but break the trolley pole also. A safety pole-head designed to prevent the breaking of the trolley pole in case it comes off of the wire and catches in a frog or the like is now available.

This pole-head, sold by the C. & S. Pole-Head Co., Keystone, W. Va., is shown in the accompanying illustration. It consists of a socket to which the harp is attached, and a tapered pole end to which the cable is connected. The socket slips over the pole end and is held firmly but not tightly by a spring clip. A sharp blow or a heavy pull will cause the socket and its wheel to fall free of the rest of the pole.

Pole Pulled Apart Shows Details

A spring catch of the friction rather than positive type holds the socket on to the pole end. A heavy pull frees the trolley wheel, instead of breaking the pole.

In case the wheel leaves the trolley wire and catches in something before the motorman can pull the pole down, the socket and wheel are jerked off the end of the pole and fall to the ground. After the trip is brought to a stop, the socket and wheel are retrieved and slipped back into position on the end of the pole. The long delay caused by the insertion of a new pole is entirely avoided.



The poles have been used on the 30-ton locomotive of the Keystone Coal & Coke Co. and the safety feature has operated several times most satisfactorily. Delays to the locomotive due to a broken pole or torn-down wires have ceased to hinder operation.

Transmits Power with Shafts Out of Line or Offset

In the accompanying illustration may be seen a partial cross-section of the new Sykes universal flexible coupling, manufactured in sizes from ¾ to 8 in. by the Farrel Foundry & Machine Co., Inc., of Buffalo, N. Y. This device is practically a ball-bearing, universal joint capable of transmitting motion between shafts as much as 5 deg. out of line or offset as much as 4 per cent of the shaft diameter. In either case the movement of the balls upon their races is slight, never exceeding 1/32 in. per revolution.

Simplicity of construction is a distinguishing characteristic of this new coupling. It is composed of three main members—two hubs keyable to the ends of the driving and driven shafts respectively, and a two-piece sleeve inclosing and covering the whole device. Each hub carries ball races arranged around its periphery which match similar races on the inner surface of the sleeve sections. The balls, which are of standard sizes such as are used in bearings and journals, are placed be-

Digitized by Google

Partial Cross-Section Showing Internal Construction

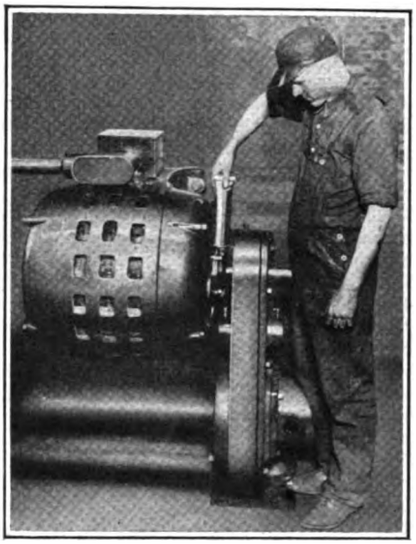
In this picture a portion of the two-piece sleeve has been cut away, showing the balls and the races within which they operate. Although this coupling ought to be lubricated it can run "dry" for a long time without perceptible damage.

tween or within the races thus formed.

Analysis of the action of this coupling shows that irrespective of the amount of misalignment of one shaft with respect to the other the balls always maintain line contact with the races. Lubrication of this coupling is of minor importance. Because of the large area of ball contact and the small and comparatively slow movement of the balls a thin film of grease on each is all that is necessary. In fact that coupling may be run for long periods entirely "dry" without appreciable damage.

Tube Applies Grease to Ball Bearings of Motor

Proper lubrication of motors always has been a vexatious problem. It was greatly simplified, however, through the advent of the ball-bearing motor with its inherent low bearing friction. Fairbanks, Morse & Co., of Chicago, believes that by use of a suitable grease the lubrication of such machines can be reduced to a 20-minute job once a year.



This firm recently introduced an improvement that further simplifies motor lubrication. This consists in furnishing the proper greases in collapsible tubes, each containing just enough lubricant for a motor's annual requirements.

After flushing out the old grease with kerosene the new grease is squeezed from the tube directly into the bearing. Directions show exactly how much to put into each bearing for the best results. Four sizes of tubes are available for corresponding sizes of bearings.

Many advantages inhere in this tube method of greasing. The kind of lubricant best adapted for ball-bearings is used. This is of the proper adhesiveness to cling to the balls; it maintains its consistency through all normal temperatures without being too stiff when starting in cold weather, and without melting and flowing out of the bearing when the motor is carrying full load.

The manufacturer guarantees it free from gritty or corrosive constituents and when the grease tube is used no outside dirt or other deleterious matter is likely to be introduced into the bearing. The probability that a stick or other handy object of questionable cleanliness will be used for transferring grease from an open can to the bearing is entirely eliminated. The cap of the housing is not removed; only the plug. No lubricant is wasted or smeared outside the housing, and no wiping is needed. Just the right quantity of grease for the most perfect lubrication is used in each bearing.

The makers state that it must not be assumed, because the grease is furnished in tubes, that this is an expensive method of lubrication. It is found, in practice, that the slight cost of the tubes usually is offset by the elimination of waste in the use of the lubricants. This method of greasing therefore affords both economy and convenience and maintains the efficiency of the bearing at its highest point.

Greasing by Tube

Method of using the new grease tube in lubricating ball-bearing motors. All waste is eliminated and use of a lubricant of proper consistency is assured.

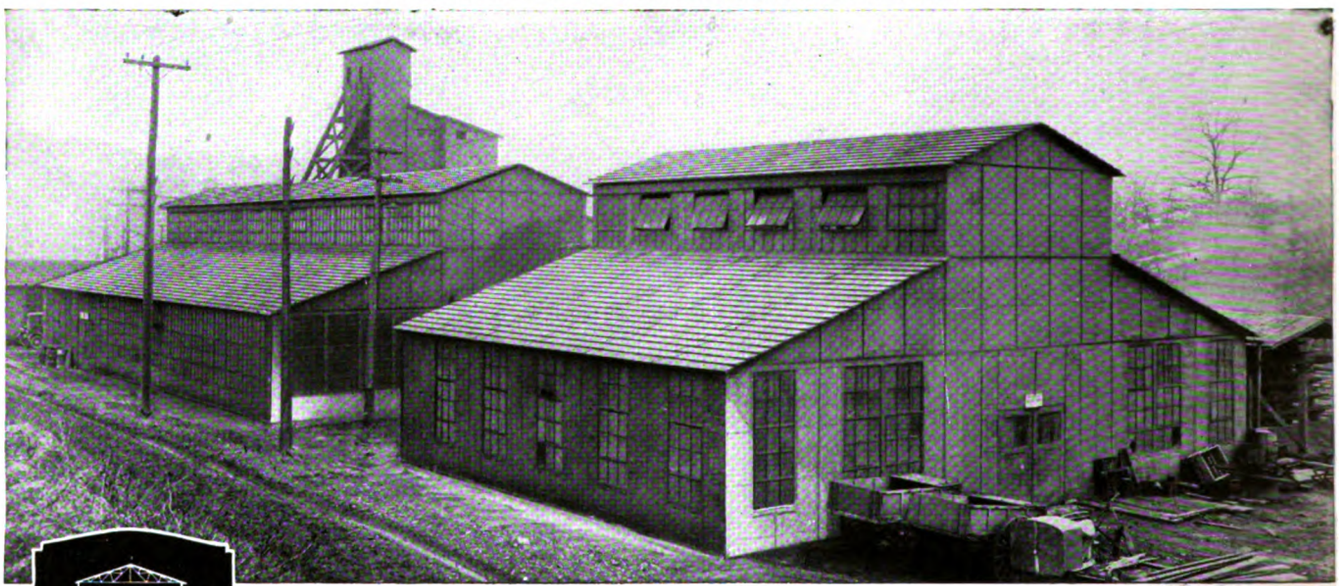
Detroit Stoker Co., Detroit, Mich., has issued a 24-p. bulletin, No. [illegible], describing and illustrating its Multi-**Retort Underfeed Stokers.** The [illegible] fuel bed and the method for controlling movement of the fuel throughout the entire process of combustion are some of the illustrated features.

Climax Engineering Co., Clinton, Iowa, has issued three bulletins describing its "Trustworthy" Engines in relation to various types of drive units. Bulletin E describes its Power **Units;** bulletin F its Engines Direct **Connected to Generators;** and bulletin G the Climax Engine Direct Connected **to Centrifugal Pumps.** Tables and illustrations are included.

Homestead Valves. Homestead Valve Mfg. Co., Homestead, Pa. Catalog No. 33. Pp. 51; 6x9 in.; illustrated. The catalog should interest industrial users of water, air steam, acids, oils, hot liquids, oil residue, etc.



Sangamo Meters. Sangamo Electric Co., Springfield, Ill. Bulletin No. 19; 8x10½ in.; illustrated. Contains instructions for Sangamo type [illegible] watthour meters.

TRUSCON *COPPER STEEL BUILDINGS

Permanent Types of Standardized Construction

*COPPER ALLOY STEEL RESISTS RUST

Truscon Service *Includes* Planning-Manufacture-Erection-*One Contract* *No Extras*

Standardized for the Mining Industry!

You obtain from Truscon a better steel building designed to meet your special requirements. The right building at the right time and at the right place.

You obtain at no extra charge, Truscon Service, which involves problems of construction from preliminary studies, layouts, simplification of ideas, refining of cost, to the complete erection of the structure.

You obtain a permanent, non-burning building made from rust-resisting copper alloy steel. You obtain Truscon Steel Windows, Doors, and Roof, all quality products. There is something superior about a Truscon Building. It is built to last indefinitely.

National Coal Association Issue

Coal Age this week has pleasure in presenting most of the papers read at the Convention of the National Coal Association last week. They will be found of vital interest to all coal men, especially executives. They give definite, clean-cut counsel. They afford specific help. Thus they advise coal men:

How to equip salesmen for their work.
How to eliminate false compensation claims.
How to avoid bad credits in the store.
How to reduce malingering.
How to buy goods for the store at minimum prices.
How to decrease accidents.
How to increase haulage efficiency.
How to discover faults in the cutting schedule.
Why we need statistics in our industry.

Take your *Coal Age* home with you and read it through from end to end. You should know what the National Coal Association is doing for the industry and what it could do if it had more members. We need management at the mines but still more do we need co-operation in the management of the industry to solve our problems corporately.

Coal Age "reads easily." It is edited with that end in view. The information is made brief enough not to take too much of your valuable time, yet simple enough to make you grasp the meaning at a glance.

Bet on Bulldog!

always to lead the way~

SOME dogs will condescend to trot along at your side. Just ordinary canines, these are. Other poodles you simply have to drag along. These are pests, pure and simple. But take your Bulldog out and watch him strain at the leash---out ahead all the time.

That is what O-B Bulldog Clamps are like. Always ahead in economy, reliability and new progressive ideas.

O-B Bulldog Cable Clamp

Adapted to feeder cable suspension

The same clamping principle as the popular Bulldog Trolley Clamps. Sling jaw holds the feeder cable while the feeder is being strung, then the smaller jaw clamps it securely and relieves strain from the dead-end points.

What Can the National Coal Association Do?

MANY WONDER whether anything is gained by an association among coal men, yet men in nearly every industry bind themselves together and find the practice helpful. Some of our forefathers questioned whether they desired any United States. They said let the various commonwealths come together to meet an emergency, just as the coal men met in the war when dangers assailed the industry. They proposed to be separate in the interim. The question was settled. The states of America have become the United States. One cannot conceive conditions otherwise. Secession would now be regarded as criminal and suicidal. Some day coal men will wonder how anyone could seriously question the necessity for unity in their counsels if not unanimity in opinion and union in action.

The statistical work of the National Coal Association if conducted in a careful manner should do much to prevent undue development in the industry. When the coal men and the public learn the facts regarding production costs and market prices they will be able to see what the profit in the industry really is, and we shall not find so many anxious to enter the overcrowded ranks of producers. The public has only a small conception of the many items entering into the production of coal and believes that all the men in the mines are "miners" and that what is paid them is and should be the whole cost of producing coal.

* * *

During the past week the National Coal Association met in its ninth annual convention and the present issue is largely devoted to its proceedings. Never has the Association produced more striking contributions to the progress of the industry. Early meetings were marked by severe repression. The papers presented were feeble indeed compared with those of the recent meeting, many of which appear almost in full in the pages that follow. Any one reading them, even if possessed by a complex against the industry, will realize that the operators met with the intention of solving the problems that confront them and the nation, with a constructive program, not perhaps definitely formulated but in process of formulation.

Few organizations have a complete program covering all phases of development. This nation itself, as a whole, has no definite plans. A few general principles govern us in the direction of our domestic and foreign relations; but about many matters we are still greatly at variance. Yet we, as a nation, have had not nine anniversaries but over a hundred. No one has up to the present written in plain unmistaken language a statement of the principles to which nationally we adhere, and if they should be written they would lack much of meeting the many complex situations which we as a nation face. As the American people are divided and irresolute about certain matters, so we cannot anticipate perfect unanimity among coal operators.

* * *

But the National Coal Association apart from the formulation of policies has a definite reason for being. When operators learn just how much coal is going into a certain market and what the price in that market actually is, at any moment, we will have fewer no-bill cars and less distress coal. When mine workers who malinger, who will not work, who do not pay their bills or who do not protect their lives and limbs have their records writ plain we shall soon eradicate them from industry. A like exodus of wholesalers and retailers who will not pay their bills will occur when their records also are known and tabulated.

Though what follows may not represent the purpose of the Association, the coal operators, when they meet together, will absorb a sense of mutuality. It may pay better at times to produce coal at a loss rather than to leave houses empty and mines deteriorating, but a sense of solidarity will induce operators to regard this practice as one harmful to the coal industry as a whole and to themselves also in particular. They will also learn that large immediate gains bring misfortune on the industry, adverse criticism and legislation, excessive development and demoralization, and a disposition eventually will be established to correct these evils. This attitude of mind will not establish itself immediately nor uniformly, but the sense of solidarity will come in time, and the men of the industry will at length come to have courtesy rules that condemn alike excessive profit and unbridled competition as being entirely contrary to the spirit of the times.

* * *

The National Coal Association is determined, while living strictly within the law, to develop, and will eventually create, the right spirit. All operators who wish for the industry a day when it will serve itself and the nation better than in the past should be found in its ranks.

Think a minute. Our interest in the success of the United States exceeds our personal interests in our own industry. If we did not have good government, order and a proper public sentiment in this country we would not have the basis for even endurable existence. So with the coal business—it is profitable, progressive, healthful only if we have taken time, not only for the proper handling of our affairs, but the proper direction of the corporate business of the whole industry.

National Coal Association Spends Three Days Formulating Plans for Coming Year

Staff Correspondence

EXPANDING SERVICE to meet the growing needs of the bituminous industry was demanded by the operators at the ninth annual convention of the National Coal Association, held at the Drake Hotel, Chicago, June 9-11. More statistical information, more marketing data, more scientific research, greater co-operation within the industry, intensive study of accident prevention work were set forth as services in which the organized bituminous trade should take the lead in furnishing its members.

While attendance was exceeded by that at some of the earlier meetings when war-time control made membership almost obligatory, the convention last week set a new record in genuine interest and enthusiasm and in the broad sweep of the program presented for the consideration of the delegates present. The innovation of group meetings to discuss pooled purchases and sales methods proved specially successful, and the attention given to the safety movement made it certain that the National Coal Association as an organization will play a larger part in accident prevention work in the future.

The convention, in a resolution adopted on the closing day, again went on record as unalterably opposed "to any federal legislation which singles out the coal industry for regulation." At the same time, it was made clear in committee reports and floor discussion that the industry proposed to so enlarge its statistical activities that there would be no excuse for compulsory fact-finding. Continuation of the statistical program undertaken by the association was specifically authorized in another resolution.

Walter Barnum

Walter Barnum, president of the Pacific Coast Co., with headquarters in New York City, was elected president of the association for the ensuing year. Ira Clemens, president, Clemens Coal Co., Pittsburg, Kan.; Michael Gallagher, general manager, M. A. Hanna Co., Cleveland, Ohio, and George B. Harrington, president, Chicago, Wilmington & Franklin Coal Co., were re-elected vice-presidents. E. C. Mahan, president, Southern Coal & Coke Co., Knoxville, Tenn., was elected vice-president to succeed Mr. Barnum. C. E. Bockus, president, Clinchfield Coal Corporation, New York, was again the choice for treasurer. Harry L. Gandy again was named as executive secretary.

At the opening of the convention on June 9, the following committees were appointed:

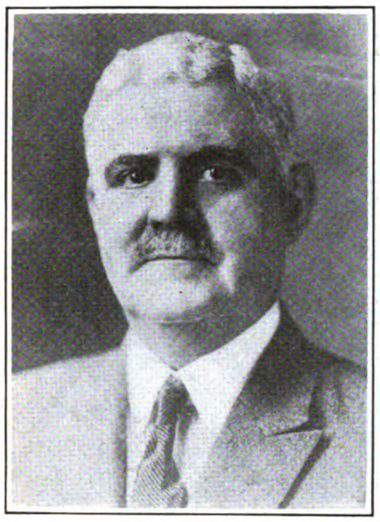
Nominations and Elections: Otis Mouser, Virginia, chairman; R. N. Sherwood, Indiana; George Bausewine, Jr., West Virginia; George J. L. Wulff, Missouri, and T. W. Guthrie, Pennsylvania.

Credentials: D. H. Morton, West Virginia, chairman; J. C. Nelms, Ohio; Irvin Johnson, Kentucky, and W. L. A. Johnson, Missouri.

Resolutions: Louis C. Madeira, III, Pennsylvania, chairman; John J. Lincoln, West Virginia; Warren Blauvelt, Indiana; C. F. Richardson, Kentucky; P. J. Quealy, Wyoming; George C. Eastwood, Michigan; E. C. Mahan, Tennessee; Lee Long, Virginia, and D. F. Hurd, Ohio.

President M. L. Gould, who had yielded the chair to Mr. Madeira, made his address to the convention a strong plea for increased membership. Those now in the association, he said, constitute "a splendid, loyal nucleus of forward-looking operators, who are contributing their support ungrudgingly to hold the lines firm against the know evils of disintegration and to make steady advances of practical value.

"In our Washington offices we have a most competent staff. It is needless for me to deliver any eulogy of Mr. Gandy. You know him, as I know him, for a most efficient executive, who, in the face of obstacles with which we are all too familiar, has not only held this organization together dur- the past three years, but has considerably strengthened it."



The association, asserted Mr. Gould, had a construction program which was bound to further the interests of the industry. But more operators must share the financial burdens of carrying out that program. As a private in the ranks, Mr. Gould pledged his support in a membership campaign. "When competitors in this business decide to get together and to direct their efforts toward increased efficiency, such as will come through learning from each other and through widespread co-operative effort, this industry will begin to realize its vast possibilities."

At the conclusion of his address, Mr. Gould was given a unanimous vote of thanks by the delegates for his labors in their behalf during his term of office.

The report of Harry L. Gandy, executive secretary, was a brief review of some of the major activities of the past year. Discussing the threats of regulation, he expressed the belief that time would make it clear that the economic problems of the industry could not be solved by legislation such as now proposed at Washington. Fact-finding, he pointed out, had not averted coal crises in Great Britain. Government intervention in wage disputes had not brought industrial peace. "The record here and in England justifies the statement that the advance recognition of an industrial emergency will bring the emergency. The setting up of a body political to which either side may appeal will make practically certain that employers and employees cannot agree."

Mr. Gandy acquitted the national administration of

Digitized by Google

M. A. Gallagher

G. B. Harrington

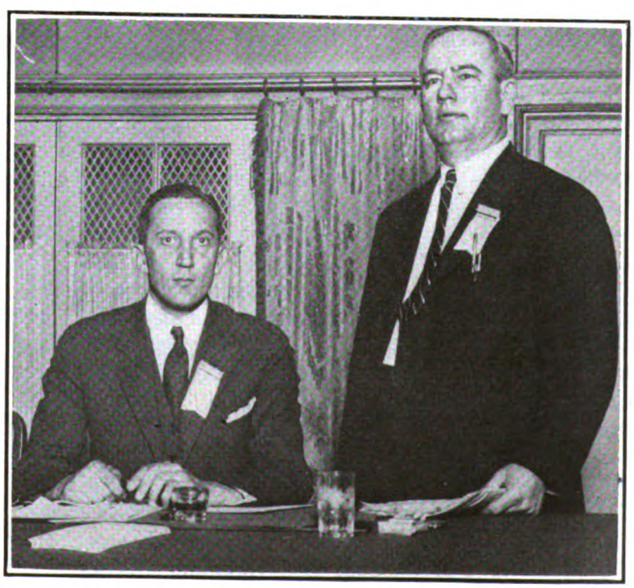
E. C. Mahan

any desire to injure the industry. "The statement of the Secretary of Commerce before the House committee and his reply to questions indicated a friendly attitude. We may disagree on just what should or should not be done, but at the same time I grant a sincerity of purpose to those with whom we disagree."

The coal trade is making slow, but certain, progress toward better merchandising, reported Mr. Gandy. Statistical activities of local associations are expanding. "That voluntary effort on the part of the industry, and the progress thus far gives promise that it will be successful, will eliminate the reason given by those who advocate statistical activity on a compulsory basis by the federal government."

C. E. Bockus, treasurer, reported that receipts for the year ended March 31, 1926, had totaled $158,516 and expenses, $160,309, leaving a deficit of $1,793, as compared with a deficit exceeding $23,000 a year ago. Outstanding accounts receivable far exceeded the liabilities. "If we can realize 10c. on the dollar, our association is solvent. I think we can realize at least 50c."

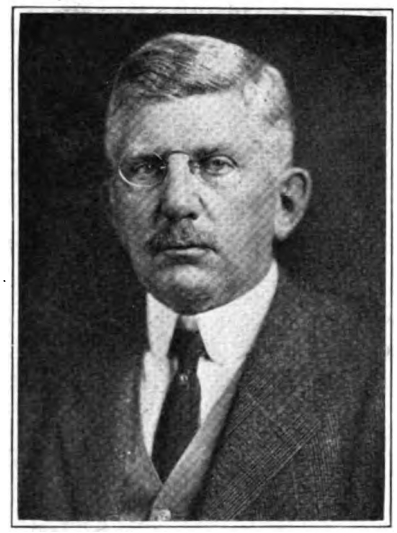
Although 138 association and individual members had been added to the rolls the past year, the losses numerically had outrun these gains, according to the report of S. Pemberton Hutchinson, chairman of the membership committee. The increase in tonnage represented, however, was over 16,000,000 tons.



Local and Group Advertising

Local and group advertising was urged by George B. Harrington, chairman of the committee on publicity, who also reported a more favorable attitude toward the industry on the part of the daily press. There has been little gain in overseas business, said the report of H. N. Taylor, chairman of the committee on foreign trade. American shipping is handicapped by arbitrary laws which inflate costs and work against the export trade. Ira Clemens, chairman of the transportation committee, stated that no major problems had come before his group the past year.

"The price of progress is research," declared Walter Barnum, chairman of the research committee. Those who will not pay the price will fall by the wayside. Until membership in the National Coal Association has been increased, however, the research activities of that organization must be limited largely to missionary work and co-operation with engineering societies and others engaged in research investigations.



The committee is co-operating with the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers in a consolidation of research activities in the mechanization of mines. Contact has been established with the Massachusetts Institute of Technology through membership of the committee of the Institute which gives counsel regarding the graduate course in fuel and gas engineering. The association also is financing a graduate research fellowship in the Carnegie Institute of Technology.

"We are proceeding in a purposeful way as far as our funds will permit. The old saying, 'knowledge is power,' is true. We must equip the rank and file of producing and selling organizations so that they won't be hopelessly handicapped by a lack of knowledge of their own goods and service. How can we meet oil competition, for example, without the rank and file of our industry, not just the occasional expert, being thor-

Louis C. Madeira III and Harry L. Gandy

Digitized by Google

S. P. Hutchins n

M. L. Gould

Ezra Van Horn

oughly at home and familiar with combustion differences and steam costs?"

The oil industry considers a $500,000 fund for research only a drop in the bucket. "To an industry in greater need of research than is the oil industry," concluded Mr. Barnum, "even half such a drop would be extremely helpful. It would be a humble, but a real, beginning."

SEEK FOR MOTOR FUEL

Coal as the future source of motor fuel was the picture held up in a paper on "Hunting for the Elements Produced by Low-Temperature Distillation." This paper, the work of R. L. Brown and R. B. Cooper, was presented by Mr. Cooper, who is the National Coal Association graduate research fellow at Carnegie. The basis of all motor fuels, said the authors, is carbon. With petroleum reserves diminishing, the commercial conversion of coal into motor fuel cannot be long delayed.

The first general session ended with a review of mine water pollution of streams by Richard D. Leitch, associate chemical engineer, U. S. Bureau of Mines, Pittsburgh, and the report of the credentials committee.

The greater part of the Thursday morning session, presided over by Ezra Van Horn, general manager, Clarkson Coal Mining Co., was given over to a discussion of accident-prevention work. This new departure in the activities of the convention, covered in detail elsewhere in this issue of *Coal Age*, aroused such interest that prosecution of further work along the same lines was authorized in a resolution adopted the next day.

The report of the committee on nominations and elections, approved by the convention, named the following district directors: Walter Barnum, Pacific Coast Co., Washington; C. E. Bockus, Clinchfield Coal Corporation, Virginia; Ira Clemens, Clemens Coal Co., Kansas; T. F. Farrell, Pocahontas Fuel Co., West Virginia; David Ingle, Ayrshire Coal Co., Indiana; T. W. Guthrie, Hillman Coal & Coke Co., and L. C. Madeira, III, Madeira, Hill & Co., Pennsylvania; George B. Harrington, Chicago, Wilmington & Franklin Coal Co., Illinois; H. Denman, Paris Purity Coal Co., Oklahoma, Arkansas and Texas; C. W. Taylor, W. G. Duncan Coal Co., Kentucky; S. L. Yerkes, Grider Coal Sales Agency, Alabama; H. N. Taylor, U. S. Distributing Corporation, Wyoming and Montana; George C. Eastwood, Consolidated Coal Co., Michigan. With the exception of Messrs. Ingle, Denman, C. W. Taylor and Eastwood, the directors named had been chosen to succeed themselves.

For directors at large, the following were elected: P. H. Penna, Indiana Bituminous Coal Operators' Association, Indiana; W. H. Cunningham, Burgess Branch Coal Co., West Virginia; P. J. Quealy, Gunn-Quealy Coal Co., Wyoming; Thomas DeVenny, Williamson Coal Operators' Association, Kentucky. Messrs. Penna, Cunningham and Quealy were elected to succeed themselves.

Voluntary statistical activities upon the part of the industry received the unqualified indorsement of the committee on trade information. Compulsory reporting was as unqualifiedly condemned. "As an industry," said C. E. Bockus, chairman, "we are opposed to any system of compulsory reporting to a federal agency, not because we desire to have the facts concealed, but because we believe that such a move may well prove the first step in the direction of federal regulation of the industry."

In the opinion of the committee there were many lines of desirable statistical activity which the industry should undertake. The association, however, has been concentrating on the promotion of past sales reports, with the idea that, as soon as those reports become general, the organization will then seek to foster other fact compilations.

TAX AND COST ACCOUNTING

The major problems to which the tax and cost-accounting committee had devoted itself during the past year, said R. C. Tway, chairman, in addressing the convention at the closing session on Friday morning, June 11, were the interpretation of Article 224 of the income-tax regulations and changes in the income-tax law of 1926. In this the committee had received the assistance of W. B. Reed, former secretary of the National Coal Association, and now its tax adviser. Routine work included the handling of taxation questions referred to the committee by individual members and the preparation, by Mr. Reed, of short digests of decisions and rulings affecting federal taxation.

Article 224 is the regulation in which distribution

Digitized by Google

is made between capital charges and expense items. The association has taken the position that expenditures to maintain production should be treated as expense items and expenditures to increase production should be capitalized. Efforts to maintain that position, however, have not been very successful. Each ruling promulgated has appeared more drastic than its predecessor. The most recent decisions, for example, have taken rails and lesser items out of the expense account and put them in the capital account.

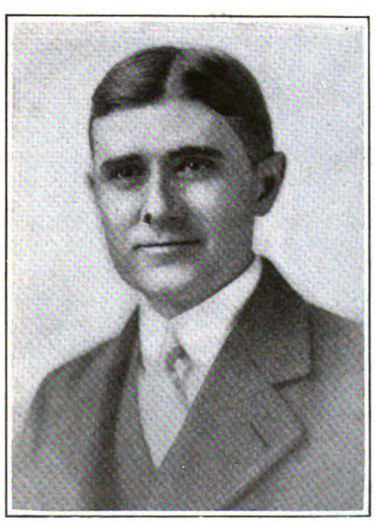
The association still is fighting to secure acceptance of its position. The question of interpretation is now before the federal courts in *Beech Creek Coal Co. vs. Collector of Internal Revenue.* The association also is laboring to have the article liberalized in the redrafting of the regulations made necessary by the new income-tax law "to eliminate all reference to major and minor items of expense or to the probable duration of the life of the article for which the expense was incurred. It would base the distinction absolutely and solely upon the question of the effect of the expenditure upon output or upon cost of production."

Capital-Stock Tax Is Property Levy

During the consideration of the new tax law by Congress the association filed a brief opposing the capital-stock tax, the stamp tax on original issues of stock and the retroactive features of section 204 of the act of 1924. The capital-stock tax, the committee emphasized, had to be paid regardless of earnings and was virtually a property tax. "Though definite figures are not available as to capital investment in the bituminous industry on which the tax was based, yet a conservative estimate would be that the repeal of the capital-stock tax law saved the bituminous operators something between $2,000,000 and $3,000,000 annually."

Trade information, stream pollution, a threatened transfer of safety work to the Bureau of Labor Statistics, proposed modifications of the Sherman anti-trust law and the campaign for regulation of the coal industry were the subjects discussed in the report of the government-relations committee presented by W. H. Cunningham, chairman. The committee commended the revival of statistical activity and indorsed the recommendations of the trade information committee for an expansion of that work. While stream pollution was a local, not a federal, matter, so many mines are affected that the organization should keep in touch with developments to prevent injustice being done.

The committee reported success in its representations to Congress that the proposal to establish a division of labor safety in the Department of Labor should exempt the mining industry and leave the safety work under the control of the Bureau of Mines.



Facing All Issues Squarely

Reviewing the drive for federal legislation on coal, Mr. Cunningham declared that "the association conducted no lobby, it made no pussyfooting efforts. It faced the issue squarely. It believed the industry had nothing to hide. The effort against legislation was made without apology; the record of the industry was cited with pride.

"The present Congressional session is nearing its end, and it is the belief of many who are in touch with the situation that there will be no further activity for coal legislation before adjournment. The bills mentioned (the Copeland and Parker measures) will go over to the December session, where efforts may again have to be made on behalf of the industry.

"In fact, gentlemen, this is a continuing effort for the protection of the industry. There is a part of our citizenry constantly striving for increased governmental activities. Bituminous operators must always be on the alert. They should strengthen their position by strengthening their local associations and in turn strengthening their national association. Further, they should make it their business at all times to fully acquaint their fellow citizens—and that includes members of Congress—with the fact that the bituminous industry is fueling this great nation at a lower cost than that enjoyed by any other coal-consuming public in the world."

In the discussion which followed the reading of the report, C. F. Richardson, West Kentucky Coal Co., urged members to keep in touch with the national lawmakers. J. G. Bradley, Elk River Coal & Lumber Co., declared that the coal industry did not want the

R. C. Tway

Melvin Traylor

H. B. Lindsay

Digitized by Google

government to deprive it of its initiative and to take away the responsibility the operators had towards their stockholders and their employees. E. C. Mahan, Southern Coal & Coke Co., said that the efforts of the National Coal Association at Washington had prevented legislation and had placed the industry in a more favorable light with the public.

WHAT THE COAL INDUSTRY NEEDS

The essentials required for the successful and independent conduct of the bituminous industry, as seen by Melvin A. Traylor, president of the First National Bank, Chicago, and first vice-president of the American Bankers' Association, who addressed the convention on "The Layman's Viewpoint," are:

(1) Peace within the industry, meaning thereby freedom from labor troubles, and continuous operation with an adequate supply of coal.

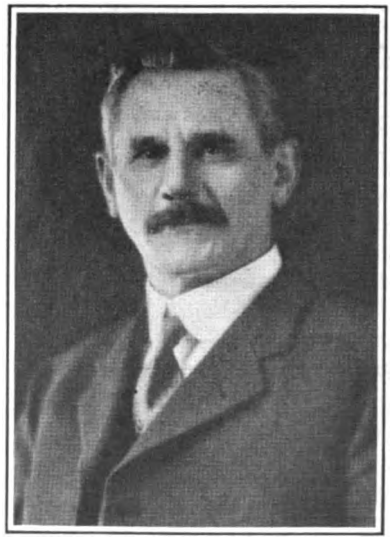
(2) Constant striving for more efficient salesmanship and such better marketing conditions as will bring fair prices at all times—fair prices to the operators, the miners and the public.

(3) Provision for continuous fact-finding and publication of statistics by the industry itself.

The wisdom displayed in the coal industry, said the banker, "seemingly has not kept pace with its importance and its extent. The history of coal mining is an account of a long series of quarrels between operators and employees, and the blame has apparently lain with both parties to the quarrel." In support of this contention, Mr. Traylor traced the union movement in Great Britain and the growth of the socialistic conception among the mine workers there. On this side of the water, he admitted, socialism has been less rampant, but labor disturbances have been too frequent.

"The public," he maintained, "should not be expected to tolerate periodic dislocation of our economic structure simply because the various parties in an industry seem unable to compose their differences without a complete cessation of work for some months." Eleven per cent of the strikes in this country have been in the coal industry. This record is exceeded only by the building trades, with 19½ per cent, but these latter strikes were less important and involved far fewer men. Strikes are followed by investigations, but little or no improvement in the situation. "Are we going to admit the failure of individual enterprise and end with nationalization?"

Unless the industry can demonstrate its ability to settle its own affairs, warned Mr. Traylor, government control will be inevitable. Federal supervision was not the curse commonly painted, but it can cure no ills. It can merely watch the symptoms and give the alarm if danger approaches. The ills of coal have been diagnosed with care and precision. Overdevelopment, accentuated by the war, is generally recognized as the fundamental cause of bituminous instability.



"Inseparably bound up with the factor of overdevelopment is the factor of labor relations. That strikes tend to cause overdevelopment has been well understood, but it is quite as important to understand that overdevelopment causes strikes. Competition between fields with a fixed labor cost and other fields with a flexible labor cost makes the industry fundamentally unstable and tends to increase overdevelopment. Hence, a permanent cure for overdevelopment must provide something like uniformity of labor standards.

"In a broad sense it is economically unsound that one-half of the industry should be governed by a fixed and the other half by a flexible labor cost. A rigid wage rate spread uniformly over a wide territory where working conditions and living costs vary materially is also illogical. The ideal wage contract, flexible to the point of adjusting earnings to various working conditions and to the changes in living costs and profits in the industry, is not in sight for the immediate future, but we may expect a gradual improvement in the mutual understanding by employers and employees of each other's problems and needs, from which improved relations between them, contractual and otherwise, will naturally ensue."

This development of better labor relations, continued Mr. Traylor, must be left to the industry itself. "The government can do no more than enforce the law and protect both sides in the exercise of their rights as citizens so that the issues can be settled by peaceful means and not by force. This calls for the suppression of lawlessness, both in union communities like Herrin and in the non-union mountains of West Virginia and Kentucky. The public should insist that the

J. G. Bradley

John H. Jones

D. H. Pape

Digitized by Google

collective bargaining question should be decided in each district on its merits by the employers and the men who work in the mines, and should condemn any resort to violence by either party."

Elimination of high-cost operations is the obvious remedy for the present unstable conditions. It had been hoped to accomplish this by the long-term Jacksonville agreement, but this hope was blasted by the competition of non-union mines. The law of supply and demand has been working against the union fields. "The penalty has, in many cases, fallen upon operations not basically uneconomical, but placed in that category by a situation which imposed on them a higher cost of production than prevailed in competitive fields in non-union territory."

Larger units of production were recommended as one of the steps in the ultimate solution of the problem. "Gradually we are beginning to realize that under modern conditions large corporations offer the only means of handling certain of our industries effectively and economically. Under unified control of financial and physical operations it would be possible to accomplish more effectively the economies inherent in co-operative marketing associations. The elimination of unnecessary costs in distribution, improvements in methods and standards of quality, building up wider markets, adjustments of production to fluctuations in demand, and the disappearance of surplus mines and workers are possibilities which can most effectively be realized under consolidations of ownership. The first practical step in promoting the plan is to impress the idea upon operators, financial interests and the public."

Stumble Along After Great Britain

In the closing minutes of the session, Retiring President Gould conducted his successor to the chair amid applause. Mr. Barnum declared that he saw three major problems confronting the association—government relations, research and membership. "Unless we are careful," he said, "we may find to our dismay that Great Britain has written the history of our coal industry in advance."

Turning to research he stated that if the gas companies could market their product at 50c. per 1,000 cu.ft., fuel-oil competition would be eliminated. The disparity between summer and winter loads at this time prevents this and holds back the campaign for domestic heating business. The gas interests, however, are trying to find new summer markets or methods of storing gas in summer for winter use. The accomplishment of either of these ends means a broader market for coal.

Another possibility is the development of an automatic stoker for domestic furnaces. Experiments are being made with equipment to carry a hopper charge of 500 to 1,000 lb. of coal and to be electrically controlled. One test with high-ash, low B.t.u. coal had given 7 lb. of steam per pound of coal. The perfecting of such equipment also would put fuel oil at a disadvantage. With these possibilities in mind, President Barnum felt that the day when increased coal consumption would offset the deductions due to increased efficiency was not so far distant.

The resolution of the National Retail Coal Merchants' Association for co-operation in working out and using a slogan to advertise the use of coal was read and referred to the publicity committee.

Association Shows Active Interest in Safety

Records of Employees Essential to Keep Compensation Rates at Minimum—Problems of the Convalescent

Staff Correspondence

COMPLETE ELIMINATION or all preventable accidents was the goal set for the coal mining industry at the safety conference held at the Drake Hotel, Chicago, June 10, as part of the program of the ninth annual convention of the National Coal Association. There was general agreement among the coal men present that education of the workers was the most necessary step in accomplishing this result. This educational campaign, it was felt, could be made most effective if put upon a competitive basis. More complete records on the accident history of individual employees and more intensive studies of accident curves plotted from mine records also were urged as aids in reducing the number of accidents.

Man the Biggest of Our Hazards

The human element is the biggest factor in accident-prevention work, declared Phil H. Penna, chairman of the committee on safety, in opening the discussion. "Recklessness is a typical American characteristic. It is not only in the coal-mining industry that deaths in the United States are at a higher rate than in European countries. The same thing is true of practically all occupations and is to be accounted for to a considerable extent by the unfortunate readiness of American workmen to take chances.

"In many industries the individual pays the penalty of his own heedlessness. In our industry, on the other hand, only too frequently the carelessness of one causes the injury of others, as well as the destruction of property and loss of time to the operator. Your committee believes that it cannot put too much emphasis on the importance of training the individual in 'safety-first' knowledge and habits. It believes that money expended in promoting proper carefulness on the part of mine employees will be returned manyfold to the operators incurring it."

Mr. Penna cited the rapid increase in the number of chapters of the Joseph A. Holmes Safety Association as proof that interest in the safety movement is growing. The association at its last annual meeting divorced itself from all legal control and responsibility for the local chapters, which now are members of an unincorporated society known as the Holmes Safety Association. The parent body continues as a national incorporated organization.

How one company by reorganizing its safety work was able to reduce its accident rate per 1,000 man-days from 1.33 to 0.71 per cent in less than three years was explained to the convention by J. William Wetter, general manager of the bituminous operations of Madeira, Hill & Co.

Competition is the keynote of the accident-prevention campaign undertaken by producers in the Southeast, according to R. E. Howe, secretary, Southern Appalachian Coal Operators' Association, who addressed the convention on "One Way to Interest Employees in Safety Work." His organization has formed a sub-

Digitized by Google

Phil H. Penna

Secretary-Treasurer of Indiana Coal Operators Association and Chairman of the Committee on Safety.

sidiary body known as the Southern Appalachian Efficiency Association to which superintendents, mine foremen, safety inspectors, fire bosses, electricians and other key men belong.

Accident prevention, of course, is the most certain method of keeping the cost of compensation insurance to the minimum, stated J. T. Rupli, superintendent of the compensation department of the Chicago, Wilmington & Franklin Coal Co. Without minimizing the importance of preventive work, however, it was the speakers opinion that the industry had not given enough attention to the efficient handling of the accident situation after the accident has occurred. One great drawback to this consideration has been the "compensation complex." Operators have treated compensation claims as a matter of insurance instead of as an operating problem, despite the fact that insurance rates are based upon the physical and moral hazards of the industry and its accident experience.

As the first step in reducing compensation costs after accidents, Mr. Rupli recommended the establishment of compensation or personnel bureaus to maintain personal contact with injured employees and function as a connecting link between the operating department and the insurance agency. Another necessary step is to employ only men physically fit for the jobs to which they may be assigned. Administration of first-aid by specially trained men is essential. Inexpert first-aid treatment in many cases does more harm than good and may aggravate the injury.

Report Before Aggravation or Infection

Every injured man should be required to report to the company surgeon or doctor for examination at the earliest practical moment. Such a requirement safeguards all parties of interest. The injured man receives proper treatment, the employer receives the necessary statistical and medical data, and malingering and fraudulent claims are effectively discouraged. The personal contact maintained with the injured by the compensation bureau likewise reduces the number of unnecessary claims and also impresses the employee with a sense of company interest in his welfare. Working of the "compensation complex" under such conditions is impossible.

When the injured man is ready to return to work, the decision whether he is able to resume his former tasks or should be given lighter duties should rest with someone competent to pass judgment. Mine bosses as a rule, said Mr. Rupli, are inclined to act upon the theory that the man's discharge from medical care is proof that he is ready to take his old job. At other times, they will encourage exaggerated claims by giving the returned worker a lighter task.

Every accident, however, trivial, should be reported. Neglect of slight injuries sometimes leads to serious permanent disabilities. Such reports will furnish data for a statistical study of accident curves which may be compared with similar data from other mines. This comparative study will give the groundwork for further investigation of accident-prevention methods. These studies should be made by mine safety committees consisting of the operating executive, mine superintendent, bosses, safety inspector and manager of the compensation bureau.

"And when I say safety inspector," Mr. Rupli declared, "I do not mean the old practical miner who has seen his best days at the face or the technical engineer fresh from college, but one who has had sufficient technical and practical experience to give him the balance of discretion. Such safety inspector should report direct to the executive management." His duties should include "periodical inspections of the mine properties with the view of checking unsafe and dangerous mining practices and violation of mining law and company rules from the standpoint of accident prevention."

The Harlan County Coal Operators' Association, W. A. Ellison, president of that association, told the convention, has installed a system of centralized reports to show the location of any employee and his credit standing with former employees and a complete record of accidents.

Does Rate of Pay Affect Accidents?

Mr. Ellison criticized the insurance companies for their varying rates. Some companies, he said, are withdrawing from the mining fields and refuse to renew expiring policies. Ratings are not always based on performance. He knew of cases where a mine with a low accident rate had been penalized and one with a high accident rate had had its premiums reduced. The National Coal Association, he thought, should look into the question of ratings so that safe mines might receive the proper consideration.

J. G. Bradley, Elk River Coal & Lumber Co., Dundon, W. Va., and Tom L. Lewis, New River Coal Operators' Association, Charleston, W. Va., took sharp issue with the statement of one speaker who claimed that high rates of pay discouraged accidents. Mr. Lewis asserted that wages had nothing to do with the question. E. C. Mahan, Southern Coal & Coke Co., Knoxville, Tenn., indorsing what Mr. Ellison had said upon the attitude of the insurance companies, declared that many operators were being forced to carry their own insurance. One company, taking its chances under its common-law liabilities, had cut its compensation costs $30,000 in nineteen months. Undue liberality on the part of insurance companies in paying claims had caused increased rates.

The session closed with the first showing of "The Story of a Rock-Dusted Mine," a film produced under the direction of the U. S. Bureau of Mines in cooperation with the Chicago, Wilmington & Franklin Coal Co. Most of the scenes had been taken underground at New Orient. A few sequences pictured some of the experimental explosions at Bruceton.

By Pooling Purchases of Mine and Store Supplies Operators Hope to Reduce Expenditures

Standardization Makes Pooling Easy—Bituminous Industry Spends 157 Million Dollars Annually for Mine Maintenance Supplies—Co-operative Buying Makes Smaller Stocks Permissible

Staff Correspondence

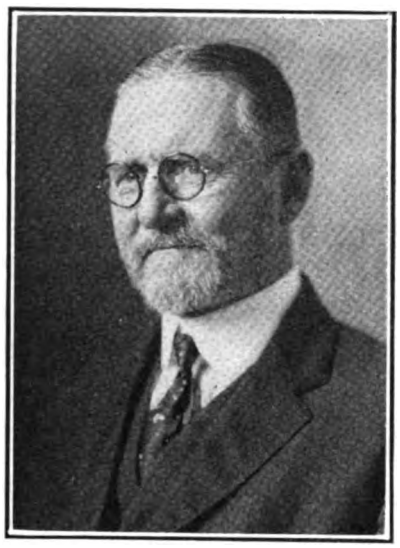
THE BUYING POWER of the bituminous industry and how it may be marshalled effectively to reduce costs through pooled purchases, was the theme of a group meeting of operators' purchasing agents held at the Drake Hotel, Chicago, June 9, as part of the program of the ninth annual convention of the National Coal Association. At this meeting, the methods by which the operators in one field—the New River district of West Virginia—were substantially reducing the cost prices on merchandise purchased for resale in company stores were explained. This development still is in its infancy, but those participating in it already are studying how the movement can be extended to take in some of the mine supplies for which the bituminous industry spends over $157,000,000 per year.

John C. Dinsmore, assistant professor, commercial organizations, and purchasing agent for the University of Chicago, opened the presentation with a discussion of the general principles of pool buying. Walter Muir, purchasing agent, Raleigh Coal & Coke Co., and chairman of the purchasing agents division of the New River Coal Operators' Association, followed with a recital of what was being accomplished in his district in group buying of merchandise for company stores. Allan H. Willett, director, Bureau of Coal Economics, National Coal Association, brought the discussion to a close with a review of the buying power of the industry and a consideration of some of the problems to be met in pooled purchases of mine supplies. M. L. Garvey, president, New River Coal Operators' Association, presided.

John C. Dinsmore

The American plan of distribution, said Prof. Dinsmore, is built up around the fact that larger volumes make it possible for the factory to operate more economically and for the distributor to reduce his unit costs. "The problem of the pool buyer is to secure the co-operation of the individual members of a certain group in order that their joint order might be large enough to warrant the lower price." When an attempt is made to secure this co-operation, the pool buyer immediately discovers a wide variation in the standards used by the individual members. This means that there must be a careful analysis and comparison of existing standards and general agreement upon new ones.

With something approaching standardization in specifications, cost variations quickly challenge attention and the way is opened for a campaign for uniformity in prices. Variations on identical commodities, said Prof. Dinsmore, have ranged from 10 to 3,000 per cent. "It is evident that the mere act of routing the orders for any group of individuals through one central office must automatically call attention to so many price variations on identical commodities that big savings would result."



Reciting the savings effected by pooling purchases for small colleges, social agencies, universities and building managers' associations, Prof. Dinsmore felt that the experiences of these groups made it "safe to conclude that any group of purchasing officers who will co-operate can through their joint purchasing power reduce the average unit costs of supplies 10 per cent. Pool buying, to be effective, must go hand in hand with a study of the relative effectiveness of the various commodities offered, and these studies should result in further reducing material costs. These savings from both sources sometimes cut unit costs in half. The direct financial returns on these studies and these pools should never be less than four times the expense, and they frequently run higher. Pool buying, skillfully directed, should sometimes mean just the difference between writing the result of the year's business in black ink instead of red."

The principle underlying the associated purchasing plan of the New River producers, said Mr. Muir, "is the application of the power of concentrated effort as distinguished from individual effort." Quantity buying means lower unit prices and, in many cases, carload, instead of the higher less-than-carload freight rates. So pleased are the companies with results already attained that "it is our intention to gradually work this up to a point where we will be buying a large volume of our merchandise in pooled cars, which will make a tremendous saving at the end of the year."

Dr. Willett carried the discussion a step further by presenting some of the problems to be met if the plan is extended to take in purchases of mine supplies. Psychological drawbacks to such an extension are inertia and the ultra-competitive conditions under which the bituminous industry is operated. "Of the practical obstacles in the way of the success of co-operative buying, the most serious is due to the large number of styles, sizes and shapes of some of the common kinds of mine supplies. The companies entering into the co-operative purchasing of mine supplies will benefit most in the purchase of those materials which are widely used in standard forms. The final result of the present active interest in standardization will be to widen the profitable field of operation of co-operative buying."

Digitized by Google

Maintenance of a common store of surplus mine supplies, however, is not necessarily an exclusive complement of co-operative buying. But such common stores are necessary if the full benefits of co-operative buying are to be realized. There are, of course, obvious limitations to the profitable application of the common store. Where mines were widely scattered, high distribution costs might easily negative the gains made in pooled buying. "An essential condition of the successful operation of the plan," said Dr. Willett, "would be a group of mines located so near one another that supplies could be distributed among them from a common center at comparatively slight expense."

Allen T. Willett

In the opinion of the speaker, the gains from co-operative buying were so patent that they required no detailed consideration. Occasionally individual companies attempt to obtain these benefits by purchasing large quantities of material in advance. In those cases, however, these gains are diminished by losses "that are almost sure to occur" from deterioration or disappearance of materials between the time of purchase and the time of utilization. One large operator had estimated that the cost of carying excess stores and supplies approximated 3 per cent per month. This cost, equal to $360 per annum for every $1,000 invested in supplies not needed in the near future, included interest, deterioration and disappearance.

"It is precisely in the minimizing of such losses," continued Dr. Willett, "that there is to be found the chief advantage of the maintenance of a common stock of mine supplies. The gain from co-operative buying is positive and is realized through lower prices. The gain from a common stock of supplies is negative, and consists in avoiding the loss and expense involved in maintaining large individual stocks. It is obvious that a dozen or twenty or fifty mines drawing supplies from a common warehouse could safely maintain a much smaller stock than the aggregate of the individual stocks of all mines if each provided for its own possible needs. This reduction in stocks would mean a smaller investment and lower interest charges, reduced cost of storage and supervison, and less loss and deterioration of the materials themselves. And even where the maintenance of a common store of supplies is impracticable because mines are too widely scattered, or for any other reason, co-operative buying is entirely feasible and practical."

The average annual realization at the mines on bituminous coal produced in the past three years has been $1,207,727,000. Dr. Willett estimated that $905,795,250 of this amount is distributed as salaries and wages and $157,004,510 is expended for materials and supplies. Most of the disbursements for wages and salaries are in turn expended by the recipients for the necessaries and the luxuries of life. In other words, the bituminous industry as a whole has a combined buying power in excess of $1,000,000,000 per annum and anything that affects that buying power unfavorably must necessarily have like reaction upon general business.

In addition to these direct disbursements, the bituminous industry also contributes several hundred millions of dollars (estimated at $856,242,000 in 1923) to the railroads for transportation. At the same time the industry is furnishing the carriers millions of tons of coal (126,340,181 tons in 1924) at declining prices. The average cost of railroad fuel, including freight, has dropped from $4.10 per ton in 1921 to $2.62 for the first two months of 1926—a decline of $1.48, or 36 per cent. Another large item not included in the estimate of the buying power of the industry is the expenditures for new equipment and replacements charged to the capital account.

NO DATA ON STORE AND IMPROVEMENT PURCHASES

There also must be considered the expenditures to supply employees with the necessaries and comforts of life, including company-store purchases, expenditures for town improvements and the maintenance of company houses. "From the scanty information available on this class of expenditures," stated the speaker, "one is justified in going no further than the broad generalization that in the aggregate it represents scores of millions of dollars of investment and many millions of annual upkeep and turnover."

Mine supplies cover a wide range of commodities, for many of which, said Dr. Willett, there were no accurate data on costs and quantities purchased. Therefore, he confined his analysis of this phase of the buying power of the industry to expenditures for explosives and mine timber. The soft-coal mines consume more than one-third of the explosives manufactured in this country for domestic use. Approximately 323 lb. are used per 1,000 tons of coal produced, as compared with 446 lb. in 1922. During the period 1917-24, black blasting powder constituted 77.8 per cent of all explosives used. By 1925 the proportion had dropped to 70.8 per cent and the proportion of permissible explosives had increased from 15.8 to 23.8 per cent. "This substitution of permissibles for black powder is an evidence of the disposition on the part of the operators to adopt methods dictated by consideration of safety as it is well known that high explosives are more expensive in themselves and more detrimental to the grade of coal produced than black blasting powder."

The bituminous industry consumes approximately 1.6 per cent of the annual timber cut. Consumption since 1906 has increased 26 per cent, but the production of coal in 1923 was nearly 80 per cent greater than in 1906. "The incentive to economy in the consumption of mine timber, as well as the use of substitutes is to be found in the rising cost." In 1906 this cost averaged $5.16 per thousand board ft.; in 1923, it averaged $16.17, an increase of 213 per cent. This increase has inspired mine managers to seek diligently for methods of economizing in the use of mine timber and for new sources of supply at reduced costs. This latter search is responsible for the rapid expansion in reforestation projects by Pennsylvania mines. This movement, predicted Dr. Willett, will spread to other states as the native supply of suitable forest timber diminishes.

A Selling Organization Should Concentrate on Merchandising a Single Kind of Coal

Independent Jobbers Charge Ten per Cent of Sales Price Whereas Company Department Will Handle It for Six per Cent—Coals Sold by Sales Department Should Be from Same Seam and Railroad

Staff Correspondence

BETTER MERCHANDISING METHODS as the key to a profitable bituminous coal industry were advocated at a group meeting of sales managers and executives held at the Drake Hotel, Chicago, on June 10 as part of the program of the ninth annual convention of the National Coal Association. "It is very common for an operating company to spend thousands of dollars to save 10c. per ton in production costs," declared one of the speakers in epitomizing the spirit of the meeting. "It seems to me entirely possible, if the same brains and effort, and only a part of the money were appropriated for proper merchandising methods, to add this 10c. to our realization much more easily."

"It would be difficult to imagine a more appropriate time than the present to give serious consideration to the sale and distribution of the products of our industry," asserted Ralph Knode, president, General Coal Co., Philadelphia, Pa., who was the first speaker at this meeting presided over by John H. Jones, president, Bertha-Consumers Co., Pittsburgh, Pa. "I cannot imagine," continued Col. Knode, "a more valuable asset for capital invested in the coal industry than a capable sales organization."

H. A. Glover, vice-president, Knox Consolidated Coal Co., Indianapolis, Ind., laid down the dictum that "every operating company of whatever size should sell its own coal either directly to a consumer or retailer or through a sales agency of common ownership." The most expensive and least efficient method of distribution is through independent jobbers, where the costs run as high as 10 per cent of the selling price. Sales through a separately organized, but mine controlled, selling agency absorb 6 to 8 per cent of the selling price. The most efficient method of selling is through the operating company's own sales department, where costs are considerably below 6 per cent. The average cost for all classes was estimated at approximately 6 per cent of the selling price.

The only solution for the industry, as Mr. Glover saw it, "lies in concentrating our physical properties and selling organizations into larger units, the intelligent use of a larger percentage of our gross income in modern merchandising and the co-ordination of sales activities through close co-operation." Physical consolidations cannot be successful unless proper weight is given to sales consolidations. "In other words, the mere gathering together of a heterogenous group of physical properties, either large or small, will not make a successful consolidation."

The essentials of a successful consolidation, as outlined by the speaker, were:

(1) Each property must have an established business.

(2) The coals controlled must be from the same seam or seams, have the same preparation and, usually, be served by the same railroad. "One small isolated mine of a different seam or a different preparation will require as much attention from the sales department as an infinitely larger tonnage in the main group. In the Middle West, and I think it applies in the majority of fields, the originating railroad helps the operator by taking certain resultant sizes upon the movement of which the mine must depend for its successful operation. For this reason, coal is not fully interchangeable unless it originates on the same railroad."

Material progress toward general centralization of marketing can be made by the formation of local associations to co-operate in production and distribution and to report closed transactions, average realizations and unfilled orders. "By close co-operation among any small group of operators, it will be found that almost invariably some one in the group can take resultant sizes of which his neighbor may have a surplus and thus avoid dumping them on the market." Once mutual confidence has been established in this group the way is open for the formation of a single selling company owned entirely by the operators.

The third, "and the only permanently effective, step is the actual consolidation of ownership into a single company of the mines and selling agencies. It is possible, in fact desirable, to form larger units, even taking in tonnage in many fields. However, I insist, no concentration, consolidation, or even close co-operation, can achieve the greatest measure of success unless the foundation is laid in small groups of properties with the same identical operating and marketing problems. Sales efficiency lies in concentration of effort on one particular thing. It is no more possible for a sales organization to efficiently market five or six competing coals than it is for an automobile agent to properly represent five or six different cars in the same price class."

Chairman Jones agreed with the speaker that too little has been spent on marketing. One of the sore spots in selling is the fact that large consumers, particularly the railroads, dictate prices and operators are stampeding into accepting business at such prices because some competitor is willing to ship coal on that basis. C. F. Richardson, West Kentucky Coal Co., Sturgis, Ky., concurred in that view and complained that the majority permits a minority which does not know its costs to set the prices for a whole field.

In answer to a question from Mr. Richardson, Mr. Glover said that the common selling agency was only a step in a process which must end with the actual consolidation of mines as well as sales departments. F. W. Wilshire, Consolidation Coal Co., New York, stated that a common selling agency had worked successfully in the Fairmont district for a number of years, but that with the development of new mining companies not in the

Digitized by Google

H. A. Glover

F. W. Wilshire

W. H. Cunningham

original group "we reached a point where we have had serious price wars in Fairmont, just as serious as in any place I know of."

Mr. Richardson again emphasized the drawbacks of competition from uninformed operators. Alabama, he remarked ruefully, appears to have been fairly successful in "organized selling" despite variations in grades. "We can't do it. We haven't done it. The only time we make money is when we can't help it. We are dependent as a rule and as a whole on weather conditions, car shortage or a strike, and anybody knows that there is not one of those three things that is sound. If we would spend more money in getting higher-class men, who know what it means to reduce the price a nickel, they would fight for that nickel rather than cut it to get the order."

Failure of many operators to maintain standards of preparation hurt those who took pride in their coal, declared Mr. Jenkins. When business is slack "every one commences to figure how low he can sell to keep from losing money, rather to shut down the mine and lose a lot more." If they lose a piece of business upon which they have quoted a fair price, they go out and quote 5c. less on the next bid. "Right there is the missing link."

In the absence of J. G. Puterbaugh, president, McAlester Fuel Co., McAlester, Okla., the question of fuel-oil competition was discussed extemporaneously by W. L. A. Johnson, commissioner, Southwestern Interstate Coal Operators' Association. The mines in his organization, he pointed out, are in the heart of the Mid-Continent field and have lost heavily to fuel oil in both the industrial and the domestic trade. These losses probably approximated 5,000,000 tons. Kansas City alone has over 18,000 oil-burners.

W. H. Cunningham, Basic Coal Co., Huntington, W. Va., believed that the meeting proved that the industry was alive to the value of improved facilities and methods of marketing. He knew that he was selling coal in competition with oil, but admitted that he knew little about oil. Here was a field in which the National Coal Association might well play a larger part.

That the coal industry was not as greatly overdeveloped as many believed was the contention of Warren Blauvelt, Vigo Mining Co., Terre Haute, Ind., who pointed to the excess capacity in steel and copper despite the smaller number of units in those industries. There was, too, less variation in demand for coal than in many other lines of business enterprise. Coal men, however, often make the mistake of trying to put their coals where they do not belong and cannot compete.

Fred W. Braggins, Lorain Coal & Dock Co., Columbus, Ohio, assailed speculative production and open billing of coal as demoralizing factors.

Mr. Johnson stressed the necessity of greater confidence between competing operators. He wanted help in spreading the doctrine of centralized selling agencies and was ready to volunteer to call group meetings of producers "in a private place where I could hold them all together long enough to tell them some of the things we have talked about today." C. F. Richardson expressed the thought that the association could assist in such work if funds were provided.

Just as soon as a group is assembled, remarked Mr. Johnson, the question of legality crops up. The purchasing agents, said F. W. Braggins, meet frequently to discuss coal supply and prices, "and yet we as coal operators don't meet often enough in bodies to discuss sales and production problems. If every association distributed figures on past transactions as is done in the furniture business, in the cement business and in a lot of other businesses, all the sales departments of the different companies would soon get on their toes to see that their department was not selling coal at less than the competitor's rate."

"I should like much," said Mr. Jenkins, "to see a committee appointed and immediately asked to get all the information it can from a legal standpoint and at the same time requested that there be a committee appointed in each district under the jurisdiction of this association. Then when this national committee has obtained all the information it can, I would suggest that that committee call a meeting of all the other committees and at the time of that meeting they should have something concrete and constructive to put up which the other committees could take back to their districts."

This suggestion was accepted as a motion and adopted by the meeting. The meeting then adjourned.

Coal-Mine Commissaries Lessen Costs by Co-Operative Buying

By Walter Muir
Store Manager and Buyer Raleigh Coal & Coke Co., Raleigh, W. Va.

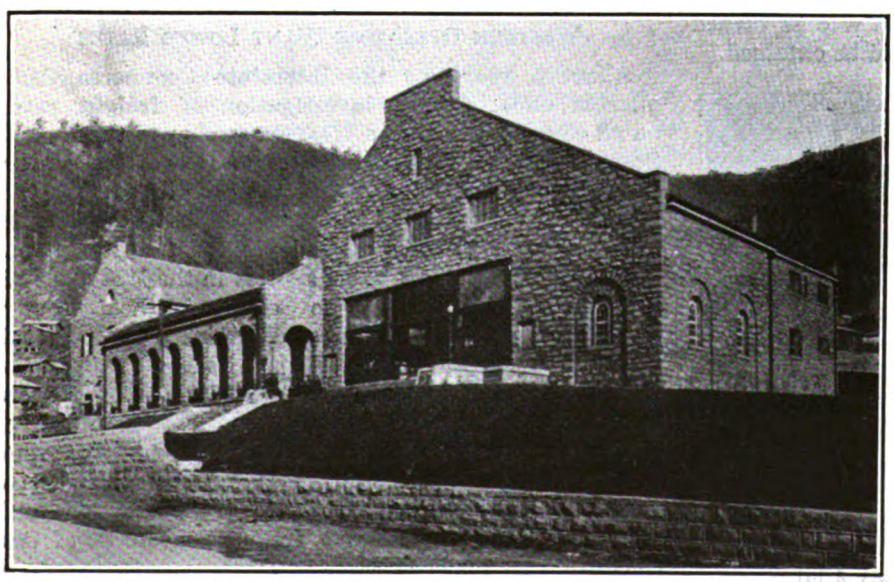
THE OLD MAXIM that "goods well bought are half sold," even in this age of advanced efficiency, still holds good. Consequently the efforts of the store manager should be directed more to intelligence in buying than to urgency in selling, though I would not like to feel that our managers were lacking in a keen appreciation of the importance of selling their merchandise.

Because of the necessity of buying good merchandise at the lowest price attainable the New River store managers decided to co-ordinate their purchases and unite their buying strength, and they are confident that this is only the beginning of a great movement in an essential part of the bituminous coal industry. This movement will enable them to make definite savings in their purchases and to extend greater advantages to their patrons while adding materially to the income obtained from the conduct of their stores.

Every purchasing agent knows that most manufacturers set a lower price on one hundred cases of their product than on ten cases, and that on carlots there is a still greater differential. Moreover where carlots can be purchased, there is the further freight saving not only because of the difference in rate between a carload and less than a carload, but also because the goods can be shipped direct from the factory, which is often less distant than some central "headquarters" from which any smaller quantities of the commodity are usually shipped. Thus, by concentrating buying power and unit-

Walter Muir

ing purchases, it is possible to make worthwhile savings.



This has already been demonstrated in the New River field, where in the past few months several buyers have pooled their orders in the purchase of many commodities, thereby gaining carload prices on less than carload quantities. They have been able also to arrange to pool their purchases of canned vegetables so that they will be able to handle two cars of corn in the New River field and about the same quantity in the Winding Gulf field, thereby getting quite a concession in prices, and saving the difference between carload freight and local freight. They intend to develop gradually this practice so that they will be buying a large volume of their merchandise in pooled cars, thus making a large saving at the end of the year.

Of course, in commissaries a great variety of merchandise is handled, and some of it is put in stock in a small way for the convenience of only a few patrons. But if the hundred-and-one things dealt in at each individual commissary were multiplied by a hundred, it would make a formidable quantity of every article, even of the smaller items.

These are possibilities lying wide open to store managers. They have many units from which to draw. each manager has need for definite and fixed quantities of merchandise. By combining his requirements with those of others and purchasing with others at such times as would best serve all, great benefits would undoubtedly be derived.

I realize of course, that the volume of business on every article varies in our different commissaries. Some

Abstract of paper entitled "Benefits Derived Through Associated Buying" read at the sectional meeting of the Coal Operators' Purchasing Agents at the Ninth Annual Meeting, National Coal Association, Chicago, June 9. Mr. Muir is chairman of the Purchasing Agents' Division, New River Coal Operators' Association, Mount Hope, W. Va.

Store and Office Building, Pocahontas Fuel Co., Ittman, W. Va.

This beautiful building is located in Wyoming County. The structure adds dignity and attractiveness to the little mining village, being built of native stone and made attractive by well-kept lawns. It is unfortunate that mining towns do not usually have buildings so well designed as this. Too many fine store buildings bear the manifest marks of amateur architecture.

articles sell more freely in one place than in another, and one commissary will frequently close out the goods it has purchased and will want more when most of the others still have plenty of the same goods on hand.

To meet that contingency it will be a comparatively easy matter for those whose stock is short to draw on those whose stock is long. Indeed, an arrangement for exchange under such circumstances can be made a valuable adjunct to the general plan, prevent the accumulation of dead stock and furnish an outlet for the disposal of articles that now and again have been bought injudiciously, and yet with the best of intentions.

No buyer, no matter how expert he may be, fails, at some time or another to get merchandise in his stock, which at the time of the purchase looks like a good "buy," but which when placed on the shelves for sale soon turns into dead stock. It is also true to some extent, more perhaps than is thought, that certain goods which are sold in one section are not used at all in another. This would be offered as proof that the plan could not be applied uniformly.

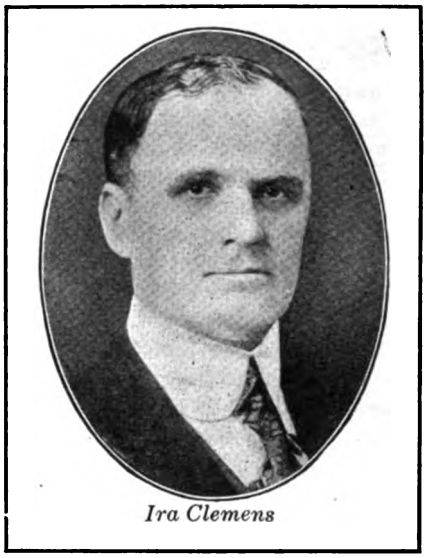
CANNOT APPLY SCHEME TO ALL COMMODITIES

But the scheme is not expected to be of universal application. Every commissary would still have to buy much merchandise independently in addition to what it bought in association with other companies. The idea is to utilize the strength of the combined commissaries in a district as users of large quantities of standard lines of merchandise, in buying all together instead of separately.

Some will claim that the saving in lower prices, etc., through associated purchases, would be more than offset by interest, storage, insurance charges and the risk of overbuying. In addition some may think that pool buying would detract from the initiative of the individual manager and cause him to lose interest in the conduct and success of his store. It would in other words, take away that personal touch that counts for so much in the success of any project.

There is only one answer to such objections. The proposal is sound in principle, and proven by experience. It will not grind out merchandise at 50 per cent profit or eliminate 25 per cent of the help in the stores, but it will save something on every associated purchase made and, on the large volume turned over in a year, substantial savings should be obtained.

Shoe Department in Big Mine Commissary



The largest saving in co-operative buying will probably be in comestibles where carload lots can be handled, but even in shoes big savings are possible.

Railroads Give Good Service But Some Ask Increases

Try to Obtain Greater Scale Tolerance—Western Roads Demand Higher Rates of Interstate Commerce Commission

By Ira Clemens
Clemens Coal Co., Pittsburg, Kans.

FOR THE FIRST TIME in the history of the National Coal Association more than a year has passed without the efficiency of the transportation service making a meeting of the transportation committee necessary. Throughout the winter the car shortages were insignificant and confined to small areas. Transportation facilities are ample to meet the needs of the industry at the present time and for some time in the future.

Ira Clemens

Several minor matters have been handled by correspondence and have been either disposed of satisfactorily or are being handled to a conclusion. Among them is the effort which some of the railroads have made to increase the scale tolerance on coal. Realizing that this is a question that more directly concerns the wholesalers and retailers, the traffic manager of the National Coal Association has been instructed to co-operate with those branches of the industry in opposing general increases in tolerance. This is being done. The question of prepayment of freight charges on coal to Canada has received the attention of the traffic manager, in co-operation with the foreign trade committee of the Association.

WESTERN OPERATORS WANT LOWER RATES

About a year ago the Interstate Commerce Commission undertook an investigation of freight rates on all commodities in the Western section of the United States. After carefully considering the scope of the Commission's investigation, it was concluded that the matter was of sectional interest and that the national organization therefore should not participate in it. Hearings were held in various cities in the West during the Fall and Winter, and the Commission has recently listened to oral arguments at Washington. The coal industry in general in the Western section is urging a decrease in rates, and the carriers are asking for an increase.

The secretary of the transportation committee, who is also the traffic manager of the Association, keeps the membership informed as to transportation and traffic matters. In this way frequent meetings of the committee are made unnecessary.

Report of transportation committee at ninth annual meeting of National Coal Commission, Chicago, June 9. Mr. Clemens is chairman.

How Madeira-Hill Co. Has Reduced Accidents 40 per Cent Since 1924

By J. W. Wetter
General Manager, Bituminous Operations, Madeira, Hill & Co., Philipsburg, Pa.

UNTIL THE FALL of 1924, the safety effort of Madeira, Hill & Co. was directed along the same lines as is pursued by most other coal companies. It had as a member of its organization a competent safety engineer who devoted the greater part of his time to making physical examinations of the operations, both inside and outside, in an effort to detect all substandard conditions.

At the regular monthly organization meetings, at which the safety engineer was always present, his recommendations were carefully considered, and none were permitted to be carried over without definite action being taken. If the recommendation of the safety engineer entailed much time and expense, such as providing additional clearance on a main haulage road in old workings, a cost estimate was prepared as well as a time estimate, and provision was made to correct the substandard condition over a period of time, expending thereon a fixed sum each month. In some unusual cases, the removal of a substandard condition was spread over as long a time as two to four years.

The company felt it was making progress, as every month certain conditions which it thought contributed to accidents were removed, and the rating sheets showing the physical condition of each mine indicated a vast improvement. In the Fall of 1924, a survey of the operations showed that practically every major substandard condition had been removed, but notwithstanding this fact, neither the number of accidents, nor the number of days of disability had materially decreased.

AFTER ALL THE MAN COMES FIRST

The company then began to realize that its safety work was not producing results and this for the reason that it had been dealing with the physical mine conditions and neglecting the human element entering into the mine hazard. This brought a realization of the fact that no substantial and permanent results could be expected until every employee was impressed with the necessity of his complying with the mining law and with the safety rules and regulations of the company.

A survey of the organization was then made to determine whether all the men in the organization holding supervisory positions were competent to advise the workers as to the requirements of the mining law and instruct them in safe practices. It was found that a number of supervisors needed instruction in safety. From this it was plain to be seen that a safety program could not be impressed on the minds of the individual workers unless the men responsible for it were fitted and sufficiently informed to pass along the information. In other words, a successful safety program could not be made to reach all the individual employees until the top of the house had been put in order. The first step, therefore, was to organize schools for the supervisory forces, the benefits of which will be fully reflected in the results to be given later.

Abstract of paper entitled "Reducing Hazards in Mining of Coal" read at the ninth annual meeting of the National Coal Association, Chicago, June 10.

J. W. Wetter

The second step was to devise a daily reporting system which would show the exact situation in each assistant mine foreman's territory. Each assistant foreman was required to keep a written report of every working place and condition coming under his observation during the day. This at first met with much opposition from the superintendents, who took the position that it would require the assistant foreman to do too much clerical work. However, the company finally formulated a reporting system in the form of a code which would eliminate as much clerical work as possible but at the same time would convey to the general foreman the conditions as the assistant foreman found them. This plan met with favor and made the superintendents willing to give it a trial. The report book consists of a leather binder in which is inserted a pad of the assistant foreman's daily report. On the inside of the cover the code letters are printed as in Table I.

REPORTS BROUGHT QUICK RESULTS

The report form is divided into five columns showing the name or number of the heading, the room number, the check number of the miner, the code letter and the time of visit. These reports were first used Jan. 1, 1925, and an improvement in the accident record was almost immediately noticeable.

In fact, after using this reporting system for about three months, the superintendents requested that we furnish a summary sheet upon which the assistant foreman could post the daily reports each night, for they felt that thereby they would be better able to study them. The question was raised as to the manner in which this extra clerical work would be handled.

To this, the superintendents replied that the general

Digitized by Google

foreman and the assistants were so enthusiastic over the plan that they would gladly post the records on the summary sheet each night before going home.

This summary sheet was furnished and covers one-half month. At the top of the sheet is shown the period, such as the first half of May or the second half of May, with the year, the name of the mine and the names of the assistant foremen. The sheet is 14 in. long and 25½ in. wide. The first vertical column is headed with the room, heading and check numbers, and then the dates for each half-month period, namely, from the first to the fifteenth, and from the sixteenth to the thirty-first.

Across the sheet under these captions are inserted the numbers of the rooms and headings inspected, together with the check numbers of the men working therein, and then below the check number under the dates the condition of each place as found on the day of inspection is entered.

This summary sheet shows the general foreman at one glance the conditions prevailing in every working place at the mine, and he gets this information before he goes home at night. The result is that the general foreman is informed regarding any unusual condition which needs his personal attention, and he can visit these places early the following morning and can take proper steps to remove any substandard condition. The code letters in the table cover not only safety matters, but also much valuable information relating to operating matters.

Table 1—Code Letters for Assistant Foreman's Daily Report

E	—Care and use of explosives
MC	—Handling of mine cars
P	—Preparation of coal
R	—Condition of roof
S	—Spragging of coal and boney
T	—Timbering of working place
NM	—Place not mined or cut
NC	—No coal
WC	—Waiting on cars
W	—Water in working place
FR	—Fall of roof
MF	—Misfire
NR	—Short of rails
DO	—Disobeying orders
CV	—Clay veins or rolls
M	—Miscellaneous items coming under your observation that should be brought to the Mine Foreman's attention.

Note—It is important that all time lost be marked below the code letters.

The system, therefore, permits the general foreman to put immediately his finger on the important items, and he knows at all times exactly what is taking place. For instance, if the assistant foreman's report shows that a number of men in one section of the mine has lost time waiting for cars, it is immediate notice to the general foreman that his haulage system is at fault. If, on the other hand, the report shows that a number of places have not been mined or cut, he knows that something is wrong with the cutting in that particular section. The summary sheet is also invaluable to the general superintendent and the safety engineer. They would not think of going into the mine without first having reviewed that record because it shows at a glance the places where normal conditions prevail and those which are subnormal and need attention.

The company formerly held one organization meeting each month at which both operating and safety problems were discussed, but these new reports furnished so much valuable information, both from a safety and an operating standpoint, that each month thereafter two organization meetings were held, one of which was devoted to operating questions and the other to safety matters.

Before each monthly safety meeting, two separate detailed statements are prepared for each mine. One shows a classification of every accident occurring during the month under each supervisor and the man-days lost due to each accident. This statement is 15 in. long and 16 in. wide and covers four mines.

In the first vertical column is entered the name of each general foreman, and in the second opposite this name are listed the names of the assistant foremen. The third vertical columns shows opposite the name of each assistant foreman, the accidents during the month and the man-days lost due to such accidents. The remainder of the sheet is divided into twenty-four vertical columns, the first twenty-two of which classify the various accidents such as fall of rock, fall of coal, handling of material, etc. The last two vertical columns show the totals for the month and the totals for the year.

It will readily be seen that this form enables the management to compare the degree of operating safety attained by each general foreman as well as by each assistant foreman. Copies of this form are furnished to the general manager, to each general superintendent for his district and to the safety engineer. One copy is posted at the mine for the benefit of the general and assistant foremen. At these organization meetings each accident is discussed as to its cause, and such action taken as will, in so far as possible, prevent a recurrence of an accident from that same source.

Another form is prepared covering the operations in each district, and this form shows the accident experience for the month. On this sheet is entered for each mine the details shown in Table II and in addition the number of compensable accidents, that of no-time-lost accidents, the number of temporary accidents, the number of specific accidents, the estimated compensable days lost, the estimated days lost from temporary accidents, the days lost from specific accidents, the accidents per 1,000 man-days worked, the accidents per 1,000 tons mined, the days lost per 1,000 man-days worked and the days lost per 1,000 tons mined.

KEEP RECORD OF FATALITIES SEPARATELY

In entering the days lost due to accidents the fatalities are not included because, though many ways of figuring an equivalent for these accidents have been devised and used, these accidents are of such vital importance that they are kept separate for special consideration and are not included with the non-fatal injuries.

It will be noted that the latter form, having been computed on a basis of 1,000 man-days worked and 1,000 tons mined, places each mine on a comparable basis, and in a like manner each district is placed on a comparable basis, because the form shows the average for each district for the current month and then also the average monthly experience for these same mines for the year to date as well as for the preceding year. The results of the campaign of Madeira, Hill & Co. at its bituminous operation are given in Table II. It covers six operations in one district.

TEMPORARY JOBS NOT DEDUCTED

The item, "number of man-days" in Table II covers only the days when the mine was working, whereas the total number of man-days lost due to accidents includes every day lost not only for compensable accidents but for non-compensable and temporary accidents as well. If a man was injured and could not follow his usual occupation, the total days lost from his usual occupation are included even though the man might have

Digitized by Google

worked temporarily at some job other than that in which the accident occurred.

Also in the "days lost" each month is included the total loss incurred due to each accident. That is to say, if twenty accidents occur in any one month and five of them are specific accidents entailing a loss of 300 days each, the total loss would be 1,500 days, and if the other fifteen accidents are of a temporary nature entailing a loss of, say, ten days each, there would be another 150 days lost, or a total of 1,650 days, which total time would have to be included in the month in which the accidents hereinbefore specified occurred.

Table II—Accident Record, Six Operations, Madeira, Hill & Co.

	1924	1925	First 4 Mos 1926
Number of employees	1,043	864	1,101
Number of working days	272	284	91
Number of man-days	283,696	245,357	92,108
Number of gross tons mined	640,842	608,501	277,540
Number of fatal accidents	2	1	1
Total number of accidents	307	231	66
Total number of man-days lost due to accidents	5,759	3,419	933
Accidents per 1,000 man-days worked	1.33	0.94	0.71
Accidents per 1,000 tons mined	0.48	0.39	0.29
Days lost per 1,000 man-days	20	14	10.1
Days lost per 1,000 tons mined	9	5.6	4.11

If a man sustains a specific accident, such as the loss of a finger, which requires under the Pennsylvania Compensation Law the payment of a fixed sum, this compensation would be divided by the compensation rate per day and included in the figure for "total days lost." I make mention of this because the number of days lost as shown on the experience record might be considered as exceedingly high unless it were clearly understood that the total incurred loss is included in the figures. The yearly figures are, of course, computed on the same basis.

The figures given for the year 1924 give the experiences before this system was put into effect. It will be seen that the days lost per 1,000 man-days worked is 30 per cent less for 1925 than for 1924, and 50 per cent less for the first four months of 1926 than for the year 1924. The decrease in the number of accidents is just about in the same proportion.

The cost of compensation and medical service at the mines in this district was approximately $6,000 less in 1925 than in the year 1924. And at the present rate, the 1926 cost will be about $4,000 lower than that of 1925. In addition to this saving, the valuable operating data obtained from this system has greatly increased operating efficiency, and the cost sheets reflect the fact that the improvement in safety performance has also carried with it an improvement in production costs.

HELPS TO PROMOTE DISCIPLINE

This system has not only promoted better co-operation between the members of the organization and all the employees, but it also permits the exercise of strict discipline in enforcing the provisions of the Pennsylvania state mining law and the company's safety rules and regulations. Any employee who willfully or negligently violates a safety order is cited by the assistant foreman on his daily report. For the first offense, such employee is admonished, and, for the second offense, he is notified that the third breach of an order will mean instant dismissal.

In over two years, it has been necessary to resort to a discharge in only two cases, and in both instances the officials' action was upheld by the state mine inspectors. The employees all realize today that the instructions which are given are issued from a standpoint of protecting every individual, and the management has noted in many cases that where a man at the working face has been cited once for, say improper timbering or failure to set timbers, upon the next visit of the assistant foreman he has shown great concern as to whether his place has been timbered in a manner satisfactory to the assistant foreman so as to make certain that he would not be cited the second time and classified as an unsafe workman.

Strictly from a business point of view, the financial saving has more than made the effort worth while, but aside from this, the point of chief consideration is its value to the men themselves and their families. The management finds much gratification in the fact that in less than a year and a half nearly 50 per cent of the accidents at the mines under its supervision have been eliminated, together with the suffering of the injured employees and the hardships that would have been imposed upon their dependents.

More Timber Is Cut for Fuel Than for Any Other Single Purpose

Allen T. Willett, statistician of the National Coal Association, in discussing mine timber uses in his paper on the "Buying Power of the Bituminous Industry" at the ninth convention of the Association said:

"It is somewhat surprising to learn that of the timber cut in the United States 38.33 per cent is consumed for fuel and only 33.31 per cent goes into the next smaller class of product consisting of lumber, dimension material and sawn ties. In contrast with these important uses mine timbering furnishes a market for only 1.60 per cent of the annual cut. Nevertheless the actual amount so used is considerable. The data relate only to mine timber used underground, and do not cover lumber used outside the mine.

"In 1906 bituminous mines consumed the equivalent of 1,236,500,000 board feet of timber underground. In 1923 the consumption had increased to the equivalent of 1,559,000,000 board feet, an increase of only 26 per cent, although the output of bituminous coal in the latter year was nearly 80 per cent in excess of that of the earlier year. The report does not show the number of tons of coal produced by the mines from which figures for lumber consumption were obtained.

"If we assume that the output of these mines represented very nearly the same percentage of the total production in the two years, we find that the amount of lumber used underground per 1,000 tons of coal produced declined during that period from four to two and three-quarters thousand board feet, a decrease of more than 30 per cent. However far short of precision this percentage of decrease may be, it is a matter of common knowledge that the quantity of mine timber per ton of coal has actually decreased, the decrease being accounted for partly by greater economy in the use of timber, partly by the more general use of timber preservatives, and partly by the use of substitutes chiefly in the form of iron and steel or concrete."

Have Statistics Any Value to the Coal Industry?

By C. E. Bockus
President, Clinchfield Coal Corporation, New York City

UNTIL THE LOCAL membership associations have inaugurated sufficient statistical work to give an adequate conception of market conditions the officers of the National Coal Association are not disposed to attempt to compile district returns believing they would not be representative of conditions in the industry.

There are many lines of desirable statistical activity, and the trade-information committee does not believe it would be well for the National Coal Association to start the work with only one line of statistics, that of the past sales report. It must be realized that though some local associations engage in much broader statistical efforts, many still do not collect and disseminate any trade information. The committee has been, and is, of the opinion that as soon as past sales reports are general, the National should take up another desirable line of reports and develop it until such trade information is available as will enable the industry to know more about itself.

At the time of the committee meeting in September, past sales reports were being compiled in the Williamson field and in the low-volatile fields of southern West Virginia through the Stover Bureau. Since then Harlan, Virginia, northern West Virginia, southern Appalachian, Kanawha and Alabama have inaugurated such activity. Kanawha has entered into an agreement with the Williamson field under which both these districts report to a common agency located at Huntington, W. Va. It is predicted that other nearby high-volatile fields in eastern Kentucky and the western part of West Virginia may become members of the same statistical bureau.

In accordance with the recommendations of the committee, the National is making up two tables weekly based on the district reports now received from seven high-volatile fields. Of these tables, one shows the average price received for coal sold during the previous week, distinguished as between prepared sizes, run-of-mine and screenings and the other arranges the same transactions for all the fields combined in price groups varying by 25c. intervals.

These tables are not given general circulation, They are sent only to the secretaries of the organizations sending in the district tables. The committee does not feel that, as yet, a sufficient tonnage is covered by the reports to justify giving them to the public. It is its hope that, as operators in other districts become acquainted with the work now being done and of its value to the operators receiving such reports, other associations will inaugurate similar work and that before long the National will be receiving reports from a sufficiently representative tonnage to justify it in giving out a combined tabulation as an approximately accurate picture of sales conditions in the industry.

C. E. Bockus

Abstract of report of trade information committee presented to the ninth annual meeting of the National Coal Association, Chicago, June 10. Mr. Bockus is chairman of the trade information committee.

CALL A HALT ON SELLING BELOW MARKET

The committee urges that the most careful consideration should be given to the advantages obtainable by gathering and distributing statistical reports dealing with conditions in the industry. It seems unnecessary to enter into a lengthy argument in favor of such work, but brief reference will be made to a few specific lines of statistical information, the usefulness of which is obvious even on superficial examination.

The bituminous-coal mining industry is highly competitive. As a result of that condition too much coal is being put on the market at unremunerative prices, often at materially less than production cost. Would not the operator be in a better position to bargain with buyers if he was informed about prices being obtained by other suppliers in the same market? Past sales reports will enable them to see what prices have been obtained currently for their commodity and should enable them to call a halt on their selling agents if the former find that the latter are making sales at prices below the market average.

Reliable figures on the geographical distribution of coal from each field would serve a similarly useful purpose in assisting the operators to decide in what consuming territories it would be particularly advantageous to attempt to push the sale of their product. It is to be hoped that such statistics showing week by week the volume of coal moving from the several fields into different consuming areas would ward off the possibility of such excessive congestions of distress coal as sometimes result from the uninformed efforts of operators anxious to find a market for their coal and would thereby remove from

Digitized by Google

market a most demoralizing factor. In many industries *great* economies of operation have been brought about through the inauguration of a system of so-called comparative cost reports, that is, reports in which detailed costs of every separable step in production are brought together by a central agency and a compilation of average costs for each such step is then sent to the individuals furnishing the information.

SHOW OPERATOR HIS SHORTCOMINGS

Such reports in the case of bituminous-coal mining would enable an operator to discover those phases of his production in which his costs run higher than the average and, at least, be an incentive to him to institute inquiries into the reasons for this variation. In an industry in which methods of operation vary greatly from field to field there might be little practical advantage in comparative cost reports on a national scale, but separate district reports of that sort would be a yardstick for all the operators in the district.

There are other lines of statistical activity well worth considering as possibilities such as transportation, including car supply, safety measures required by law or introduced by other companies, together with reports on mine accidents, workmen's compensation measures, taxation, insurance, credit and improvements in the methods of burning bituminous coal and new uses for its byproducts. On all these the mine operator should have full, accurate, up-to-date information, if he is to be in a position to make the most of his business opportunities and responsibilities.

It is now several years since the National first considered the question of inaugurating an adequate statistical service. For some years, however, it was deterred from such activity by the uncertainty of the legality of such inquiries which, by the way, cleared up only last year. Some of the large companies do some of that work at their own expense and for their own guidance.

It is obvious, however, that only companies operating on a large scale can afford to incur the expense involved in individual efforts of that kind. If the majority of operators are ever to receive the benefit to be derived from statistical information, such information must be compiled on a co-operative basis. The committee urges operators to give careful thought to the question of expanding this profitable form of association work.

Nothing has been said about the public aspect of statistical reports. The members of the National Coal Association are all familiar with the efforts at Washington to procure the enactment of legislation making it compulsory upon bituminous-coal operators to send in reports to the Department of Commerce. The industry is opposed to any system of compulsory reporting to a Federal agency, not because it desires to have the facts concealed, but because it believes that such a move may well prove the first step in the direction of Federal regulation of the industry.

Pool Buying No New Idea But One Well Attested

By John C. Dinsmore
Assistant Professor, Commercial Organizations, University of Chicago, Chicago, Ill.

IN THE UNITED STATES more than in any other country distribution is built up around the fact that larger volumes of business make it possible for the factory to operate more economically and for the distributor to reduce his unit costs.

There is therefore every desire upon the part of most vendors to quote materially lower unit prices for large orders. The problem of the pool buyer is then usually to secure the co-operation of the individual members of a certain group in order that their joint order might be large enough to warrant the lower price.

Purchasing agents like to feel that they are buying every commodity at the lowest possible price but that is not so. The price differences for identical commodities vary ordinarily from 10 to 3,000 per cent. For instance a certain purchasing agent in Cook County recently paid 44c. per lb. for saltpeter which is worth about 4c. per lb.

It is evident that the mere act of routing the orders for any group of individuals through one central office must automatically call attention to so many price variations on identical commodities that large savings would result. If this routine scrutiny is coupled with organized research to determine just the particular commodity best fitted to do a particular job the savings effected are astounding. The supply investigator for the American Telephone and Telegraph Company recently told me that such studies frequently reduce annual costs 50 per cent.

With these generalizations as a background let me relate briefly the pertinent facts concerning two of five buying pools with which I have been associated.

About nine years ago there was in Chicago the executive office of the Association of American Colleges with a membership of some 600 small denominational colleges. As a part of the service rendered their members the Association helped prepare advertising copy. This led to the purchasing of "boiler plate" insides for booklets and this in turn led to the purchase of the paper and the printing as a joint venture. This service reduce the cost of the finished booklets about 40 per cent.

The plan worked so well that a committee was formed to buy other items on the same basis. I was called in as purchasing consultant and directed the studies which developed some interesting data. The experiment was interrupted by the war but a final survey showed that purchases had been made for eighty-six colleges in twenty-six states, had reduced average unit costs 38 per cent, and that the money saved was at the rate of a little over $100 for each hour of service rendered. In one instance a much better product was supplied at less than one-third the average price paid before the pool was formed.

The next study was made for the Chicago Council of Social Agencies. This is an organization of nearly two hundred charitable organizations in Chicago ranging all the way from the great hospitals to the visiting nurse's association and the settlement houses. This study showed that the cheapest price on liquid soap was 8c. and the highest price $2.75 per gallon. The fact also was developed that the price paid for similar quantities of bulk milk varied nearly 100 per cent.

Abstract of paper read at ninth annual meeting of National Coal Association, Chicago, June 9.

With Competition as Incentive Employees Will Back Safety Movement

By R. E. Howe
Vice-president Climax Coal Co.,
Knoxville, Tenn.

ACCIDENTS are expensive and for that reason should be avoided as well as for the larger reason that their elimination is a duty that the operator owes to humanity. They disorganize the mine force and cost much money; they run up the compensation-insurance rates and often take the men who are most valuable in the operation of the mine. However, the chief reason for the prevention of accidents is the saving of life and limb.

Safety, however, has a three-fold aspect: First and foremost, the protection of the men employed in the mine. Second, the preservation of equipment and supplies. Whenever a machine, track or wire is in jeopardy from bad top, it should be removed, bearing in mind the safety of the men whose duty it is to remove it. The safety of equipment from outside influences, such as lightning, storms, vandalism and other preventable causes, should have constant attention. Third and finally, the protection of the investment of those who have put their money into the business.

R. E. Howe

We should not, through our own negligence—and in the final analysis it is the negligence of the operator—permit our employees to overlook or forget safety in its three-fold aspect.

How much safety work in the mines can accomplish is shown by innumerable instances. One large company in the Tennessee field, which has several mines, gives a prize once a month to the keymen of the mine which has the least number of accidents in proportion to output. For the last three consecutive months the most hazardous mine in this group has received the award, showing conclusively that carefulness prevents accidents.

Records kept by one company in the South, employing 1,400 men show that the percentage of injuries to men who have not had first-aid training, is eight times that of those who have. This shows the desirability that all employees should take such first-aid training and some large companies in the West, I understand, do not permit a man to work for them until he has had this instruction.

With these facts in mind, the Southern Appalachian Coal Operators' Association has formed a subsidiary organization, known as the Southern Appalachian Efficiency Association. Its purpose, as the name indicates, is efficiency, and the greatest single division of efficiency is safety.

This organization consists of the superintendents, mine foremen, safety inspectors, firebosses, electricians, and other keymen employed by the members of the Southern Appalachian Coal Operators' Association. The mine inspectors of the insurance companies that carry our compensation insurance, the State Mining Department and the Bureau of Mines all hold honorary memberships. Meetings ars held once a month, at which there are round-table discussions on accident prevention and the production of coal.

This association has fostered safety and first-aid teams, has awarded prizes, both money and medal, has conducted contests and, in fact, done almost everything to keep before the employees the question of efficiency. The great problem we have found is to maintain the interest of all the men in the mines in the safety movement. The Association has found that competition is the keynote. Prizes are offered for new ideas which will prevent accidents or reduce costs and to the teams exceeding in first aid. Medals are given for meritorious service.

Much has been accomplished in this organization by merely bringing operating men together where they can learn of one another how best to meet their difficulties. Some sage has said that we are part of all we touch, and one hundred of these operating men cannot get together without increasing their interest in their work and absorbing something from others. Having this in mind, the Association has fostered local organizations, everyone where possible being given some definite work.

Mine discipline is an important matter. One large Alabama concern which employs a large number of colored men, kept a record of accidents covering a period of ten years. These records show that per number of white men and per number of colored employed, there were twice as many white men injured as there were colored, the natural assumption being that this was because the colored men obeyed orders better than the white men. A white man will obey orders if he sees the reason behind the order.

Every general and every leader no matter in what walk of life knows that team work is what counts, and if competitive co-operation can be established at the mines safety can be brought to its highest pitch.

Abstract of paper entitled "One Way to Interest Employees in Safety Work," presented at ninth annual meeting, National Coal Association, Chicago, June 10. Mr. Howe is secretary of the Southern Appalachian Coal Operators' Association, of Knoxville, Tenn.

Coal Salesmen Should Know How Coal Is Prepared and Mined

Thus Being Stimulated to Maintain a Reasonable Price and Enabled to Defend Quality

By Ralph Knode
President, General Coal Co., Philadelphia, Pa.

NOT FOR A long time has the salesman had as his sole function the duty of explaining just why the operating department could not make full shipments against its orders. Certainly, that condition never occurs today. Every salesman is busy selling coal.

No more valuable asset can capital invested in the coal industry have than a capable sales organization, in which every salesman believes heartily in the coal industry and in his company. Every salesman meeting the consumer should be fully familiar with all general phases of the production of coal, the general chemical analysis of the product and the comparative values of the coal he is selling as compared with that marketed by others. This knowledge can be obtained in a practical way only by having the salesman spend a reasonable length of time at the mines by which the coal is produced where he will learn in a general way just how coal is mined, prepared and inspected for the market.

Established Standards of Preparation

Most producing companies have, I believe, a standard of preparation and inspection for the particular coal they are mining. Some coals require little preparation, others receive all the preparation at the face, some are prepared over picking tables, and still others cleaned by various mechanical methods. When these facts are realized by the salesman he can the more intelligently carry on a conversation with possible consumers.

The companies with which I am associated have a standard preparation for the particular coal being mined, and it is the duty of each mine superintendent to prepare the coal each day to that standard, and he is held responsible for the results.

In order further to satisfy the sales organization that the coal is being mined and prepared to that standard, an inspector is stationed at each mine that is of sufficient size to justify the practice. If an inspector finds one or more cars of coal which have not been prepared to the standard previously determined, the coal in that car or group of cars is re-prepared or used for business where a coal of the agreed standard is not required.

In order that the inspection department shall be absolutely unbiased in its work, these companies have found it advisable to put the inspection department directly under the sales department or under an executive officer in charge of not only the mining of coal, but its sale and distribution, so that there will be no organic connection between the local operating department at the mines and the inspection of the coal.

Abstract of a paper on "Coal Salesmanship" delivered at the sectional meeting of bituminous coal sales' managers during the ninth annual meeting of the National Coal Association, Chicago, June 10.

Ralph Knode

One can readily see how much more confident a salesman will be in discussing intelligently a spot order or a contract, when he realizes that each car of coal is and must be prepared to the standard which has been fixed and is maintained by his company.

The time spent by the salesman at the mines gives him a direct idea of the expenditures of capital needed to produce a ton of coal, so that he is more able to explain intelligently why a reasonable price must be obtained for the coal which he is to sell than perhaps is paid for other coals offered in competition where the question of value seems to be of little concern.

Many operating and sales organizations have developed a real pride in the quality of coal being produced and sold and, when the individual salesman is imbued with that spirit of pride in his own particular coal and company, it is not a great effort to pass that feeling to the consumer.

Individualizing One's Product

I cannot think of a more important phase of coal salesmanship than the practice of individualizing and trade-marking a particular coal, for this unquestionably takes even average-quality coals out of the average class and puts them in position to command a better price than coals lacking this distinction. English coals are thus marketed perhaps to a greater and more satisfactory degree than those of any country in the world. Outside of the coal industry in this country are many concrete illustrations of what can be done by specializing and trade-marking a product.

Representatives of sales organizations meeting the public should be familiar not only with the method of mining and standard of preparation of their coal, but should understand also the conditions prevailing in the various competing fields. Thus they will be in position to carry on an intelligent conversation with possible

Digitized by Google

consumers and be helpful in providing consumers with information that will prevent their coal supply from being in any way embarrassed.

It is not difficult to realize that the salesman who has fitted himself in this respect is a much more welcome visitor at a consumer's plant than one who is not so well fitted. Sales organizations should keep their salesmen informed of prevailing conditions in their own and competing fields by semi-monthly or monthly meetings.

The salesman with such knowledge is frequently in position to clarify in the minds of consumers the erroneous opinions many of them have today with regard to the coal industry as a whole.

It does not seem practical to provide that each member of a sales organization meeting the public should be a qualified combustion engineer, but he unquestionably should have a general knowledge of how his particular coal will perform and the purposes for which it is best suited. Many organizations have individuals who have made a careful study of the consumption of their coal for special purposes, such as illuminating-gas manufacturing, byproduct coking and other uses, where most efficient results must be secured.

Every sales organization should have a combustion engineer who can be helpful in demonstrating the coal to the consumer, in meeting complaints that often are not caused by the coal, but by the methods of combustion. To him, salesmen can submit their troubles in their daily contact with consumers.

Consolidations in the coal industry have been given much consideration during the past three years. They have been hailed as a solution of the difficulties of the coal business. The subject can in a general way be divided into two phases. First, consolidation of physical properties and second, consolidation of sales and distribution units. In an effort to accomplish the first phase in a proportion worthy of consideration we are faced with two major difficulties. The large capital required and the vast difference of opinion which exists with regard to the values of mines.

Easy to Consolidate Selling Forces

These two factors are, however, of little importance when considering the consolidation of sales and distributing units. The main feature necessary to accomplish this purpose which unquestionably would be helpful for the industry is complete agreement of purpose by the parties involved. There is unquestionably real merit to this form of consolidation, but we do not seem to have reached the point of action on the subject, as nothing worthy of mention has been accomplished up to this time. Therefore, meanwhile, sales organizations will do well to adopt as their slogan the rule "No sale is worthy of consideration unless the return represents a reasonable profit on the capital invested," from the standpoint of an average cost and reasonable investment.

Just as soon as the sales organizations in the industry dispose of their products, with their value in mind, just so soon will those companies that have a cost that is in general competitive be able to market their products at a price which will represent a reasonable return on the capital invested. The great majority of consumers do not wish to purchase their coal below the actual cost of production of mines able to meet competitive conditions.

Substantial consumers have told me that many times, particularly during the past two years, but they add that they deserve to be assured that their competitors will not be able to purchase like grades of coal for similar purposes at prices materially lower than they receive. We cannot in all fairness to the consumer expect him to pay a reasonable price for coal when he can at materially lower prices, purchase approximately the same quality of coal from others.

I believe, therefore, that the industry can go a long way toward improving its situation, if salesmen are given proper training and education before coming in contact with consumers, so that they will be better able to understand why it is uneconomical, and in fact ridiculous, to dispose of the product of the mine without any regard to value.

I have a high regard for the sales organization or individual salesman that has the courage to say to a consumer that they or he, as the case may be, cannot accept business at other than a reasonable price; when other sales organizations are perhaps doing a larger volume of business but without regard to value.

Foreign Trade Increases Only Temporary

By H. N. Taylor
President, Sheridan-Wyoming Coal Co., New York City

Little, if any, progress has been made in increasing the quantity of coal exported during the past year, except during the past few weeks due entirely to the British strike. It is yet too early to state the real effect of this disturbance in England on our future foreign coal trade. Some coal was brought into this country from various European countries during the anthracite strike, but the importation ceased with the conclusion of the strike, and was never large.

H. N. Taylor

Among the subjects that the foreign-trade committee has studied are the American merchant marine and the requirement that coal consigned to Canada should have the freight prepaid. The ships of this country are handicapped by arbitrary laws which hamper them in competition with ships of foreign countries. The American people need to be awakened to the fact that there will be no real American merchant marine until our ships are permitted to meet world competition on a more equal footing.

The negotiations as to the prepayment of freight charges on coal to Canada is in general making satisfactory progress, but the matter is not entirely settled. Efforts are being continued toward a complete elimination of this requirement.

Report of foreign-trade committee of National Coal Association at its ninth annual meeting, Chicago, June 9. Mr. Taylor is chairman of this committee.

Centralized Service-and-Accident Reports: Their Advantages to the Coal Operator

By W. A. Ellison
General Manager, Southern Harlan Coal Co., Harlan, Ky.

THE HARLAN COUNTY Coal Operators' Association at its office in Harlan, Ky., has established a system of records to accomplish the following results: First, to be able to locate any employee and to record his indebtedness, if any, to his former employer; Second, to provide information regarding accidents showing the name of the injured employee, the date, cause and nature of injury.

In our field, as no doubt in others, the problem of how to prevent overdrafts gives much anxiety. This was especially true during, and following, the war period. A scarcity of labor and a desire to increase output at the mines always has a tendency to encourage the operator to take chances in the giving of credits to his employees.

Retail and wholesale businesses protect themselves through the medium of credit associations or bureaus, but the coal mine office and commissary are at the mercy of the dishonest employee. It was thought, and it has since proved to be true, that a Bureau similar to a credit association could be conducted by the association for the protection of its members. Consequently the association installed a card-index system showing the name of the man employed, the mine at which he worked and the date on which he left the service, together, with his indebtedness on leaving, if any.

Each operating company makes a weekly report to the association, giving this information which is transcribed to 4x6-in. cards, and which are filed alphabetically in a desk filing cabinet according to the names of the employees.

If an employee leaves "Company A" owing that company, say $50, and is employed by "Company B," the service record form of "Company A" would show the date of the employee leaving its service and a similar form of "Company B" would show when he entered the employment of that company.

When this happens, the association office, on receipt of the service record report, from "Company B" sends to "Company A" a form reading as follows: "Mr. X who left your service April 1, 1926, owing you $50 is now employed by 'Company B' at ———, Ky." The function of the association ceases with the transmission of this information. The collection of the debt is left to the creditor company.

This method has reduced losses by overdraft to a minimum. There are, however, no attempts made on the part of the association to ascertain the amount of money collected, and it has no way of discovering how much "Company B" has saved by knowing in advance that the man newly hired is a "debtor employee," but it is natural to suppose that caution will be taken in extending credit to him.

During the latter part of 1925, a safety-first meeting was held in our field, at which meeting several insurance carriers were on the program. They explained that the high cost of compensation insurance appeared to be due to the large number of malingerers. Lack of a clearing house seemed to be the reason for this situation as well as for other conditions that resulted in high compensation costs.

The only information any mine had of accidents and their causes was the experience supplied by that mine alone, so the association devised a system of reporting accidents and recording them, which, though it has been in effect only since Jan. 1 of this year, has materially improved conditions already.

The operators belonging to the association are requested to send it a copy of the accident report which they make to the compensation board. These reports, when received, are classified, both as to the cause of the

Digitized by Google

accident and the nature of the injury. The causes are classified as in Table I and the injuries in Table II.

A report is made by the association showing the various causes of the accidents for the month, together with the nature of the injury. In addition to this, a bulletin is issued each month, showing the names of the various employees who for any cause have been injured in the previous month, also the total number of times injured is carried forward for each employee.

The bulletins are posted at the various operations, one at the mine mouth, one on the tipple and one on the bulletin board at the mine office. These bulletins show each month, in addition to the name of the injured party, the number of tons of coal mined in the field per accident. A plea is made in the bulletin that this record be improved from month to month. The publicity given to the men injured has a telling effect on all employees.

With the record thus installed in the office, each mine in the field is rated according to the tons mined per accident, and a circular is sent to each mine monthly showing how its tonnage per accident compares with that of other mines in the same field. Fatal accidents at any mine place it automatically at the bottom of the list. The officials of the various mines try to get near the top of the list and stay there.

Table II—Nature of Injury

As reported to Harlan County Coal Operators' Association.

Fatal
Arms, contused, lacerated, etc.
Arms, fractured, broken, etc.
Back and hip fractures
Back strained
Bad air or gas
Body, external injuries to
Body, internal injuries to
Ear
Eye
Fingers mashed, cut and broken
Fingers amputated
Feet and toes, minor injuries to
Feet and toes, fractured, broken, etc.
Feet and toes amputated
Hand injuries to
Hands amputated
Head, major injuries to, fractures, concussions
Head, minor injuries to, contusion, lacerations, burns
Hernia
Legs, contused, lacerated
Legs, fractured, broken, etc.
Mouth, jaws, and teeth
Neck and throat
Total for this month
Total for last month

When the accident reports are received by the association, proper records are made according to the classifications mentioned and the name of the injured person, the date of the accident, the mine at which it occurred and a brief description of the cause and nature are card-indexed in the service record. This entry is made on a card 4x6 in. and of a color different from that of the card previously described. The service record of the man is also transferred to this card, which is regarded as the permanent record.

After accidents have been recorded, should the injured employee move to another mine in the field, his accident record follows him on a form as follows:

"Mr. X whom you have recently employed was injured at Mine No. — on ————. Cause of accident was ———— and nature of injury was ————."

This information acquaints the new employer with evidence of the care or carelessness of the new employee and has been helpful in establishing the malingerer. To illustrate its effectiveness, it uncovered one case where a man had been paid compensation for a double hernia on three different occasions. Only the high spots of the system have been covered in this paper but it should be added that the members have found it most helpful.

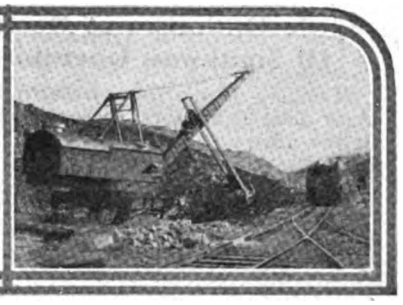
Research the Life Blood of Commercial Progress

By Walter Barnum
President, Pacific Coast Co., New York City

SEVERAL MONTHS ago an article appeared in the Membership Bulletin of the National Coal Association, which quoted Dr. O. P. Hood, Chief of the Fuels Division of the U. S. Bureau of Mines as follows: "The hope of the coal industry lies in the fields of research and invention." I was pleased to note this comment on Dr. Hood's statement in an editorial in the *West Virginian*. "Nothing truer has been said about the coal industry in years, but the importance of the remark lies in the impression it has made upon the national organization of coal producers. It is going to take a lot of pressure to make the coal men of this country take an interest in the possibilities of research and it would be a hopeless undertaking if the coal men's organization were not sympathetic."

In replying to this newspaper, I think I can safely speak for the members of the National when I say that the operators' association is sympathetic towards research. I pledge my personal efforts to press the cause of research in every possible direction. I hold to the creed that the price of progress is research. Just as soon as the ranks of the National are augmented by a sufficient number of non-member coal producers who owe it to their industry to contribute financial support to this organization of the industry, it will be possible for us to pay the price of progress, whereupon we shall enjoy progress. In the meantime, however, we will do as much missionary work as possible and co-ordinate activities of engineering societies and others employed in research as effectively as means permit.

On this point permit me to quote from the preliminary program of your Research Committee, prepared last winter. "The Committee has determined upon a policy which contemplates in the beginning at least no original research work as that word is usually understood, but on the other hand, the closest possible contact with and first-hand study of the work of the numerous research bodies, private, institutional and corporate, whose work is in any way related to coal, to the end that it may collect in permanent form knowledge and information to be used (1) for the library, (2) for distribution to the members of the National Coal Association, and (3) for distribution to the users of coal and the public generally.



"Thus the Committee will keep producers informed of what consumers are developing, so that the producers can realize all the opportunities and possibilities in their respective territories. The Committee will be a clearing house of practical and progressive information, serving both producers and consumers."

Excerpt from an address on "Research and Its Value to the Coal Industry" delivered at the ninth annual convention of the National Coal Association, Chicago, Ill., June 9. Mr. Barnum, now president, was then chairman of the research committee.

News Of the Industry

Court Refuses Injunction Sought to Enforce Union Wage Agreement With Mines in Scott's Run Field

The United Mine Workers was unsuccessful in its first effort to use injunctions to prevent non-union operation of coal mines covered by a union wage agreement. Judge I. Grant Lazelle in the Monongalia County Circuit Court at Morgantown, W. Va., on June 9, refused a restraining order sought by members of the union against four companies operating in the Scott's Run coal field, which he had been asked to enjoin from operating at wages lower than the union scale, from employing men not members of the union and from ousting union members from company houses.

Saying not only that contracts ought to be enforced if enforceable, but that labor unions should be granted injunction, in proper cases, as quickly if not quicker than other parties, Judge Lazelle, however, ruled he could not consider the one in question an enforceable contract.

Finds Baltimore Pact Obscure

The so-called Baltimore agreement between the union and the Monongahela Coal Association he declared to be one of the most difficult to understand that he had ever seen, but his principal point was that it could not bind the four companies defendants in this case because although he had little doubt that some of the signers for the operators were connected with these companies, there was nothing from which he could take judicial notice of that fact.

Reading the signatures of the scale committees, including those of Stephen Arkwright and Samuel Pursglove, he pointed out that it was not signed by the Monongahela Coal Association or by the Cleveland & Morgantown Coal Co., the Pursglove Coal Mining Co., the Arkwright Coal Co., the Connellsville By-Product Coal Co., the four defendants, nor by the United Mine Workers as corporations or organizations.

The agreement, he said, purported to be between the membership of the union and the membership of the coal association and the membership does not constitute such an entity that it can contract and be contracted with.

In regard to the employment of non-union men the Court said he believed that if the contract were not too broad, so that it would cover the entire coal business, and if it were for a proper consideration, one could be made provided it could be carried out. The time has not come, he said, when a few men can sit down at a table and sell the labor of thousands without their consent and compel them to work. He added that he did not believe such was the purpose of the organization, but that a man has the right to quit just as he has the right to start work and that, if a better opportunity offered, he had the right to go there, which could not be taken from him by a court or by anybody else.

The Court said the third phase of the injunction petition, eviction of the miners from company houses, included no allegation that there was not an adequate remedy at law for any grievance of this sort, although if there had been a violation of contract he conceded obtaining of damages might not be an adequate remedy.

Judge Lazelle expressed the belief that the renting of houses to the miners by the operating companies was a separate contract, though it was true they could not work without the houses.

The four defendant companies closed down the mines as union operations and shortly afterward reopened them, offering a scale of wages substantially the same as the 1917 scale. All are now operating on a non-union basis, although union officials assert that their output has been much curtailed. The union men, defendants in many injunction cases, including several granted by Judge Lazelle, asked injunctions against the companies, charging they had violated a contract in ignoring the terms of the Baltimore agreement.

It had generally been expected that, whatever the decision in the Circuit Court, the case would be appealed to the Supreme Court. After the decision was announced, union counsel went into consultation without making an announcement as to their next move.

Rescue Men in Get-together.—The Smoke Eaters' Association, composed of mine-rescue men of West Virginia, Pennsylvania and adjoining states, will meet in the Hotel Morgan, Morgantown, W. Va., on June 19, beginning at 1:30 p.m. A banquet will be one of the features.

The West Virginia Mining Institute will hold its summer meeting July 13 and 14 at Bluefield, W. Va.

Big Advance in Efficiency Of American Industry

Increased manufacturing efficiency of American industry since pre-war days is strikingly evidenced by figures recently issued by the National Industrial Conference Board, New York. The volume of production in 1923, according to an analysis of industrial productivity in the United States made by the Board, was 33 per cent greater per wage earner than it had been in 1914, and required 25 per cent less labor, 13 per cent less power, 17 per cent less management personnel per unit of production, and 7 per cent less actual working time per man.

The explanation of our increased industrial productivity, according to the Conference Board's study, is largely to be found in the greater application of power, more intensive mechanization and increased managerial efficiency. In 1923, 16 per cent more primary installed power was back of each worker in American factories than in 1914, correspondingly increasing his productive capacity and making possible the higher wage level. Labor cost per wage earner per month in 1923 was 36 per cent greater than it had been in 1914, against a production increase of 33 per cent, and although 25 per cent less labor was required per unit of production in 1923 than in 1914, the total amount of wages paid for an equal amount of production was still nearly 2 per cent higher. The cost of management, on the other hand, or the total of salaries paid to management personnel, decreased 12 per cent from 1914 to 1923 per unit of production.

Pineville, Ky., Soon to Have Mine Rescue Station

A mine rescue station with a mine rescue car and a trained force of operatives will be established at Pineville, Ky., within a week, according to a telegram from Congressman J. M. Robsion. The matter of establishing a mine rescue station there has been under advisement for some time.

The Bureau of Mines has agreed to open the new station so that the car and equipment can be used throughout the Harlan and Bell coal fields, it was said. The car and equipment for this field will be sent from Columbus, Ohio.

Little Optimism at Meeting Of Southwest Operators

Members of the Southwestern Interstate Coal Operators' Association met in the offices of the association, Keith & Perry Building, Kansas City, Mo., June 7 and 8, made four changes in the list of officers of the organization, unanimously agreed that business was "rotten," and adjourned. It was the twenty-third annual convention of the association.

The one optimistic note in the annual report of W. L. A. Johnson, general commissioner, concerned the efficacy of the Interstate Joint Commission, consisting of Mr. Johnson for the operators and John P. White, formerly international president of the United Workers, for the miners, in settling disputes with employees.

Its success not only in the immediate adjustment of disputes referred to it but in establishing precedents in the interpretation of the contract by which subsequent misunderstandings of a similar nature may be avoided is evident in the steadily decreasing number of disputes reported.

Figures quoted in the commissioner's report showed that the production in the four states of the Southwestern district, which in 1918 was 20,470,493 tons, had dropped to 10,511,000 in 1924, and to 10,248,000 in 1925. Of the 1924 production, 6,340,279 tons was produced by members of the Southwestern Interstate Coal Operators' Association, paying the union scale. Of the 1925 production, only 5,352,817 was from that source.

Officers elected for the coming year are as follows: President, George J. L. Wulff, St. Louis, Mo.; vice-president at large, John A. Sargent, Kansas City, Mo.; vice-president for Kansas, Frank Thomas, Pittsburg; vice-president for Arkansas, Robert Boyd, Huntington; vice-president for Oklahoma, William Harkes, Kansas City, Mo.; vice-president for Missouri, A. E. Marriott, Moberly, Mo.; secretary, C. H. Markham, Kansas City, Mo.; treasurer and assistant secretary, George Manuel, Kansas City, Mo.; general commissioner, W. L. A. Johnson, Kansas City, Mo.

Norfolk & Western Cuts Rate To Cincinnati

The long sought reduction on coal freight rates has finally been granted by the Norfolk & Western Ry., which recently announced a cut of 10c. a ton on coal shipped to Cincinnati and Cincinnati switching points. Effective Sept. 1 next, the new rates on coal from the Tug River and Pocahontas fields will be $1.89 per ton and the Thacker and Williamson fields will be given a rate of $1.79 a ton.

Efforts to obtain this reduction in rates have been going on for several years and the operators feel that they are now on an equal footing with the western and southern Kentucky fields served by the Louisville & Nashville Ry. Prior to granting of the new rate West Virginia operators said that they were unable to compete on a parity with the Kentucky fields in the Cincinnati district.

Illinois Institute to Hold Four-Day Meeting

The Illinois Mining Institute will hold its annual meeting aboard the steamer "Cape Girardeau," which will make a 450-mile trip from St. Louis, Mo., to Nauvoo, Ill., and return, lasting from June 24 to 27. Besides the scenic attractions an interesting program has been arranged. Six business sessions will be held on June 25 and 26, including the following papers:

Opening address by F. G. Lewis, president of the Institute, followed by Frank Farrington, president, District 12, United Mine Workers; "Freight Rates on Competitive Coals," W. Y. Wildman, Illinois Coal Traffic Bureau; "The Geological Story of the Mississippi Valley Above St. Louis," Dr. M. M. Leighton, chief, Illinois State Geological Survey; "Sealing Fires in Gaseous Mines," John T. Ryan, Mine Safety Appliances Co.; "Open-Pit Coal Mining," Chas. Gottschalk, consulting engineer; "Predominating Hazards in Coal Mines and Their Remedy," H. T. Bannister, safety inspector, Madison Coal Corp.; "Safety Practices in a Southeast Missouri Lead Mine," J. H. Steinmesch, superintendent, Desloge Consolidated Lead Co.; "Cleaning and Preparation of Mechanically Loaded Coal," F. F. Jorgensen, general superintendent, Superior Coal Co.

Merger of 41 Midwest Mines Reported Under Way

Negotiations for the merger of forty-one Illinois and Indiana coal mines are under way, according to advices from Pinckneyville, Ill. Capital stock of $5,000,000 and a $17,000,000 bond issue is said to be contemplated. Twenty-four mines in Illinois and seventeen in Indiana are said to be involved in the big deal.

The report gained strength following the sale on June 8 of three coal mines and 3,000 acres of coal land owned by the Southern Gem Coal Corporation and $145,000 of bonds of the Wabash, Chester & Western R.R. owned by the coal corporation to W. A. Brewerton, wealthy mine operator of Chicago. The price bid for the Southern Gem holdings was $60,000 subject to taxes and other liens. The purchasers are said to contemplate the purchase of the remaining $455,000 bonds of the railroad outstanding.

Coal properties mentioned in connection with the reports of the big deal include the O'Gara Coal Co., Greene County, Illinois; John A. Logan Coal Co. and Franklin County Coal Co., Franklin County; several mines of Southern Gem Coal Corporation in Jefferson County, Perry County and Franklin County; Chicago Fuel Co. mines in Perry and Jackson counties, and several mines operated by W. A. Brewerton in Sangamon County.

Burning Shaft of Ebbw Vale Mine Still Sealed

Since May 12, when fire was discovered at 11 p.m., the Ebbw Vale Coal Co.'s mine at Sullivan, Ind., has been burning. A 3-ft. clay-and-sand seal lies over the mouth of the shaft, this having been placed on the shaft head following the fire. This fire is believed to have originated in the locomotive charging station about 40 ft. from the bottom of the shaft. Thence it spread to the main shaft feeding on the wooden lining and buntons.

Three men were in the mine when the fire was discovered but could make no headway in fighting the blaze. Before the seal was completed the flame had traveled to the top of the 250-ft. shaft, and one cage which stood at the ground landing was "white hot" when the rope parted and let it drop. Arrows on the illustration point to the points where the steel warped and the guides were charred.

The Ebbw Vale mine is a new development. The first coal was hoisted in the winter of 1922-23. Production has been at the rate of 2,000 to 2,500 tons per day. The mine is gaseous. There is considerable speculation as to the fate of the mine because it is said that the wood-lined shaft penetrates a thick bed of quicksand.

Ebbw Vale Coal Co.'s Shaft After Sealing Against Fire

Arrows show where the intense heat has bent the bracing girders. This headframe was braced in three directions.

Acrimonious Debates Mark Meetings Of British Miners and Operators; Charge Falsity in Owners' Figures

Despite the hopeful indications recorded last week the coal operators and mine workers of Great Britain appear as far apart as ever. In fact, the relation between the two was rather envenomed than improved by the pourparlers of June 8, which are reported to have been acrimonious. The miners not only declined to budge an inch from their position not to work longer hours or to accept less pay but denied the facts submitted by the operators as to economic ability of the industry to pay the present wages; even declaring that the figures were falsified.

Evan Williams, C. B. Crawshaw, Sir Adam Nimmo and W. A. Lee represented the operators and Herbert Smith, A. J. Cook, W. P. Richardson and T. Richards spoke for the miners. The latter wanted a voice in the setting of coal prices and suggested a joint arrangement for the creation of a joint selling agency to regulate the price of coal to domestic users. The miners proposed that a subsidy be given by the government to enable the mine owners to enter the foreign market, recognizing that prices could not be raised arbitrarily in foreign countries as they were determined they should be in Great Britain.

"Make some consumers pay more for coal," said Mr. Cook and his coadjutors, "so that the miners' status can be maintained. Charge more or obtain a subsidy for the export of coal or sell to foreign competitors just what you can. Let the miners join with the operators in establishing a coal monopoly."

Show Price of Reorganization

In vain the operators pointed out that a reorganization of the industry would close 50 per cent of the mines and permanently dispossess of employment 500,000 miners. In vain they protested that higher prices for coal would put the British manufacturer who had to pay the price at a disadvantage which he could not overcome in selling his product in Europe. In vain they declared that a ton of steel in its manufacture required four tons of coal and that therefore the cost of coal was an important item in the market price of that product. Discussing the conference, A. J. Cook for the miners said:

"The coal owners at yesterday's meeting declared the only terms they would consider included an eight-hour day and the 1921 wage agreement. This would mean a reduction of 13½ per cent from the national minimum. Failing this, they said wages would have to be based upon the capacity of the various districts to pay, which would mean that in some districts they would be lower than the 1921 agreement.

"All suggestions of reorganization of the selling agencies and the shutting up of uneconomic pits they treated with the utmost contempt, stating there was nothing in them."

Much condemnation has fallen on the mine workers because of their acceptance of Russian contributions. Said Lord Birkenhead June 9 at the British Imperial Conference:

"The moneys received by the British miners do not come from the Russian miners, but officially from the Soviet Government, whose intentions, openly avowed, are to foment revolution in this country.

"We are furnished by the miners' leaders with the suggestion that a higher price for coal should be charged to the domestic consumer than to the foreigner. It appears never to have struck them that if you charge a higher rate for coal to our manufacturers than that paid by foreign manufacturers you will deal one fatal and final blow to every industry except their own.

"And this higher price is to be paid in the interests of men working shorter hours and receiving higher wages than any others in the world except those in America. It is too ridiculous.

"Mr. Cook, who once described himself as a humble disciple of Lenin, and recently 'thanked God for Russia,' has explained that £400,000 is being received 'from comrades in Russian mines to support the dependents of their English colleagues.'

"This confession has revived, if it ever flagged, our faith in our common human nature. It is indeed a touching reflection on the miners of Russia, who have to work ten hours a day so that their British colleagues may work seven and subscribe a portion of their wages of 25s. a week so that their British comrades may get 40s.

"Prominent representatives of the Soviet openly boasted that they attempted to assist the general strike here, and it has been claimed by persons speaking in Moscow that the money sent to the miners here is being paid officially not by the Russian miners but by the Russian Government.

See Revolutionary Motive

"Therefore it becomes necessary to ask from what motive these moneys have been advanced which have led Cook to 'thank God for Russia.' They are undoubtedly sent to encourage revolution in this country. The government has not yet had time to deal with the latter, but it will eventually make time to deal with it."

Colonel Lane-Fox, answering a question in Parliament, stated that Russian miners work from eight to ten hours daily to get the equivalent of a $6.50 average weekly wage. The conclusion is that they are incapable of making a sacrifice for their British comrades and, if capable, it would be hypocritical, for their own condition is much worse.

Government intervention in the coal strike is thought by some to be probable. Meantime some of the miners show a more reasonable spirit, and A. J. Cook has been trying to discipline them, but has found the miners' executive board deemed it best to leave the matter to the Miners' Federation. The men whose action has angered Mr. Cook are Frank Hodges and F. B. Varley.

Merryweather Named to Head Wholesale Association

G. H. Merryweather, Chicago, was elected president of the American Wholesale Coal Association at the closing session of the tenth annual convention of that organization held at the Hotel Secor, Toledo, Ohio, June 7-9. Leonard F. Leighton, Boston, Mass. succeeds Mr. Merryweather as vice-president of the organization. Roscoe B. Starek, Chicago, was re-elected secretary-treasurer.

The directors named were E. H. Hemingway, Hartford, Conn.; J. W. Dykstra, Detroit, Mich.; B. H. Read, Baltimore, Md.; W. N. Clark, Omaha, Neb.; F. H. Hoag, Buffalo, N. Y.; G. N. Snider, New York City; R. M. Buck, Watertown, N. Y.; Fred Legg, Cincinnati, Ohio; John M. Taylor, Columbus, Ohio; Arthur Kuppinger, Philadelphia, Pa.; Warren Bixler, Pittsburgh, Pa.; W. J. Prescott, Memphis, Tenn.; S. L. Platka, Burlington, Vt.; E. S. Simpson, Richmond, Va.; W. C. Maas, Milwaukee, Wis.; C. C. McGill, Toronto, Ont.; G. W. Harsh, Toledo, Ohio, and H. E. Northrup, Troy, N. Y.

The association formally reiterated its opposition to federal control as unnecessary, inadvisable and a contradiction of the principle of less government in business.

Industrial Coal Stocks Fall To 36,876,000 Tons

Coal stocks in the hands of industrial consumers on May 1 totaled 36,876,000 tons, a considerably lower figure than that shown for April 1, according to the National Association of Purchasing Agents. Conservative retrenchment has principally caused this depletion of supply on hand. The fact that only twenty-six days' supply was the estimated amount of stocks on hand at the end of April indicates the result of the above policy. Industrial coal consumption for the month of April is estimated at 39,048,000 tons.

Production in the bituminous fields fell off over six million tons during April, the total for the month being 40,079,000 net tons. Unusual weather conditions maintain the anthracite production rate, a 7,929,000 tonnage showing a decrease of approximately 300,000 tons from last month's figure.

The coke industry slowed up slightly on production during April, the by-product plants operating at 91 per cent of their capacity, producing 3,602,000 tons. The beehive ovens produced 981,000 net tons, 15 per cent less than the figure for March.

Comparative Estimates of Output, Consumption and Stocks

(In Thousands of Tons)

	Output	Industrial Consumption	On Hand in Industries
December	55,281	39,040	67,433
January	52,328	41,892	68,399
February	48,654	43,747	66,190
March	54,038	46,313	60,014
April	48,008	39,048	49,150
May	.....	.....	36,876

Days' Supply on Hand May 1 In Selected Industries

Steel plants	20
Electric utilities and coal-gas plants	48
Byproduct coke plants	15
Railroads	24
Other industries	18

How Coal Produced in And Imported Into the United States Is Used

The sources of coal used in the United States are well covered by statistics relating to the quantity of coal produced in various territorial subdivisions of of this country The question "Where does the coal go?" cannot be so readily answered by statistical material because of difficulty in tracing coal through the numerous channels of distribution and consumption, which offer many chances for misstatement and error. Therefore, distribution statistics are not so often compiled. Many factors influence the movement of coal to the ultimate consumer. Besides the vagaries of weather, and customs and preferences which obviously play their part in controlling the movement of household fuel, far greater influences are exerted by varying demands among industries, which are the principal users of coal. In accounting for the disposition of the annual supply of coal, imports and exports must be considered, as well as net changes in quantities moving into or out of storage.

The apportionment to major consumptive groups of anthracite and bituminous coal used during the calendar year 1923, the latest year for which information is sufficiently complete to afford estimates, as compiled by the U. S. Bureau of Mines, is as in the accompanying table.

Balance Sheet for Coal, 1923

Anthracite (a)

Coal to Be Accounted For

	Net Tons
Production	93,339,000
Imports	300,000
	93,639,000
Less exports	5,090,000
	88,549,000
Less increase in stocks during year	1,635,000
Balance—United States consumption	86,914,000

Distribution of United States Consumption

	Net Tons	Per Cent of Total
Power and heat at coal mines(b)	8,018,000	9.2
Railroads	4,578,000	5.3
Artificial gas plants	1,101,000	1.3
Electric utilities, including electric railways	2,273,000	2.6
Domestic trade(domestic sizes not included elsewhere)	52,344,000	60.2
Steam trade (steam sizes not included elsewhere for heating and industrial use)	18,600,000	21.4
Total	86,914,000	100.0

Bituminous (a)

Coal to Be Accounted For

	Net Tons
Production	564,565,000
Imports	1,882,000
	566,447,000
Less exports	21,447,000
	545,000,000
Less increase in stocks during year	26,000,000
Balance—United States consumption	519,000,000

Distribution of United States Consumption

	Net Tons	Per Cent of Total
Power and heat at coal mines.	8,765,000	1.7
Mines and quarries, other than coal	4,190,000	.8
Railroads	155,795,000	30.0
Public Utilities:		
Electric, including electric railways	36,800,000	7.1
Gas	5,150,000	1.0
Beehive coke plants	30,085,000	5.8
Byproduct coke plants	54,280,000	10.4
Bunkers:		
Foreign	5,095,000	1.0
Coastwise and Lake trade	2,940,000	.6
Iron and steel works, not including coal for coke(c)	30,220,000	5.8
General industrial and other unspecified uses	119,280,000	23.0
Domestic consumers	66,400,000	12.8
Total	519,000,000	100.0

(a) Figures are in part estimates based on information contained in Bureau of Foreign and Domestic Commerce, Census, and Interstate Commerce reports. (b) Includes 167,000 tons, or 0.2 per cent of coal used at mines and quarries other than coal mines. (c) Includes blast furnaces, steel works and rolling mills.

U. S. Coal Miner's Output Tops All Others

The American coal miner produces almost three times as much per man as a worker in the mines of any of the other leading coal countries, according to the U. S. Bureau of Labor Statistics, which has made an analysis of the recent report of the British Coal Commission. This report contained a table giving the annual per capita output for some 50 years past.

In 1924 American bituminous miners produced an average of 781 tons a year; American anthracite miners, 550, with a total average for all miners of 731. This is an increase over the period 1919-1923, when the total average was 698. From 1879 down to the World War, our production rose conspicuously and steadily. There was a setback after 1918, and the high total average of 795 for the period 1914-1918 has not been reached.

The British production per man, however, the Commission pointed out, was decreasing. As long ago as 1879-1893 per capita output was 358 tons. In 1924, however, it was 246, and in 1925, 243.

In France the average yearly output of coal per person employed in 1925 was only 170 tons; in Belgium, 158; and in Germany, 262.

The principal reason for the great increases in American output is the widespread use of machinery and the development of better methods of production, it was said.

Editors Nominate Officers

The Nominating Committee of the Editorial Conference of the New York Business Publishers' Association, Inc., reports the following nominations for officers and directors of the Editorial Conference for the business year 1926-1927: Chairman, Robert J. Patterson, *American Hatter;* vice-chairman, W. W. Macon, *Iron Age;* secretary and treasurer, Sidney D. Kirkpatrick, *Chemical and Metallurgical Engineering;* directors, Roy V. Wright, *Railway Age;* Ray W. Sherman, *Motor;* S. A. Dennis, *Electrical Record.*

Program for Fall Meeting of A.I.M.E. Takes Shape

A tentative program for the 134th meeting of the American Institute of Mining and Metallurgical Engineers, which is to be held in Pittsburgh next autumn, was drawn up by the members and the ladies' auxiliary of the Pittsburgh section, following a dinner at the Pittsburgh station of the U. S. Bureau of Mines on April 26.

According to the plans thus far arranged, the meeting will open Wednesday, Oct. 6, and technical sessions will be held in the morning and in the afternoon. In the evening a smoker will be held for the men and a special entertainment arranged for the women.

On the second day an all-day trip will be taken on the Monongahela River to Clairton and return. This trip will give the various members an opportunity to become acquainted and at the same time get a glimpse of the various industries located along the banks of the Monongahela River. A visit will be made to the Clairton byproduct coke plant of the U. S. Steel Corporation and possibly to the National Tube Works at McKeesport. In the evening a private view of the International Art Exhibit at the Carnegie Institute is being arranged for the members and guests of the Institute in advance of the regular opening.

A technical session is to be arranged for the morning of the third day, but those who do not care to attend this session will be guided on several trips to various industrial plants in the district. The afternoon will be taken up by a visit to the Experimental Mine of the Bureau of Mines at Bruceton, Pa., and by trips elsewhere. The meeting will close with a banquet.

Coal Used and Power Output By Utilities Waning

Public-utility power plants in the United States consumed 3,482,347 net tons of coal in March, according to the U. S. Geological Survey, compared with 3,312,902 tons in the short month of February and 3,722,597 tons in January. Fuel-oil consumption by these plants in March totaled 724,308 barrels, as against 735,807 barrels in February and 1,025,746 barrels in January.

The daily production of electricity by public-utility power plants in March was about 1½ per cent less than the output for February. In 1925 the decrease in average daily output from February to March was about 2½ per cent. The average daily production of electricity by the use of water power again exceeded all previous rates for the month, amounting to 72,500,000 kw.-hr. per day. This rate is about 7 per cent larger than the rates for February, 1926, and April, 1925—the two months whose average daily production by water power ranks next. The proportion of the total output produced by water power in March, however, was slightly less than that in March, 1925.

The total output for the first quarter of this year was about 15 per cent larger than for the same period in 1925.

Inflexible Attitude of Operators and Lewis Feared as Wage Pact Nears End; Senate to Resume Retail Price Probe

By Paul Wooton
Washington Correspondent of *Coal Age*

While some members of Congress are convinced that the bituminous operators are spoiling for a showdown with the union, they also feel that the United Mine Workers have been just as lacking in constructive suggestions for safeguarding the public fuel supply as have the operators. They discern that the union does not accept the idea of a mediation board. This is in spite of the fact that it is much more to the interest of the union to avoid a strike than it is to the operators.

Recent testimony before the House committee on interstate and foreign commerce brought out clearly that the offensive power of the United Mine Workers in the bituminous field is less today than formerly. This has given rise to the hope that Mr. Lewis will see that the wise thing for him to do is to settle with the operators in October and avoid an open break. If he does not do so many expect him to learn by experience that the expansion of non-union capacity and the drift away from the union have made it possible for the non-union fields to supply the needs of the country. Even Pennsylvania now has enough non-union tonnage to meet its urgent requirements.

Strike Would Hurt Union Prestige

With the prospect of a suspension, consumers would stock up months ahead of time. Under present conditions there would be little prospect of bringing them to their knees. These considerations lead to the hope that the miners will do their part to avoid a fight.

At the same time it is realized that a strike would have a particularly harmful effect on business under conditions which exist now and which may continue next spring. The effect of a coal strike always is demoralizing. The threat of a strike arouses great uncertainty and is especially hurtful when business is somewhat on the downgrade. In a situation likely to prevail for the next year it is regarded as important in the interest of the country that no feeling of uncertainty be permitted to allow the decline to proceed to the point of a depression.

An indication of the prevailing sentiment in Congress toward the coal industry may be had from the action of the District of Columbia committee of the Senate, which has voted to continue its investigations of retail prices of coal in the District. The committee began its investigation during the anthracite strike. Not satisfied with the presentations of the retailers, the committee appointed an expert accountant from the office of the Comptroller General to get a more accurate idea as to the prices which had been paid for coal and the profits which had been taken. The accountant just has reported to the committee that the dealers refused to make available the information necessary to determine these facts.

Members of the committee were outspoken in their criticism of the attitude of the retailers and it was voted to confer with representatives of the Department of Justice as to what steps that agency could take.

This is a straw which indicates the way the wind is blowing in Congress. This Congress is distinctly conservative and the majority is disposed to listen to the pleas of business, but there can be no disputing the fact that the impression is general that neither the operators, the retailers, nor the mine workers are taking a constructive position, and have withheld any assurance of better service in the future.

Ohio Pig Iron Men Discuss Coal Problems

Coal production and distribution came in for extensive consideration at the annual meeting of the Ohio Pig Iron & Coke Association, recently held in Cincinnati. Frank A. Ray, of Columbus, presented a proposal that the union fields adopt a bonus system whereby the mine workers would be paid a portion of the profits—if any—in six-month periods. J. R. Burton gave a talk on the sampling of Elkhorn coal; Samuel A. Taylor, president of the A.I.M.E. delivered an address on stream pollution, and C. E. Lesher, assistant to the president, Pittsburgh Coal Co., spoke on the evaluation of coal.

Illinois Associations Merged In New Organization

The three operators' associations in Illinois were consolidated in Chicago last week in a new organization called the Coal Operators' Association of Illinois. Rice Miller, of Hillsboro, was elected president; Herman C. Perry, of St. Louis, vice-president; C. L. McLaughlin, Chicago, secretary, and Luce H. Smith, Chicago, treasurer. The merger, which was the culmination of efforts to that end extending over ten years, includes the Illinois Coal Operators' Association, the Central Illinois Coal Operators' Association and the Coal Operators' Association of the Fifth and Ninth Districts of Illinois.

Coming so close to the opening of the National Coal Association convention at the Drake Hotel in Chicago, June 9, there was considerable talk on the prospects of the new association joining the National Coal Association. The Illinois operators withdrew from membership in the National four years ago when differences of opinion arose while the negotiation of the wage agreement with the United Mine Workers was on. Illinois operators objected to methods employed by the National Association officials. The National took no direct part in the agreement, however, and since then, it is believed, the major part of the dispute has been ironed out.

A board of directors of the new association and an executive committee has been formed.

The executive committee, composed of nine members, follows: L. H. Smith, Spring Valley Coal Co.; M. S. Peltier, Peabody Coal Co.; S. A. Shafer, Pana Coal Co.; O. L. Lumaghi, Lumaghi Coal Co.; E. C. Searls, Crerar-Clinch Coal Co.; J. D. Zook, O'Gara Coal Co.; George B. Harrington, Chicago, Wilmington & Franklin Coal Co.; M. S. Coleman, Saline County Coal Corporation, and F. S. Pfahler, Superior Coal Co.

Increased Industrial Efficiency, Says Mellon, Holds Future of Prosperity in United States

America can no longer depend on her natural resources but must place her faith in increasing the efficiency of her industrial system, Secretary of the Treasury Mellon stated recently in an address by radio to the annual convention of the National Electric Light Association at Atlantic City.

Comparing economic conditions in this country and Europe, Mr. Mellon declared that America had adjusted herself to the economic laws of the new industrial era, and has evolved an industrial organization which can maintain itself, not only because it is efficient but because it is bringing about a greater diffusion of prosperity among all classes.

The success of American industry and America's rapid growth in wealth, he said, is based on private initiative. The foundation of her present development was laid in a system in which free play was given to the energy and initiative of the individual and which at the same time encouraged competition and permitted corporate organization in industry, he continued.

"Whether we shall continue to grow and expand depends upon whether we pursue an intelligent and constructive, or a hostile and destructive policy toward those forces which have brought about our present development," Mr. Mellon said.

"A sound industrial policy must square with economic laws. And a consistent policy is necessary in order that capital, labor and the public may know what to expect. President Coolidge has pursued a clear, consistent course and has made it plain that his administration will not interfere with legitimate business merely because it is big, but desires that business and industry, so far as possible, shall work out their own problems, provided they conform strictly to the law."

Industrial Conference Board Elects Officers

Loyall A. Osborne, president of the Westinghouse Electric International Co., was elected chairman of the National Industrial Conference Board at the tenth annual meeting of that organization in New York City.

In accepting this office, Mr. Osborne assumes the chairmanship of a body whose members are the delegates of 27 national and state industrial organizations and four government departments, comprising more than 50,000 manufacturing concerns employing a total of more than 7,000,000 men and women. The board maintains a large staff of economists, statisticians and engineers who are continually investigating domestic and foreign problems of economic-industrial interest, and since its organization in 1916, has issued 115 research and 35 special reports and many monographs on subjects of timely and practical concern.

Mr. Osborne, who is a graduate of Cornell University, '91, joined the Westinghouse organization immediately upon leaving college, and was made vice-president of the Westinghouse Electric & Manufacturing Co. in 1902. He is now senior vice-president of that organization. During the war, he was a member of the Council of National Defense, a member of the War Labor Planning Commission, and of the War Labor Board. He succeeds Frederick P. Fish, Richardson & Neave, Boston, as chairman of the Conference Board.

Other officers of the Conference Board are: Frederick P. Fish, honorary chairman; Charles Cheney, of South Manchester, Conn., vice-chairman; John W. O'Leary, of Chicago, vice-chairman; Magnus W. Alexander, New York City, president; Fred I. Kent, New York City, treasurer; James M. Robertson, New York City, secretary. These with William W. Coleman, of South Milwaukee, Wis., Irenee du Pont, Wilmington, Del., Russel H. Leonard, Boston, and William H. Nichols, Jr., compose the Executive Committee of the Conference Board.

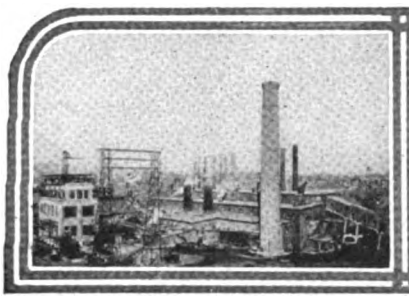
Loyall A. Osborne

President of the Westinghouse Electric International Co., who was elected chairman of the National Industrial Conference Board at its tenth annual meeting.

Co-operative Mining Banned By Ohio Union

Members of the United Mine Workers are prohibited from participating in co-operative mining operations in all sections of Ohio by an order issued June 9 by the Ohio union. Since competition under the Jacksonville scale has become so strong and many southern Ohio operations have suspended, many co-operative mining ventures were started in which union miners produced coal, sold it on the market and divided the profits. These operations were generally small ones and were leased from the owner on a royalty basis. A considerable tonnage had been produced in that manner and it is said that miners participating did not realize the union scale, according to the Jacksonville agreement.

The order was the result of a meeting held at Nelsonville recently by about 1,500 idle miners, who brought the matter to the attention of the union officials. The threat is made that unless the miners comply they will be disbarred from the union. Operators do not expect the order to be complied with by all miners, especially in the Pomeroy field, where some special agreements are in force.



Coal production in West Virginia in 1925 was a record breaker, with 123,061,985 tons produced, according to an announcement made on June 12 by Robert M. Lambie, chief of the state Department of Mines. This is an increase of 20,000,000 tons over the previous year. The final figures have just been struck.

Coal-Mine Fatalities During April, 1926, by Causes and States

News Items From Field and Trade

ARKANSAS

Speedy Trial for Dalrymple. — William R. Dalrymple, suspended president of the District No. 21, United Mine Workers, will be given a trial before international board members immediately, L. R. Kendricks, District Board member announced at Fort Smith last week. Charges will be pressed by the District Board, which ordered his suspension and named Gomer Jones, district vice-president, to succeed him. Dalrymple was given a trial at Muskogee, Okla., recently, but the findings were incomplete and were never announced.

Coal mines at Prairie View which have not been operated for several months, have been reopened, with about 20 men at work.

ILLINOIS

New Orient After More Records?— The New Orient mine of the Chicago, Wilmington & Franklin Coal Co., generally known as the world's largest mine, has resumed operations with full force. This plant laid off about three-fourths of its normal working force on March 30 and confined the activities of the remaining limited force to developing new territory in order to increase daily output. New men will be added to the force as the newly developed territory can be made ready for them and the force of about 1,400 now employed will be increased probably to 1,600 by the time snow flies.

During April 158 Illinois mines averaged 15.1 days work and produced 4,647,003 tons of coal, 51,879 miners were employed, 9 were killed and 1,463 injured. In April, 1925, 3,700,159 tons was produced.

IOWA

Corn Belt Dealers Organize.—H. J. Bane, of Iowa City, was elected president of the Corn Belt Coal Dealers' Association, formed by Iowa and Minnesota coal men at a recent meeting at the Hotel Savery, Des Moines. Des Moines was designated as the location of the central office.

KANSAS

Three Mines to Reopen Soon.—Three large mines in the Pittsburgh district are reported to be preparing to resume operations within three weeks, after a long period of idleness. The mines said to be getting ready to resume are No. 9 of the Hamilton Coal & Mercantile Co., north of Cherokee; No. 19 of the Sheridan Coal Co., near Mulberry, and No. 17 of the Jackson-Walker Coal & Mining Co., near Frontenac. The last two will be operated by sub-lessees. The three operations employ a total of more than 500 men.

The Frontenac State Bank, of which J. S. Patton is president, closed its doors June 4 after 22 years of continuous operation. Mr. Patton for many years has been a coal operator in the Pittsburg district, largely in steam shovel mines. Frozen assets were given as the cause of closing. There has been little activity the last year or two in the coal mining zone from which the Frontenac bank drew its business.

To Try Coking Kansas Coal.—A test to determine the adaptability to coking of southwestern Kansas coal will be financed by the Pittsburg Realtors' Association. This decision was made at a meeting of the association June 2. It was announced arrangements have been made with a coking plant to make the tests.

John Fulton, lessee of the Jackson Walker Coal & Mining Co.'s mine No. 16, near Pittsburgh, reopened it June 4, with thirty-nine men, after it had been closed down nearly a month.

KENTUCKY

Walkout Short-Lived.—After being out just one and one-half days, 350 workers in the plant of the Norton Coal Mining Co., Nortonville, near Madisonville, in western Kentucky, returned to work on June 3. The men quit work at noon over a disagreement on the wage scale, alleging that the company attempted to work them nine hours at an eight-hour price. The old scale was ratified before the men returned to work.

State Institutions Want Coal.—The Kentucky Board of Charities & Corrections has announced that bids will be opened and contracts let on July 1 for approximately 45,000 tons of screenings to be supplied to seven state institutions, located at Eddyville, Hopkinsville, Lakeland, Greendale, Lexington and Frankfort. Milton F. Conley, Commissioner of Public Institutions, stated that 550 forms had been sent to operators and jobbers. More than a hundred bids were received last year, and the average contract price was $1 per ton f.o.b. mine.

Columbus Mining Co. Expands.—The Columbus Mining Co., Chicago, is rejorted now to control the largest tonnage in the Hazard field of eastern Kentucky, having taken over the production of the Meem-Haskins Coal Corporation at Carrs Fork, which operates two mines; one mine of the Diamond Block Coal Co., at Hazard, and one mine of the Apex Coal Co., in the Elkhorn field, all of which was formerly sold through the Pocahontas Coal Sales Co. The Columbus outfit now handles the production of twelve mines.

A fire loss of around $25,000 was reported at the Elkhorn-Shelby Creek Coal Co. plant at Esto, near Pikeville, on June 2, when commissary, supply house, post office, etc., burned. Dynamite was used to prevent the spread of the flames.

MONTANA

The Chicago, Milwaukee & St. Paul Ry. is testing a Montana lignite at the shops at Aberdeen, S. D. It is called Geneva coal and is expected to furnish a cheaper fuel. The shops use from 700 tons a month in summer to 1,400 tons a month in cold weather, and if the new coal maintains its promise of economy, it will make a material saving.

OHIO

Consumers See Ohio Mines. — A special train containing owners of coal-consuming factories in Cleveland, Akron, Canton and Kent visited the eastern Ohio coal fields during the last week as part of a "Use-Ohio-Coal-Campaign." The mine owners financed the trip.

Mine No. 119 of the Sunday Creek Coal Co., of Columbus, located at Millfield, has been reopened after a suspension of several months.

Toledo Docks Busy. — The Hocking Valley docks at Toledo dumped 321,957 tons during the week ended June 2 as compared with 356,401 tons during the corresponding week last year. The New York Central docks loaded 208,989 tons as compared with 84,195 during the corresponding week last year. The total tonnage loaded to date by the Hocking Valley was 1,766,062 as compared with 2,110,566 tons last season up to June 2 while the New York Central docks handled 719,575 tons as compared with 485,217 tons in the season of 1925 up to June 2.

Starr Mine Equipment Sold. — The Southern Ohio Coal Co., with headquarters in the Brunson Bldg., Columbus, recently purchased at receiver's sale, the equipment of the Starr-Jackson Mining Co., which operated the old Starr mine on a lease, but which was forced into bankruptcy several months ago. The mine is owned by the Southern Ohio Coal Co., of which J. S. McVey is president and manager. Joseph P. Eagleson was receiver. The property

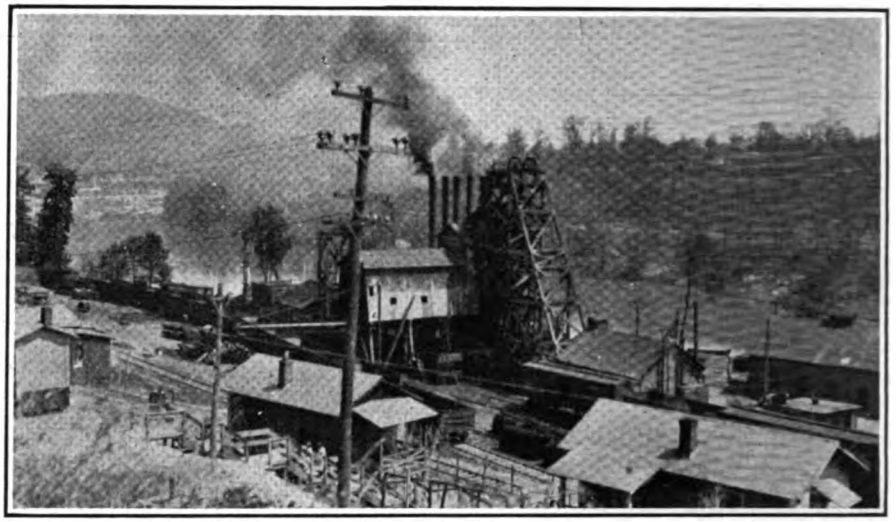
Digitized by Google

consisted of mining machines, mine cars, three 6-ton electric locomotives, blowers and pumps.

The Green's Run Coal Co., of Nelsonville, recently chartered with a capital of $25,000, has taken over the property of the Northern & Southern Coal Co., located at Jacksonville, on the New York Central lines. C. C. Sharp has been elected president, and Edwin Sharp, secretary and treasurer. The property consists of 500 acres of coal, with modern equipment. The mine is now being put into shape for operation when market conditions improve. The capacity of the mine is about 700 tons daily.

PENNSYLVANIA

Many Idle as Mine Slows Up.—More than 100 men have been laid off in the mines of the McKinney Steel Co. at Wolfpit, where, it is reported, the mining of the lower seam of coal is suspended and only one seam is now being worked. A similar situation faces the Greasy Creek mines, a few miles away operated by the same company. Fewer men are out of employment at Greasy Creek as it is a smaller operation.



Receiver for Pennsy Coal Co.—The Pennsy Coal Co., of Franklin, the sales office of which was formerly at Buffalo, with E. T. Bline general sales agent, has gone into the hands of a receiver. The liabilities are given as $500,000, with less than $100 cash on hand and no means for paying on either sinking fund or coupons. The company has five mines, four at Summerville and one at Sligo, all on the Lake Erie, Franklin & Clarion R.R. The receiver is I. W. Lesher, of Clarion. The mines had been taken over by W. R. Calverly, of Pittsburgh, who failed to make good on the operation of them. Production was at one time nearly 1,000 tons a day.

The Jones & Laughlin Steel Corporation has awarded a contract for four miles of railroad to its new coal mine in Greene County on which work is now being rushed to permit its opening for production by the end of the year.

Two Firms Taxed for Same Tract.—It developed recently at the Northumberland County court house that the Colonial Coal Co. and the Coxe estate, of Hazleton, have been paying large taxes on the same property in Shamokin for a number of years. The Colonial has paid on a valuation of $200 an acre while the Coxe interests have been assessed on a $50 acre basis. It is held that the Coxe interests are the real owners of the tract, which consists of 174 acres in Coal Township. It is understood there are thousands of tons of unmined coal in the property.

Bituminous coal (revenue) transported by Reading Company during April, 1926, totaled 1,454,854 gross tons. In the corresponding month a year ago the company moved 1,262,490 tons.

Glen Alden Dividend $5.—Directors of the Glen Alden Coal Co., Scranton, at their meeting June 8 declared a dividend of $5 covering the past six months. It also was announced that hereafter dividends will be declared quarterly. The previous dividend has been $3.50 semi-annually, the last being paid Dec. 31, 1925. The dividend is payable June 21 to stock of record June 10. It is generally believed that the present declaration of $5 a share places the Glen Alden stock on a $10 annual basis.

No. 42 Mine of Bethlehem Mines Corporation, near Fairmont, W. Va.

The name of this operation is Dakota Mine. A tributary of the Monongahela River can be seen in the rear. Owing to the narrowness of the valley the plant is located near the water. The railroad is the Baltimore & Ohio.

Coke Plants Slower.—The H. C. Frick Coke Co. closed down a number of plants in the Connellsville coke region last week, including Wynn, Brownfield, Fairchance and Continental Nos. 1, 2 and 3. The Oliver & Snyder Steel Co. closed down No. 1 and 2 plants and is operating No. 3 mine about full, shipping to its byproduct coke ovens at Troy, N. Y. W. J. Rainey, Inc., and the Hillman Coal & Coke Co. coke region plants are operating about full, being nearly the only companies doing so.

SOUTH DAKOTA

The state has placed orders for fuel for state institutions for the first time on a guaranteed performance basis. Successful bidders were the Sioux Falls Fuel Co., Schoenemann Bros., Mills Grain & Supply Co. and H. T. Parmley, all of Sioux Falls, besides the state owned mine. The state mine is to furnish 20,405 tons; 11,400 tons of Western coal will be used and about 10,000 tons will come from Illinois, Kentucky and Virginia.

TENNESSEE

O. P. Pile, Chief Mine Inspector, and the board of mine foreman examiners will hold an examination for mine foremen at the Post Office building in Knoxville on June 9 and 10.

The storeroom of the College Coal & Mining Co., Pikeville, recently was destroyed by fire with a loss of $20,000.

UTAH

Certain stockholders of the Sevier Valley Coal Co., with headquarters in Richfield, are to be prosecuted, according to the State Securities Commission, for the alleged act of offering personal stock of the company held in escrow. Some time ago the company was authorized to sell 60,000 shares of its stock at $1 a share, and it is charged that while this treasury sale was in progress some of the stockholders violated the escrow agreement and sold some of their personal holdings, handicapping the treasury sale and the proper financing of the company.

B. F. Bauer was the successful bidder for the lease of the 80-acre tract of coal land located near Thompsons, in Grand County. Bauer outbid N. B. Knight, on whose petition the land was offered. The successful bid went $1,000 above the terms of the lease. The land adjoins the property of the Chesterfield Coal Co., of Salt Lake City.

The Rains mine in Carbon County, operated by the Carbon Fuel Co., has been on fire for a few days, but it is now under control and plans are under way to reopen it on June 7.

The 1926 school year book of the Carbon County High School at Price is dedicated to the coal mining industry of Utah. Illustrations show mines and tipples and the like.

VIRGINIA

Rail Orders for Virginia Mines.—Contracts for more than 2,000,000 tons of railroad coal in the Virginia field have been announced. The Southern Ry. will get approximately 1,000,000 tons from the Stonega Coke & Coal Co. Between them the Seaboard Air Line and the Atlantic Coast Line will purchase 1,203,000 tons from a dozen different mines in the Virginia field. It is stated that the Toms Creek mines of the Virginia Iron, Coal & Coke Co. will obtain a liberal portion of the orders. Much of the Seaboard Air Line and Coast Line business was placed through the Whitney-Kemmerer Company, some tonnage coming through other agencies and some being placed direct with the contracting mines.

To Extend Coal Development?—W. E. D. Stokes, Jr., who has succeeded his father, the late W. E. D. Stokes, as president of the Chesapeake & Western Ry., a 40-mile road that runs across the Shenandoah Valley from Elkton to Stokesville, will bring engineers to Virginia within a few weeks to investigate the anthracite deposit near Stokesville,

Digitized by Google

which his father discovered. Young Stokes plans to extend the railroad west to the mining field, if such a project is found feasible. If conditions warrant, Mr. Stokes will operate the road on a more comprehensive scale.

The Raleigh Smokeless Fuel Co. has been awarded the contract to supply 12,000 tons of Pocahontas or New River Navy Standard coal to the city of Norfolk, at $1.74 per net ton, mines. The State of Virginia divided its 60,000 ton annual contract between several firms, the bids ranging from $1.60 to $1.75.

WEST VIRGINIA

Scholz Denies Deal Is Closed.—The Raleigh-Wyoming Coal Co., of Charleston, announced recently that it had started work on 100 additional miners' houses, 50 at Edwight, in Raleigh County, and 50 at Glen Rogers, Wyoming County. The firm expects to spend $200,000 for houses at these towns. The work will be completed in 75 days. An additional fan will be installed by the company at Glen Rogers, which will be completed in 60 days. Carl Scholz, vice-president and general manager of the company, was in new York City last week, presumably in regard to the deal with the Old Ben Coal Corporation, of Chicago, which has been reported as being closed frequently, but which the management of the Raleigh-Wyoming company contends is not a fact. There are 1,800 acres of coal land in the two properties, 9,000 acres at Glen Rogers, which is smokeless coal, and 9,000 acres at Edwight, which is byproduct coal land. There are 175 houses at each mining town.

Fletcher & Farley are erecting a storage plant for bituminous coal at Alderson, Monroe County. The coal will be retailed locally.

Seven men will be graduated from the mining engineering department, University of West Virginia at Morgantown this year. They are Percy Henry Gillie, Harry Greene Kennedy, Russell Warden King and Patrick Daniel McMurrer, all of Charleston; Ivan Allen Given, of Sutton; Grier Hartzell Pierce, of Huntington, and Franklin Pierce Tallman, of Beech Hill.

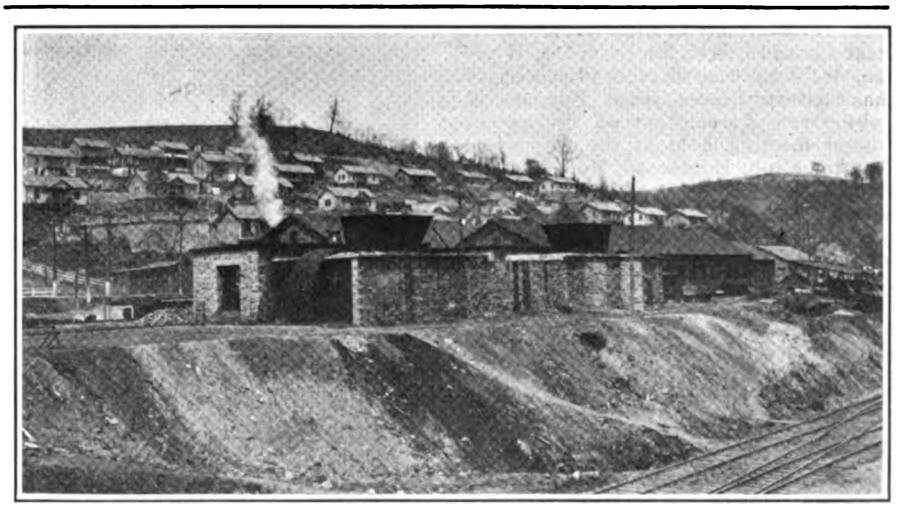
Thompsons May Build Plant.—It is reported that the Thompson interests are preparing to begin the construction of a plant at their holdings on the Durbin branch of the Western Maryland R.R. in Pocahontas County. This will be the first coal mine opened in that field. A seam of smokeless coal has been found there, it is reported.

Ocean Mine Resumes.—Officials of the Elk Horn Coal Corporation announced a resumption of operations at the Ocean mine, between Clarksburg and Bridgeport, on June 1. The mine has been shut down since about the middle of March. The company expects to be in a position to operate the mine regularly until the middle of November, when the lake season closes, and possibly even for a longer period. About 125 men are being employed.

May Develop Large Lorain Tract.—The Lorain Coal & Dock Co. may open up a 16,000-acre tract of coal land on Big Wheeling Creek, south of Elm Grove, in Ohio County, according to a semi-official report. Engineers of the company in eastern Ohio have been surveying the area during the last few weeks, with a view to making certain openings. The tract was purchased by the company about four years ago, but no development work has ever been undertaken. If new mines are opened, coal will be produced on a non-union basis. Three of the five mines of the company in Belmont County are now closed down, ostensibly because of inability to operate under the Jacksonville agreement.

Tait Mine Resumes Open-Shop.—Operations were resumed on an open-shop basis May 28 at the Tait mine, in the Maidsville section of Monongalia County, after an idleness of three years. The mine, which is owned by John and Gordon Tait, of Morgantown, has a capacity of about 10 cars a day. It is proposed by the owners to push production to capacity. About 20 men were at work on the day the mine was opened, but the force will be increased as additional men are needed. The Maidsville section, which has now become exclusively open-shop, was one of the last strongholds of the union prior to March 31.

Keen Competition on Railway Fuel.—Railroad fuel business closed recently included contracts for 500,000 tons for the Seaboard Air Line placed with firms in West Virginia along the Chesapeake & Ohio. This road paid $1.30 to $1.50 for mine-run. Keen competition marked the bidding, with the result that the price levels are down to a point close to the production cost. The Atlantic Coast Line placed 370,000 tons in southern West Virginia, paying $1.30 to operators along the C. & O., $1.35 to concerns located on the N. & W. and $1.50 to firms with mines in the Clinch Valley.



A new sternwheel steamboat of the Ohio River Co., a subsidiary of the West Virginia Coal & Coke Co., has been launched at Charleston. The boat will be operated in the coal towing trade between Huntington and Cincinnati.

Eagle Mine Under Hammer.—The Gauley By-Products Coal Co.'s Eagle mine, located near Vaughan, Nicholas County, recently was sold at a trustee's sale and the property was purchased under a leasehold by the Federal Coal Co., of Scranton, Pa., which owns the coal land. Six hundred and fifty acres of splint and gas coal land is included in the tract together with the equipped mine, which produces 250 tons of gas coal a day. The property was put under the hammer at the Nicholas County court house, at Sommersville.

The Detroit Mining Co., owned by Fred Essex, of Columbus, Ohio, and associates, recently opened up a new mine on White's branch of Little Coal River, Boone County, near Van. The mine is now under development and produces 6,000 tons of coal a month, but ultimately will mine 20,000 tons a month. A wooden tipple and a rope and button conveyor have been installed. Twenty miners' houses have been built. Splint and high-volatile low-sulphur coal is being mined.

CANADA

To Reorganize British Empire Corp.—The British Empire Steel Corporation, Ltd., and constituent companies, which include the Dominion Coal Co., for the year ended Dec. 31, 1925, had an operating loss of $1,133,443 before depreciation, depletion, interest, etc., comparing with operating profit of $923,774 in 1924. President Roy M. Wolvin announces that the deficit in operation since the inception of the corporation amounts to a total of $5,738,-018. He anticipates that the interest and sinking fund payments on the company's bonds probably will not be met when due on July 1 next. Among the causes assigned for this unsatisfactory condition of affairs are keen competition with European and American steel products owing to inadequate tariff protection and the losses occasioned by the five months' strike of the Cape Breton miners. Under these unfavorable circumstances a reorganization of the corporation and its subsidiary companies has been decided upon, and it is expected that within the next sixty days some plan will be formulated for submission to all who may be concerned in the corporation's affairs.

Fan Installation at Mine No. 41, Bethlehem Mines Corporation

Here, as may be noted by the two short evasé stacks, is a double fan installation, one driven by a uniflow engine and the other by an electric motor. This was installed about 1923. The village is that of Barrackville, W. Va. The picture is taken from the rear of the fan houses.

Among the Coal Men

Thomas F. Farrell, a vice-president of Burns Bros., New York City, has been elected a director to succeed Mason B. Starring, who resigned because of his removal to the Pacific Coast.

Ed Holyoke, formerly of the Wyoming Coal Sales Co. and the Cory-Mann-George Co., has been appointed Western manager for the Indian Run Coal Co. and its offices have been moved to the Fourth National Bank Building, Cincinnati. **James C. Layne Jr.,** who formerly had this position, is now devoting all of his time to the Katoma Coal Co.

Erskine Ramsey, chairman of the board, Alabama By-Products Corporation, Birmingham, Ala., who recently left to attend the Kiwanis International Convention, at Montreal, Can., will be away about a month. He will return by auto, stopping at New York on the way.

C. Bascom Slemp, chairman of the board, Wakenva Coal Co., representing a merger of fourteen companies, and former secretary to President Coolidge, recently joined the "hole-in-one" coterie of golfers. He did it at the Burning Tree Club, near Washington, D. C., on a hole of a little more than 150 yards.

A Dorman, managing director, and **W. L. Johnson,** an associate director, of Dorman, Long & Co., and **E. D. Morgan,** general works manager of the Port Clarence Iron & Steel Co., were among a party of prominent English industrialists who visited the Birmingham (Ala.) district recently to inspect the steel plants, coal and ore mines and for a study of industrial and trade conditions. They were conducted on a tour of the plants of the Tennessee Coal, Iron & Railroad Co. by **George Gordon Crawford,** president, who later entertained the visitors at an informal dinner. They proceeded from Birmingham to Chicago.

H. E. McDonnell, superintendent of blast furnaces, Weirton Steel Co., Weirton, W. Va., was elected president of the Eastern States Blast Furnace & Coke Oven Association at the recent annual meeting held at the Edgewood Country Club, Edgewood, Pa. He is a charter member, was secretary-treasurer in 1924-1925, and vice-president last year. **Charles R. Meissner,** superintendent of coke plant, Weirton Steel Co., who has been secretary-treasurer of the association during the last year, was elected vice-president. **B. W. Winship,** superintendent of the coke plant of the Bethlehem Steel Co. at Steelton, Pa., was named secretary-treasurer.

Eugene C. Hultman, chairman of the Massachusetts Commission on the Necessaries of Life, calls the attention of commercial and industrial coal consumers of New England to the possibility of serious effects on the coal market from the British strike. He says that the foreign demand for American coal is likely to increase considerably, and the result is likely to be felt more quickly in New England than in any other section of the country. While admitting that bituminous mines might increase output sufficiently to take care of the larger demand, he thinks that the foreign demand would be largely for the kind of coal desired in New England and would, therefore, be more likely to interfere with supplies to that part of the country.

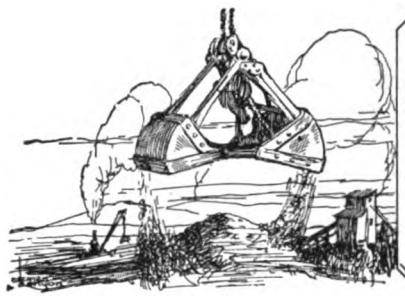
J. W. Powell, since 1924 chief mining engineer of the Autonomous Industrial Colony, Kuzbas, which is located in the Kuznetz Basin, Southwestern Siberia, sailed on the Cunard liner "Carmania," on June 12 for London, where he will reembark for Riga, Latvia. From this point he will travel by rail to Siberia. Mr. Powell was formerly Inspector of Mines in the Province of Alberta, Canada, and later was general superintendent of the Elkhorn division of the Consolidation Coal Co., Jenkins, Ky. Mr. Powell has been in the United States for the past three months on a vacation, during which time he has availed himself of the opportunity of investigating the latest types of coal mining machinery and equipment adaptable to conditions in the Kuznetz coal basin. He expects to remain in Siberia for three years to develop and carry to completion projected plans. He reports great progress during the 1½ years he has been connected with the Kuzbas enterprise.

Obituary

Joseph Louis, age 62, general superintendent of the Chicago, Wilmington & Franklin Coal Co., better known as Uncle Joe, died on June 8 as the result of a fall and head injury in alighting from his automobile near Vandalia, Ill. Prior to the accident he enjoyed good health. Mr. Louis had been in the services of the Chicago, Wilmington & Franklin Coal Co., and the old Chicago, Wilmington & Vermillion Coal Co. for about 40 years. His early years were spent at work in the mines of the last-named company in the Wilmington field of northern Illinois, where he rose from his first mine job of weighman to superintendent in 1905. In 1912 he was transferred to southern Illinois and appointed superintendent of Orient No. 1, and in 1920 was promoted to general superintendent. His headquarters and residence were in Benton, Ill. He leaves his wife and six daughters.

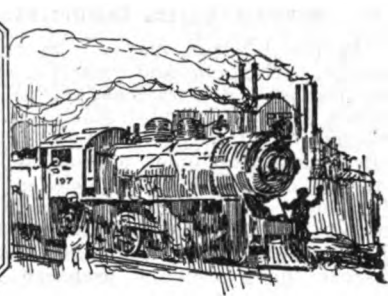
Joseph Louis

Charles James Myles, head of the firm of Thomas Myles, Sons, Ltd., Hamilton, Ont., died at his home in that city on June 7, following an illness of three weeks. Mr. Myles, who was 82 years of age, was born in Limerick, Ireland, and had lived in Hamilton nearly all his life. He entered the coal business with his father when very young, and carried it on successfully until his death. In the early days Mr. Myles owned several sailing vessels, in which the first coal was brought to Hamilton by water. These gave place to steamboats in 1876. He was a promoter of the Hamilton, Grimsby and Beamsville Radial Ry., and was a former president of the road.



Association Activities

The Central Pennsylvania Coal Producers' Association and the Association of Bituminous Coal Operators of Central Pennsylvania held their annual meeting in Altoona on June 10. The Producers' Association elected the following officers: President, B. M. Clark, Indiana; vice-president, G. Webb, Shillingford, Clearfield; secretary-treasurer, Charles O'Neill, Altoona; statistician, W. A. Jones, Altoona. The association of operators, which deals with labor problems, elected Charles O'Neill president-secretary-treasurer. Plans were completed for the appearance of the association's representatives at the rate hearings in Washington on June 14 and at Atlantic City on June 21.



The Pennsylvania Retail Coal Merchants' Association at its recent annual meeting, re-elected Samuel B. Crowell, of Philadelphia, as president. Other officers re-elected were: Vice-president, Walter L. Montgomery, Harrisburg, treasurer, J. Arthur Strunk, Reading; directors, Frank Sener, Lancaster; James C. Tattersall, Trenton; John Robinson, Camden; Leon Walker, Wilmington, and Thomas J. Murphy, Phillipsburg, N. J.

The West Virginia State Coal Association met in the Kanawha Hotel, Charleston, on June 1, and re-elected the following officers for the ensuing year: President, J. G. Bradley, of Dundon; vice-president, G. H. Caperton, of Charleston; secretary, Walter H. Cunningham, of Huntington, and treasurer, C. C. Dickinson, of Charleston. Plans were made to close the mines in the state on Mine Safety Day, which will be observed on Aug. 21, when mine-rescue contests will be held in Huntington. The association at its meeting went on record as being opposed to the passage of the proposed Parker bill.

Production And the Market

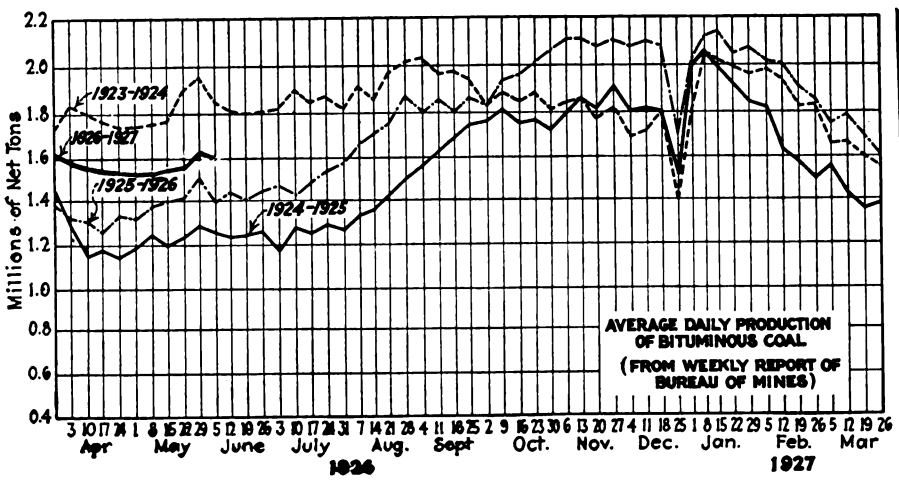
Seasonal Dullness Pervades Soft-Coal Market; Lake Movement a Steadying Influence

There has been comparatively slight surface change in the bituminous coal trade of the country during the last week. While the customary seasonal dullness is in evidence in most sections, the market is holding its own in good style. An important factor, of course, is the steadying influence of the heavy movement of coal to the lakes, which, after a belated start, is exceeding the weekly flow at this time last year. Last week 13,171 carloads passed through Cincinnati headed lakeward, an increase of 964 over the total for the corresponding week of 1925.

A further factor of favorable effect is the continuance of the British strike. From a speculative standpoint, however, this development has been a distinct disappointment, for the demand has fallen far short of expectations, and as a consequence the effect upon prices has been almost negligible. The export trade at Baltimore has increased noticeably, though not to an extent sufficient to exert a marked effect on the home market. On the other hand, in New England, where the possible effect of demand from consumers usually supplied by British coal was most feared, a distinctly weaker tone is evident from the standpoint of both demand and price.

Midwest Mines Curtail Running Time

Midwestern markets reflect such an indifferent attitude on the part of consumers that Illinois and Indiana operators are curtailing running time. The dullness extends to steam as well as domestic grades, and prices show a wobbly tendency. Kentucky coals are moving with a little more freedom and prices are somewhat firmer. Shipments from the Northwest docks are no better than normal, but a firmer tone has appeared with the cessation of price cutting. A backward disposition prevails in regard to contracting. The balancing effect of tidewater demand and lake movement, however, has served to preserve some semblance of price stability.



Average spot quotations registered a further decline during the week. *Coal Age* Index of spot bituminous prices on June 14 stood at 156. The corresponding price is $1.89. The figures for the previous week were 157 and $1.90, respectively.

The observance of Memorial Day caused a pronounced falling off in the output of bituminous coal during the week ended June 5, the total for which is estimated by the Bureau of Mines at 8,651,000 net tons, or 1,032,000 tons less than during the preceding week. Lake dumpings during the week ended June 13 totaled 1,038,369 tons of cargo and 48,885 tons of vessel fuel. Anthracite production during the week ended June 5 was 1,665,000 tons, a decrease of 424,000 tons from the week previous.

Hard-Coal Demand Easing Off

The decline in anthracite output was a development devoutly to be wished, as distributing channels are hard put to keep pace with production. As a matter of fact, some of the independent producers have already placed their operations on part time. Though fill-up orders are far behind the volume usual at this time, some consolation is felt in that much business of this character is still to be placed. Demand for stove coal is good and company egg moves without much difficulty. Independents are shading egg a little, and chestnut drags. The steam sizes are quite weak and surpluses are accumulating. One company shipper is said to be willing to shade prices on good sized tonnages.

In the Connellsville coke market production has been more evenly adjusted to contract requirements, with prices and demand practically unchanged.

Estimates of Production

(Net Tons)

	1925	1926
BITUMINOUS		
May 22	8,451,000	9,282,000
May 29 (*a*)	8,141,000	9,683,000

Midwest Buyers Indifferent

In the Chicago market the buying public, both steam and domestic, shows no interest in the purchase of fuel, and mines in Illinois and Indiana are curtailing operation. Demand for anthracite is extremely quiet, but coke is moving in fair volume, as is smokeless coal in prepared sizes. Prices in smokeless, however, are anything but firm. Mine-run is offered at $1.65 to $2.10, according to the grade, and prepared sizes vary widely. The demand for high-volatile coals from eastern Kentucky and West Virginia is weak, price concessions having failed to stimulate the demand. The steam-coal market is extremely unsatisfactory. Those who have 2-in. or 1¼-in. screenings are having difficulty in finding buyers at a satisfactory price, though production has been sharply curtailed.

Railroad coal is about all that keeps the southern Illinois field going. True there is a little steam trade and some mines are crushing mine-run to carry out their contracts and here and there a little lump, egg and nut is moving, but for the most part the larger sizes have blocked up the mine tracks and all mines have a large number of "no bills" in these sizes. Strip mines are working practically all the time.

In the Duquoin field the mines are working about three days a week. In the Mount Olive district some mines are working and crushing mine-run for steam contracts and others are shipping lump on railroad mine-run orders. In the Standard field conditions are unusually bad. The mines getting the best working time are co-operatives.

At St. Louis domestic business continues quiet. Practically nothing is going into storage—neither anthracite, smokeless nor southern Illinois. Coke also is unusually quiet.

Movement Gaining in Kentucky

Kentucky coals are moving somewhat better, and prices have stiffened a little in both eastern and western Kentucky. Except for a little off-grade distress coal not much 4-in. block is being offered at $2 in eastern Kentucky, and mine-run is $1.35@$1.60. In western Kentucky 6-in. block is $1.75@$1.85 and mine-run $1.10@$1.40. Screenings are holding firmly.

Demand for screenings is increasing somewhat due to public institutions and others stocking winter supplies and steady movement to utility and industrial plants. Steam coal has been in good general movement, and railroad consumption is normal.

Movement of coal from eastern Kentucky to the lakes is increasing steadily. There also is a fair scattered movement to the Southeast, and also north of the Ohio. Western Kentucky hasn't moved as much coal North and West as had been expected as a result of arrangements made with Chicago and Northern jobbers, but buying is improving.

Northwest Market Steadier

Conditions at the Head of the Lakes are more stable than a week ago. The price war for contracts with industrial

consumers seems to have spent itself.

May receipts at the docks were 115,538 tons of anthracite and 1,691,569 tons of bituminous. Compared with the same month last year hard-coal receipts decreased 269,840 tons and soft-coal increased 115,938 tons. The latest weekly report shows the arrival of 46 cargoes, including 2 of anthracite, and 26 cargoes, including 4 of anthracite, were reported en route.

Shipments of coal from the docks during May totaled 11,808 cars, as compared with 11,855 cars during April and 12,302 cars during May last year. Shipments so far during June have been about the same as last month.

Buying at the Twin Cities is confined to current needs. There is little stocking for the future, though prices now quoted are tempting. Coal is moving out so slowly at Milwaukee just now, while receipts by cargo continue so heavy that it is difficult to keep the docks clear for incoming cargoes. The dullness is largely seasonal. Prices are unchanged since the recent shading of Pocahontas to stimulate bin filling.

Storage Buying Brisk in Southwest

Only a few Kansas shafts are working on contracts. Most of the coal from this field now marketed is from shovel mines, and much of it is being crushed. Shaft screenings, when they can be had, sell for $2.50, but this trade for the most part, is being supplied with crushed shovel mine run at $2.35@$2.50. There is a good demand for Kansas coal for threshing. Orders for Arkansas semi-anthracite for summer storage are so brisk that operators expect no difficulty in keeping the mines working full time all summer.

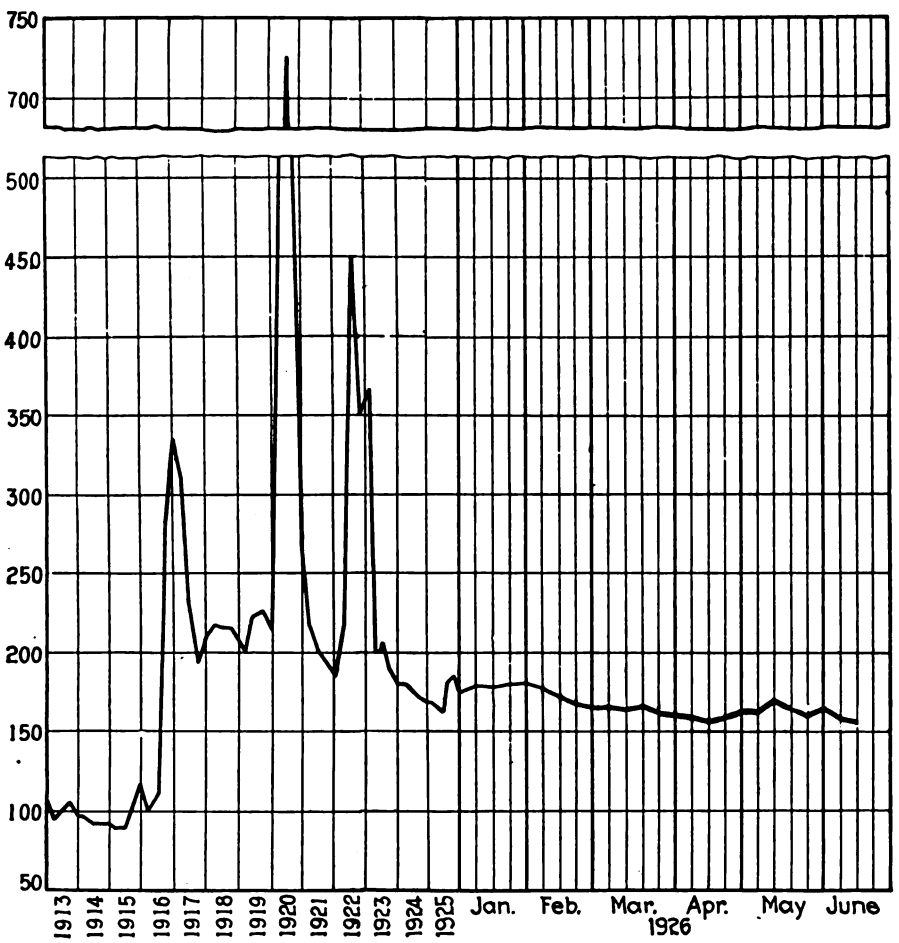
Domestic trade is sluggish in Colorado, but steam demand is somewhat better. The mines are at about 50 per cent running time and the trade is not in the mood for much storage coal. Prices reflect little change.

In Utah the market is unusually active for June, due to the low prices of larger sizes to induce summer storage. Lump of the best quality is retailing at $6.50 and $6.45 c.o.d., compared with $9 not long ago. "No bills" have been cut down about 80 per cent. The slack situation is improving.

Dullness Settles in Cincinnati

Dog day dullness is beginning to settle on the Cincinnati market. During the past week demand from the lakes has been just strong enough to keep pace with that from tidewater and keep prices on an even keel.

A little better tone to the west helped prepared smokeless, but there were a few concessions under $3 for both lump and egg. Stove holds about to the June circular as does nut. Mine-run is still firm at $2. The heavy "make" for the lakes precluded much change in screenings.



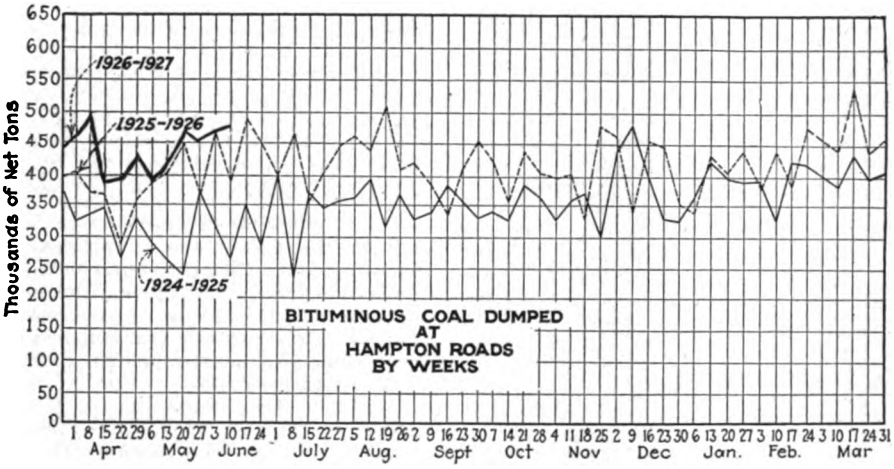
The spread in the price of high-volatile lump is $2@$2.50. Egg business has been fairly good since the price has advanced. Mine-run, after a spurt, has lulled a little, but slack holds its own.

Last week 13,171 carloads of coal moved through the Cincinnati gateway. This total, which was a decrease of 1,693 compared to last week, but an increase of 964 compared to same week last year, included 3,635 cars of lake coal en route to Toledo and Sandusky. There was an increase of 60 in the number of empties sent to the mines.

Columbus More Active

With the lake trade running along smoothly and a better feeling developing in domestic circles, slightly more activity is reported in the Columbus market. Retail stocks as a rule are not heavy and buying to replenish them is expected to be steady.

Steam business shows no particular change in the last week. Many manufacturing plants have been cutting in on their reserves, which has reduced spot purchases and contract shipments. Public utilities are about the only exception to this rule. Railroads are taking their usual requirements, but in some cases are buying on the open market. Contracting is slow in every way, owing to the low prices on distress coal. Individual embargoes against lake shipments during the past week forced considerable cheap coal onto the Columbus market.



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	June 14	June 7	May 31	May 24	June 15	June 16
Index	156	157	160	157	160	166
Weighted average price	$1.89	$1.90	$1.94	$1.89	$1.94	$2.01

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

Output in the southern Ohio field is now about 15 per cent and will be lower soon as the result of an order by the Ohio Mine Workers, closing all mines being operated on a co-operative basis.

In eastern Ohio a slight improvement is discernible, in that coal is less abundant and prices are a little firmer.

The railroads are taking normal tonnage, and the No. 8 field is participating to at least one-third of the weekly output, but the retailers are very quiet, especially in so far as Ohio coals are concerned.

About 75 per cent of the lake movement is via the ports of Toledo and Sandusky and the No. 8 field is participating in this movement less during the present season than ever before. Ohio mines, however, are furnishing considerable vessel fuel, but not in the same volume as formerly.

Eastern Ohio production for the week ended June 5 aggregated 161,000 tons, or about 27 per cent of potential capacity. This was 45,000 tons under the corresponding week a year ago.

Pittsburgh Trade Still Slipping

Conditions in the Pittsburgh market continue to grow poorer. The field of distribution is being narrowed by offerings of West Virginia and other fields, which is sharpening competition among the Pittsburgh operators who are trying to run.

The steel industry has been tapering off less than it did a year ago. Prices still show a softening tendency.

Seasonal dullness and keen competition are reflected in short working time and low earnings in the central Pennsylvania field. The district is now working about one-half normal.

Conditions at Buffalo show little change. Prices maintain recent levels. Low volatile is very quiet and the movement of high volatile is light. The hard-coal trade is not improving.

At Toronto there is a fair volume of business in anthracite. The yards are well stocked, with plenty of supplies coming through from the mines. Little activity is reported in soft coals, however, as industrial concerns have not yet begun placing orders. Prices are unchanged.

New England Still Sinking

The bituminous market in New England is a shade nearer the bottom, although the low point of the season doubtless is yet to be reached. Prices all along the line have slumped, although the modifications from day to day are not so noticeable.

Hampton Roads accumulations are not large, but prices are depressed. No sales in the last few days have been noted at more than $4.35 per gross ton f.o.b. vessel for No. 1 Navy Standard, and it is possible that $4.25 has actually been touched. Distributors at this end also are finding the going hard.

Pennsylvania coals are at a minimum, and this means that consumers in the twilight zone are trying their luck here and there with all-rail coal to the exclusion of the smokeless grades. This accounts for only a small tonnage, however, though it has a bearing on the large stocks on hand at most of the storage yards. On cars Boston and Providence it can hardly be said that the current level is anything in excess of $5.50 per gross ton, if indeed actual sales are made at figures higher than $5.35.

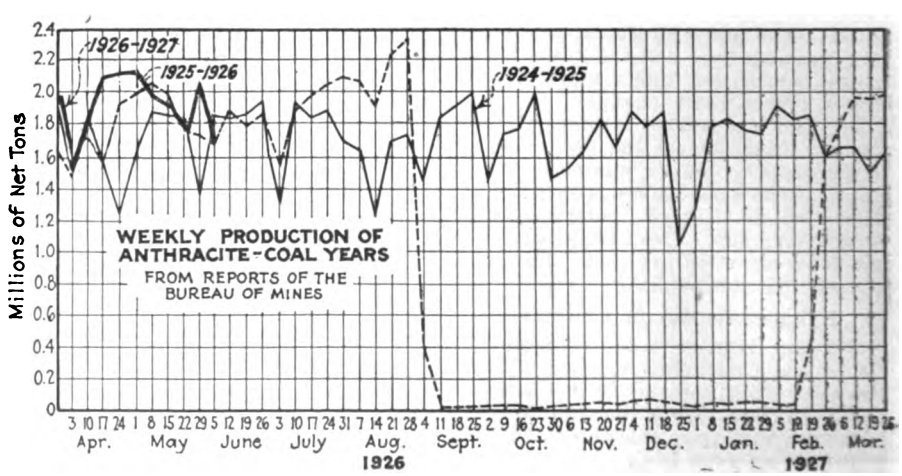
New York Market Quiet

The New York market is dull. Railroads as well as industrial consumers are holding off contracts in many cases and either buying from month to month or living on their stockpiles. Stocks have got down to a point, however, where many consumers who have not been in the market recently will have to do some buying before long. Exports are quite heavy as a result of the British coal strike, but this business is confined largely to Southern coals. A little extra bunker business is coming to this port, but it has had no noticeable effect on the market, tidewater prices remaining stationary.

A tendency to mark time still prevails in the Philadelphia market. Many large railroad contracts are still unsigned, but the roads have a receptive ear if the price is in accordance with their ideas. The market in slack seems to be an in and out affair. Tide conditions are quiet outside of bunkers.

The only element of decided interest in the Baltimore trade is an increase in demand for exports and bunkers, though this has not been heavy enough to cause any flurry in the home market.

Birmingham Trade at Low Level



At Birmingham the volume of business is at the lowest point for the year. Most all the regular industrial contracts have been renewed. The Southern and Seaboard Air Line awards, the last of the large rail contracts, are still pending. Bunker trade shows no stimulus from the British strike. Quotable prices are virtually unchanged. The average running time is about four days per week. Spot demand for foundry coke is fairly good at $6, and some contracting is being done for the third quarter at $5.50 per ton. Domestic sizes are $3.50 to $5, with only a moderate inquiry.

Anthracite Demand Weakens

Demand for anthracite at New York is easing off to such an extent that the selling end is unable to keep up with output. Some of the independents, in fact already are operating part time. There is still a good demand for stove coal, and company egg is moving well. Independents also have no trouble in disposing of egg at a price, but chestnut is hard to move on any terms, and as a result the price has weakened further. Independent stove is short in supply but has come down a little in price. No. 1 buckwheat and rice are about equally soft, with some extremely low prices heard of on distress lots at tidewater. Barley also is weak.

A further falling off is noticeable at Philadelphia. Retailers cannot induce customers to take in coal, but are standing quite firm on prices. The steam market is dull and there is much surplus coal. Independent prices for distress coal are quite low, and now it is reported that at least one company shipper is willing to accept $2.25 for buckwheat and $1.75 for rice in fairly sizable tonnages. Extreme dullness prevails at Baltimore.

Anthracite shipments by lake from Buffalo during the week ended June 10 totaled 53,700 tons, of which 25,200

tons cleared for Duluth and Superior, 14,300 tons for Chicago and 14,200 tons for Milwaukee.

Spot Coke Market Tone Firmer

Connellsville spot furnace coke is quotable at $2.75@$2.90, but there seems to be a better adjustment of production to contract shipping requirements, which presages greater firmness if any considerable tonnages have to be bought.

Negotiations on third-quarter or second-half contracts are dragging, not so much through haggling about prices on renewals as because some consumers would like to switch to better brands.

Standard foundry coke remains quotable at $4@$4.50. Some contracts for second half have been made at $4.75, while others, for practically standard coke, have been made at slightly less.

Production in the Connellsville and Lower Connellsville region in the week ended June 5, according to the *Courier*, was 80,400 tons by the furnace ovens, a decrease of 5,100 tons, and 61,590 tons by the merchant ovens, a decrease of 2,950 tons.

Western Europe Takes Most of British Coal Exports

Great Britain's principal markets during the coal year from April 1, 1925 to March 31, 1926, were in western Europe. British shipments to that area of more than 16,000,000 tons almost equalled the total United States coal exports during the same period, according to the Minerals Section of the Department of Commerce.

Northern Europe was second in importance as a receiving area of British coal, with imports for the period mentioned above amounting to 10,000,000 tons; southern Europe followed with 7,000,000 tons; South America took 4,000,000 tons; Africa 3,000,000 tons and North America about 1,000,000 tons.

France was the largest importer of British coal during the year with receipts totaling 7,962,000 tons. Italy was second with imports amounting to 6,124,000 tons; Argentina followed with receipts of 2,489,000 tons; while Egypt ranked in fourth place with a total of 1,946,000 tons. Following Egypt in the order of the size of their imports were Brazil, 1,149,000 tons; French Africa, 994,000 tons; Canada, 573,000 tons; Uruguay, 339,000 tons, and Chile, 102,000 tons.

Canada Increases Coke Production

The increasing use of coke as a household fuel in Canada is indicated by the production of 152,480 net tons during March, an increase of 10 per cent over the same month last year, but an 8 per cent decrease from February, 1926. Coke imports during March totaled 102,485 tons, compared with 73,796 in February. Most of this fuel was brought into the Province of Ontario, which always has been the principal market in Canada for imported fuel. The marked advance in imports appears to have been accompanied by an increase in coke consumption to 249,633 tons in March, compared with 235,359 tons in February and 200,364 in March, 1925.

Of the 237,565 tons of bituminous coal used for coke-making, 151,005 tons was imported from the United States and the balance supplied by domestic mines. Of the total production, 65,619 tons was sold to consumers, 67,967 used in smelters and 18,919 in coke plants. The Province of Ontario led with a production of 75,720 tons, followed by Eastern Canada, with 53,386 tons.

Exports decreased from 5,453 tons in March, 1925, to 5,332 tons in the corresponding month of the current year.

Penna. Soft-Coal Output 135,266,612 Tons in 1925

Total output of bituminous coal in Pennsylvania in 1925, according to figures just compiled by Frank Hall, Deputy Secretary of Mines, was 135,266,612 net tons. The total production of coke was 10,589,359 tons. The largest production of both bituminous and coke was in Fayette County, which produced 28,684,339 tons of coal and 6,273,261 tons of coke.

The Department of Mines' figures on bituminous coal and coke production in net tons by counties follow:

(a) Note that the coal statistics of the Geological Survey for a given year include only the mines that had an output in that year. Many mines that operated in 1923 produced no coal in 1924: moreover, many of the mines that did produce in 1924 worked for a short time only. The number of active mines of commercial size in Iowa was 151 in 1923 and 256 in 1924.

(b) Includes also loaders and shotfirers.

Statistics issued by U. S. Bureau of Mines.

Foreign Market And Export News

Strict Regulations as Well As Continuance of Strike Tie Up British Coal Trade

London, June 4.—The strictness of the regulations governing release very nearly prohibits export business in Welsh coals, and transactions are closed only in rare instances. The intention at present is to bunker vessels at Welsh ports from cargoes due from Germany. Exporters are handling American and German coals for home and depots, and through coal f.o.b. Rotterdam is 25s. 6d.@27s. 6d., and American mine-run, $7.50@$8, Hampton Roads. Some bunkers have been sold f.o.b. Brixham at 42s. 6d. The growing list of lost contracts includes the Portuguese State Railways, which have bought 15,000 tons of American and German coal and the South American Railways, which have purchased 50,000 tons of American coal.

Stocks of British bunkering coal at foreign depots have been exhausted and are being replenished from America and Germany. Some of the British Channel ports still hold fair stocks of domestic coal, and in some cases these have been augmented by French supplies. The public utilities, foreseeing industrial trouble have laid in good stocks, but all the chief railways are operating on a reduced schedule.

Coal is being strictly rationed to householders at the rate of 56 lb. per week for each house. Those houses which have gas or oil cookers or any alternative form of heating or cooking are not allowed any coal at all. There is no restriction on coke. Prices at foreign depots have risen from 10 to 50 per cent in the past few weeks.

French Coals in Brisk Demand Due to British Strike

Paris, May 28.—Owing to the stoppage of British collieries, French coals are much sought at the present time and most of the French mines are behind in deliveries. Some British steamers are bunkering at French ports. Transportation from the Nord and Pas-de-Calais coal field both by rail and by water is unimpeded.

Canal freight rates are on the increase; the Béthune to Paris rate is now 30 fr. to 30 fr. 50c.

The Nord and Pas-de-Calais collieries are regularly enforcing their new schedule of prices, which implies in the main, the following increases per ton as from May 16: 10 fr. on unwashed industrial coals, 13 fr. on washed industrial coals, 20 fr. on domestic sizes and 15 fr. on cokes. French miners in the other coal fields are now suing for an increase in wages similar to that obtained by workers in the Nord and Pas-de-Calais, namely, about 3 fr. per day.

The inland selling prices of the Sarre coal field have been increased by 5 per cent, namely, by 4 to 6 fr. for unwashed coals, 6 fr. for washed coals and 6 to 9 fr. for cokes. Ordinary coke of the Sarre is now sold at 152 fr. and special coke at 162 fr. per ton.

Deliveries of indemnity fuels during the first eight days of May, to the O.H.S. included 102,800 tons of coal, 69,700 tons of coke and 7,600 tons of lignite briquets. During the first twenty-five days of May the O.R.C.A. received from the Ruhr 219,275 tons of coke.

Belgian Market Rushed For All Grades

Brussels, May 28.—The Belgian coal market has undergone a complete transformation in the last few days and there is now almost a run on all kinds of coal. No fresh orders are being accepted for anthracite, whatever the price offered by purchasers. Of course, the stoppage of British collieries is the cause of this reversal of conditions, as Belgian collieries have now practically no more foreign competition to contend with.

The inland demand is strong and that from the East of France also has increased. Prices have become quite firm both for industrial and for domestic coals.

During the month of April, Belgium received 254,969 tons of indemnity fuels from the Ruhr.

Reich Makes Cash Grant to Aid German Coal Industry

An important decision which will materially benefit the German coal-mining industry, amounting in effect to a substantial subsidy, was recently reported in a Reuter dispatch.

Under the reparation agreement the price credited to Germany was the inland price of coal. Subsequently the British inland price was taken as the basis, but as the British subsidy to the mines was not taken into calculation, the German mines suffered heavy losses on reparation coal, averaging 3 marks a ton on average monthly deliveries of one million tons.

The German owners demanded that the Reich should meet this deficit on the ground that the Reich issues the orders for the reparation deliveries, and the government committee which deals with such economic questions has decided that the government is liable for the difference in price. The German industry will, therefore, receive immediately large cash payments, stated to exceed 15,000,000 marks.

The importance of the decision, however, lies in the protection it affords against future losses caused by the differences between German and British coal prices.

Coming Meetings

American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Illinois Mining Institute. Annual summer meeting on steamer "Cape Girardeau," leaving St. Louis, Mo., June 24 and returning June 26. Secretary, Frank F. Tirre, Central National Bank Bldg., St. Louis, Mo.

American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

Illinois and Wisconsin Retail Coal Dealers' Association. Thirty-first annual convention, Highland Hotel, Lake Delavan, Wis., June 28-30. Managing Director, N. H. Kendall, Great Northern Hotel, Chicago, Ill.

Fifth International First-Aid and Mine-Rescue Contest, San Francisco, Calif., during the first week of September, 1926, under the auspices of the Bureau of Mines, Department of Commerce.

Coal Mining Institute of America. Annual meeting, Chamber of Commerce, Pittsburgh, Pa., Dec. 8, 9 and 10. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

New Companies

The Washington Star Mining Co., 230 South Clark Street, Chicago, has been incorporated with a capital of $18,000 to own and operate mining properties. The incorporators are J. F. Spoerri, W. A. Bradford and H. C. Nagle.

The Talbot Coal Corp., New York City engaged in coal mining, has been chartered at Albany, N. Y., with a capital of 750 shares of no par value. F. H. Butehorn, F. C. Taylor and J. T. Aspbury, 120 Broadway, New York City, are directors and subscribers. Weeks Brothers, 52 William St., New York City, are attorneys for corporation.

Gulf Roan Smokeless Coal Co., Clarksburg, W. Va., was organized recently to mine coal, manufacture coke and coal briquets in Harrison County, with Levi W. Keaster, George G. Lynch, Walter Elliott, Mamie Lee Morris and Dennis S. McIntire, all of Clarksburg, as incorporators. The capital stock is $300,000.

The Watts Coal Co., capital $20,000, has been incorporated in Corydon, Ky., by Alex. Watts, Wm. Kavanaugh and others.

The Logan-Central Coal Co., of St. Albans, W. Va., was organized recently to mine coal. The incorporators are E. R. Milligan, N. E. Milligan, C. L. Milligan, W. C. Sharpe and I. F. Sommerville, all of St. Albans.

New Equipment

Full-Revolving Shovel with Upsetting Scoop

The underground loading machine invented and developed by R. S. Butler, assistant manager of the Barnsdall Zinc Co., Joplin, Mo., first placed on the market by the Lake Superior Loader Co., of Duluth, Minn., is now made by the Nordberg Manufacturing Co., of Milwaukee, Wis.

Since its acquisition by that company, the design has been materially changed. The new shovel operates in the same general way as did the earlier model—that is, it is of the full-revolving type, and the dipper is pushed into the material, loaded, filled and dumped. The design, however, has been changed throughout. Instead of using castings for the dipper arms and side frames, steel bars and rolled shapes are employed. It is also stated that in the old shovel the dipper, when dumped, operated in the same manner as the dipper of the ordinary steam shovel—that is, the bottom dropped open, permitting the material to fall through. In the new shovel the bucket is rotated and dumped in an entirely different manner. This may readily be seen from the accompanying illustration of the shovel.

Dipper Turns Completely Over

With the old shovel, it is also stated, it was somewhat difficult to handle coarse broken material, as there was a tendency for this to clog in trying to pass through the bucket. With the up-to-date machine, it is possible to load a single rock that is much larger than the dipper, as it does not have to pass through the dipper when being discharged. On the old machine, furthermore, there were hydraulic cylinders or pots to control the lifting stroke of the dipper. These have been eliminated entirely in the new machine.

The design, says the company, has been strengthened and simplified in many ways, which will eliminate the breakage that was not uncommon with earlier models. It is furthermore stated that the new shovel is extremely rapid in its operation.

The new model consists of three principal parts: the base, the operating cylinder, and the dipper assembly. The base casting or truck frame is of steel, to which is attached the wheels for transporting the machine underground; also the clamping device for securing the machine to the rails. This casting serves to support the rotating portion of the shovel, which revolves on a set of steel balls. This revolving member consists of two side frames that support the cylinder and arms of the dipper assembly. The power required for rotating is supplied by a small four-cylinder air engine attached to the base.

One Cylinder Gives All Movements

All the movements of the dipper arm assembly are supplied from one operating cylinder. This cylinder has a 10-in. diameter and 42-in. stroke, in which there are two pistons acting as one when imparting the crowding motion or lifting motion to the dipper. For the digging and dumping motions, air is introduced between the pistons, which forces them apart and then by means of cables and links gives a positive and effective dipper action. The dipper when digging exerts most of its reaction against the floor of the mine, thus absorbing the pressure and preventing strains from being imparted to the frame of the machine. The dipper assembly is made of materials well suited for such severe service. Side arms are of heavy bar steel, but the design is such that strains encountered in digging are borne by the dipper and not by the arms.

Cars Can Be Loaded on Any Track

The shovel is of the full-revolving type and will therefore load cars at either side or at the rear as desired. The compact design of the shovel permits its use in drifts 5½ x 7 ft., and its wide clean-up radius of 18 ft. 6 in. makes it suitable for use in large tunnels, rooms, and other underground

Butler Loader

Small in size and full-revolving, with its scoop turning over in discharge this loader is well adapted to use underground. Its comparatively light weight also makes it easy to move from place to place. It can load cars spotted either beside or behind itself.

Digitized by Google

workings. It can dig below grade in any direction and will load cars 48 in. or higher, and will leave the floor and corners clean.

Its air consumption is low, not exceeding 135 cu.ft. of air per minute at 70 to 90 lb. pressure, according to the manufacturers. Large capacity is claimed for the shovel, inasmuch as the quarter-yard dipper is operated at a speed of 3½ passes a minute. In actual performance, under ordinary conditions, this means that it will handle from fifteen to thirty tons an hour. Tonnage, however, will depend on the specific gravity of the material handled.

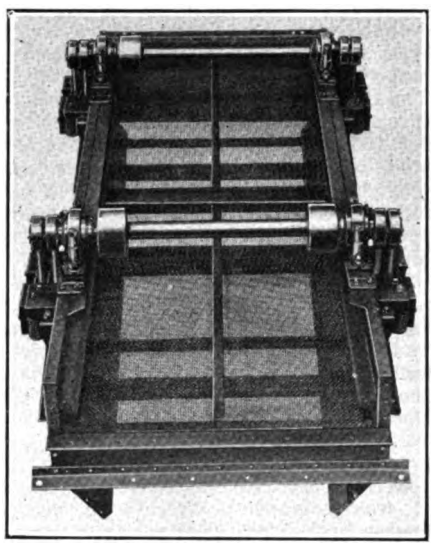
SHOVEL IS EASILY TRANSPORTED

The shovel is light, weighing only 4,000 lb., and can, therefore, easily be transported about the mine on its roller-bearing wheels. It can be run or a mine cage 36x54 in. without disassembling. If necessary, the operator's platform, which extends 12 in. from the side, can be unshipped to reduce the width.

The two controls for the shovel's movements are simple, convenient, and naturally positioned, according to the company. This makes it possible for a new operator to handle the shovel without difficulty.

Roller Bearings That Adjust Themselves on Each Turn

The bearing shown has at the bottom of its housing two oil wipers of copper, one at each end, to prevent oil drifting along the shaft and out of the bearing.



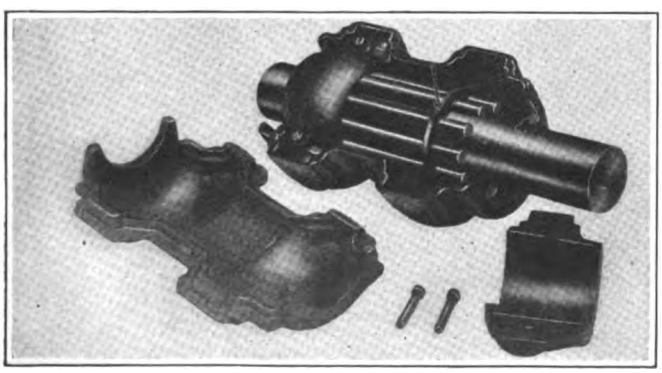
The two load collars are built wide, so as to carry a heavy load, and they are split and held together by long screws, so that the housing can be taken apart and re-set together over the shaft in a very short time. The collars have a groove in the middle for housing the steel spacing rings, which keep the rolls in their respective places and apart without friction, thus insuring smooth running.

It is claimed that no end thrust is produced in these bearings, as the rolls readjust themselves on every turn, the two load collars that carry the rools being self-aligning in a vertical as well as in a horizontal direction. The lubrication of this bearing is one of its particularly interesting features. The rolls rotate around their axes as well as around the shaft, and on each turn dip into the oil cellar, which actually creates an oil bath all around the shaft. The bearing described is manufactured by the Chandler Machine Co., of Ayer, Mass.

Screen Imparts Vibration To Material Sifted

Another new model of vibrating screen has recently been added to those on the market by the Pittsburgh Coal Washer Co., of Pittsburgh, Pa. This is a so-called "vibratory" screen, the action being attained by an eccentric shaft mounted in self-aligning ball-bearing pillow blocks, the eccentric connecting rods being carried on self-aligning ball bearings and attached to the screen-frame supports. Other details of the screen are as follows:

A screen cloth of suitable mesh is mounted on a steel frame, securely fastened to supporting members located outside the sheet-metal frame. These members are carried on four coil springs, which float the frame and permit it to vibrate freely under load.



Screen and Its Frame

Positive vibration of the wire cloth screening surface prevents clogging. Light weight and positive lubrication assures easy operation.

Attached to each of the spring-suspended supports at each side of the frame is a rigid connecting rod, the upper end of which is connected to the main driving shaft through the connecting-rod bearings.

Both the self-aligning main bearings and the connecting-rod bearings are equipped for high-pressure lubrication.

The screen cloth is made of sections of standard meshes and is attached to the screen frame in a manner which stretches and holds the cloth securely in place. The frame may easily be removed by taking out four bolts.

Split Bearing

Being split horizontally this bearing is easily put in place or removed. Two oil wipers prevent oil drifting along shaft and out of bearing.

Trade Literature

Cableways for Coal Storage and Reclaiming. Lidgerwood Mfg. Co., New York City. Bulletin No. 36. Illustrates and describes the systems in use at the Westport generating station of the Consolidated Gas, Electric Light & Power Co. of Baltimore and the Toronto super-power station.

Climax Engineering Co., Clinton, Iowa, recently published the following: **Gasoline Power Units,** portable and stationary types. Bulletin E., 11 pp. **Electric Generators, Direct-Connected, Alternating and Direct Current,** 20 to 75 kw. Bulletin F, 6 pp. **Centrifugal Pumps, Direct Driven.** Bulletin G, 6 pp. These are all 8½x11 in. and illustrated.

Steam Economy. Republic Flow Meters Co., Chicago, Ill. Catalog No. S-33. Pp. 55; 8½x11 in.; illustrated. Covers steam, water and gas meters, liquid level recorders and indicators, pyrometers, draft instruments, CO_2 recorders and coal meters.

The Pyramid Grate. Pyramid Iron Products Corp., New York City. Pp. 12; 8½x11 in.; illustrated. This grate is designed for the use of any size or kind of coal and can be installed in any size or type of boiler.

Brown Pyrometers. The Brown Instrument Co., Philadelphia, Pa. Catalog 15. Pp. 80; 8x10½ in.; illustrated. Recorders, new moisture-proof rotary switch, thermocouple protecting tubes, are some of the equipment illustrated and described.

Handling and Preparing Coal at the Mine. Link-Belt Co., Chicago, Ill. Book No. 555. Pp. 72; 8½x11 in.; illustrated. Describes some of the preparation plants built by this company.

Direct-Injection Oil Engines for All Purposes. Ingersoll-Rand Co., New York City. Pp. 31; 8½x11 in.; illustrated. Describes the "PO" oil engines of 55, 110 and 150 hp.

Engberg's Electric & Mechanical Works, St. Joseph, Mich., have issued bulletin No. 302B, supplement to catalog No. 302 covering vertical engines. Bulletin 302b contains horsepower tables. This company also has issued Bulletin No. 601, describing and illustrating the Engberg **Direct and Alternating-Current Generators** and their application to internal combustion engines, and bulletin No. 801 covering **Alternating Current, Direct-Connected Generating Sets.**

Crouse-Hinds Co., Syracuse, N. Y., has issued the following: **Condulets for Grounding Service Wire and Conduit System.** Bulletin No. 2089, four-page 3½x6-in. folder, illustrated. Bulletin No. 2075, illustrating and describing their **New Service Entrance Condulets.**

Steel Cross Ties. Carnegie Steel Co., Pittsburgh, Pa. Ninth edition. Pp. 45; 5x8 in.; illustrated. Covers mine ties, ties for portable tracks and ties for steam and electric railroads.

Ernest E. Lee Co., Chicago, Ill., has issued catalog 26, illustrating and describing the power plant equipment of the concerns the company represents. The book has 15 pp., is 8½x11 in., illustrated.

A definite step ahead toward mine car design!

The "Car Foundry" achievement in developing the "Continuous Service Car"—the Car with the "Backbone"— marks the first definite step ahead toward mine car design.

With the standard "Backbone," steel floor sheets and removable flooring, this "Car Foundry" Car fills a long-felt want of the mining industry.

If you do not already know all the important new features of this "Continuous Service Car" (You may have seen it on exhibition at the Convention) get in touch with "Car Foundry," Send for the Bulletin describing this new achievement in long service cars.

Keeping Production UP and Costs DOWN

No mine can produce up to capacity unless it has a smooth-running haulage system. Next time you have storage batteries to renew, try Exide-Ironclads and you will find that the increased efficiency of your haulage system is reflected throughout the entire mine. That is one way you can ship more coal without spending a nickel for extra equipment.

When a haulage motor is equipped with an Exide-Ironclad Battery, you can depend upon it staying on the job month after month and year after year. So ruggedly built is this battery that it rarely if ever loses any time out of service for repairs.

This miner has done his part. Now will the haulage system do its part? It will if the haulage motors are equipped with Exide-Ironclad Batteries; for when this battery is used, there is seldom any waiting for the loads to be gathered and the empties brought in.

This battery motor is coming out with the last trip of the day. Yet it still has plenty of power to breeze upgrade with a heavy trip, for it is equipped with an Exide-Ironclad Battery.

Send for a copy of our new booklet, "Facts for Consideration in Selecting a Storage Battery."

He Puts Ideas in His Copy

Have you noticed *Coal Age's* advertising copy? In earlier days the advertiser would put his name in large letters on his space, give his address and then designate what he sold. You could learn as much—and as little—from his "copy" as you could learn from the name over a store or the sign over a tavern.

But all that has been changed. Modern copy for the most part is instructive. It is attractive as much by what it says as by its manner of presentation. Every advertisement that is worth its snuff gets over an idea.

Would You Work Without Tools?

Progress is possible only with the right tools. Advertising illustrates and describes the newest and best tools and tells why they are good and suited to your use. Every advertisement presents you with an opportunity. Being a mining man, you may find just what you want for the special purpose you have on hand.

With the device that you have, one man perhaps can do in a day indifferently well what he could do better in half, a third or a fourth of the time if he were properly equipped. Why then shouldn't you go to the advertiser and his "ad" in *Coal Age* for help, and if he doesn't cover your need in his advertisement write him? He will be glad to give your requirements careful attention.

The average manufacturer is looking for leads that he can develop, new problems he can tackle and makes frequent trips to the coal fields for just that purpose. He will welcome correspondence.

Now, Mining Is Something Else Again

MANUFACTURING and mining have little in common. In one case the material to be wrought is brought to the worker, sometimes hundreds of miles; in the other the worker goes to the material. In the one case, therefore, the material is movable and the worker is stationary, and in the other the worker is transferred from place to place and attacks material in place. However, the working face changes, and there again is the rub. If it stayed where it was, the worker and his tools would not have to be moved.

This is what makes mining a difficult industry for mechanicalization. It is making marvelous progress wherever it can adopt mechanical methods. Compare it with the construction industry, one just as old and having similar difficulties and one which has progressed marvelously but nevertheless selectively. It still uses trowel, hod, bar, chisel, wheelbarrow, hammer and other like elementary tools. The equivalent of the hod is the basket. Some hundreds of years ago that adjunct of primitive transportation was discarded in mining. The wheelbarrow is rarely used in the coal mines beyond the first 25 ft. from the surface. Despite its advantages on a short run such as this, it has been quite generally discarded for the mine car even there.

Ask a manufacturer to move his tools from shop to shop several times daily; deny him the use of an overhead crane; demand that no tool shall be more than 6 ft. above the floor; give him a floor of clay instead of firm foundations and he will wonder if he can meet such difficult conditions. Yet the manufacturer of mining equipment is confronted with them, and he is preparing to meet conditions even more onerous with no small degree of probable success.

Worthy of Support

CREATED BY THE exigencies of war, the National Coal Association has quietly grown into an effective instrument of peace. The transitional days of costly floundering, during which the organization was trying to adjust itself to post-war conditions, are history. Despite the drawbacks of inadequate financial and numerical membership support, the association has succeeded in establishing a definite program responsive alike to present-day needs of the industry and flexible and forward-looking enough to meet the demands of the future.

Whether all the possibilities of this program will be fully realized rests with the industry itself. The officers and directors of the association give freely of their time, their judgment and their energies to the formulation and execution of constructive policies. But they can travel no farther than the financial resources of the organization will carry them. They can make the insignificant mill per ton paid by each member do its utmost—but no more. If more is to be done—and more should be done—there must be more mills per ton and more members to share the financial load.

Even the most implacable critic of the association must admit that organization is necessary in the contacts between the industry, the public at large and the federal government. The National Coal Association is that point of contact, which must be preserved. There is too much at stake, and individual operators are too big to let petty jealousies, old wounds, past mistakes or present grievances stand in the way of active affiliation with the constructive work of the association.

Goggles Lessen Eye Injuries

SAFETY IN MINES includes protection to both life and limb. In other words, it embraces not alone immunity from accidental death but also immunity from accidental injury as well. By far the greater part of the injuries sustained within the mines are of what might be termed a minor character—not really dangerous but truly inconvenient and frequently painful.

Of all his senses man depends most upon sight. Unfortunately the eye is one of the most delicate organs of the entire body, and because of this delicacy and its exposed position it is readily liable to injury if not protected by some artificial means. The more progressive companies have long made their employees wear goggles when performing certain kinds of operations, notably chipping and grinding on brittle or abrasive substances. Usually glass goggles either with or without wire reinforcement have been used. Non-breakable transparent substances, such as celluloid, have also been adopted to some extent.

Any goggle has its obvious shortcomings; all require the wearer to look through something which at best is not entirely transparent, and thus obstructs sight more or less. They put an added strain upon the eyes they protect. If made of glass they are frequently broken or shattered by pieces of flying material.

A somewhat recent type of goggle is one that employs no glass or other transparent substance that the vision of the wearer must penetrate. It consists simply of a netting of spring-steel wire of suitable mesh, formed to fit the face. This is held in place by a strap around the head. This netting effectively protects the eyes from flying particles of any appreciable size or those large enough to do harm. The netting is, of course, "out of focus" and has the effect of obscuring the object viewed to only a slight degree.

Some mining companies have made the wearing of goggles compulsory for all underground workers. At one group of operations a certain type of goggles has been adopted as standard, and no man allowed to go to work underground until he has procured a pair and

Digitized by Google

knows how to wear them. The safety inspector at these works states emphatically that the number of eye injuries reported to him since the wearing of goggles has been made compulsory has been greatly reduced.

Test the Latch

ONE DIFFICULTY that purchasers of coal and other bulk materials sometimes encounter is the receipt of cars of the usual hopper-bottom type, the gates of which often are opened with difficulty. In such instances the ordinary wrench will not operate the ratchet, and only by a sledge and bar can it be released. When the door finally opens under such treatment, the ratchet spins and is liable to catch the bar with disastrous results to those nearby. Severe bruises, broken bones or fractured skulls sometimes result.

It would seem that no campaign for safety is adequate that is limited to putting safeguards around the placing of the mine product upon the car. Of course, cars should be in proper condition when placed on the mine sidetrack, but that this care is not always taken is eloquently attested by the piles of extra doors and the bales of excelsior that may be seen at many mines. A few minutes spent in putting the gate-latching mechanism of a car in workable condition before loading may be the means of averting a severe accident at destination. Next to protecting its own employees every coal producer should endeavor to protect those of its customers.

Preparation for Winter

WHAT OUR patient submission to the rigors of winter costs us we may never know. Some have thought it a preposterous notion to heat city streets and sidewalks, yet meantime the Illinois Central R.R. has been actually endeavoring to melt the snow on its railroad tracks. Three methods are used: Steam pipes laid *on* the ties, laid *between* them at switches and laid in melting pits between the tracks. The first method is new; the other two have been used on parts of the company's terminal lines.

A large development of the practice is being installed in Chicago. In one place where there are inclined tracks on a 3-per cent grade to pass under a right of way the incline is protected for 365 ft. by a steam radiator system with ample drains to carry off the melted snow in addition to ordinary surface drainage. The main steam pipe and its headers will remain in position permanently, but the radiator pipes and return headers will be placed early in the winter and removed in the spring.

It is needless to refer further to the pipes between ties at switches but something should be said as to snow-melting pits. Snow could be shoveled into cars by hand shovels, but frequently that is not practicable because traffic would be blocked while the snow was being removed. Only too often the snow has to be carried in shovels by hand and dumped at some convenient point. That practice is both dangerous and expensive.

Snow-melting pits, 3 x 6½ ft. wide and long respectively and 20 in. deep are placed between some of the tracks at intervals of 95 ft. In these are laid pipes with small holes drilled in them so that jets of live steam aid in melting the snow. The various pieces of heating equipment described receive steam from the boiler of a locomotive which is run onto a side track for that express purpose, whenever conditions demand it.

The large number of people traveling on urban and suburban roads justifies the taking of expensive means to assure that the tracks will be available at all times. Heating is timorously moving outside of buildings into the open air. It will involve too large an expenditure, however, if care be not taken to keep the convection and radiation from heating the air instead of the snow.

The heating of the air entering the shaft at Glen Rogers to prevent the freezing of the shaft is another example of this use of steam. In these days when skyscrapers are many times as high as the streets are wide, and when the people in the high buildings are so numerous that if there were a fire they could not all congregate on the sidewalks in front of the building, something must be done, and will be done, to make possible the elimination of snow. Some day a snowfall in a crowded city will be unthinkable.

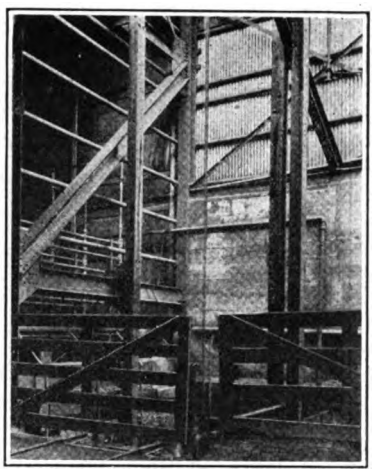
On Probation

THE SEVEN-THIRTY morning whistle at the New Orient mine, Illinois, heralded, on the first day of this month, the resumption of operation at a plant which had been idle for several months previous. Old employees were notified of this even in advance, so that on the reopening day a nearly complete complement of men was available. News that the great operation had resumed, spread far and wide, and each day brought scores of men to the plant in search of work.

At noon on the fourth day the rush for jobs attained its greatest impetus. The New Orient shafts are sunk on the outskirts of West Frankfort on a hard road which makes easy travel to and from Benton (six miles away) and other nearby towns. The surface buildings and yards at the plant are fenced in and admission to the inclosure is through a gate on the road. Immediately within the gate is an employment office.

Scores of miners travel to work in automobiles. On the day noted the road-end of the inclosure was crowded with automobiles to the number of 198, by actual count, exclusive of those belonging to the employed miners who park their machines further within the gate. Many other machines were parked on the outside along the road. The owners of these automobiles and their companions formed in a line which extended through the gate and backed on to the highway. There were probably more than three hundred of them. These men represented one day's crop of idle miners of southern Illinois in search of work.

Unless the local chapter can enforce discipline within its ranks to the extent of securing an honest day's work from each of its members, in addition to those now idle, about eleven hundred more men, the approximate number now employed at New Orient mine, may also find themselves jobless. The daymen must earn their wages and the contract miners must load easily merchantable coal, if New Orient or any other mine under the Jacksonville scale is to compete successfuly with non-union mines.



These men are on probation and from now until the termination of the present contract will demonstrate to the point of finality the possibility of operating under the union system. Only by producing a larger tonnage per man than the non-union miners who receive less pay, and by meeting competitive conditions, can they show that their demands for a high-wage rate are reasonable.

Pre-Heat Air at Glen Rogers Mine Chiefly to Prevent Ice Formation in Wet Shaft

Exhaust Steam from Fan Engine Passes Through Radiators and Is Then Discharged Into Intake—Pre-Heating Saves Concrete Lining by Eliminating Frost

By Alphonse F. Brosky
Assistant Editor, *Coal Age*, Pittsburgh, Pa.

The headpiece shows the collar of the shaft at Glen Rogers mine with some of the heating pipes which warm the air in winter thus preventing the formation of ice and the injurious effect of frost on the shaft lining.

AS A MEANS of humidification, the pre-heating of air by radiators and the introduction of the heated air and steam together into the mine after the steam has lost much of its heat, is an old scheme. But at the Glen Rogers mine in Wyoming County, W. Va., the practice was primarily adopted not for humidification but to prevent the formation of ice in the intake compartment of the hoisting shaft which is exceedingly wet and, concurrently, to avoid deterioration of the concrete lining in cold weather. Steam radiators were installed at the head of this shaft for this purpose last year when the mine was owned by the Raleigh-Wyoming Coal Co. Reports declare that by virtue of a recent deal this plant became the property of the Old Ben Coal Corporation, of Chicago, Ill.

The seam being worked at this mine is the Beckley, which lies at a depth of 640 ft. as measured in the hoisting shaft. The latter is of three compartments, two of which are equipped with skips. The third serves as an upcast to the fan. The lining is of concrete of a 1:2:3 mix, the inside measurements of which over-all are 14x28 ft. The skip compartments which measure in aggregate 14x18 ft., serve as a downcast.

From the surface to solid rock is 300 ft., this interval bearing water in such quantity and of such pressure that about 100 gal. per minute seep through the lining, though the latter is of rich concrete and has back of it drains of generous proportions which handle about 400 gal. per minute. Below the 300-ft. level the strata are devoid of water. Incidentally, it may be said that the water which is caught by the drainage at the back of the lining is pumped to the surface for domestic use and for power-plant purposes.

THE SCHEME WORKS

AT Glen Rogers it has been proved as a fact that exhaust steam can be used not only to humidify the air which passes into a mine during the winter months but also effectively to heat that air to the degree at which no ice will form on the sides of the shaft and other intake passages. The installation greatly increases the relative humidity of the air, and by eliminating the ice it also preserves the concrete lining and assures uniform ventilation by maintaining an intake of constant area on warm and cold days alike. The plan is successful even though a number of experts predicted that it would fail of its purpose.

The afore-mentioned shaft, though used at the present time as the main hoistway, is intended eventually to serve as the second opening. A 10x20-ft. shaft has been sunk and lined, which eventually will serve as the sole hoistway for coal. Both shafts made much water during the sinking operations and were extensively grouted before the linings were placed. The grouting in the shaft which will serve for hoisting in the final plan thus far is holding back the water; but that in the shaft now being utilized for hoisting has not acted so effectively. It served its purpose for a while, but gradually leaked under the hydrostatic pressure behind it to the extent already stated. The idle shaft is now serving as a downcast, assisting in this capacity the two skip compartments of the present hoisting shaft.

Glen Rogers lies high in the mountains of Wyoming County where in the winter months the thermometer registers many degrees lower than it does at places which are not far distant but lie at lower levels. The temperature often hovers around 10 deg. below zero for days at a time. Occasionally the mercury drops to —20 deg. Last winter the weather at this place was unusually severe. Prior to 1925 much difficulty was experienced in hoisting coal on very cold days, because some of the water which leaked through the lining into the downcast skip compartments froze on meeting the cold intake air. In consequence, much time was lost in ridding the shaft of ice, and in extremely cold weather the mine sometimes remained idle throughout the day so rapidly did the ice form in this shaft.

As a result not only was hoisting at a standstill part of the time, but, as might be expected, ventilation was impaired to the degree to which the intake was constricted by ice. Furthermore, the freezing action caused deterioration of the lining, particularly as the

Digitized by Google

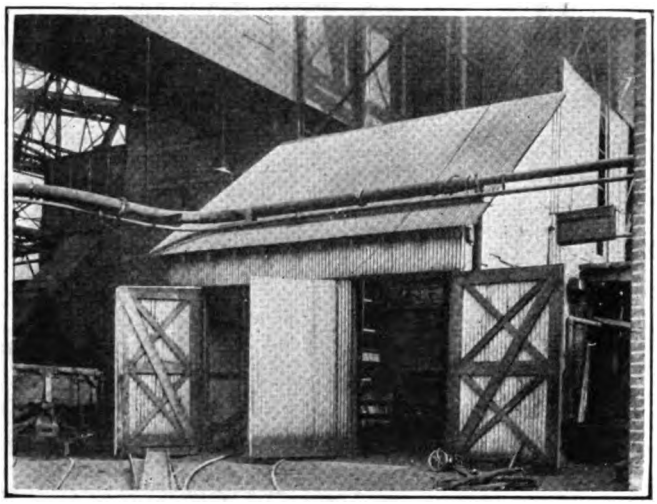

Fig. 1—Shelter in Which Air Is Pre-Heated

The sheet-iron structure and the box-like annex on the left inclose about 25,000 cu.ft. of space in which is installed the radiators or heaters. Air is drawn over these heaters through the skip opening in the roof of this housing. In the winter time the doors shown are kept closed. The chute over the contractors' side-dump car seen on the left is for rock. It is inclosed and heated so as to keep from freezing any water which might accompany the rock.

weather has proved to be changeable at this place. A cold day is frequently followed by comparatively warm weather.

These are the primary factors which compelled the management to install a combination system by which the intake air is both pre-heated and humidified before entering the hoisting shaft.

To this end a series of radiators are located in a housing over the mouth of the skip-hoisting shaft, and through them exhaust steam from the fan engine is conducted. After passing through these radiators this steam is exhausted into the shaft where it further assists in raising the temperature and also humidifies the intake air.

SHEET-METAL HOUSING PROTECTS SHAFT

As indicated in Fig. 1, a sheet-metal housing has been constructed over and around the mouth of the skip compartments of the shaft. This structure shelters about 15,000 cu.ft. of air and is provided with an opening at the top through which the skips travel, and with doors on the front through which men, cars and supplies are admitted.

A somewhat similarly inclosed shelter lies on one side of the shaft and connects with the main housing. It is covered by canvas and roofing paper in such a way as to shelter a rock chute leading from the tipple. This chute must be thus protected to render it operative on cold days because much of the rock which is deposited in the chute is wet. In addition to sheltering the rock chute, this wing or annex incloses 10,000 cu.ft. of space in which pipes can be installed clear of the shaft and its approach. The present covering of canvas and roofing paper is to be replaced with sheet iron.

In these two connecting shelters are installed the radiators which pre-heat the air as it enters through the top opening for the skips. The fan engine (see Fig. 2) which furnishes the exhaust steam is a 14x14-in. reciprocating unit which drives a 14x6-ft. fan. It has a speed of 120 strokes per minute and a working pressure of 170 lb. per square inch.

The exhaust steam from this engine is conducted through a 6-in. pipe which is run around three sides of the shaft. From this pipe is tapped a tier of eight 3-in. pipes, each 14 ft. long, on each of two sides and a tier of six 3-in. pipes, each 28 ft. long, on the third side. The general arrangement of these is shown in the headpiece.

On each side of the main housing, between the exit doors and the safety gates of the shaft, is a radiator which is made up of seven 2-in. pipes, each 10 ft. long. One of these tiers of radiators is shown in Fig. 3. In the annex housing which incloses the rock chute are three sets of heaters, each of which is composed of seven 1½-in. pipes, each 16 ft. long.

PIPES GO DOWN INTO SHAFT

These pipes are in a continuous circuit, from which the steam is exhausted through twenty 1-in. pipes which project vertically into the shaft in the manner shown in Fig. 4. The lines are connected so that live steam from the boilers may be turned into them on extremely cold days to assist the exhaust steam from the fan engine in heating and humidifying the air which enters the mine. As now arranged the heating system consists approximately of 56 ft. of 6-in. pipe, 392 ft. of 3-in. pipe, 336 ft. of 2-in. pipe and 140 ft. of 1½-in. pipe.

At the time of my visit the mine management expressed its intention of increasing the size of this heating plant to two to three times its present capacity. The additional heaters would be installed in the annex which incloses the rock chute. The proposed plans call for a 6-ft. slow-speed fan which would be installed in

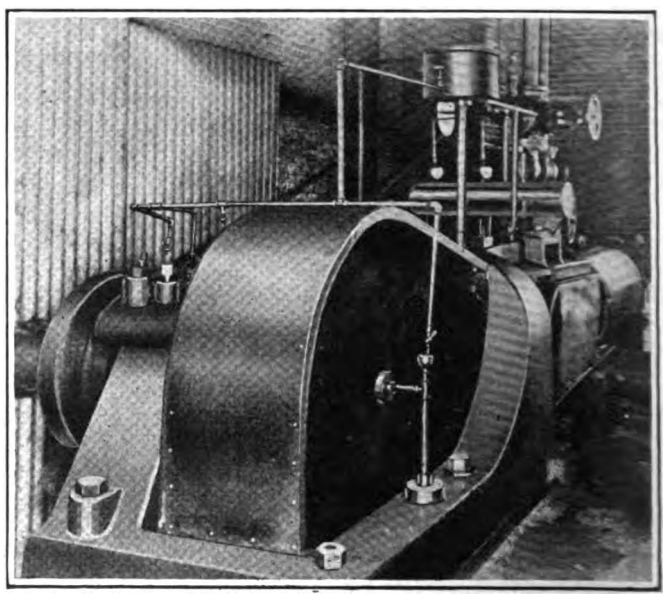

Fig. 2—This Fan Engine Supplies Exhaust Steam

This is a 14x14-in. reciprocating engine which operates at 120 strokes per minute under 170 lb. of steam. In extremely cold weather live steam is introduced with the exhaust from this engine into the radiators.

the far wall of this annex so as to draw air from the outside and blow it over the heaters and at the same time minimize the quantity of air which would find its way directly into the shaft through the skip openings in the roof of the main housing.

Each heater or radiator would be controlled by a valve so that any of them could be cut out should a leak occur. All of the exhaust from this enlarged unit would be discharged into the shaft where it would mix with, and be absorbed by, the warm air of low relative humidity which would enter the mine.

It is believed that some advantage would be derived by inclosing the headframe legs to a greater height.

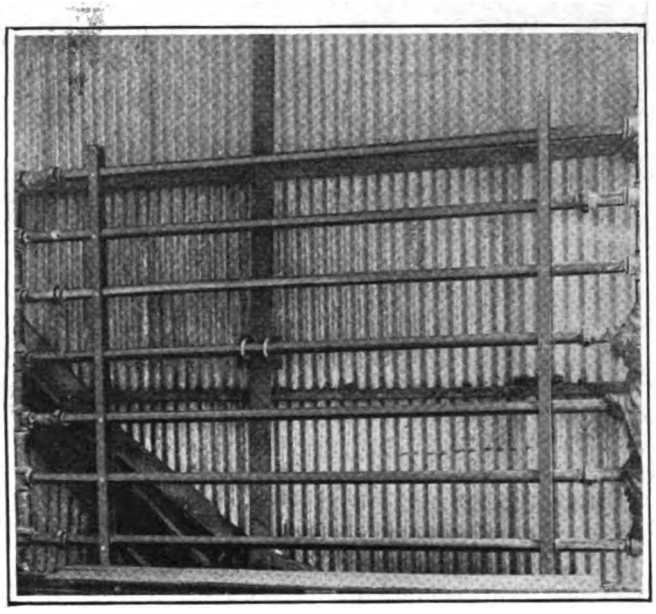

Fig. 3—One of the Radiators for Pre-Heating Air

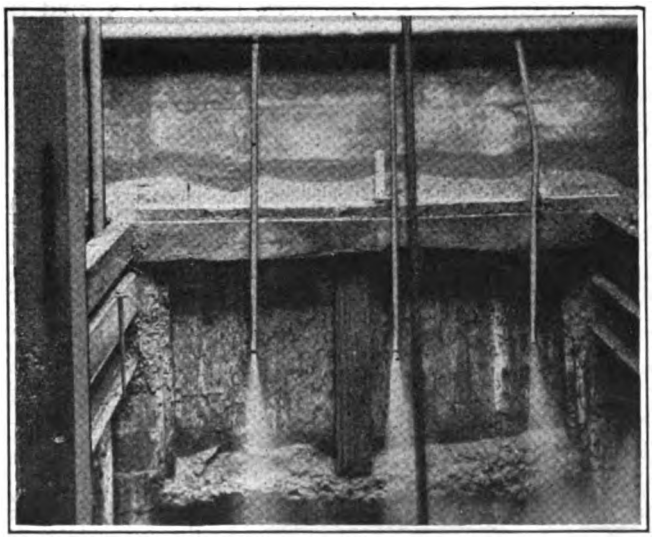
This is one of two heaters which are installed on each side of the housing in the approach to the mouth of the shaft. The management expects to alter and enlarge this heating system. When this is done each of the radiators will be controlled by a valve so that any one of them can be cut out from the steam circuit should a pipe or fitting leak.

The proposed changes would be made more to increase the radiation surface and thereby boost the temperature of the intake air with a minimum discharge of steam into the shaft. The present heating system was found of sufficient size during the past winter to prevent the formation of ice in the shaft and to maintain a fairly comfortable temperature at the shaft bottom even when the outside temperature falls as low as 20 deg. below zero.

Glen Rogers is extremely gassy, and though rock dust is being applied to attenuate the coal dust, the maintaining of a high relative humidity in its atmosphere by this conditioning plant gives a further assurance of safety to the management and men. The plan not only keeps ice out of the shaft and preserves the concrete lining, but also tends to keep down the dust. It is said that when the thermometer registered 20 deg. below zero a relative humidity of 90 to 100 per cent was maintained in this mine.

This practice has not caused any noticeable slacking of the roof at the shaft bottom, as it is said to do in other like cases. The introduction of much steam into a shaft will cause a fog unless the air is sufficiently heated to maintain a fairly uniform and high temperature within comparatively wide limits as measured from the shaft bottom. The management at Glen Rogers expects to maintain this condition after the heating plan is increased in size.



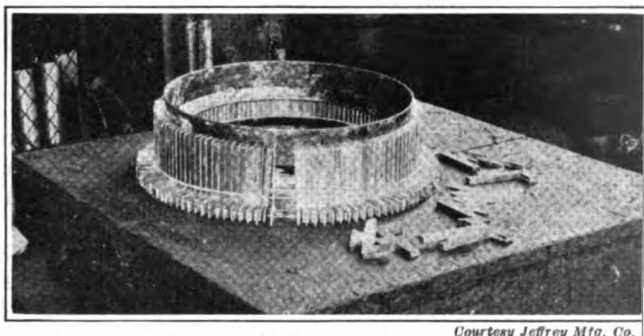


Fig. 4—Exhaust Steam Discharging Into Shaft

After passing through the radiators in a continuous circuit, the exhaust steam from the fan engine is discharged into the shaft. By this means, it is said, the relative humidity in this mine has been maintained between 90 and 100 per cent in the coldest weather. The heating system by eliminating ice in this extremely wet shaft is preserving the concrete lining. Note the deterioration of the lining which was caused by freezing prior to the installation of the heating plant.

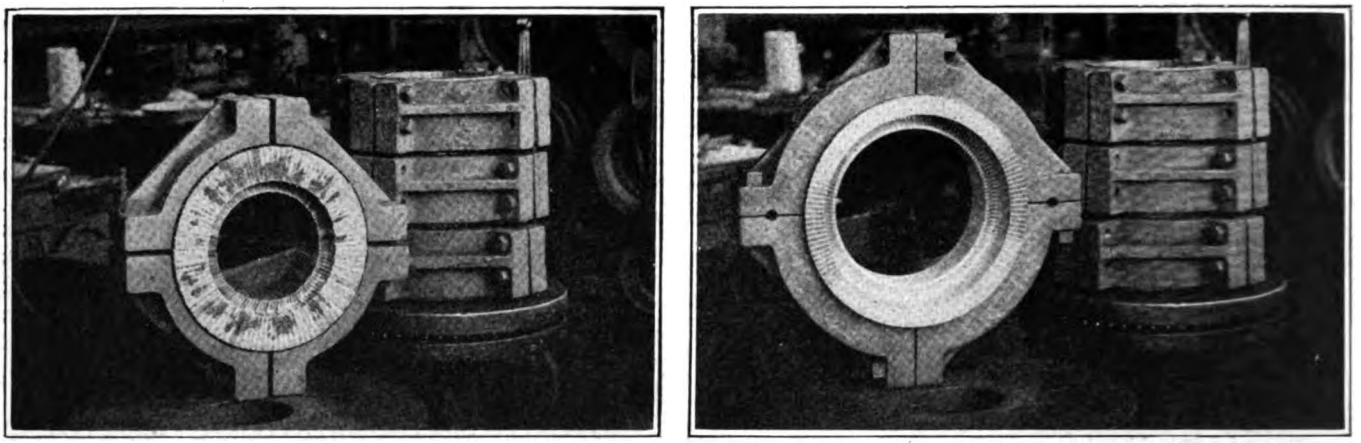
Commutator Refilling Is Not a Mine Shop Job

Among the factors that have been responsible fo reducing the maintenance cost of direct-current motors "better commutators" holds an important place. N doubt the manufacturers of electrical equipment ar

Courtesy Jeffrey Mfg. Co.

Fig. 1—Refilling with New Mica in a Mine Shop

Ten to fifteen years ago work of this kind was common in mi repair sho s. Commutators rebuilt in this way seldom give servi comparable to that afforded by a factory job.



largely responsible for this improvement. Nevertheles the tendency of the users to do less commutator r pairing or rather, "patching," has resulted in a marke decrease in armature failures.

The commutator is more than simply "a link in th chain of parts," making up the complete motor. Fo example, a short circuit between two adjacent bars ha a more serious effect than to cause a shutdown of th motor for the purpose of removing the short. Usual such trouble is not detected until one or more armatu coils are damaged or completely burned out. Becau of the difficulty encountered in raising coils in windin that have been dipped and baked, any attempt to repa or renew one or two coils is likely to end in a comple rewinding of the entire armature.

It is significant that many of the large coal produce do their own rewinding but a number have practical abandoned all commutator repairs. They may in a emergency renew a few insulating segments or a mi V-ring, but as a rule, they either buy a new commutat or send the damaged or worn one back to the man facturer or to a commutator specialty company for r filling.

It is in the shops of the small to medium-sized co panies that commutator repairing is still the rule. however, those responsible for the work in such sho could see the special equipment used and the care tak in building up a commutator at the factory, they t would realize the shortcomings of their repair metho and would follow the lead of the larger coal compan in sending their commutators away for refilling.

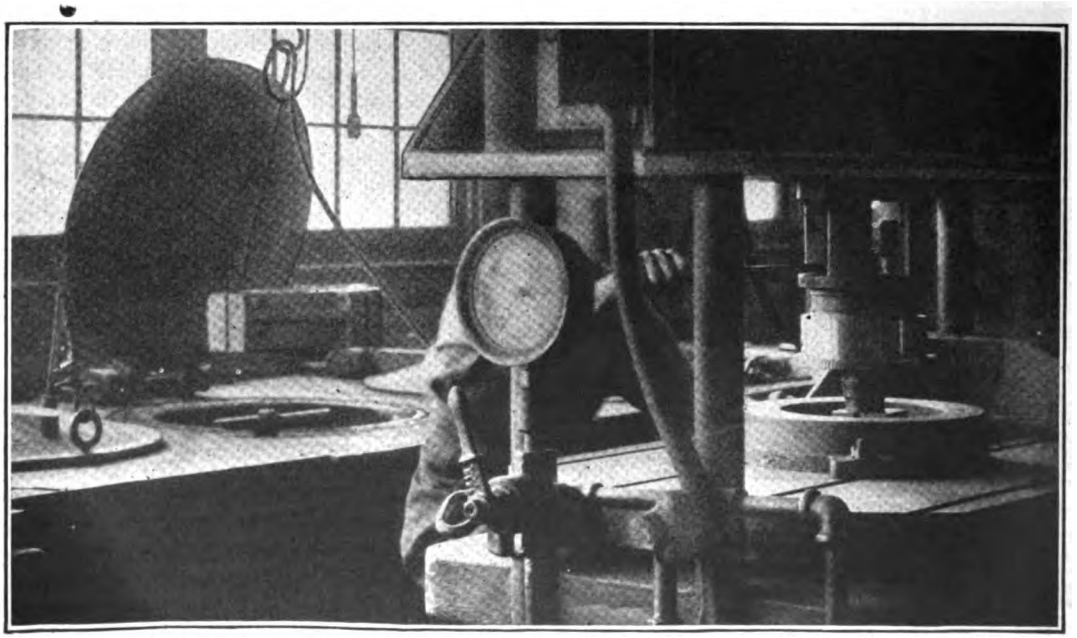
Fig. 2—Factory Views of Building a Mine Locomotive Commutator

At the left is a rough commutator after it has been built up, heated in the electric oven, and the clamping bolts drawn down tight. The combination of heat and pressure drives out all excess binder from the insulating segments. The three rough commutators, in clamps, piled on the ball bearing stand, are being given a few days to "set" during which time the clamping bolts are tightened at regular intervals. At the right is a commutator after it has been bored and the ends faced. The true inside surface assures a perfect seat for the bars on the mica V-rings and assures that all parts will be in proper position.

Fig. 1 is typical of commutator repairs in the ordinary mine shop. In this case a complete set of new mica segments is being installed. After the assembly is completed, the commutator will be tightened by drawing up the V-ring bolts while heat from a blow torch is applied to the bars.



Common faults of this method include: (1) frequent use of mica of improper thickness or of mica that has been damaged by handling; (2) unbalanced armatures as the result of commutators being assembled slightly out-of-round or eccentric on the inside; (3) commutator bars not properly seated resulting in operating troubles from high or low segments; and (4) mica segments not sufficiently compressed to prevent oil or other foreign matter from working into the commutator, collecting dust or other impurity and eventually causing sparkover.

A marked contrast to the procedure depicted in Fig. 1 is presented by the typical factory method illustrated in Figs. 2 and 3. After the bars, which are in the rough so far as the edges are concerned, are assembled with the mica segments, the whole commutator is put into a four-section clamp, as shown in Fig. 2. Next the entire assembly, clamp and all is heated in an oven and the heavy bolts of the clamp tightened as much as possible. This compresses the mica segments so tightly that all superfluous binder is squeezed out.

After the initial heating and tightening, it is the usual practice to let the commutator stand several days during which time the bolts of the clamp are tightened at regular intervals. Next comes the boring and end-facing operation, which is done with the clamp in place. Fig. 2 (right) shows the appearance of the commutator after this machining has been completed. The inside is perfectly true, affording an opportunity for uniform seating of the bars against the V-ring.

Assembly of the commutator and V-rings on the shell is done in a hydraulic press. This results in imparting the same tightness to these insulating rings as was imparted to the segments. The clamp is not removed until after the final tightening of the V-ring bolts. Turning of the wearing surface and milling of the lead slots completes the job.

It is easy to see the difference that will likely exist between a commutator assembled by factory methods and one put together in a mine repair shop. The use of special clamps and the practice of boring the inside after assembly of the bars are prerequisites of a high-grade commutator. This work is not of a kind that can be handled economically in the mine shop.

Courtesy Jeffrey Mfg. Co.

Fig. 3—Press and Oven

Hydraulic pressure is applied in assembling the clamped commutator with the mica V-rings on the shell. After the V-ring bolts are tightened under pressure the clamp is removed and the wearing surface turned. In this photograph a completed commutator was placed in the press to illustrate how the bolts may be tightened while the commutator is under pressure. In the left background is a clamped commutator ready to be lowered into the electric oven.

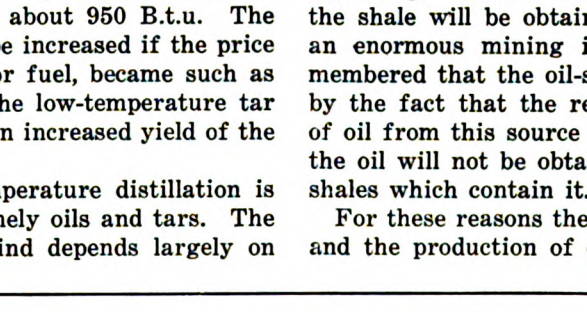
What Oils Can Be Obtained from Coal By Low-Temperature Distillation, and What Will Be Their Commercial Use

By R. L. Brown and R. B. Cooper

AS LOW-TEMPERATURE carbonization will furnish us with a smokeless household fuel, will broaden the use of the lower grades of coal and will reduce wastes, it is a subject well worthy of study. By low-temperature distillation a combustible can be made from bituminous coal that will replace our diminishing anthracite supplies, giving a fuel that is less difficult to fire than coke. In fact, responsible engineers have proposed distilling coal at a low temperature, recovering the oil and passing the resultant coke directly into the boiler furnaces of a power plant.

Low-temperature carbonization will convert coal into coke and gas and, with this process, coal could be used that was neither suited to the making of metallurgical coke nor particularly well fitted for gas making. However, for the manufacture of gas there seems to be no advantage in low-temperature carbonization. The high-temperature process gives 11,000 cu.ft. gross of 575 B.t.u. gas, whereas low-temperature carbonization gives about 4,000 cu.ft. of about 950 B.t.u. The volume of this latter gas could be increased if the price of gasoline and, therefore, motor fuel, became such as to make it profitable to crack the low-temperature tar under pressure, thus obtaining an increased yield of the latter.

The third product of low-temperature distillation is liquid or semi-liquid bodies, namely oils and tars. The value of any process of this kind depends largely on the profitable utilization of the products so obtained. In England and in Germany some progress has been made in ascertaining the composition of this class of material, but in this country the tars have had only limited study. Inquiries into the possibility of utilizing low-temperature oils and tars should include a study of their possible use as motor fuel and as fuel oils and as to their availability for use as creosoting material and in Diesel engines.



As a consequence of the creation of a Federal Oil Conservation Board, the Board of Directors of the American Petroleum Institute has investigated the quantity of oil in reserve has reported that there are 5,300,000,000 bbl. of pr reserve recoverable from existing petroleum wells fields by present methods, and that the annual p leum consumption is about 800,000,000 bbl. As cated by M. L. Requa, head of the Oil Division o U. S. Fuel Administration during the war, an others, it would appear that in a relatively short new sources of motor fuel must be found to re those rapidly becoming exhausted.

If the deficiency is to be met by oil from fields u American control outside the borders of this cou the cost must necessarily be higher than at pre and if the oil required is to come from outside under foreign control, the cost will be still greater

It must be remembered, however, that the depl of the oil supply from wells will possibly be para or followed by developments in the production of oil, though oil thus obtained may not be cheap be the shale will be obtained only by the developme an enormous mining industry. It must also b membered that the oil-shale industry will be ham by the fact that the residue left after the produ of oil from this source is practically worthless, so the oil will not be obtained without difficulty fro shales which contain it.

For these reasons the price of oil is likely to be and the production of oil from the distillation of will doubtless assum dimensions of a larg dustry. We shall pro have a greatly incr recovery of light oils coke-oven gas in the m facture of which high peratures are being Processes have been oped that yield about of motor fuel per which figure can be m doubled by subjectin tar fraction to cra under pressure. Coke easy burning domesti and, moreover, time probably show that well suited for us power plants.

During recent yea technology of the leum industry, and ticularly of petro refining, has made strides. Only a few ago gasoline wa straight-run. As th mand has increased industry has dev technically, cracking,

breaking up of heavy oils into gasoline, has made so much progress that now it is reported that nearly 90 per cent of certain oils is converted into gasoline. A short time back, gasolines were being universally treated with concentrated sulphuric acid to remove the olefine hydrocarbons. Research has shown that these olefines are actually desirable as they give gasoline its anti-knock properties.

Other conditions being the same, the higher the temperature in the cracking process, the greater the production of lighter oils, and with still greater increases in temperature, there is a greater production of olefines and aromatic hydrocarbons. Both of these types of hydrocarbons are of an anti-knock quality. In general, the same principles hold in the distillation of coal.

The light oil from high-temperature carbonization is aromatic. The nature of the products obtained at various temperatures is well understood but the character of the products derivable from low-temperature distillation are only slowly being discovered.

Light Oils Recovered from Gas in Low-Temperature Distillation

	Per Cent
Pentane	2
Isopentane	8
Amylenes	30
Hexanes	10
Hexenes	17
Heptanes	7
Heptenes	5½
Cyclic olefines of seven carbon atoms	3½
Octanes and above	7½
Octenes and above	9½

Though our rich heritage of petroleum is rapidly being exhausted, we hold about 60 per cent of the world's supply of coal which will be adequate for the needs of many centuries; so coal will ultimately and inevitably be our principal source of motor fuel. It follows that before many years the United States must discover how best to convert its coal into motor fuel. At present there are three paths which research has blazed to that goal. These are being sedulously followed by investigators in the hope that a commercial process may be developed.

The first of these is the conversion of coal into water gas and the conversion of the water gas into liquid fuels. The second is the hydrogenation of coal to give heavy oils; and the third is based on the carbonization of coal at both high and low temperatures. The first of these three methods is under investigation, both in this country and abroad; inquiries into the second are being conducted solely in Europe. The third is certain to play an important part in augmenting our motor-fuel supply. One of the first two must come or we shall be, sooner or later, seriously short of such fuel. In looking for the valuable elements of coal, as released or generated by low-temperature distillation, the authors of this paper have looked, among other things, for motor fuel.

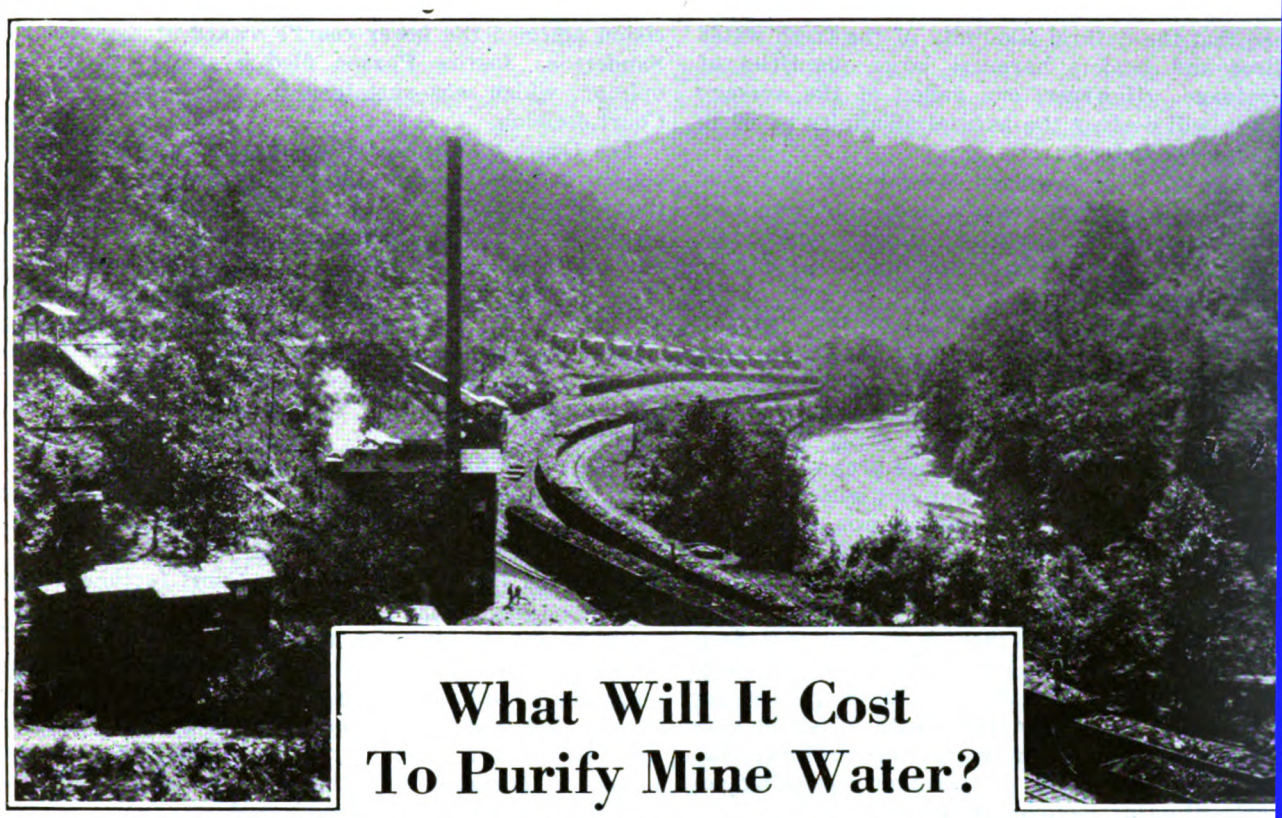
Research is always expensive, possibly because it can never be put on what is commonly called a production basis. It demands, and inherently must demand, individual brain and hand work, in fact, special piece work. In our investigation, we were able to take advantage of another inquiry in progress at the Bureau of Mines, and where, therefore, apparatus, retorts, cooling systems, coal and assistance were available. The miniature plant was such that the exact conditions existing in the distillation of coal could be duplicated. The distillation products from a weighed quantity of coal totalled 31 gal. and were stated as in the lower box.

A complete study has been made of the light oils recovered from the gas. Chemically, the oil boiling between 20 deg. and 200 deg. C., which is 68 deg. and 392 deg. F., was a mixture of the chemical compounds recorded in the upper box. This mixture has the same physical characteristics as casing-head gasoline, but has, in addition, the great advantage of containing over 50 per cent of olefine hydrocarbons. Consequently, if used as motor fuel it would possess in a high degree those anti-knock properties that are so much desired by motorists. It would, therefore, be exceptionally valuable for blending with other gasoline. It is a most interesting fact that in contrast to similar material from high-temperature distillation, it is relatively low in diolefines, which otherwise would have to be removed by a refining process; also, it is free from carbon bisulphide, a most objectionable constituent of gasoline, which is present to a considerable degree in similar material produced by high-temperature distillation. The increasing scarcity of casing-head gasoline for blending purposes puts particular emphasis upon these facts.

The presence of such a high percentage of anylene suggests a possible source of supply for the production of amyl alcohol and its esters by chemical synthesis. These compounds are extensively used in the fields of plastics, lacquers and smokeless powder. The oils and tars from low-temperature carbonization processes differ from high-temperature tars in having a greater resemblance to petroleum. They contain no benzol, toluol, naphthalene, anthracene or carbolic acid. However, instead of the ordinary carbolic acid, a low-temperature tar contains similar bodies of a much higher molecular weight.

We all know that high-temperature tar can be used not only as fuel but in timber preservation, the manufacture of tarred felt or tarred paper for building purposes, and as paint for stone, brick or ironwork. It is used extensively for road building, both as a binder and as impregnating material for wood blocks. It finds aplication as waterproofing and roof paints. It yields oils, benzol, toluol and carbolic acid, which are used for dyes, explosives and medicinals.

Whether low-temperature tar contains such a wealth of primary material can be discovered only by research or by further chemical investigation. It is probable that phenolic bodies are present, these being members of the carbolic-acid family. This suggests that, from coal, wood preservatives may be manufactured.



The physical properties of the neutral middle oils should be determined in order that these oils may be applied to uses for which they are fitted. The thought naturally occurs that, as the light oils are entirely aliphatic or petroleum-like in character, will not a lubricating grade of oil be present in the less volatile oils?

Low-Temperature Distillation
Yields per Ton of Coal

Resin condensate	100 lb.
Wax condensate	110 lb.
Medium oils	8 gal.
Light oils, recovered from gas	2 gal.

Of the medium oils slightly over 2 gallons were suitable for motor fuel.

What Will It Cost To Purify Mine Water?

Acid Effluent from Mine Can Be Made Neutral at Expense of From 37 to 57 Cents per Ton Mined and River Water Made Soft at a Cost of Between 70 Cents and $1 per Ton of Product

By Andrew Crichton
Consulting Engineer, Johnstown, Pa.

STREAM POLLUTION by mine drainage has long been a local problem but pending legislation and important court decisions adverse to the coal-mining interests have recently made it of national importance.

The pollution of domestic water supplies with acid mine drainage has resulted in many coal-mining communities in the abandonment of water supplies, the water company being compelled to find new sources of supply. To obtain satisfactory supplies the water companies were obliged either to move higher up stream above the coal measures or other source of pollution or to seek at great expense a source of water remote from contamination.

No subject, to my knowledge, has been so misunderstood as that of the pollution of streams by mine drainage. Misleading statements regarding it have been published and broadcasted by radio, by prominent National and state officials. Officers of sportsmens' clubs, conservation leagues, Isaac Walton leagues, fish commissions and others have erroneously stated how simply and inexpensively this pollution can be remedied. Prominent mining officials and waterworks engineers have misunderstood the problem and have made statements which are bound to confuse the public and may result in ill-advised legislation if not corrected.

After several years' study of this problem, I feel safe in saying there is now no known satisfactory s of this problem and no method by which acid water can be satisfactorily treated. If the wate be made fit for use at a cost of a few cents p as some government officials claim, the coal in once it realized the effect of mine drainage fresh-water supplies, would certainly not oppose ment.

No Longer Serve for Domestic Supply

At present nearly all the important streams of and western Pennsylvania are seriously contam from acid mine water. Most of these streams years ago were used for domestic water suppli are now unfit for any use.

Pittsburgh, the center of one of the greatest and manufacturing districts of the world, depe its water supply almost entirely upon the Monon and Allegheny rivers. The water in these rive to mine drainage and manufacturing wastes, is n for certain periods of the year and is growin acid year by year.

In an article on this subject written in 1923, the statement, since widely quoted, that of th square miles of coal on the Monongahela River d area above Pittsburgh only 400 square miles ha mined out. If mining but 6 per cent of the c made the flow from that entire area acid during part of the year, it will be but a comparativel time until the stream is acid all the year, and eve its usefulness will be destroyed beyond recovery

At present the total quantity of mine drai small as compared with the total stream flow

Article entitled "Mine-Drainage Stream Pollution" read at the "Annual Convention of Coal-Operating Officials" held under the auspices of the American Mining Congress at Cincinnati, May 24-28. The headpiece shows the Tug River at Panther, W. Va. where are the mines of the Panther Creek Coal Co. The Tug which receives the waters of Elkhorn creek and Dry Fork as well as those of other streams has for a long time resisted the acidifying action of its tributary creeks but is gradually becoming acidulous.

Digitized by Google

rivers, so that the natural alkalinity of the fresh water neutralizes and renders harmless large quantities of mine drainage. However, one gallon of the average mine water will destroy the natural alkalinity of 80 to 100 gal. of fresh water.

Practically all mine drainage is acid. Of over 300 mines examined in central Pennsylvania, only four were found to produce alkaline water. Dilution or contact with limestone would account for these exceptions. Rainfall is the source of all surface and underground waters. Of the total rainfall 40 to 50 per cent is run-off reaching the streams almost immediately and only about 25 per cent of the rest penetrates the ground, a portion of which becomes mine drainage. Only a small portion of the percolating waters reach great depth, so there is less water in deep mines than in shallow. Mine development is constantly increasing, producing more acid mine drainage, leaving less alkaline water in the streams with which to neutralize the mine water. The more mine drainage, the less fresh water, and with the constantly growing demands this situation requires attention.

On the Monongahela River drainage area are 7,000 miles of coal land and only 400 square miles have been mined out—just about 6 per cent. This has made the flow from the entire area acid part of the year. What will happen when sixteen times the area has been mined out, in view of the fact that the old abandoned mines still discharge acid water.

Our largest industries and public utilities have suffered most from the pollution of streams by mine drainage, because of their large and growing needs for pure water supplies. Nearly one hundred water companies in Pennsylvania have also similar problems, which are daily becoming more serious.

For years the interests of the mining industry have been considered paramount, but we are forced to admit that though coal is necessary, we must have water for our very existence, that one is dependent upon the other and that both are vital to the welfare and prosperity of our nation. The development of the coal industry has gradually progressed during most of the past century and cannot be said to have nearly reached its maximum. It has been a highly important industry to the welfare and security of our nation, as only the recent World War could demonstrate. Whatever ills have come with it have likewise been long in developing, so that good judgment and patient investigation, rather than drastic legislation, should govern us in handling this problem.

Sanderson's Water Supply Polluted

Mine drainage necessarily follows coal development, and any apparent disregard of the rights of others or the protection of water supplies may in a measure be attributed to the principle laid down by the Pennsylvania Supreme Court in the now famous Sanderson Case.

In 1886, Sanderson bought a property in the City of Scranton through which flowed Meadow Brook, a pure unpolluted stream. He built a dam and developed a water supply for his own use. The Pennsylvania Coal Co. at about the same time opened a coal mine, which soon produced acid mine drainage, destroying the use of this water. Sanderson brought suit for damage resulting from loss of the stream.

The case was twice tried in the courts of Lackawanna County, Pennsylvania and was twice before the Supreme Court of Pennsylvania. The first Supreme Court decision affirmed the lower court's award of damages to Sanderson; Justice Paxson filed a strong dissenting opinion, which was sustained in the second Supreme Court decision.

The Court took the position that if Sanderson could collect damages, every riparian owner thus affected could do likewise, and if they could collect damages they could also enjoin the pollution of streams by mine drainage, which would practically stop all mining operations, except by consent of the lower riparian owners; that trifling inconvenience to particular persons must sometimes give way to the necessities of a great community, especially where the leading industrial interest of the state is involved.

The Court further stated in its opinion that the coal company was making the natural and ordinary use of its property, and that Sanderson, with others, was then obtaining an abundant supply of pure water from other sources, but that it would not say that a case "may not arise in which a stream, from such pollution, may not become a nuisance, and that the *public interests* as involved in the general health and well-being of the community may not require the abatement of that nuisance."

The Pennsylvania R.R. forty years ago had to give up a water supply at Portage, Pa., due to mine-drainage pollution. It is one of the largest users of water in the state, and from time to time ever since has had to seek new sources of supply as older ones became unusable.

Reservoir Built to Escape Pollution

Shortly prior to 1905 the country suffered a severe drouth, old sources of supply had become polluted, attempted treatment of the water in large quantities was unsatisfactory, resulting in numerous engine failures, so that the railroad was compelled to haul water at great expense and with subsequent delays in operation.

Millions of dollars were appropriated to obtain an adequate supply for the present and future needs of the company, in the building of impounding reservoirs and in the laying of hundreds of miles of distribution lines. At that time it was not possible to find ample supplies of water reasonably convenient to points of consumption that were not being polluted or were not subject to pollution from mine drainage.

The Mountain Water Supply Co. was organized in 1905 and appropriated the waters of Indian Creek to supply the Pennsylvania R.R. system in southwestern Pennsylvania as far west as Pittsburgh, Pa. A large storage dam was built about four miles from the mouth of Indian Creek. The drainage area above this point is 110 square miles, of which 55 square miles is underlaid with the lower productive coal measures.

At the time, numerous small "country-banks" had been opened to supply coal to the farmers in the valley, but the coal lands had not been developed on a commercial scale. Several years later the Indian Creek Valley R.R. Co. constructed a standard-gage track from Indian Creek, a point on the Baltimore & Ohio R.R., up the valley to its head waters, but there was no material development of the coal resources until about 1917.

Digitized by Google

The Mountain Water Supply Co. and the Pennsylvania R.R. Co. have been anxious that some mutually satisfactory solution of this difficult problem be found, and they have spent thousands of dollars in an effort to find some means that would permit the mining of the coal without the destruction of this valuable water supply. The operation of their entire system in western Pennsylvania is dependent upon this reservoir for its water, and the anxiety of the companies regarding the result of the litigation is understandable. They appealed to the courts for protection of their rights only after it was apparent that the supply was gradually being ruined by mine water and nothing else could be done. The Fayette County court decided there was no public use of the water and that preventing the mining companies from discharging their water into Indian Creek would deprive them of the use of their property. The court refused to grant an injunction restraining the mining companies from putting mine water into this stream.

THE sludge from mine water will purify gas and it may be used in the manufacture of paint, but the demand is small enough now. What would happen if every mine were manufacturing it? It would then not even pay the barreling charges. New uses would have to be discovered. Until they are the cost of treatment will have no offsetting return.

COURT DECLARES MINE WATER A NUISANCE

The Pennsylvania Supreme Court reversed the lower court, declaring that it was not a question of property rights, but that it was a nuisance to pollute the stream, and that the coal companies should not after a certain period discharge their mine water into Indian Creek or its tributaries above the dam of the water company. The United States Supreme Court concurred in this opinion.

It should be added that the water company not only supplied water to the railroad but also to several municipalities in western Pennsylvania, aggregating about 75,000 people.

The court's opinion states, "It is controlled by one fact and a single equitable principle: The fact that the stream has been polluted, and the principle that this creates an enjoinable nuisance, if the public uses the water." As a result of this decision, there has been much discussion as to what constitutes mine drainage or mine water. It was admitted by both sides that eventually this mine drainage would destroy this water supply for the purpose for which it was then and is now being used.

Some of the leading chemists, waterworks and mining experts of the United States were witnesses in that case, and there was no disagreement as to the facts; that continued pollution by mine drainage would eventually render the water of this stream unfit for any use.

Much testimony was introduced regarding the treatment of mine water, and there was no material disagreement on that point. When a water supply contains 4 grains of sulphates per gallon (sulphates being a product of sulphuric-acid pollution), it will require softening, and when the pollution exceeds 12 grains of sulphates per gallon, treatment is no longer effective, for it requires the use of so much soda-ash that the waters become so heavily charged with solids that they foam in the boiler. It would, therefore, be but a short time between the period when treatment is required and when treatment would no longer be effective.

The neutralization of acid mine water by the introduction of lime does not make the water fit for either domestic or industrial use. This matter was clearly before the court and was undoubtedly the reason for the decree that the mine waters be kept out of the stream.

The difference between the Sanderson and the Indian Creek decisions is that Sanderson, an individual who had access to another good supply of water, was not permitted to stand in the way of Pennsylvania's greatest industry, whereas in the Indian Creek case the public, also represented by the Commonwealth, is fighting to preserve one of the last available pure water supplies in the state. However, this decision important as it is should give much less concern to the mining industry than pending legislation, for the Mountain Supply Co. had a case with some unusual merits to justify the decision of the court. The value of the water company's property is several times that of the coal, equipment and development of the mining companies. The water company's dam was erected nearly ten years before any of the coal was developed, and the company notified each coal operator in writing prior to development that that company would be held responsible if by any act it polluted the stream.

I do not believe that, because of this decision, any water company can prevent a coal company from discharging mine water into a stream from which the water company gets its supply without supporting facts and conditions to warrant it. However, I feel the time has come when the few remaining unpolluted freshwater streams of the state should be protected; otherwise, where will we get good water for our growing needs? The policy of the Pennsylvania Sanitary Water Board, represented by W. L. Stevenson, to protect the present unpolluted streams, should have our support.

SHALL USE OR BEAUTY BE TEST?

Much has been said about the cost of treating mine water, and there is much more confusion as to what is meant by treatment. The Conservation League wants a water in which fish will live, which will not kill bird life or vegetation. Every one would like the oxide of iron (which colors the beds of streams yellow) kept out of the water, and the domestic and industrial user wants a water fit for human consumption and commercial use.

From numerous determinations the average total acidity of mine water in central and western Pennsylvania has been found, as already stated, to range from 80 to 100 grains per U. S. gallon. The cost to neutralize a thousand U. S. gallons of such water has been variously estimated by different chemists at from 15 to 25c.

This depends upon the cost of lime, the cost of gathering the water to one central plant, the capacity of plant, the labor involved, and the cost of handling the sludge which in itself is an exceedingly difficult and expensive, if not impossible, proposition. The cost to construct a plant for lime treatment would be about $100 per thousand gallons daily capacity, or for a 1,000,000-gal. plant $100,000.

Digitized by Google

From measuring the flow of mine drainage and comparing it with the coal area exhausted in nearly 200 mines in Pennsylvania, we find the average yield to be 1,000 gallons per acre per day. A recent estimate of the acreage worked out in the bituminous mines of Pennsylvania, based on the total tonnage produced, would indicate a total daily production of mine drainage of 750,000,000 gal.

WOULD COST SEVENTY-FIVE MILLIONS

The cost to build lime treatment plants for this enormous quantity of water would be $75,000,000. The annual cost of treatment at 15c. per thousand gallons would be $41,062,500, and at 25c. per thousand gallons would be $68,437,500.

The estimate by Charles Dorrance of mine drainage reaching the streams from anthracite mines is 700,000,000 gallons daily, so that the above estimates for the entire state of Pennsylvania would be about doubled.

It must be understood the above cost is for neutralization only, and that even after this treatment, which is the one to which reference is most often made, the water is still unfit for either domestic or industrial use. To soften the water would cost more than double the above estimate for neutralization, and even with that the value of the product would be doubtful.

It will be seen that, with an annual production of 120,000,000 tons in the bituminous fields of Pennsylvania, the cost will be from 34 to 57c. per ton for neutralization and from 70c. to $1 per ton for softening.

In the bituminous fields of Pennsylvania alone from 4,500 to 5,000 tons of sludge would have to be handled daily, or 1,825,000 tons yearly. Even if dried and piled outside, it would be likely to reach the stream beds with every rainstorm. These beds eventually would be filled with this deposit. This iron oxide may be used for purifying gas and in the manufacture of paint, but it has a limited market, and with such quantities as would then be available it would be as common as dirt and without value. To mining men it would be nothing but slimy yellow mud, too thick to pump and too thin to shovel.

J. R. Campbell, formerly chief chemist for the H. C. Frick Coke Co., who built and operated the lime-treatment plant at the Calumet mine, has verified the above figures as to cost of treatment. Mr. Campbell has long been interested in this subject and probably knows more about it than any one else.

STAGGERING AND WITHOUT JUSTIFICATION

It is fair then to say that, with these tremendous costs in Pennsylvania alone, the cost of treatment for the coal industry throughout the nation would be staggering and without justification.

The Stephens Bill, H.R. 8310, introduced at this Session, is an amendment to the Rivers and Harbors act of March 3, 1899. It is similar to the Rosenbloom bill of the last session. It makes it unlawful within the limits prescribed by the Secretary of War to discharge any free acid into navigable waters or their tributaries. It places in the hands of the Chief of Army Engineers the power to require neutralization of acid water or wastes and provides a fine for each offense of $500 to $2,500 or imprisonment of not less than thirty days or more than one year.

The state and individuals have spent thousands of dollars in an attempt to solve this problem, but without success, so that the time has surely come for wise Governmental action—not the hasty passage of drastic laws as now proposed that would so greatly embarrass the mining and manufacturing industries but a sane public policy that will tend to preserve our water supplies at as little cost to the community as possible.

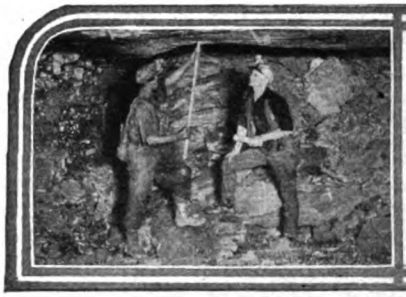
Secretary Hoover's suggestion of a careful investigation of the entire problem before the passage of legislation, is wise, and should not only have the approval but the hearty co-operation of the entire coal industry. Unless some mutually satisfactory solution of the problem is soon found, endless litigation may result between the waterworks and mining interests.

SHOULD RESTRICT NEW DEVELOPMENT

One thing seems certain, and that is that we cannot mine the coal without destroying the water in the mining regions. Therefore, I feel the only sure and practical method of conserving the water supply is to stop mining coal in some of the little-developed areas yet remaining. This cannot well be done as between individuals, and the Government or state would be justified in purchasing, if necessary, under some plan to be devised, the coal lands necessary for the protection of our few remaining water supplies in western Pennsylvania. That the state recognizes the importance of this problem is evidenced by its participation with the water companies in the Indian Creek case.

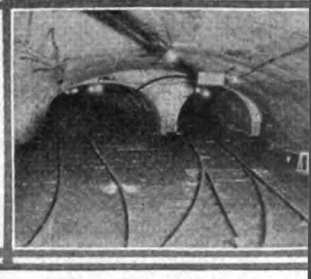
The coal industry is so greatly overdeveloped that an opportunity is afforded for a worth-while beginning of this policy. The coal industry is little to be censured for the pollution of the streams that its operations have caused. What it has saved thus far by its failure to take care of the water its mines have discharged has been passed to the public, as the industry for a long period of years has not been profitable.

Trace Sixty-Five Coal-Mine Disasters to Non-Permissible Powder



From 1909 to 1924 the quantity of permissible explosives used annually in the United States increased from less than 9,000,000 lb. to over 50,000,000 lb.

"Sixty-five of the explosion disasters occurring in American mines from 1908 to the early part of 1923, says D. A. Lyon, of the U. S. Bureau of Mines, were definitely found to have been caused by explosives igniting gas and dust. The total number of men killed in these 65 explosions was 758. All these explosions were found to be due to the use of non-permissible explosives. In fact, the bureau has no record of an explosion disaster having resulted anywhere, at anytime, in the United States from the use of permissible explosives.



"There is unquestioned evidence that undercut coal can be blasted by permissibles as cheaply as by non-permissible explosives. Under other conditions, where the direct cost of using permissibles may be greater, the indirect savings offset this, when the cost of compensation for killed or injured workmen, of interruption to work and of damage to property from explosions or fires caused by non-permissible explosives are taken into consideration."

THE WEST VIRGINIA COAL MINING INSTITUTE'S meeting which was to be held at Bluefield, W. Va., June 1 and 2, has been postponed until July 13 and 14 in order to avoid a conflict with other meetings.

Underground Operation

With Mechanical Loading, Cars Can Be Manipulated if Face Be Well Shot and Trips Available

All Car-Spotting Difficulties Vanish Where Machine and Main Haulage Give Loaders and Spotters Opportunity to Develop a Happy Rivalry

By Charles Gottschalk
Consulting Engineer, Evansville, Ind.

Spotting empty mine cars at a rate which results in the minimum delay to a mechanical loader is a difficult problem, for the principal reason that the rate of loading is seldom uniform. For instance a loader upon first entering a room or working place will often load out the first few cars at the rate of a ton a minute or better, and yet will require five, ten or even fifteen minutes to load a car when the standing coal is being attacked.

I am referring to loading machines as now employed in the Indiana and Illinois fields. They average according to conditions from 125 to 175 tons per shift. It is apparent that if the machines could load uniformly at the average rate of one ton per minute and do useful work 60 per cent of the time, the output would be 288 tons per shift. This is the tonnage that I predict present machines will approximate when their handling is better understood.

If coal is to be loaded mechanically at a uniform rate, the first problem is to bring the coal down in a free state or to employ a loading machine which is designed to mine as well as load, with or without blasting, as the case may be.

Second, where mine cars are employed there should be a reservoir between the discharge of the loading machine and the car, so that car changes can be made without stopping the loading machine.

Third, as long a face should be prepared at each location as roof conditions will permit, so that the loader will have to make but few locations per shift.

Fourth, each working place should be well lighted and ventilated.

Fifth, the partings for accumulation of loads and supply of empty cars should be of adequate length, and sufficient extra cars should be on hand to provide a surplus to draw on when unavoidable delays occur in haulage or in tipple operation.

Many other suggestions might be made, but I consider these to be the fundamental needs. The success of any plan that may be devised is so dependent upon these five basal requirements, all contributing to loading at a uniform rate, that a program in which they are not mastered will not be properly balanced and cannot result in success.

It is true that all operators look lightly upon these feat loading, and the attention t giving them is being refle larger and larger output p chine.

I have referred to the desi of getting a uniform flow Until this is accomplished reasonable working limits, it possible to deal intelligently v mechanics of car manipulatio us examine in detail the fac volved.

IDLE LOCOMOTIVES COST

If half the time two loco are required to furnish ca loader and at other times o motive is sufficient, the result about 50 per cent of the t investment in one locomoti the pay of one operator is loss. Also, it becomes almost sible to work out a main- schedule which will be efficie out demanding more idle c sidings than are normally r When these problems have be sidered, and only then, w changing efficiency be the ma of production per loader.

Digitized by Google

problems have been worked out with due regard to their importance, the problem of car changes becomes comparatively simple. In fact it almost vanishes. Under good conditions with no bad luck about 290 tons have been loaded repeatedly. This would represent an average flow of coal of one ton per minute for approximately 60 per cent of an 8-hr. period. This leaves 192 min. for car changes, for machine moves and for other delays. Provided the work is in rooms and pillars and in 6-ft. coal, and crosscuts are loaded out by machine, probably six moves per shift would be required. The time lost in moving should be well within 10 min. per move, leaving 132 min. Allowing another half hour for attention to the loader would leave 102 min. for car changes. Using a 5-ton car, fifty-eight car changes would be required. This would necessitate making a shift in 1¾ min.

If switches are kept within 150 ft. of the loader, the changes during an entire shift can be made well within that time limit. The arrangements of switches in rooms depends upon conditions which vary not only in different mines, but sometimes in the same mine. It depends also upon whether mules or locomotives are employed or a combination of both.

MULE SLOW FOR SHORT MOVES

Where the cars do not hold over 3½ tons of machine-loaded coal and grades are not severe, changes by mule have the advantage that by the use of a small parting in the room the mule can hook onto either end of the car, and the storage and switching space can be maintained at a minimum length. The big disadvantage of using a mule, however, is the clumsiness with which it will shift a car the short distances that are needed during process of loading if the car is to be filled to maximum capacity.

The loading machine can be moved while loading so as to maintain the proper relation of discharge to mine car, but that cannot be done without delaying the work. In rolling seams, the mule is at a much greater disadvantage than in moderately level beds. Under some conditions a mule and motor would work to good advantage, but the exact system of tracks and combination of equipment for making car changes must remain in many respects a problem varying with the conditions.

A pioneer operator in machine loading recently remarked that mechanical loading was 10 per cent equipment and 90 per cent organization. Certainly, organization does play a most important part. To obtain this organization, requires men with ability to lead and inject the spirit of friendly competition among the different loader sections.

Many skilful and loyal men utterly lack the power to give orders. Each machine operator should have this ability so as to be able to direct the little gang backing up the machine and keep them "pepped up" to the performance of their duties.

My theory is that if you keep the coal coming off the end of the machine conveyor, at a regular rate, the average organization will somehow contrive to take it away as opportunity immediately begets competition between the haulage gang and the loader crew. If, on the other hand, the coal is loaded in a dilatory manner, because of an irregular delivery of cars or imperfect preparation of the coal for loading, no possible arrangement for car manipulation will make up for this deficiency.

Nemacolin Finds Fire-Fighting Equipment Essential in Electrical Mine

By W. Z. Price
Assistant Superintendent, Buckeye Coal Co., Nemacolin, Pa.

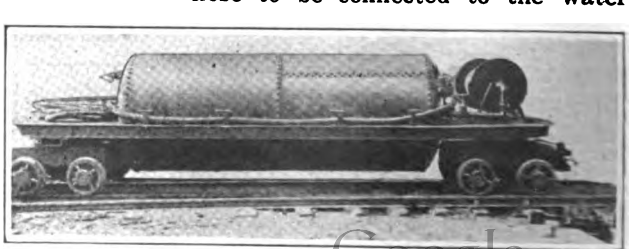
Mine fires originate from many causes and are a serious and formidable menace to operation regardless of their extent. Danger is ever present because of the evolution of noxious gases. A slight back-draft from the fire will preclude the workers from doing anything unless they are amply protected with smoke or gas masks.

The purpose of this article is to describe what the Nemacolin mine of the Buckeye Coal Co., a subsidiary of the Youngstown Sheet & Tube Co., is doing to prevent fires from assuming serious proportions. It must not be infered, of course, that the precautions it is taking are the last word in fire protection, but they represent the best means that they have been able to devise against this ever-present danger.

The first fire-fighting equipment on a large scale at Nemacolin was the so-called "tank-car." Two of these cars were built several years ago and have been extensively used for fire extinguishment.

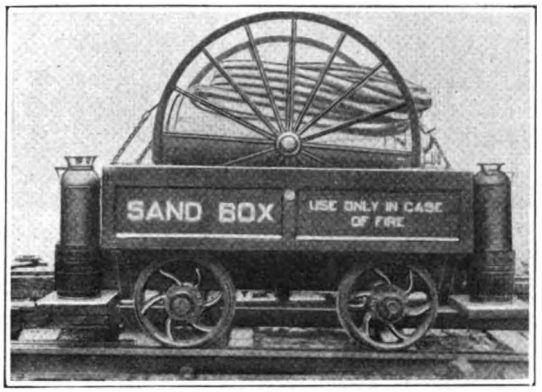
This car is a cylindrical tank with curved ends, 11 ft. long and 4 ft. in diameter. It rides on two platform trucks, being suspended horizontally between 5-in. H-beams. Its overall length is 18 ft. 6-in., its height 4 ft. 6-in. The width of the trucks is 4 ft. 9-in., yet the car will round with ease a curve of 16-ft. radius. It holds 700 gal. of water when slightly over two-thirds full, the remaining space being occupied by compressed air under a pressure of 100 lb. per square inch.

At one end, mounted on the same carriage is a reel holding 200 ft. of standard 2½-in. fire hose. This reel has a tank connection along its axis and is directly connected to the hose, so that in case of fire, the operative after extending the hose and opening the valve has a stream of water under pressure that bears favorable comparison to that available in most surface fire fighting.



As the tank will completely discharge the water in from 3 to 5 min., a second tank is necessary, the first being recharged meanwhile. The two cars have 400 ft. of hose. This will undoubtedly suffice to reach the fire in most places, certainly until additional lengths can be forwarded from the surface. Government-approved portable air compressors are provided throughout the mine, and these are used for charging the tanks after the water is discharged and the connections are closed.

On each car is a set of hose adapters which will enable the fire hose to be connected to the water



Article entitled "Fire Protection Underground" presented at the Annual Convention of Coal-Operating Officials held by the American Mining Congress at Cincinnati, Ohio, May 27.

Tank Car

Foamite Truck

This tank holds 40 gal. of liquid extinguisher. The truck, it will be noted, is mounted on a car, so that it can go on the track as far as the track extends and then can be dismounted and run on its own wheels to the fire.

lines which are standard. The hose couplings have threads conforming to the rules established by the Underwriters.

It is frequently necessary to get close to the fire and in such cases a Hayward nozzle is used. This is capable of throwing four separate streams simultaneously: A lateral spray at right angles to the nozzle with a working radius of 35 ft., a diagonal lateral spray just ahead of the first, another diagonal spray at the end and a direct stream.

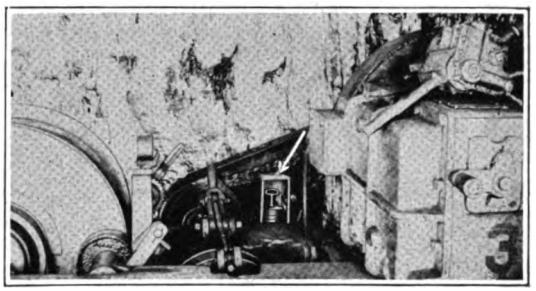
The nozzle has several detachable rings which vary the flow so that twelve different combinations of streams may be obtained. It is kept in a glass box in the lamphouse so that it can be seen and its availability known to all employees. Its great advantage is apparent for the three sheets of water will drive smoke ahead of the hoseman, thus enabling him to reach the scene of the fire with comparative ease and safety.

In addition, each working face has a 1-in. water line and a 2-in. line close behind. Thus water for refilling the tanks is always available. This sprinkling system is under a constant head maintained by a tank on the surface. The pressure is at least 100 lb. per square inch at all times. Each working face has a ½-in. sprinkling hose, so that in most cases a fire can be extinguished without bringing in the tanks. The main sprinkling line is a 6-in. pipe subdividing into fours and twos.

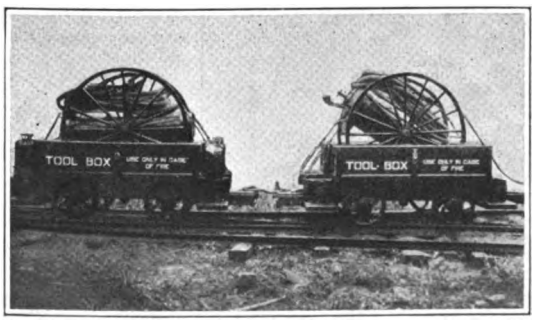
In passing, it may be said that the opposite end of the tank car from the reel can be equipped with a horizontal perforated pipe, so that the roof and ribs may be sprayed as by a street sprinkler. This was regularly used in Nemacolin until rock-dusting began. One tank load was found to sprinkle adequately 2,000 ft. of heading.

Other methods, however, are used at Nemacolin for fire fighting when the use of water, for any reason, is impractical. Each electric locomotive whether it be of trolley, cable-reel, or storage-battery type—and there are thirty-four in all—is equipped with a carbon-tetrachloride extinguisher. In each section of the mine are several 2½-gal. carbonated-solution sulphuric-acid extinguishers. This equipment has already prevented several serious fires. Defective blasting caps may ignite the explosive and hence the coal; a fall of rock on a battery locomotive may "short" the cells and another on a trolley wire may make "a short" on the rail thus igniting the loose roof coal thereabout. These are samples of potential mine fires which these 2½-gal. extinguishers have successfully smothered. The extinguishers are distributed in the ratio of one to every 100 tons of production. They have been found invaluable.

Lastly the mine is equipped with 40-gal. Foamite tanks. These are necessary adjuncts to the tank cars, as fires are likely to occur in places, such as aircourses, where no track is laid. Were the fire-fighters to wait, before acting, until sufficient hose was rushed in from the surface, the blaze might assume tremendous proportions.



These Firefoam engines are endorsed by the Underwriters. They are mounted on wooden carriage wheels and placed on small flat cars built especially for them and by which they can be transported over the rails as close as possible to the scene of the fire. They can then be pulled off the truck and pushed to any point desired like any two-wheeled cart.



On each flat car, in addition to the Foamite engine, are four 2½-gal. extinguishers like those previously described, a box of sand and another containing shovels, picks, axes, saws, hatchets, a bar, nails and a sledge hammer. These boxes are kept locked and sealed but are easily broken open if necessary.

This equipment, the management at Nemacolin believes, is needed at any electrically operated mine. Some thirty or more automatic reclosing section circuit breakers, and several hundred sectional line switches are helpful in handling fires, but these, of course, cannot be classed as fire-fighting equipment.

Extinguisher on Portable Air Compressor

Arrow indicates extinguisher.

Practical Pointers For Electrical And Mechanical Men

Control Power Taken Ahead Of Main Disconnects

Testing to determine the continuity of circuits and their freedom from grounds and from shorts to other wires usually afford the quickest way to locate trouble. A visual inspection seldom reveals the point of failure unless it is aggravated and has damaged the equipment.

In order to facilitate testing of the automatic control boards of substations and mine fans, J. F. MacWilliams, electrical engineer of the Pennsylvania Coal & Coke Corp., has not followed the manufacturer's diagram but instead has connected the operating transformers on the line side of the machine disconnecting switches. A close-up of the connection at Ehrenfeld No. 1 substation is shown in the above illustration.

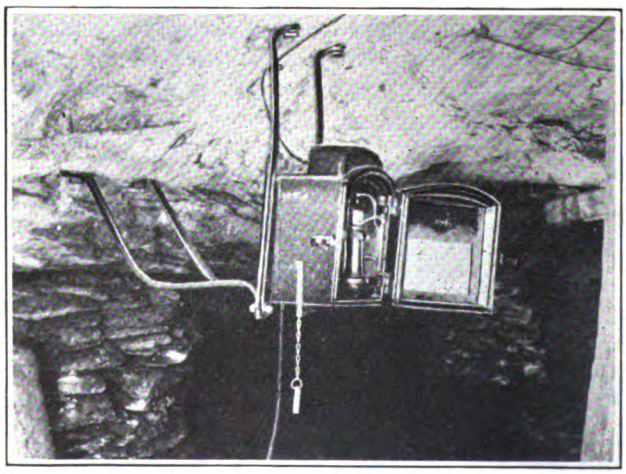
Arrangement at Ehrenfeld Station

Connecting the control transformer on the line side of the disconnecting switches allows the automatic boards to be tested without starting the motors or opening the leads to prevent starting. In the substations of the Pennsylvania Coal & Coke Corporation all bare high-voltage parts are kept above ordinary reach.

The conduit, through which the 2,200-volt line enters, terminates between the two disconnect switches. One switch feeds the fan motor and the other the motor-generator. At the top where the wires branch to the switches, the smaller leads which feed the control transformer, can be seen. This transformer is mounted on the wall in front of the lower left corner of the window.

Porcelain fused cutouts serve as disconnecting switches for the transformer. Many engineers object to the connection outlined above, believing that the function of a disconnecting switch is to "disconnect," and that therefore but one such switch should be used and that this switch should be in the main line so as to "kill" all wiring and apparatus when it is opened.

With the connection used by the Pennsylvania Coal & Coke Corporation, the only wiring left alive after opening of the two disconnect switches is the short run to the operating transformer. The other live lines are the low-voltage circuits on the control board. The arrangement permits making a complete sequence test of the control board without actually starting the motor or opening the leads.



Hung From Roof Telephones Give Less Trouble

Nothing is certain in a mine. Falls of roof and wrecks frequently disturb any stationary equipment that is installed in an exposed place along the roadway. Wrecks can be reduced to a minimum if sufficient money is expended in maintaining rolling stock and tracks. In most mines, however, derailments are common rather than rare, and this fact must be taken into account when installing certain equipment.

The usual method of hanging a mine telephone not located in an underground office or waiting room is to fasten the instrument to a post. But if a wreck knocks out the post the telephone is rendered useless or perhaps destroyed.

To overcome this trouble the Edgewater Coal Co., of eastern Kentucky suspends the telephone from the roof as shown in the accompanying illustration made from a photograph taken in No. 3 mine at Coaldale. The mine electrician claims that this method has the added advantage that it affords better air circulation around the instrument thus minimizing possible trouble from moisture.

Whenever equipment is to be operated under vacuum, says *Power*, none of the exteriors of the parts likely to be subjected to that vacuum should be painted before the equipment has been erected, started and the vacuum established. When thus painted any pores or cracks are thoroughly filled, and a visible improvement in the vacuum will be observed. If the painting is done before that time, the small openings will be covered over by a thin coat and paint will not penetrate them.

Telephone on Roof Bracket

Cars when derailed often knock down posts. If mine telephones are suspended from the roof their maintenance cost is reduced and more continuous service is obtained from them.

Current in Bearings May Cause Rapid Wear

Excessive bearing wear without noticeable overheating puzzled the chief electrician of a mine in central Pennsylvania. The troublesome bearing was on a 2,300-volt induction motor of the wound-rotor type. When a worn lining of the bearing was being renewed it was noticed that the shaft had a peculiar appearance instead of the usual polish.

From this the chief electrician concluded that stray current flowing through the bearing was the cause of the wear, and he proceeded to clear up grounds found in the rotor and control circuits.

How to Detect Current

This cause of excessive bearing wear is so unusual that it is liable to be overlooked. Whether an appreciable current is flowing through the bearing can be determined by connecting an ammeter of low resistance, or a millivoltmeter, from the shaft to the bearing.

Another way which in some cases can be used to indicate a current is to connect a short piece of small copper wire from a rubbing contact on the shaft to the bearing. Heating of the wire by the shunted current is the indication, but it should be ascertained that the heat is not generated by friction of the one end of the wire on the shaft.

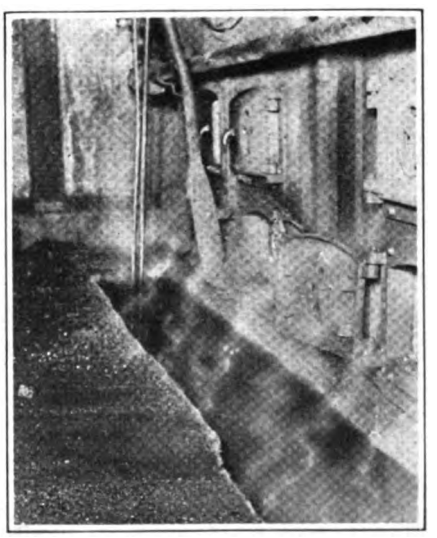
If the trouble is not due to grounded circuits then it can probably be blamed to faulty design. Correction of this fault is of course difficult. A possible remedy is to insulate the bearing shells from the frame or base of the machine.

Barbed Wire Protects Line From Lightning

Every summer lightning causes much damage to mine substation, especially to those equipped with motor-generator sets. Puncturing of the motor insulation occurs in many instances even though the installation is protected, apparently, by approved arresters.

J. F. MacWilliams, electrical engineer of the Pennsylvania Coal & Coke Corp., Cresson, Pa., had such a case, but judging from last summer's experience he has practically eliminated, or at least greatly lessened, the chance of further trouble.

One of the Moss Creek substations, is fed by a 2,300-volt line passing over two high hills. Two arresters of approved type were used, and much care was taken to obtain a good ground. Nevertheless the insulation of the motor-generator set was punctured several times each summer.



Electric Storms Harmless

The step which seems to have eliminated the trouble was taken somewhat over a year ago. Mr. MacWilliams ordered 2,000 ft. of galvanized barbed wire and strung this on the pole line over the tops of the two hills. Extensions were added to the pole tops to support the wire.

Grounds were made at every fifth pole by a ground rod with a pancake coil at the bottom. During the succeeding summer months no trouble was experienced in the substation even though many severe electrical storms occurred.

Mine Water Carries Ashes From Boiler to Dump

At small boiler plants, of capacity, say under 400-hp., ashes are usually carried to the dump by wheelbarrow. Though the quantity of material handled may seem large to the fireman, it is hardly enough to justify the installation of expensive ash-handling apparatus. But these are days when men do not "appreciate" work which can be done satisfactorily by mechanical means.

Trench in Front of Boilers

The only cost of this ash-disposal scheme was the digging and concreting of the trench which diverts the discharge from the mine pumps through the boiler room on its way to the creek.

The fireman of the two 150-hp. boilers at the Exeter mine of the Kingston - Pocahontas Coal Co., Hemphill, W. Va., is relieved of any work connected with carrying the ashes away from in front of the boilers. He simply rakes them out from under the grates and they drop into a trench in front of the ashpit door. A stream of water flowing through the trench carries the material into the nearby creek.

The trench and boiler fronts are shown in the accompanying illustration. In this case the water passing through the trench is part of that pumped out of the mine. The scheme proved so satisfactory that one or two other plants of the company have been arranged in the same way. The plant at Exeter is used to supplement purchased power and to act as a standby should the purchased power fail.

How Far Can a Single Belt Transport Coal?

Single-belt conveyors a mile long between head and tail pulleys are not outside of the realm of possibility, according to C. H. Adamson, engineer for the Stephens-Adamson Manufacturing Co.

Probably the main factor limiting the distance between centers is the working stress of the conveyor belt. Reduced frictional resistance in drive, idler, take-up mechanism and carriers has lowered belt stresses, with a corresponding increase in allowable conveyor lengths.

In nearly every instalation of belt conveyors the belt itself costs from 30 to 50 per cent of the entire installation. Long belt conveyors require high tensile strength, and the cost of the belt per foot of length is correspondingly increased. The belt depreciates more rapidly than the machinery; therefore conditions which increase the life of the belt, such as ball-bearing carriers, lower the unit cost per ton of material handled. Single-belt conveyor installations will rarely be made in greater lengths than are now standard, concludes the same authority. Probably long-distance belt-conveyor transportation will, therefore, continue to be of the multiple-unit type.

In reaching this conclusion, Mr. Adamson does not consider the degradation consequent on the use of the multiple unit, nor the difficulties due to the creation of dust, including when coal is transported, the danger that the material conveyed may, in being chuted, from unit to unit, introduce an explosion hazard. Furthermore the question of headroom may have to be considered.

News Of the Industry

Three-Cornered Freight-Rate Fight For Northeast Coal Markets Resumed As Hearings Open at Atlantic City

The three-cornered rate fight for the coal markets of New England and the Middle Atlantic states was resumed at Atlantic City, N. J., on Monday of this week, when the Interstate Commerce Commission reopened hearings in its so-called *Anthracite Coal Investigation* at the Marlborough-Blenheim before Commissioner Johnston B. Campbell and Special Examiners Irving L. Koch and Joseph Esselman.

This proceeding, Docket No. 15006, was undertaken in the first instance on the recommendation of the U. S. Coal Commission, which thought the time was ripe for a re-examination of the rate structure on hard coal. A number of desultory hearings on that question were held in 1923 and 1924. The case was subsequently broadened to cover the transportation charges on bituminous coal and coke. Except for certain adjustment in tariffs applicable to central New York destinations, the anthracite rates have passed out of the picture.

The original order issued in this case, 101 I.C.C. 363, establishing joint all-rail rates on prepared coal from low-volatile districts in southern West Virginia to certain points in Trunk Line and New England territory, however, gave the anthracite industry and the anthracite carriers an interest that the earlier perfunctory hearings did not win. Subsequent emergency extensions and expansions of that order, made during the recent anthracite strike, added materially to that interest.

Three Interests Make Demands

The present line-up of the contestants, therefore, shows:

(1) The low-volatile producers of southern West Virginia demanding a further extension and broadening of the routes opened up by the original order and a lower rate basis;

(2) The northern producing fields, particularly central Pennsylvania, opposing this all-rail invasion of the Northeast by their southern West Virginia rivals and demanding that the adjustment of rates to tidewater also receive the scrutiny of the Commission;

(3) The anthracite industry and the anthracite carriers watching to protect their own interests in this rich coal-consuming territory. Incidentally the anthracite operators are complaining of the rate relationships between bituminous coal and the steam sizes of anthracite. It is unlikely, however, that that point will be raised in the present proceedings.

The high-volatile interests of southern West Virginia, who were denied a new rate adjustment in the original decision, but later were accorded emergency rates, which expired April 30, trail along with the low-volatile producers. They have made a point that their rates westbound and to southeastern points are differentially related to the rates on low-volatile coal and insist that equal consideration should be given them in the establishment of rates on low-volatile to the Northeast. Eastern Kentucky and the low-volatile districts of Virginia, as well as the semi-anthracite field in the Old Dominion State, likewise insist that the benefits which may be won by southern West Virginia should also accrue to them.

Trunk Lines Oppose New Routes

Trunk line railroads, notably the Pennsylvania and the Baltimore & Ohio, object to the establishment of new all-rail routes. They base this objection on the ground that the facilities for handling business through the Hagerstown and Potomac Yard gateways were not designed for this traffic and that to burden such gateways with this movement would threaten the standards of their service.

In the original order the Commission directed the establishment, effective Oct. 15, 1925, of rates on low-volatile lump, egg and nut from mines in C. & O. group 1, as specified in C. &. O. tariff I.C.C. No. 9834; mines in Virginian Ry. group 1, as specified in Virginian Ry. tariff I.C.C. No. 1685, and mines in N. & W. group 3, as specified in N. & W. tariff I.C.C. No. 3006-B, which should not exceed the following:

(1) To Pennsylvania R.R. stations, Tuxedo to Edgewood, Md., $3.45 per gross ton; to Perryman and Iron Hill, Md., and points intermediate, $3.70; to Newark Center, Del., and Brooklyn, N. Y., and points between said stations, rates not exceeding rates from the Clearfield district by more than $1.10.

(2) To Baltimore & Ohio stations, Alexandria Junction to Van Biber, $3.45; Sewall to Barksdale, Md., $3.70; Newark, Del., to Philadelphia, Pa., $3.94.

(3) To New Haven railroad stations, Portland to Chestnut Hill, Conn., Talcottville to Willimantic, Conn., North Windham, Conn., to Forest Hills, Mass., South Windham, Conn., to Oak Lawn, R. I., Attleboro, Mass., to Boston, Mass., $5.58; to other New Haven stations named in Pennsylvania R.R. tariff AA-I.C.C. No. 1800, rates not more than $1.10 per ton above Clearfield rates.

(4) To Boston & Maine stations, Farley to Boston, Mass., $6.70; to other Boston & Maine points specified in Baltimore & Ohio R.R. Co. Coal & Coke Series Tariff I.C.C. No. 2523, rates not more than $1.35 in excess of those maintained by the Baltimore & Ohio from the Cumberland-Piedmont field.

Emergency Rates Granted

Later, following a hearing in New York City, the Commission broadened its original order by establishing the following emergency rates on prepared coals:

(1) From all mines in the New River, Tug River, Pocahontas and Clinch Valley District No. 1 fields to all points in New Jersey and the New England states, other than destinations covered by original orders, rates $1.10 over Clearfield.

(2) Clinch Valley District No. 2 to Baltimore & Ohio, Pennsylvania and Long Island R.R. stations and to destinations covered under paragraph (1) the same basis as applicable from Pocahontas and Tug River.

(3) From all mines in the Kanawha, Coal River, Logan, Kenova and Thacker districts to all points on B. & O., P. R. R. and Long Island railroads covered by original order of July 22, 1925, and to all points in New Jersey and the New England states, rates not more than 25c. over New River-Pocahontas.

(4) From all mines on the Big Sandy division of the Chesapeake & Ohio Ry. in Kentucky to destinations described in preceding paragraph, rates not more than 40c. above the New River-Pocahontas basis.

(5) Semi-anthracite from McCoy and Merrimac, Va., on Virginian Ry., and Pulaski to Vicker, Va., inclusive, on Norfolk & Western Ry., rates not exceeding rates on Pocahontas coal to destinations in paragraph (2).

The Commission, however, declined to extend the application of these rates to the movement of mine-run all-rail and ignored the pleas of western Pennsylvania and northern Ohio for consideration.

These rates became effective Dec. 31, 1925, and expired April 30, 1926. The

Digitized by Google

Commission refused to extend their life. In denying applications for such extension it announced that further hearings would be held to consider the question of the establishment of such rates on a permanent basis. These rates, therefore, will be among those considered in the present hearings.

Broadening of the issues to include the rates on coal to tidewater for transshipment followed an appeal of the Central Pennsylvania Coal Producers' Association. This appeal, the granting of which puts into issue the relationship of rates to the northern and southern tidewater piers, was bitterly opposed by the southern interests. The latter charged the northern producers with attempting to evade the responsibility of filing a formal complaint challenging the relative adjustment. Another appeal brought in all of the Upper Potomac field.

In effect, therefore, the investigation now covers the relationship of rates from practically the entire Appalachian Region, other than Alabama and Tennessee, to the Middle Atlantic and New England states via all-rail and rail-and-water routes via all ports of transshipment from New York on the north to Hampton Roads on the south. One of the recent supplemental orders in the case specifically brings in the question of the reasonableness and prejudicial character of the rates, charges, regulations and practices, "including tidewater and transshipment rates, charges, regulations and practices," on bituminous and semi-bituminous coal and coke from all mines in Pennsylvania, Ohio, Maryland, Virginia, West Virginia and eastern Kentucky to all points in Virginia, the District of Columbia and in the Middle Atlantic and New England states; and of semi-bituminous coal from mines in Virginia to all points in Virginia, the District of Columbia and in the Middle Atlantic and New England states.

The Commission has announced that evidence on the all-rail situation must be completed at the Atlantic City hearings, which may last three weeks. "If it develops," says George B. McGinty, secretary of the Commission, "that adjournment is needed in respect to the tidewater situation in order to do substantial justice, a further hearing upon that phase of the investigation will be held later."

G. H. Merryweather

"Bert" Merryweather, the new president of the American Wholesale Coal Association, has been actively identified with that organization and its predecessor, the National Coal Jobbers' Association, since the launching of the last-named body in the fall of 1917. For a number of years he served as secretary-treasurer and last year he was vice-president. Mr. Merryweather is associated with the Waubun Coal Co., Chicago.

Non-Interference of Government with Business Will Promote Continued Prosperity, Says Schwab

Continued prosperity is foreseen by Charles M. Schwab, chairman of the Bethlehem Steel Corporation, who surveyed the business situation in a recent address before the Syracuse (N. Y.) Chamber of Commerce. "With the government seeking to conduct its affairs in the most economical manner, arranging the tax laws upon the sound principles advocated by Secretary Mellon, and pursuing a policy of non-interference with the legitimate activities of business, and with the American people working together as they are now doing, we can have confidence that permanent prosperity shall have every opportunity to flourish," he said.

"I am an optimist on the business outlook," declared Mr. Schwab, "for the following reasons:

"(1) The American people are hard at work producing new wealth at an amazing speed. That means purchasing power, new savings, new opportunities for expansion of production.

"(2) Nature promises a year of bountiful crops on top of the enormous agricultural production last year.

"(3) Wage earners are working with their employers in a spirit of greater peace than I have seen for 25 years.

"(4) Business men have been carrying on their work carefully in recent years and not indulging in speculative expansion.

"(5) Railroads are providing a transportation service of greater efficiency than the people of the country have ever enjoyed.

"(6) Through the operation of our banking laws and by reason of the prudence of those in charge of our banks, credit facilities have not been taxed and the business of the country is generally sound.

"(7) The government, under the leadership of the President, stands for a policy of sanity, conservation and progress."

Southern Gem Stockholders Lose in Reorganization Plan Approved by District Court

Stockholders owning approximately $1,021,054 of the capital stock of the Southern Gem Coal Corporation, which was thrown into a receivership in January, 1924, apparently will be the only losers when the affairs of the company are finally liquidated by the receivers, providing the company that is taking over the mining properties is able to operate on a paying basis.

Under the terms of sale approved by Judge Lindley in the U. S. District at Danville, Ill., on June 17, the purchaser, the Brewerton Coal Co., of Chicago, has agreed to issue stock to holders of $440,000 in bonds of the Southern Gem Coal Corporation and to creditors having $400,000 in claims against that company. Stockholders of the Southern Gem company, however, will receive nothing.

In approving the sale of the property Judge Lindley said that he regarded it as "the best possible settlement" that could be effected for bondholders and creditors. He set July 1 as the final date for hearing on the receivership and it is believed that at that time he will order the receivers, W. S. Wilson, of Pinckneyville, Ill., and N. S. McLean, East St. Louis, Ill., to file their final reports. Following the receipt of the reports the receivership will be terminated.

In addition to issuing stock to the bondholders and general creditors the Brewerton company agreed to assume delinquent payrolls and back taxes on the mining property in Perry County. It is estimated that the total purchase price was more than $1,000,000. The Brewerton company some time ago purchased the Southern Gem mines in Franklin and Jefferson counties under terms similar to the sale at public action in Pinckneyville, Ill., in June 8.

W. A. Brewerton, head of the Brewerton Coal Co., is said to contemplate including the Southern Gem mines in a merger of 43 coal mines in Illinois and Indiana recently reported to be under way.

Sells Ohio River Interests

The West Virginia Coal & Coke Co., with headquarters at Fairmont, W. Va., has purchased the river interests of the Philadelphia & Cleveland Coal Co., which included docks at Huntington, W. Va., a boat line on the Ohio River and a large unloading plant at Cincinnati, Ohio. A. C. Ingersoll, president of the Philadelphia & Cleveland Coal Co., has been made manager of the river interests which were taken over. It is announced that the deal does not affect the remainder of the activities of the Philadelphia & Cleveland Coal Co., which consists of offices at Cleveland, Columbus, Akron, Indianapolis, Wheeling and Cincinnati. At Groveport, near Columbus, the company has an immense coal storage plant from which the Columbus Railway, Power & Light Co. is supplied

Tentative Awards Made for N. Y. State Coal Needs

Tentative awards have been announced by the Department of Purchase, State of New York, at Albany, for supplying anthracite and bituminous coal for many of the state institutions. The awards included the following:

The Lehigh Valley Coal Sales Co. was awarded the contract for furnishing 1,400 tons chestnut, 1,300 tons egg, 500 tons stove, 1,000 tons buckwheat No. 1, and 3,100 tons pea coal at regular company schedule of prices.

The D. L. & W. Coal Co. obtained the contract for furnishing to six institutions 4,500 tons barley, 800 tons stove, 250 tons chestnut, 450 tons egg and 650 tons pea at the regular schedule.

Weston Dodson Coal Co., Inc., was successful in its bid for furnishing 2,160 tons of stove coal at $9.70 per ton f.o.b. mines; 200 tons chestnut at $9.15; 1,450 tons pea at $6.25 and 8,700 tons buckwheat No. 1 at $2.04@$2.24 per ton, depending upon delivery points. For 4,000 tons barley to Randall's Island the price was $3.89 f.a.s.

Other bids accepted included that of Martin F. Shea, of New York City, for furnishing 35,400 tons of buckwheat No. 1 to three institutions at $2.19 per gross ton, f.o.b. mine. Mr. Shea also captured contracts for furnishing 7,600 tons stove coal at $9.60 per ton; 2,195 tons egg at $9; 1,920 tons chestnut at $9; 150 tons grate at $8.50, and 150 tons pea coal at $6.50.

Pattison & Bowns were granted the contract for sending 15,000 tons of barley coal to the Binghamton institutions at $1.50 per ton. They will also deliver to various other institutions 3,250 tons stove coal, 1,019 tons egg, 561 tons chestnut and 1,550 tons pea coal at $9.50, $9, $9 and $6.50 respectively.

The successful soft coal bids were:

Simpson Mining Co., Rochester, 10,700 net tons, mine-run, to Albion, Batavia and Gowanda, $1.60 per ton; 19,000 tons mine-run, to Middletown and Thielle, $1.55 per ton; 2,675 tons ¾ lump and 700 tons 1¼ lump to five delivery points, $1.80 per ton; 13,000 tons mine-run to St. Lawrence, $1.55 per ton.

Pittsburgh & Shawmut Coal Co., Pittsburgh, Pa., 18,000 tons slack at $1.30.

Northern Coal Mining Co., St. Mary's, Pa., 4,000 tons nut and slack to Newark, N. Y., $1.40.

Active British Mine Hums With Brisk Demand

Contrary to general belief, not all the British coal pits are idle. Dean Moor colliery is very much in action and unable to meet the demands. No pickets of trade unionists or Communists interfere with its operatives.

Dean Moor colliery lies in the moors of a remote district of the Cumberland Mountains—the nearest railroad station is more than twenty miles away. Its daily output before the strike was about 75 to 80 tons of coal per day. Neither the company owning the pit nor the 65 to 75 men working it are affiliated with the owners' or the miners' associations.

The men, in addition to free houses and firing and medical benefits, obtain a quarterly bonus on their output as well as their wages. And, since this mine was opened early in the century, it has had neither labor nor financial troubles. Its coal is sold in the surrounding agricultural and iron-ore districts, and in ordinary times the purchasers usually cart or otherwise convey it themselves. During the strike, however, a fleet of motor and steam wagons and lorries have been distributing orders within a vastly increased area.

Barnett Coal Co., Latrobe, Pa., 44,640 tons mine-run to seven delivery points, $1.45 per ton.

Steamship Fuel Corp., New York City, 25,350 tons mine-run to eight delivery points, $1.45 per ton.

George D. Harris Coal Co., New York City, 22,000 gross tons mine-run to Brooklyn and Manhattan, $4.44 per ton f.a.s.; 50 tons smokeless coal at $1.78 per ton and 400 tons at $1.64.

Whitney & Kemmerer, New York City, 670 gross tons slack for Randall's Island, $4.54 per ton, f.a.s., and 56,400 net tons mine-run to five institutions at $1.295 per ton.

Kaiser-Barnett Coal & Coke Corp., Buffalo, 12,000 net tons mine-run to two institutions, $1.68 per ton.

Demand Higher Rates on Coal-Mine Insurance

Compensation-insurance experience on coal-mine risks throughout the country has been so unprofitable that the company members of the Associated Companies at a meeting on June 16 decided to discontinue writing such risks except at a substantial increase in rates. In any states which will not approve of an adequate rate basis the business will be discontinued entirely so far as the members of the Associated Companies are concerned.

Coal-mine business written through the Associated Companies during the past five years shows an underwriting loss of $4,500,000. It is estimated that rates are about 50 per cent less than they should be to make possible an even break on the underwriting. On the other hand, the acquisition cost of the business has been kept as low as possible, only 10 per cent commission being allowed, as compared with 17½ per cent paid on other classes of compensation insurance. A considerable proportion of the expense of conducting the business goes into the inspection costs, without which the risks could not be written at any rate.

The Associated Companies is already withdrawing from Kansas as the laws of that state are such that coal-mine compensation risks cannot be written at any rate. The United States Fidelity & Guaranty Co., of Baltimore, recently announced that it had discontinued writing coal-mine risks, and the Integrity Mutual Casualty Co., which recently failed for several millions, charged that the bulk of its troubles was due to coal-mine loss experience.

The Associated Companies is composed of the Hartford Accident & Indemnity Co. of Hartford, the Maryland Casualty Co., of Baltimore; the Standard Accident Insurance Co., of Detroit, and the United States Casualty Co. of New York. These companies have aggregate assets of about $95,000,000.

Senator Fred M. Sackett, of Louisville, is behind a bill introduced in the U. S. Senate on June 15 to establish a mine-rescue station and equipment at Madisonville to serve the western Kentucky field.

Direct Efforts to End British Strike Await Fate of Legislative Program; Labor Scores 8-Hour-Day Proposal

Attempts at direct negotiation to end the British coal strike, now in its eighth week, apparently have been abandoned while both parties wait to see what fate overtakes the legislative program laid down by the British Government.

The first plank in the platform advocated by Premier Baldwin is the return to the eight-hour day. Commitment of the government to this proposal already has provoked a storm of disapproval from the Laborites and the Liberals. The Baldwin party, however, has given no indication that it intends to retreat from its position.

The Premier outlined his plan in an address to the House of Commons on June 15. In general it was based upon the recommendations of the Royal Coal Commission, which rendered its report several weeks ago. In his speech the Premier made specific reference to recommendations for the amalgamation of existing undertakings and the enactment of enabling legislation. He indicated, however, a reasonable time would be allowed the operators to effect such consolidations voluntarily.

Nothing was said with respect to the nationalization of mineral rights. Mr. Baldwin intimated, however, that the recommendations of the commission dealing with selling agencies, profit-sharing, family allowances, housing and re-absorption of workers displaced by mergers would be taken up later.

Although the subsidy offer of the government expired on June 1, the hope was he'd out that government aid would be made available to tide over an emergency if owners and miners composed their differences.

Baldwin Defends Longer Day

The proposal to lengthen the working day, which runs counter to the recommendation of the commission, was put forward as the necessary first step in resumption of operations. Mr. Baldwin defended the suggestion as one which gave the workers a chance to maintain their present standards of living. His failure to advocate the eight-hour day earlier, he explained, had been due to the fear that some of the owners might abuse the concession. He had since been assured that "as to 50 per cent of the coal produced, there would be no fall in wages at all, and as to 25 per cent, a fall of less than 10 per cent during the period of July, August and September. Everywhere thereafter the 1921 minimum would be guaranteed."

Nothing was to be gained, he continued, by prolonging the struggle. On the contrary, "it will leave every one worse off at the end than they were at the beginning. The commissioners declared that disaster was impending over the industry unless certain things were done. Instead of co-operating wholeheartedly to do these things, the parties to the dispute have preferred to fight. Had they agreed with the government on March 24 to stand firmly on the report we might today have made some advance with laying the foundations of a new prosperity, the men would have been back at work and our foreign competitors would not have been capturing our markets."

A. J. Cook, secretary of the Miners' Federation, was one of the most caustic critics of the Baldwin program. Lloyd George also assailed the longer working day and the Labor Party went on record in opposition.

"The Prime Minister," said "Emperor" Cook, "has confirmed the opinion already held by the miners and their leaders that he is nothing more or less in this dispute but the advocate of the coal owners. A reduction of hours has always been bitterly opposed by the mine owners. The miners have been absolutely solid on this question. There is no more prospect of their giving way than of the railwaymen, the transport workers or others agreeing to longer hours of work.

"The debate in the House of Commons has done nothing to bring a settlement nearer. Every one must see how the Prime Minister tries to act in a dual and deceptive rôle by informing the nation in a speech that was broadcast that he was not out to reduce the standard of living of the miners, and yet, in his speech in the House of Commons yesterday, he made no secret of the fact that the only proposals he has put before them are longer hours and lower wages.

"Instead of bringing forth the olive branch, he has unsheathed the sword. The miners will never voluntarily accept reductions of wages. No attempt to enforce longer hours by legislation will succeed. It is tragic that the British Prime Minister uses his position as chief officer of the Crown to defend the coal owners' interests against those who invest their lives in the mines."

The resolution adopted by the Laborites at a meeting on June 16 read:

"The declaration of policy made by the government yesterday on the mining crisis as regards hours and wages is in violation of the recommendations of the Royal Commission report, is inadequate to meet the problems of the industry; is a surrender to the demands of the owners and calculated to prolong and embitter the struggle.

"The party, therefore, resolves to offer to these proposals its most strenuous resistance."

Says Government Blunders

"It seems to me the government is blundering very badly," said Lloyd George. "When I had news last night of what had been said, I could hardly believe it. It seemed to me to be so incredible that I thought I had better wait for a full report. I was very much surprised that the summary I had last night was completely confirmed by the full report."

A meeting of a committee of the miners' international organization was scheduled for London yesterday. It was announced that this meeting would consider what steps could be taken to further aid the British miners. British members were reported to be ready to ask for more drastic measures to prevent the exportation of coal from other countries to the United Kingdom.

Tomorrow (June 25) the executives of the unions affiliated with the Trades Union Congress are to meet. Interest centers in what will happen if Mr. Cook repeats his attacks upon the labor leaders responsible for calling off the general strike last month.

Unemployment outside of the coal industry increased only 5.3 per cent last month, but June figures will undoubtedly be much more unfavorable. A mid-month review of the situation shows the iron and steel industry at a standstill, Sheffield cutlery plants hard hit, many pottery kilns closed down, cotton spinning mills phalanxing workers and the automotive industry seriously embarrassed by a shortage of supplies.

Reserves of Coal at Hornsey (North London) Station of London Northeastern Ry.

Though the British railroads are curtailing their services, they are well provided with stocks of coal. Where in this country the coal would be pitched into a pile and removed by a steam shovel with perhaps some of the earth foundation, in England the lumps are arranged on the outside as carefully as if a masonry wall was being constructed.

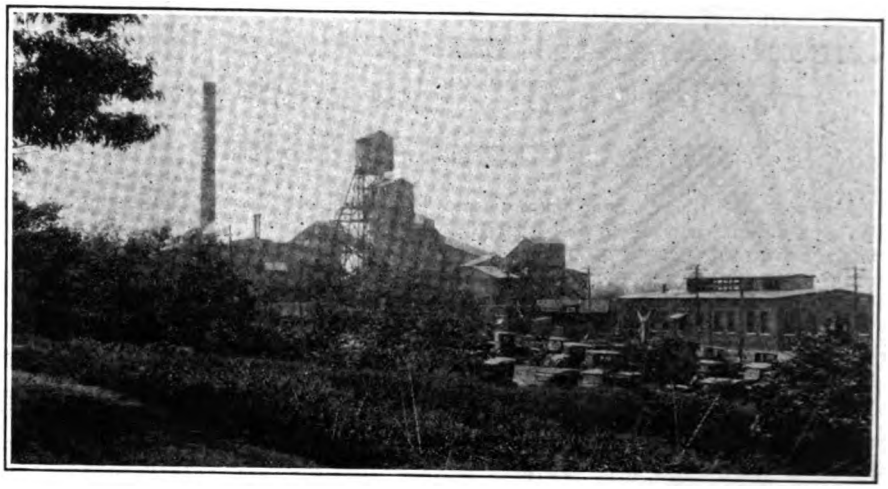
Mine Bureau Economic Plan Hinges on Funds

With the approach of the new fiscal year plans of the Bureau of Mines for the organization of its economic work are beginning to take form. Director Scott Turner and Assistant Director C. P. White up to the present have made no secret of the fact that they have been marking time in the economic end of the Bureau's activities awaiting the availability of funds carried by the 1926-1927 appropriation act.

Although the broad features of the Reynders committee's report recommending the centralization in the Bureau of Mines of the work on the economics of mining have been carried out in part, the details for handling the work inside the Bureau have not been worked out finally. Mr. White's hands have been tied by the complexities of regulations covering the handling of appropriations.

Another uncertainty has been removed in the decision of Congress not to pass coal legislation.



Though the organization plan is still under discussion the underlying principles are becoming clear. Mr. White hopes that his branch can become a great center of information concerning the mining and refining industries. With the economic and technical branches working together he hopes that the Bureau may become the handmaiden of mining in much the same way that the Department of Agriculture is the servant of the agricultural industry.

The problems of organization in reaching the objective include the linking of the economic studies of mining with the engineering studies in such a way as to give the engineers the benefit of the economic viewpoint and give the commodity specialists the advantage of engineering assistance. This can be done by detailing engineers from the technical branch to act, part time, in the economic branch and in some instances by consolidating the economic and technical work under a single commodity chief.

There also is the question of teaming the studies of production and marketing with the studies of the Geological Survey with regard to reserves.

A further need is to tie the statistics of a given commodity with the other economic and engineering studies of that commodity and at the same time provide for the necessary uniformity of statistics on all commodities. This may be done, it is believed, by decentralizing the work. It would be possible to detail the statistical personnel to the commodity divisions and provide for the general co-ordination by some person responsible for the statistical program as a whole.

The report of the U. S. Engineers of the Pittsburgh district shows that in May there were moved on the Monongahela River 1,618,474 tons of coal and 26,582 tons of coke; on the Ohio River in this district, 468,513 tons of coal and 26,582 tons of coke, and on the Allegheny River, 89,550 tons of coal.

Orient No. 1 is Still a Large Mine

While New Orient's production was curtailed for a few months by confining the work to development and repairs, the output of "Old" Orient was boosted from the usual 6,000 tons per day to 8,000 tons. This is raised in mine cars by a huge steam hoist through a shaft approximately 500 ft. deep. The older mine is 3 miles from New Orient.

Ban on Ohio Co-operatives Receives Scant Notice

Word received from all sections of the southern Ohio field indicates that little attention was given to the recent order of the officials of the United Mine Workers in that state relative to union men working on a co-operative basis. This practice had become widespread in the field and following a mass meeting of idle miners at Nelsonville recently, the order was issued.

It was announced that union men would not be allowed to work where their wages would not equal the Jacksonville scale. But outside of a few of the smaller mines which ceased operations, little effect resulted from the order. The larger co-operative concerns continued work and are selling their product at the current market quotations, which seldom if ever net the miners full union wages. It was announced that some of the co-operative concerns made slight changes in their manner of operation and will continue unmolested.

Railroads Using More Coal; Cost Declines

Class 1 railroads of the United States consumed 9,024,910 net tons of coal in locomotives in freight and passenger service during March, 1926, according to the Interstate Commerce Commission. Consumption by districts was as follows: Eastern, 4,389,628; Southern, 2,185,000; Western, 2,450,282 tons. During the corresponding month of 1925 the totals were: Eastern district, 3,917,560 tons; Southern, 1,935,515; Western, 2,296,505; United States, 8,149,580 tons.

The average cost per ton in the Eastern district in March, 1926, was $2.72; Southern, $2.22; Western, $2.93; United States, $2.66. These figures, when compared with those for March, 1925, represent decreases in all districts, as follows: Eastern, 14c.; Southern, 19c.; Western, 17c., and for the country as a whole, 16c.

Teton Coal Co. Asks Lower Rates in Idaho

Backed by the Idaho State Grange, the Teton Coal Co. has filed with the Public Utilities Commission of Idaho a petition requesting that freight rates on coal from the mines of this company to points in Idaho be ordered reduced approximately $1 per ton. The petition sets forth that the present freight rates charged for the hauling of coal in this state are excessively high. This charge is laid at the door of the Union Pacific.

"The defendant's road from Talbot to Pocatello, a distance of 140 miles, follows a water grade and is comparatively straight and easily maintained," recites the petition, "passing, as it does, practically all that distance down the Snake River valley over level ground. The rate in effect from Talbot to Pocatello is $2.20 per ton on lump and $2 on slack, while the Union Pacific R.R. system, of which the Oregon Short Line is part, hauls coal from Boise to Kellogg and Wallace, 547 miles, over three mountain ranges and up the fourth grade, for 55c. per ton in excess of the rate charged from Utah and Wyoming coal fields to Boise."

Plan Naval Coaling Station

The Navy Department is reported from Washington as negotiating to take over from the War Department all or a portion of a tract of 273 acres formerly a part of the army base reservation in Norfolk, Va., for a naval coaling station. The land sought adjoins the coal station of the naval operating base.

Commerce Bodies Study Rates

The Pennsylvania State Chamber of Commerce has notified the Philadelphia Chamber of Commerce that it has set under way a study on a state-wide scale of soft-coal rates. Representatives of the two organizations will be present at a hearing on the problem this week.

Coal Industry May Escape Legislation If Plan Is Devised Before December To Prevent Interruption of Supply

By Paul Wooton
Washington Correspondent of *Coal Age*

After six ballots had demonstrated that the House committee on interstate and foreign commerce is deadlocked on whether or not any coal legislation should be recommended, the committee on June 16 voted to make the matter the first order of business at the December session.

On the motion to report the Parker bill favorably the vote was 9 to 9. A motion to bring out an unfavorable report also was a tie. An effort then was made to obtain a majority vote on the bill after some of its provisions had been eliminated, but the nine members opposed to the legislation were not satisfied. Another proposed amendment whittled away more of the bill, but the vote still was 9 to 9. In all, four amendments were proposed, but the members opposed to any legislation were unmoved.

There was opposition to the agreement to make coal legislation the first order of business at the December session. It is contended that this is a sort of suspended sentence held over the coal producers. Some members of the committee feel that this will stimulate the industry during the next five months to devise some plan of its own which will make less likely an interruption of coal supply.

Wyant Reiterates Opposition

Representative Wyant, of Pennsylvania, a member of the committee, interprets the action of the committee as follows:

"This means that the committee at this session will not take action on the several socialistic measures designed to strangle the coal industry. Furthermore, as one who has led the fight against political interference with private business, I can assure the public that any attempt to single out this industry for the yoke of bureaucratic control will be fought stubbornly and, I believe, successfully, in the next session of the Congress.

"We are convinced that we are fighting for a supreme public interest when we oppose a movement that would inevitably lead this country into the stormy and thorny path through which Great Britain is now plowing. This nation is a business nation. Insurance against stifling of private initiative on which our prosperity rests means continuing prosperity. And my continued aim and effort, in the interests of the public and of industry, will be to keep the dead hand of government off the coal business.

"In closing, I would say that if we ever do have regulation in this country we will have it with a vengeance. It will not be confined to coal, but will embrace oil and many so-called necessaries of life. In my sober judment such regulation would spell the beginning of the end of a great republic. The importance of this issue, involving bureaucracy and supergovernment of business, cannot be overemphasized. The very foundations of our republic would be imperiled. Having faith in the future, I am confident this hysteria has reached its peak."

The feeling among some, at least, of the advocates of coal legislation is that a cross-section of the interstate and foreign commerce committee would show it to be much more opposed to legislation than the House as a whole and that the membership as a whole would show a substantial majority for the Parker bill, or even more drastic legislation. There are no evidences, however, that many members, other than a few in the anthracite-consuming region, are at all exercised over the failure of the committee to bring out legislation.

This legislative effort was one of the results of the anthracite strike. When the strike began it was predicted freely that its political results would be serious in that it would arouse a demand for regulation that could not be resisted. Despite the fact that the strike established a record in its duration, the expected political pressure was slow in materializing. When it did arrive it was not strong enough to get even the mildest bill on the calendar. Coal legislation at this session of Congress has been given more careful consideration than at any previous session, yet on the final vote it could not command a majority of the committee on interstate and foreign commerce.

Those opposing coal legislation emphasized as their strongest argument that coal should not be singled out for regulation or even near-regulation. Whatever is prescribed for coal should be extended to oil, clothing, food and other necessities of life. This point was used with telling effect and is quite strong enough to convince any ordinary member of Congress unless there are strong countervailing reasons.

Sentiment for Legislation Grows

On the other hand, the result shows that Congress has moved much nearer legislation than it was five years ago. Then with the war prices and the panic of 1920 prices freshly in mind the rather innocuous Frelinghuysen seasonal rate bill was voted down by a large margin in the Senate. At that time there was not even a rumble of legislation in the House. There is little doubt that the present House would have passed any coal bill which the interstate and foreign commerce committee might have reported. In the present Senate more than a majority voted to take up the Copeland bill. It happened that the proposal on which that vote was taken was to make the bill a special order, which requires a two-thirds vote.

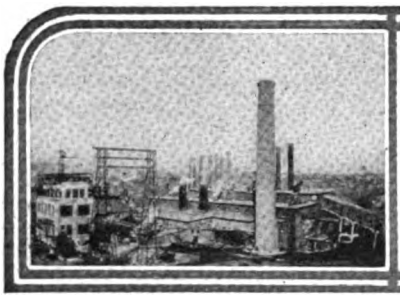
Thus it is seen that the slow growth of opinion is in favor of some public supervision of any industry that does not give reliable service or does not prevent the recurrence of abnormal prices. There is no move to regulate oil or clothing or shoes or potatoes because the producers of those articles somehow manage to keep the supply going.

To the mind of the ordinary consumer the fact that he cannot get coal when he wants it, but can get gasoline, makes a great difference. The test of strength shows that the sentiment for coal legislation has not reached the point to carry Congress but that the margin is a narrow one. If the industry can keep the public supplied with coal and prevent unreasonable increases in prices the sentiment will subside, but strike talk next winter is likely to furnish the slight additional pressure which will be needed to put coal legislation on the statute books.

Gold Medal Is Bestowed on Champion Coal Loader

Paul Dobele, a coal loader employed by the Bethlehem Mines Corporation, a subsidiary of the Bethlehem Steel Corporation, has just been given a gold medal by the company for loading 538 tons of coal in 12 working days. The coal was loaded with a hand shovel in the Dakota mine, in West Virginia. Dobele's average daily loading of 45 tons was nearly equal to the amount of coal carried in a full sized railroad coal car.

In France, Dobele's native country, the average yearly production per miner in 150 tons. In Germany and the United Kingdom the average output of coal is 225 tons per year. The average output in the United States is 700 tons. Dobele thus loaded in 12 days almost a year's production of an American miner, more than two years' production of a British or German miner, and over three years' production of a French miner.



Another gold medal has been awarded to Will Miller, the champion coal loader of another Bethlehem mine nearby. Miller loaded 413 tons in 14 days. This was during the first half of October last year. During the entire month of October, consisting of 27 working days, Miller loaded 722 tons of coal.

The medals were presented at the annual first-aid meet, at Barrackville, W. Va., by N. A. Elmslie, division superintendent, Marion Division, of the Bethlehem Mines Corporation.

Accept Less Than 1917 Scale

Employees of the Lincoln Coal & Coke Co., at Keisten, in Fayette County, Pa., have accepted a reduction in wages somewhat below the 1917 scale, at which they were working, in order to enable the company to take a contract which will insure work for several months. The company's plant is in the Connellsville coke region.

News Items From Field and Trade

ALABAMA

Montevallo Electrifies.—The Montevallo Coal Co. recently spent $60,000 for electric motors to take the place of the old steam equipment. The capacity of the mines has been increased 150 tons daily, now giving a daily output of 600 tons of coal, according to T. A. Thomas. The present officers of the company are T. A. Thomas, president and treasurer; V. J. Nesbit, vice-president, and J. M. Chapman, secretary and sales manager.

ARKANSAS

Spadra Mines to Resume.—Coal mines in the Spadra district are expected to resume operations between June 25 and July 6. The anthracite mines in the Spadra field probably will start work about July 6. J. E. Nichols, district manager for the Midland Coal Co., declared that indications point to a full run of nine months. All disagreements between operators and miners apparently have been settled, W. T. Perkins, local manager, said.

COLORADO

Coal Company to Cut Wages.—The Vickers Coal Co., of Trinidad, operators of a number of mines in Las Animas County, has filed notice with the State Industrial Commission of its intention to put a 10 per cent wage reduction into effect on June 24. The reductions, according to announcement filed with the commission, is effective among all of the employees of the company.

ILLINOIS

To Extend Coal Road.—The St. Louis, Troy & Eastern R.R., a Madison County coal road controlled by the Illinois Power & Light Corp., has been authorized by the Interstate Commerce Commission to build a 1.53 mile elevated extension to connect with the eastern end of the McKinley Bridge, in Venice. The improvement will give the railroad an important connection with the North St. Louis industrial district. The work will cost $863,000, it has been estimated.

The new National mine, at Belleville, reopened June 5, giving employment to 150 miners.

Chicago Firm Bankrupt.—D. E. McMillan & Brothers, 37 W. Van Buren Street, Chicago, has filed a petition in bankruptcy in U. S. District Court, listing liabilities as $194,140.69 and assets as $124,394.15. Failure to meet payrolls was given as the cause. The company was interested in the Sincerity Mining Co., operating in the southern Illinois field. The petition was filed by David E. and John P. McMillan, as D. E. McMillan & Brothers, a partnership. The petition has been referred to a referee and a receiver or trustee is expected to be appointed soon.

The new Edgewood-Metropolis cut-off of the Illinois Central R.R. will be hauling coal from Franklin and Williamson counties by November, according to announcements in those counties. Track has been laid complete for about twenty-two miles south from Edgewood and it is expected that further extensions of the new roadbed will allow shipments into the northwestern industrial fields by early fall or winter.

INDIANA

Air Cleaning Plant for Ayrshire.—The Ayrshire Coal Co. is installing a new coal cleaner at Mine No. 8, at Arthur, Pike County. Work started a few days ago and will be rushed to completion. The coal will be cleaned by air instead of water. The new plant will cost about $100,000 and will be modern in every respect.

Walkout Ended. — More than 100 miners who walked out at Francisco mine No. 2, Princeton, Ind., several days ago following a dispute over division of mine cars have returned to work. It was reported that the district No. 11 mine board, at Terre Haute, advised the men to return to work. The men walked out when the mine management refused to grant their demand that the output of a mine loading machine be limited to the number of cars the machine of four men could load if working by hand. This would have cut the machine's output to one-fourth its capacity.

The Twin Oaks Coal Co., at Linton, has filed a preliminary certificate of dissolution with the Secretary of State.

KENTUCKY

The Hopkins County Mineral & Mining Co., Madisonville, has leased 3,000 acres in Hopkins County for development of coal mining in the near future.

The White Cross will hold a first-aid contest at Pikeville July 5 for the coal mine teams of the Pike Sandy Valley. Many teams have already registered and many others are expected.

The Cameo Coal Mining Co., Mayking, has 900 acres of land under development. The company has a daily output of 400 tons.

The old plant of the Mayking Coal Co., in southeastern Kentucky, idle for a long time, is being placed in running shape, and will be operated by A. B. Ewen, manager of the Ace Coal Co., Caudill, for the Houser Coal Co. A bridge connecting the Mayking spur with the main line of the Louisville & Nashville R.R. is being rebuilt.

MISSOURI

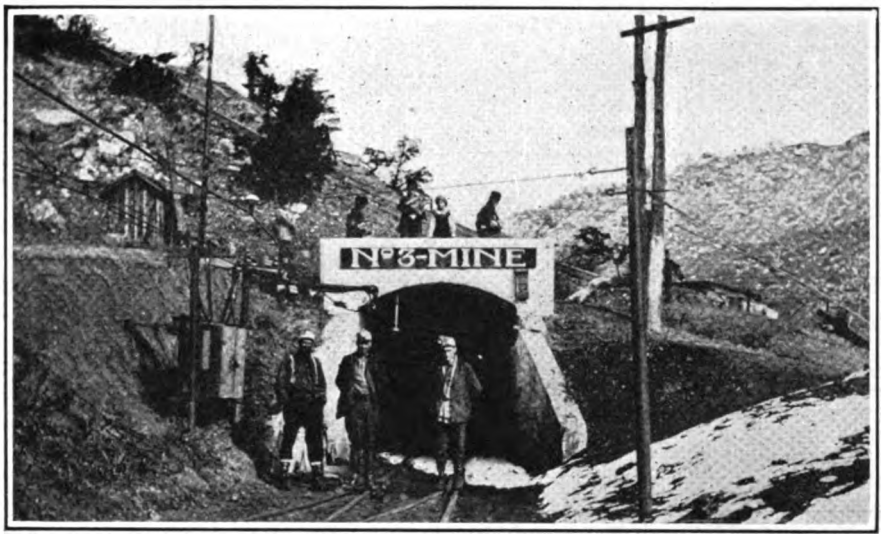
Strip Mine Nearly Ready. — Actual operation by the Howard County Mining Co. on its strip mine project near Higbee will begin soon. A contour map of the entire field has been made by the engineers, showing the location of the coal, the proposed situation of the tipple and other buildings.

The Coil Coal & Mining Co., with headquarters at Madisonville, Ky., has opened a branch office in the Syndicate Trust Building, St. Louis. J. C. Mahen is in charge.

NEW MEXICO

The state may tax coal produced on land leased from the United States, Assistant Attorney General Robert C. Dow ruled in an opinion announced recently. His opinion is in reply to an inquiry from the state Tax Commission.

NORTH DAKOTA



R. M. Stee, of Minot, and others have obtained an option on the John Coffin farm near Velva, with a view to developing the coal which is known to underlie it.

OHIO

Elkhorn City Company Quits.—Contracts with producing companies having expired the Elkhorn City Coal Co., with offices in the Dixie Terminal Building, Cincinnati, has gone out of business. In its place comes the Hatcher-Elkhorn Coal Co., of Big Shoal, Ky., its chief source of supply, which has taken over the offices. A. P. Knedler, former sales manager for the Elkhorn City company, has taken a similar position with the Hatcher-Elkhorn company.

Hughes Paying His Debts.—John Glaser, of the Midland Coal Co., of Cincinnati, who was appointed trustee for the Hughes Coal Co. last autumn, when financial disaster faced the latter company, reports that 80 per cent of the indebtedness has been paid off and prospects are favorable for all debts being paid dollar for dollar. Charles Hughes, head of his company, has worked assiduously to accomplish this and seems well on the way of fulfilling the faith which his creditors placed in him.

Portal of Main Entry of No. 3 Mine, Phelps Dodge Corporation

Substantial construction marks the modern work of this company. The foliage on the hills, stunted and scattered, marks the semi-arid character of the climate, as well as the height of Dawson above sea-level.

Johnston Mine Closes.—The Johnston mine at Dilles Bottom notified the miners to remove their tools by June 15, as the mine is to be temporarily dismantled. The duration of the shutdown is uncertain.

Chauncey Mine to Close.—The New York Coal Co., with headquarters in Columbus, has announced that mine No. 26, at Chauncey, will be closed down indefinitely. This is due to the fact that the company cannot compete with West Virginia coal as long as compelled to pay the Jacksonville scale. About 400 men were on the payroll and the mine has been operated intermittently for the past four months, averaging about half time. Mine No. 26 of the same company, located at Floodwood, has been closed since January.

Uncover 10 Ft. Seam.—While drilling a test well on the Mills farm, near Mills Station, Gallia County, the drill pierced a 10-ft. seam of coal 350 ft. from the surface. The discovery of this seam has aroused much interest among the land owners of that section.

Toledo Dumpings Heavy.—Dumpings at the Hocking Valley docks at Toledo during the week ended June 9 totaled 340,698 tons as compared with 321,957 tons the previous week. The total dumpings up to that date were 2,106,760 tons as compared with 2,304,825 tons for the corresponding period last season. Dumpings at the New York Central docks during the week ended June 9 were 171,221 tons as compared with 208,989 tons the previous week. Total loadings at these docks to date have been 890,796 tons against 561,295 tons during the same period last season.

PENNSYLVANIA

Limits Medical Allowance.—The Attorney General's Department, in an opinion written by Deputy Attorney General James O. Campbell to Richard H. Lansburg, Secretary of Labor and Industry, holds that the State Workmen's Insurance Board has no authority to authorize payment of more than $100 for medical services, medicines and supplies for employees of policyholders of the state fund entitled, because of injuries received, to have such services and supplies furnished by their employer under the provisions of the Workmen's Compensation act. It also is held that the board has no authority to pay for such services and supplies for a greater period than the first thirty days after disability begins.

Wider Market for Lehigh Field?—The Lehigh & New England R.R. has been leased for 999 years by the Lehigh Coal & Navigation Co. to the Reading Company. In anthracite circles it is believed that this may open the way for a heavier tonnage of Lehigh coal being marketed in Philadelphia.

Coal Fall Kills Two.—Two anthracite mine workers were killed by a fall of coal in the No. 8 colliery of the Lehigh Coal & Navigation Co., at Coaldale, June 17.

New Open-Shop Record.—The Pittsburgh Coal Co. reports a new high record for open-shop tonnage during the week ended June 12. Eleven mines of the company in the Pittsburgh district produced 62,235 tons during that week. There are nearly 3,000 men now working in these mines. The average for the week was 2,772 men at work.

WEST VIRGINIA

To Build Two Big Tipples.—Contracts have been awarded for the construction of two large, modern steel tipples for the Pemberton Coal & Coke Co. in the Winding Gulf field. One will be installed at Big Stick and the other at the Watwise mine. The cost will be about $100,000. The structures will be equipped with shaker screens, picking tables, loading booms, refuse-disposal equipment as well as with resizing conveyors. Each tipple will have a capacity of 300 tons an hour.

New Equipment for Koppers.—A three-track shaker screen and rope-and-button conveyor is being installed at the Koppers Co.'s mine in Boone County.

At the annual commencement exercises of the University of West Virginia, at Morgantown on June 15, nine men were graduated from the school of mining engineering: Those who will be connected with the coal industry in the immediate future are as follows: C. F. Farmer will join the force of the Crab Orchard Improvement Co. at Eccles, Raleigh County; P. H. Gillie will become a safety director of the West Virginia state Department of Mines; H. G. Kennedy and I. A. Given will make a study of mining methods in West Virginia, and G. E. Fish will join the Island Creek Coal Co., at Holden, Logan County.

James M. Thompson, an employee of the Amherst Coal Co., Logan, was fined $10 recently for failing to timber his working place. Fred Maxwell, an employee of the Chafin-Jones-Heather Coal Co. at Peach Creek, Logan County, was fined $50 for shooting six holes before cleaning up the bugdust, thereby increasing the hazard of a dust explosion.

The Fall River Pocahontas Collieries Co., a New York corporation, has reduced its capital stock from $90,000 to $30,000, according to a certificate filed in the office of the Secretary of State in Charleston.

Air Locks at Bethlehem Mines—Success is said to have followed the installation of a double air-door lock recently installed as an experiment by the Bethlehem Mines Corporation in its mines No. 41 at Barrackville and No. 42 at Dakota. The lock is designed to prevent short-circuits in aircourses. A latch, operated by a cable and spring, prevents more than one of the two doors being opened at a time. When door No. 1 is closed, a cable connecting with the latch on door No. 2 tightens, drawing the latch away and releasing door No. 2. When door No. 2 is then opened the same principle is reversed, releasing a cable attached to the latch on door No. 1. A spring, behind the latch, forces it into place so as to lock the door until No. 2 is closed again.

The Bethlehem Mines Corporation has thoroughly rock-dusted both No. 41 and No. 42 mines here, No. 41 having received five treatments and No. 42 four treatments.

Baxter Falls in Line—With three of its largest mines, Nos. 261, 251 at Coalwood and No. 86 at Carolina, using only permissible equipment, the Consolidation Coal Co. is now installing permissible equipment in its No. 96 mine at Baxter.

Opens Old Mine—Idle for several years, the old Ehlen mine of the Consolidation Coal Co., near Shinnston, will be reopened within the next few weeks. Workmen are now busy cleaning up in preparation for the opening. This mine formerly loaded some of the best coal mined in the Fairmont region, the bed being thick and containing a good grade of Pittsburgh coal.

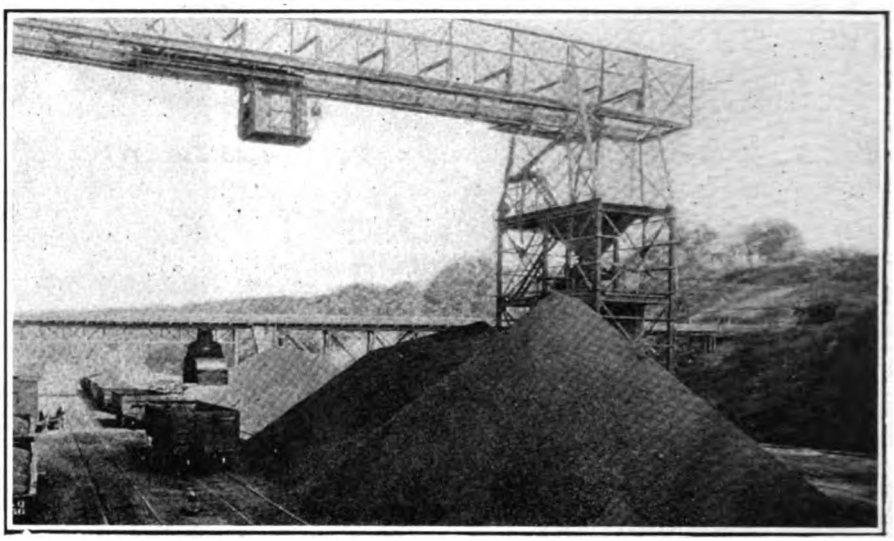
Short-Circuit Fire—A small fire, believed to have started from a short-circuit in the electrical wiring, occurring in the First street mine of the Glendale Gas Coal Co. at Moundsville recently, was extinguished before much damage

Digitized by Google

had been done by firemen from the Moundsville city fire department. The only loss was to a little timbering in the mine.

Reopen Mines to 600.—With the resumption of operations at the Wendel and Galloway mines during the first week of June, employment was given to 600 miners in northern West Virginia. The Wendel mine, located in Taylor County, is owned by the Maryland Coal Co. It had not been in operation for about two years. The Simpson Creek Collieries Co. owns and operates the Galloway mine, which is located in Barbour County, midway between Clarksburg and Grafton. The Galloway mine is being operated at capacity. This mine had been idle since Sept. 1. Both mines are on a non-union basis although formerly operated under an agreement with the United Mine Workers.

Another Non-Union Mine — Operations were resumed at the Golden mine of the By-Product Coal Co. in the Scotts Run section of Monongalia County on the morning of June 4. The mine will be run on an open-shop basis. It is owned by the Watson interests of Fairmont, but it has been leased, it is understood to several people in that city. The company has no agreement with the union. With the Golden mine resuming operations there are now 25 non-union plants operating on Scotts run, with no mines operating under agreement with the union. The non-union tonnage totals about 200 cars daily.



Testing New System—The American Rolling Mill Co., is trying out a four-room system in operating its mines Nos. 1 and 2 at Nellis, Boone County. The idea is to eliminate waste of time in furnishing the cars to the miner at the working face. Instead of one car being placed, four are furnished. The haulage is double-tracked in order to work out the plan.

The Melcraft Coal Co., with offices at 800 Union Trust Bank Building, Pittsburgh, Pa., has been granted permission to hold property and do business in this state. It is planned to operate a coal mine at Coalmont. The officers of the company include J. P. Williams, Jr., vice-president; John S. Briikes, Jr., secretary; L. R. Martin, E. C. Hugh, R. T. Rossell, F. Y. Young and F. J. Holub, all of Pittsburgh. A. W. Mellon is mentioned as a stockholder.

The Wilsondale Coal Co., Huntington, filed a certificate at the office of the secretary of state on June 2, which shows that it has been dissolved.

Improvements completed recently at Montcoal mine No. 1 of the Colcord Coal Co., in Raleigh County, include the installation of a rotary dump, 50 new steel mine cars and the replacement of one mile of track in the yard, 50-lb. rail being put down instead of 30-lb. A storage bin to place nut coal also was erected.

Arrest Law Violators — Eleven arrests were made in May for violations of the state mining laws, according to Robert M. Lambie, chief of the state department of mines. Reports show that $625 was assessed in fines. Infractions consisted of tamping holes with fine coal, shooting black powder without tamping, firing more shots than one at the same time, non-employees entering a mine and operating locomotives without authority and while under the influence of liquor, careless handling of a trip in the main haulage and other violations. The heaviest fines were for $100 which was assessed against two men, jail sentences were imposed in some instances.

Fine Coal Being Stocked at a Cement Works

Plants of the cement industry are the biggest users of pulverized coal. This is used for drying the ingredients and for burning the clinker. Joseph Harrington at the American Wholesale Coal Association's meeting in Toledo, June 8, said that 8,000,000 tons of powdered coal was used annually in cement works and only 5,000,000 tons at steam plants.

Fire Creek Coal Co., at Fire Creek, Fayette County, has let a contract to erect a new steel tipple to replace the one destroyed by fire several weeks ago. This is the oldest mine on New River, having been opened up about 1874. The Fire Creek seam of coal took its name from this concern. The tipple will have a capacity of 500 tons a day and will span three tracks. Shaker screens and loading booms are included.

The Consolidation Coal Co., Fairmont, has made arrangements with the State Department of Health to obtain filtered water from Shinnston for its mining town at Owings, Harrison County. Effort is being made also to have the mining town provided with a proper sewage system. This is among the larger mining towns of the company.

The Buckhannon Fuel Co., Buchannon, W. Va., filed a certificate at the office of the secretary of state on June 5, showing that it has been dissolved.

The Index Mining Co., Parkersburg, W. Va., has reduced its capital stock from $100,000 to $10,000.

The Winfield Coal Co., which has been operating in the vicinity of Meadow Bridge for the last fourteen or fifteen years, is dismantling its plant and removing equipment to Boncar. It is stated that the lease at Meadow Bridge has been practically exhausted.

Davy-Realty Co., Welsh, W. Va., was chartered in the office of the Secretary of State in Charleston, W. Va., on June 12, to develop coal and other minerals. The capital stock is $10,000. The incorporators are : J. H. Barker, Gary; B. O. Swope, G. A. Swope, H. H. Riley and J. N. Harman, Jr., all of Welsh.

Randall Coal Co., Morgantown, has filed a certificate of dissolution at the office of the Secretary of State.

Adamston Mine Resumes.—After being shut down since April 1, the Adamston mine of the Baltimore Coal & Coke Co. has resumed operations and is expected to run continuously. The mine will operate under the open-shop system. It has a capacity of approximately 450 tons daily.

CANADA

Canadian Roads Buy Alberta Coal.—R. C. Vaughan, vice-president of the Canadian National Rys., has announced that his company is placing orders for approximately 1,300,000 tons of coal with Alberta mine operators. The Canadian Pacific Ry. also has placed large orders for coal in that field.

The British Empire Steel Corporation have contracts which will require an output of more than 100,000 tons per week to the close of navigation. The collieries of Cape Breton will shortly be in full operation.

Begin Development Work — Equipment for the development of the McCarthy coal property, at Long Rapids, on the Mattagami River in northern Ontario, has arrived at the property after considerable delay, owing to the breaking up of the winter roads. A force of thirty men will be engaged and development actively carried on. Many claims are being staked out to the east, west and north of the original discovery.

Justice Murphy, in Supreme Court Chambers, appointed the Canadian Credit Mens' Association interim receiver for the Nanoose-Wellington Collieries, Ltd., which has been operating a colliery at Lantzville, near Nanaimo, on Vancouver Island, B. C. The company's total liabilities are placed at $115,000, of which approximately $65,000 are secured.

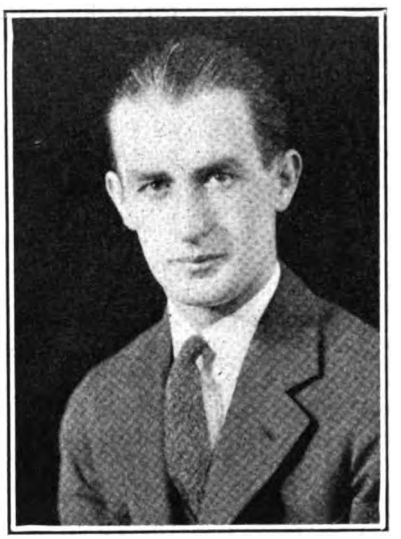
Among the Coal Men

R. D. Flippen has been appointed mine supply purchasing agent for the Norfolk & Western Ry., a position recently created. Mr. Flippen was formerly with the Williamson Supply Co. He will have his offices at the Pond Creek Collieries in South Williamson, W. Va. His duties will be to purchase all supplies for the Norfolk & Western operations, including the Vulcan Collieries, at Vulcan; Howard Collieries, at Chattaroy, and the Pond Creek Collieres, all in West Virginia.

C. B. Hotchkiss, assistant general manager of the Utah Fuel Co. of Salt Lake City, Utah, will take over the duties of general sales manager which have been performed by J. S. Critchlow for the past two or three years, but who now becomes general sales representative for the company in California. Mr. Hotchkiss will add Mr. Critchlow's duties to his present office.

Will Huffman, of Stone, Ky., who has been acting general manager of the Fordson Coal Co., has gone west for his health. He has been given a leave of absence of three months. For a time he had been in Richmond, Va.

John Dunn, who was mine foreman of the Fordson Coal Co. (Henry Ford interests) in Kentucky, has accepted a position as superintendent of the Turner Coal Co. at Ragland, Mingo County, W. Va.



T. A. D. Jones, of New Haven, Conn., coach of the Yale football team and representative of the Wyatt Coal Sales Co. in Connecticut, was one of the guests of the Kanawha Country Club opening on June 12 and 13 in Charleston, W. Va. Other coal tradesmen among the invited guests were: S. D. Fobes, of New York City, Eastern manager of the Wyatt Coal Sales Co.; Homer C. Gill of Columbus, Ohio, and Fred Lagg and W. I. Donnelly, both of Cincinnati, Ohio.

Marshall J. H. Jones, assistant to the president and general superintendent of mines, and M. D. Gibson, chief engineer, of the Bertha-Consumers Co., are at the company's Eureka mine, near Morgantown, W. Va., superintending the installation of a river tipple. When this work has been completed and the federal government has finished Lock No. 7, the mine, it is expected, will be operated at capacity.

M. R. Barrios, of Havana, Cuba, president of the American Coals Co., was a recent visitor to the southern West Virginia coal field. He called on officials of the Wyatt Coal Sales Co. in Charleston, W. Va.

Fred S. Lamb, of Pittsburgh, Pa., has been named receiver of the Short Creek Coal Co., an Ohio corporation. The receiver was appointed on the petition of William W. Keefer, of Pittsburgh, who alleges that the company owes him $86,000 on two promissory notes in addition to having other liabilities totaling $2,500,000. Mr. Keefer admits that the company is solvent, but says it is unable to meet its obligations due to the condition of the coal market. The value of the company is placed at $4,000,000, and it is said to have a capacity of 900,000 tons per year.

Dr. T. D. Scales, owner of the John Bull and Erie Canal coal mines, near Boonville, Ind., has been re-elected a director in the Hoosier State Automobile Association, which position he has held since the death of former U. S. Senator James A. Hemenway, of Boonville, about four years ago.

Jerome C. White

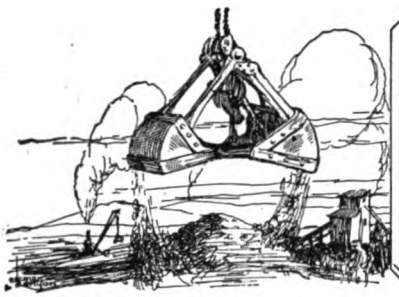
Jerome C. White, research engineer, Davis Coal & Coke Co., Thomas, W. Va., has accepted an editorial position on the *Coal Age* staff. Mr. White was born at Sonman, Cambria County, Pennsylvania, in 1896, graduated at Allegany College, Allegany, N. Y., and gained his early experience in engineering at the operations of the Rochester & Pittsburgh Coal & Iron Co. and the Buffalo, Rochester & Pittsburgh R.R. In his first year out of college he worked in mines in Colorado and British Columbia. He became mine foreman for the Penker Mining Co., Portage, Pa., later enlisting in the U. S. Navy. After the war he returned to the Penker Co. In 1922 he was associated with the purchasing department of the Lorain Steel Co., at Johnstown, Pa. He assisted in the planning and development of the Lindsey Coal Mining Co., of Corinth, W. Va. In 1924 he attended the Graduate School of Business Administration at Harvard University and at the end of the year joined the staff of R. P. Maloney, vice-president and general manager, Davis Coal & Coke Co.

Capt. James O'Boyle, president of the Pittston Coal Mining Co., of Pittston, Pa., received an honorary degree at the recent commencement exercises held at Holy Cross College, at Worcester, Mass.

Erskine Hewett, William P. Gest and Walter C. Janney have been named to represent the board of managers of the Lehigh Coal & Navigation Co. on a committee of six which will review the capital structure of the company and report back to the managers. The representatives of the stockholders on the committee are Samuel S. Walker, Walter L. Haehnlen and Thomas S. Gates.

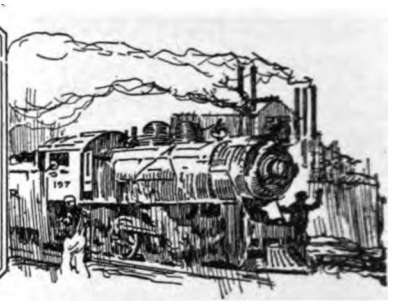
Obituary

Thomas F. Farrell Killed In Train Wreck



Thomas F. Farrell, vice-president of the Pocahontas Fuel Co., New York City, was killed in a collision of trains on the Pennsylvania R.R. near Blairsville, Pa., on June 17. He was returning from the convention of the National Coal Association, at Chicago, having been re-elected a director from West Virginia. His company has operations in Mercer and McDowell counties, in the southern West Virginia field. Mr. Farrell was a native of Sandusky, Ohio, and as a young man entered the employ of the Big Four railroad, later becoming connected with the traffic department of the Chesapeake & Ohio Ry. in Cincinnati. Probably 25 years ago he joined the old New River Coal & Coke Co. at Thurmond, W. Va., and became general manager of the western sales office in Cincinnati. After being with that firm about 12 years he joined the Pocahontas Coke Co., with headquarters at Bramwell, W. Va., and still later joined the Pocahontas Fuel Co. At the time of his death he was a director of the Smokeless Coal Operators' Association of West Virginia. During the World War he was a member of the committee from the Smokeless Coal Operators' Association to co-operate with the U. S. Fuel Administration.

After the National Coal Association meeting Mr. Farrell went to Notre Dame, Ind., to attend the commencement exercises, where one of his sons was graduated. This son was with him at the time of the accident, although he was not seriously injured, accordingly to reports.



Otto Michaelis, one of the best known operators of modern mines in the Standard field of Illinois, died suddenly June 8, at his home in Belleville, Ill., after a short illness. Born Dec. 17, 1875, in Belleville of a father who was at that time a coal-mine operator in the Standard field, he became a miner when old enough to work in the mines and retained his connection with the industry until his death. He and his brother up until two years ago operated from one to four mines at different times. The Superior mine at Belleville under his supervision was for many years noted for its economical management.

Louis T. Krebs, of Morgantown, W. Va., 50 years old, in charge of the Morgantown offices of the W. A. Marshall Co., coal brokers, of Philadelphia, Pa., died at his home June 15. Mr. Krebs had been associated with the W. A. Marshall Co. for several years and lived in Morgantown for 25 years. He was a member of the staff of the late Governor William E. Glasscock from 1909 to 1913.

Production And the Market

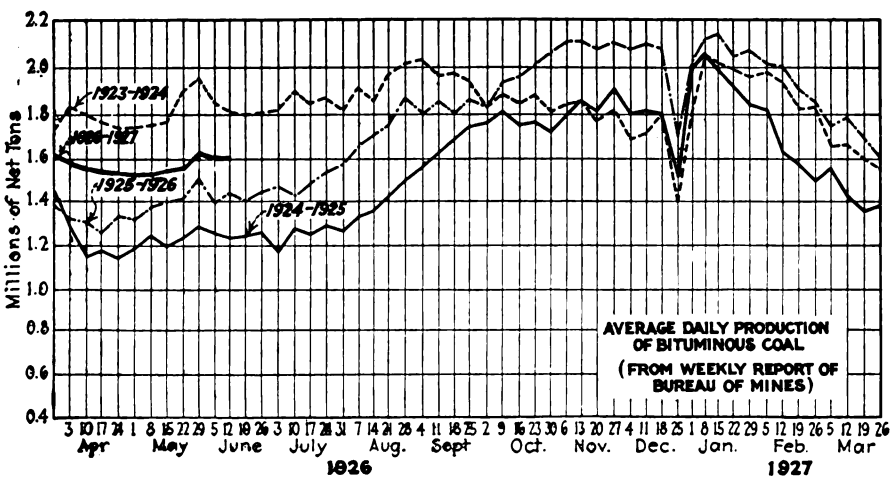
First Visible Effect of British Strike Seen in American Market; Price Change Slight

Development of a stronger demand for West Virginia high-volatile coal was the outstanding feature in the bituminous markets of the country the past week. This demand is directly attributable to the British strike and marks the first time that the cessation of British production has left a visible impress upon the market. At the outset of that strike there was a brief flurry, which disappeared as quickly as it came. Since then there has been some quiet, intermittent buying, but the volume did not become noticeable until a few days ago.

During the past week there were about sixty vessels waiting for cargoes at the southern loading piers. A number of boats also cleared from Baltimore. It was reported that British interests were in the market for 1,000,000 tons to be used on the railroads and in the gas plants of the United Kingdom. As a result of this demand, pier prices on pools 5, 6 and 7 increased 45 to 50c. per gross ton. Inland prices, while firmer, advanced only a fraction of that range.

Little Change in Price Levels

These increases, however, had little effect upon the general level of spot prices throughout the country. Pool prices at Baltimore were slightly higher. Boston prices also were higher. The general run of pool quotations at New York and Philadelphia were unchanged. Inland prices, other than those directly in the sweep of the buying movement, either remained stationary or declined. *Coal Age* Index of spot bituminous prices as of June 21 stood at 158 and the corresponding price was $1.92. This was an increase of two points and 3c. over the preceding week.



Production of bituminous coal is slowly contracting. Although the output for the week ended June 12, estimated by the Bureau of Mines at 9,600,000 tons, was 940,000 tons greater than the week preceding, that increase merely represented the recovery from the holiday depression. The actual daily rate of output showed a slight decrease. It does not appear at the present time that there will be an early substantial change in the current rate of production. More can be looked for, perhaps, in the shifts of centers of output.

Lake Movement Well Maintained

The lake trade is one of the strongest sources of support for present production. During the week ended June 20 lake dumpings totaled 998,341 tons of cargo and 46,178 tons of vessel fuel. This brings the total for the season to date to 8,299,150 tons, as compared with 7,113,347 tons for the corresponding period a year ago. 5,687,865 tons in 1924 and 9,096,840 tons in 1923. Anthracite dumpings the preceding week ended were 113,711 tons.

The recovery in anthracite production during the week ended June 12, when output was estimated at 2,083,000 net tons, hardly reflects the market situation. As a matter of fact, the principal consuming centers report a diminishing demand for domestic sizes. In sympathy with this decline several of the independent producers have adopted a policy of voluntary suspension of operations for two days a week. In no other way does it seem possible to check the downward movement of spot prices on independent domestic tonnage and the collapse of quotations on steam sizes.

The Connellsville coke market is a humdrum affair. Prices have shown no change because the spot demand has been so light. Production, however, is declining and there is little surplus tonnage offered—so little in fact, that substantial orders probably would mean an advance in furnace quotations.

Estimates of Production

(Net Tons)

		1925	1926
BITUMINOUS			
May 29		8,141,000	9,683,000
June 5 (a)		8,375,000	8,660,000
June 12 (b)		8,622,000	9,600,000
Daily average		1,437,000	1,600,000
Cal. yr. to date	(c)	212,592,000	243,004,000
Daily av. to date		1,539,000	1,757,000
ANTHRACITE			
May. 29		1,681,000	2,089,000
June 5 (a)		1,634,000	1,678,000
June 12		1,825,000	2,083,000
Cal. yr. to date	(c)	39,706,000	31,063,000
BEEHIVE COKE			
June 5 (a)		130,000	195,000
June 12 (b)		136,000	196,000
Cal. yr. to date	(c)	4,931,000	6,169,000

(a) Revised since last report. (b) Subject to revision. (c) Adjusted to equalize number of days in the two years.

Middle Western Coals Sluggish

Neither steam nor domestic coals are active in the Illinois and Indiana producing fields. Large industrial consumers are withholding orders in spite of the fact that production of fine coal has been curtailed because demand for the larger sizes is so small. A number of Chicago plants claim that current stocks must be reduced before any large-scale purchasing is resumed. St. Louis, too, is backward. Standard prices, except on central Illinois lump and screenings, continue firm.

There is, however, enough regular business moving to keep Illinois output up to 1925 levels, but Indiana is slipping. Much of this tonnage is for industrial consumption. All fields are loaded down with "no bills" of domestic sizes. Strip mines have the edge on competitive business in southern Illinois. The Duquoin district just limps along. Railroad tonnage is the support of the Mt. Olive field. The Standard district is still selling at a loss.

In the domestic market, Eastern coals command the trade. There is a steady demand for smokeless mine-run in the Chicago district and a fair movement of lump, egg and nut to country yards. Retailers have found the Eastern high-volatiles an attractive buy. Anthracite demand is slow. Coke is seasonably active. There is very little storage business being booked in the St. Louis market.

Kentucky Continues Improvement

Improvement, both in all-rail shipments and in the tonnage moving to the lakes, characterizes the eastern Kentucky trade. In the western part of the state, however, complaint is made that the demand from markets north of the Ohio River is not living up to the rosy hopes expressed when the new sales arrangements were made several weeks ago. Nevertheless, recent production figures show weekly outputs considerably in excess of the totals for 1924 and 1925.

The heavier rate of shipment to the lakes has weakened the prices on slack coal from the eastern fields and western screenings have reacted in sympathy. The general range in both fields now is $1@$1.15. Some eastern producers also have sold block at $1.75@$1.80. Most operators, however, ask $2@$2.35. Aside from these defections and a little quiet shading here and there on specific orders, the general level of spot quotations is unchanged.

The market at the Head of the Lakes is still in a state of flux. Dock operators, however, are consoling themselves with the thought that prices will become stabilized on the basis of the recent reductions. One dock officially has reduced its price on Elkhorn lump and stove 75c.; splint, 75c.@$1; Hocking, 35@50c. Screenings are weak. Kentucky and Pocahontas screenings are offered at $4 and other grades are $3.75.

No further reductions are expected. Most of the large steam contracts have

Digitized by Google

been signed. Retail buying is on a hand-to-mouth basis because of the price demoralization and unfavorable credit situations. Demand for industrial coal over the iron ranges also is light because mining operations have been curtailed and heavy stocks were accumulated earlier in the season. Receipts from the lower lake ports are substantial. The latest report shows 57 cargoes, including seven of anthracite, unloaded in a week.

Northwestern Trade Marks Time

A better industrial outlook is foreseen in the Northwest with more favorable crop prospects. Coal buying at the Twin Cities, however, is quiet. The price war at the docks put all-rail coal out of the running for the time being, as Illinois and Indiana shippers showed no inclination to follow the lead of the docks in price slashing. A steady movement is reported from Milwaukee. Up to June 17 receipts of lake coal at that port totaled 1,045,372 tons, as against 959,073 tons a year ago.

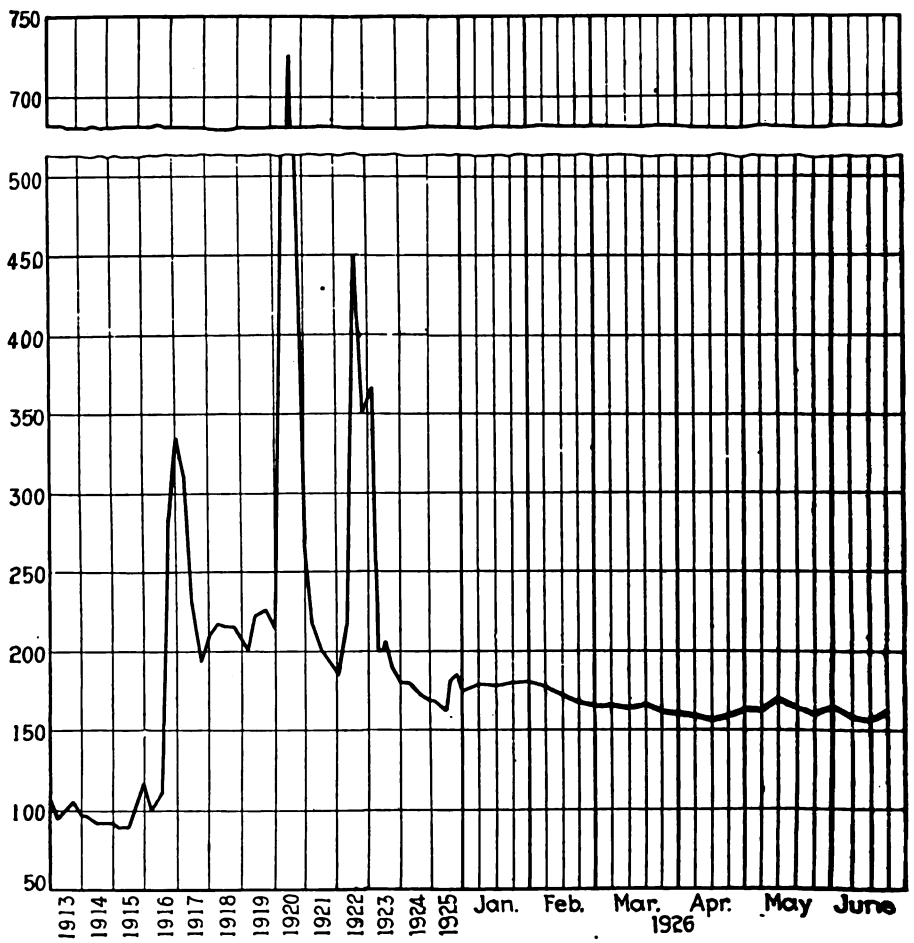
Conditions in the Southwest are steadily improving, but few shaft mines are operating in the Kansas fields. Increasing demand, however, probably will bring these mines into production within a few weeks. There is a brisk storage demand for Arkansas semi-anthracite. Prices generally are unchanged.

Retailers show little interest in storage coal prices made by the Colorado mines. Activity in the steel industry and at the sugar refineries holds up the demand for industrial coals. Colorado prices are firm. Kemmerer-Rock Springs domestic grades are $3.60; steam sizes, $1.10@$1.50. Utah retailers are keeping up their storage stocks, but the public displays less eagerness to take advantage of the low prices which have been made on summer deliveries.

High-Volatile Takes Lead

The tidewater demand for high-volatile coal held the center of the stage in the Cincinnati market last week. Heavy buying for foreign shipment put a number of Kanawha operations on a full-time basis. Logan County, too, enjoyed some of the benefits of the increased demand. All grades of West Virginia high-volatile have advanced in price, but eastern Kentucky did not share in the increase. Low-volatile coals, on the other hand, are sluggish and slack is selling at the same range as that prevailing in the high-volatile fields.

Movement through the Cincinnati gateways last week totaled 13,875 loads, an increase of 704 cars over the preceding week and 896 over a year ago. Louisville & Nashville interchange increased 841 cars; Norfolk & Western 71 cars. Chesapeake & Ohio interchange decreased 213 cars. The total interchange included 4,049 cars destined to the lakes. There were 12,845 empties en route to the mines.



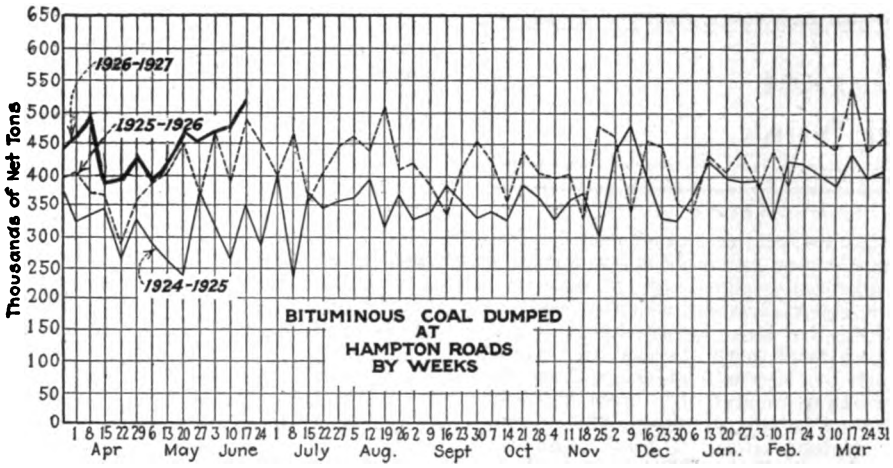
The Cincinnati retail market is so quiet that trade observers are convinced that it could not be revived by price reductions.

A broader demand for domestic grades featured the central Ohio market the past week. Urban dealers were more willing to stock splint and smokeless coals. School contracts also helped the situation. Distress offerings have disappeared and prices generally are steadier. Country buying, however, is backward. Steam demand still is sluggish. A few contracts are renewed from time to time. Spot business is slow. Public utilities and railroads are the largest buyers. Southern Ohio production does not exceed 15 per cent of capacity.

Northern Ohio Prices Weaken

Prices in northern Ohio are erratic. All grades of No. 8 coal were weaker last week. Further declines, particularly on slack, are forecast as the pressure of accumulations from the non-union fields shipping to the lakes increases. There is little life to spot trading at Cleveland. During the week ended June 12 the eastern Ohio district produced approximately 203,000 tons, or 29 per cent of capacity, as compared with 161,000 tons the preceding week and 232,000 tons a year ago.

A nickel gain in the spot prices on gas slack marks the change in the Pittsburgh district market the past



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	June 21	June 14	June 7	May 31	June 22	June 23
Index	158	156	157	160	161	166
Weighted average price	$1.92	$1.89	$1.90	$1.94	$1.95	$2.01

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

week. There is little storage buying and no real increase in the movement for current consumption. Central Pennsylvania, on the other hand, wears a brighter aspect than the western part of the state because production is slowly forging ahead of May figures. Retail buying is the explanation advanced for the gain. Prices are unchanged.

The Buffalo bituminous market remains a haven of pessimism. There has been a slight increase in gas slack prices, due more to lack of lump orders than to a bigger demand. Nominal quotations are: Pocahontas lump, $2.75@$3; mine-run, $2@$2.25; slack, $1.50@$1.75; Somerset County lump, $2.75@$3; mine-run, $2.50; Westmoreland gas lump or mine-run, $2.50; slack, $1.50; Cambria mine-run, $2@$2.25; Indiana County lump, $2.85; mine-run, $2.10; Fairmont lump, $1.50@$1.65; mine-run, $1.40@$1.45; slack, $1.10@$1.25; Youghiogheny lump, $2.15@$2.35; slack, $1.35@$1.55; Pittsburgh and No. 8 steam lump, $1.65@$1.85; slack, $1.30@$1.50.

Stronger Undertone in New England

In New England the steam coal market seems a shade firmer, due more to curtailed production and increased export inquiry than to any improvement in domestic demand. Navy Standard is up to $4.35@$4.50 at Hampton Roads, although little tonnage is changing hands at the top figure. On cars at Providence or Boston, some interests are asking $5.40@$5.50 per gross ton, but there are others who will make concessions to clean up tonnage.

Outside of inquiries for exports and contracts for the rest of the coal year, the bituminous situation at New York is moribund. The export demand is favoring Kanawha coals. It would not be surprising, however, if low-volatiles also gained. The latter are enjoying a larger movement for bunker fuel. On the contract side of the market, negotiations are impeded by the refusal of Pennsylvania producers to sign up at ruinous prices.

At the present time, factors in the Philadelphia market see nothing to lift the bituminous trade at that point out of the doldrums. Current buying shows no unusual features. Contracts are more or less of a dead issue. Baltimore centers its attention upon the export and bunker movements, both of which are more active. Although local demand has not broadened, the spot market is somewhat stronger in all pools.

Spot steam trade in the Birmingham district is slow. Deliveries against industrial contracts are well maintained, but railroads are taking only minimum allotments. The contract movement of domestic grades is steady. There is little inquiry in the spot market, however, for the medium and lower grades of coal. Spot demand for coke is more active and third and fourth quarter contracting is encouraging. The base contract price on foundry coke is $5.50; spot moves at $6@$6.50. There is some stocking of domestic coke by western dealers.

Anthracite Demand Diminishes

A diminishing demand for domestic sizes of anthracite is reported from the Atlantic seaboard markets. The point has been reached where some of the independents are compelled to shut down two days a week. The adoption of this policy has upset the plans of buyers who had hoped to pick up blocks of independent tonnage at further price concessions. Stove coal leads in demand at both New York and Philadelphia. Pea is easier, but there is no surplus tonnage to be had.

Chestnut is the weakest of the larger sizes. Many retailers are loaded up with this size and will take additional tonnages only in mixed orders. Egg, too, is somewhat sluggish, but not to the same extent as nut. Straight lots of stove, on the other hand, command a premium of 25c. in the New York spot market.

Barley alone of the steam sizes reveals indications of activity—and the signs are none too strong. Buckwheat and rice are a problem to most shippers and price concessions are the order of the day. With the policy of curtailing production adopted by the independents and storage of steam sizes by the larger companies, hopes are entertained that further declines may be checked.

Car Loadings and Supply

	Cars Loaded—All Cars	Cars Loaded—Coal Cars
Week ended June 5, 1926	945,964	155,094
Preceding week	1,081,164	177,600
Week ended June 6, 1925	998,243	153,217

	Surplus Cars—All Cars	Surplus Cars—Coal Cars	Car Shortages—All Cars	Car Shortages—Coal Cars
June 7, 1926	270,841	79,013	.....	.....
May 31, 1926	257,926	75,253	.....	.....
June 8, 1925	318,805	125,785	.....	.....

Lake shipments from Buffalo during the week ended June 17 totaled 77,300 net tons, of which 35,500 tons cleared for Milwaukee, 24,600 tons for Sheboygan, 14,400 tons for Duluth and Superior and 2,800 tons for Sault Ste. Marie.

Spot Connellsville furnace coke is $2.75@$2.90, but there is little tonnage moving. Any real demand probably would send the price to $3. Contracting for third quarter deliveries is proceeding very slowly. There is practically no contract demand for the second half foundry coke as the majority of the foundries seem content to buy on the open market, which holds at $4@$4.50.

Coke production in the Connellsville and Lower Connellsville regions during the week ended June 12 totaled 138,610 tons, according to the Connellsville *Courier*. Furnace oven output was 78,100 tons, a decrease of 2,300 tons when compared with the week preceding. Merchant oven output—60,510 tons—decreased 1,080 tons.

Utility May Use Lignite.—Officials of the Northern States Power Co., from Minneapolis, held a conference at Fargo, N. D., last week to consider the use of lignite coal in their plants. The company has a number of water-power developments with steam auxiliaries, as well as many steam plants. Two immense plants are located in the Twin Cities besides a number of lesser plants in and around the cities. The activities include several street-car systems as well as electric light and power plants.

Foreign Market And Export News

British Suspension Boon to German Foreign Coal Trade; Restrict Prices and Output

Berlin, Germany, June 5.—The British strike has opened the way to a recovery of some of the export trade lost by Germany during the Ruhr occupation. Slight gains also have been made in the local markets. No attempt, however, has been made to exploit the fuel resources of the country by pushing up production. Prices, too, have been held down to prevent a domestic labor crisis.

The policy being pursued by the German trade is that laid down by the Ruhr syndicate at the beginning of the strike. At that time many operators were inclined to pick up profits where they could and let business drift in the current of events, but wiser counsels prevailed. It was feared that a boom of transient character would be seized upon by labor to further its own interests. German operators did not want a boom at the expense of domestic labor troubles. They refused to be mere stopgaps and accepted only contracts of some duration.

This policy was strengthened by the fact that the capacity of the German coal-mining organization does not lend itself to a sudden large increase of output. At the beginning of the strike the Ruhr syndicate was producing 312,000 tons of bituminous coal per day. This output was pushed up to 352,000 tons the third week of the strike. As the consumption of British coal in Germany amounts to about 12,000 tons per day, the surplus was only 28,000 tons.

It is possible to raise the daily output to 400,000 tons per day. The other fields hardly come into consideration as their combined output is less than half of the Ruhr production and their margin of capacity, not more than about 25,000 tons per day. The total surplus tonnage which Germany could add to normal output, therefore, does not exceed 2,500,000 tons per month, which, of course, is only a fraction of the British output and requires careful husbanding.

On May 1 the Ruhr syndicate had about 9,000,000 tons stored at pits and 400,000 tons loaded in lighters and railway cars. The reserves in all other fields aggregated 700,000 tons. This reserve, however, included a fair percentage of coke, for which during the first month of the strike no visible increase of demand has become noticeable, and of bituminous coal—chiefly lean coal which is of secondary consideration in the export trade. The German reserves are therefore chiefly for domestic consumption and that such is the case has been proved by events. After a full month of the British strike it was stated that the 9,000,000 tons of the Ruhr syndicate had not diminished and only the 400,000 tons in transit were cleared to some extent.

In view of the situation it is clear that German coal mining can profit by the British strike only by recovering such export markets as have been lost during the Ruhr occupation and possibly a small percentage of the market which British coal has had in Germany. A certain amount of success has been achieved in this direction, and a number of long contracts from public institutions in France, Belgium, Finland, Sweden and Denmark have been obtained. This number will increase according to the duration of the British strike and in the same proportion as the coal shortage in Europe grows.

The conditions under which the Ruhr syndicate is booking orders are rather strenuous and nothing less than pressing need is causing foreign buyers to accept them. Such orders are drafts on long sight and there is no doubt that German coal mining will emerge from the situation created by the British strike in a stronger position.

A considerable increase of the German coal export in the months to come is already assured and every week of the British strike is adding to it, but the sudden boom which the German public, including the stock exchange, had expected will be studiously avoided no matter how long the strike lasts.

Alexandria Coal Market Quiet

The May coal market of Alexandria, Egypt, closed quietly with sales 44,000 tons, arrivals 38,000 tons and stocks 90,000 tons, according to a cable to the Department of Commerce from Trade Commissioner Richard A. May, Alexandria. Imports from Germany were 7,000 tons. Arrivals are now negligible. Prices: Cardiff, 260 piastres; Newcastle, 200 piastres.

Franco-Belgian Trade Stronger

Paris, France, June 10.—Each week the British tie-up continues adds to the strength of the coal markets here and in Belgium. Thrown back upon her own resources, France finds it necessary to husband her supplies and the French mines are limiting contract shipments to 70 per cent of contract order.

In view of the instability of exchange, some of the French government bureaus are inserting clauses in coal contracts placed with foreign suppliers fixing payment in francs on a pre-determined rate of exchange for the pound sterling, American dollar, Belgian franc or the reichmark.

Increases in mining rates are the order of the day. Effective June 1, wages in the Loire have been increased 2.25 to 2.75 fr. per day for underground workers, 1.80 to 2.25 fr. for surface adult laborers and 1.25 fr. for girls and boys.

Prices at the pitheads in the Sarre have been advanced 3@8 fr.

April output of coal and lignite in France totaled 4,200,222 metric tons, as compared with 4,566,021 tons in March.

Since May 1 prices on Belgian coals have been raised 9@44 fr. Coking smalls are scarce at 115@117.50 fr. Lean duffs are almost out of the market. Offers of 220@240 fr. bring out little anthracite sorts.

Coming Meetings

American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

Illinois and Wisconsin Retail Coal Dealers' Association. Thirty-first annual convention, Highland Hotel, Lake Delavan, Wis., June 28-30. Managing Director, N. H. Kendall, Great Northern Hotel, Chicago, Ill.

The **West Virginia Mining Institute** will hold its summer meeting July 13 and 14 at Bluefield, W. Va.

Fifth International First-Aid and Mine-Rescue Contest, San Francisco, Calif., during the first week of September, 1926, under the auspices of the Bureau of Mines, Department of Commerce.

Coal Mining Institute of America. Annual meeting, Chamber of Commerce, Pittsburgh, Pa., Dec. 8, 9 and 10. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

New Companies

The Barco Coal Co. has been incorporated in Denver, Colo., with a capital stock of $100,000, by K. S. Barnett, G. B. McClellan, and Fred Hunziker. Address Rothegerber & Appel, 650 Symes Bldg., Denver.

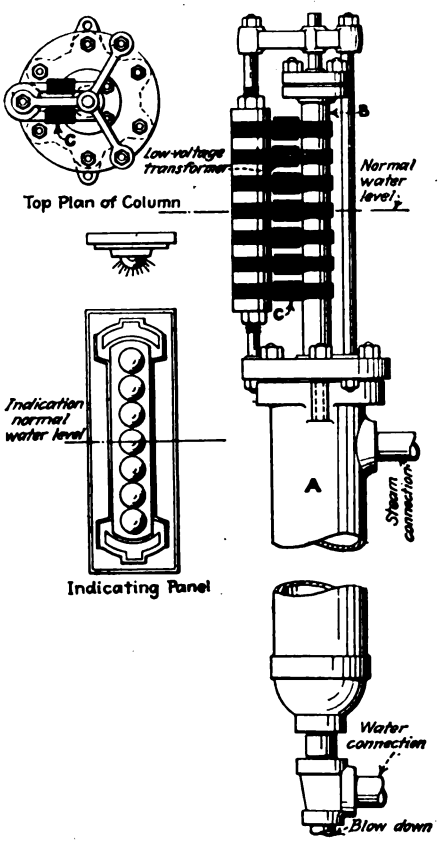
A certificate of incorporation has been issued to the **Rosedale Fuel Co.,** Fairmont, W. Va.; capital $1,000,000. The incorporators are C. H. Humphries, Charles E. Hawker and R. S. Waller, of Fairmont, and James E. Gaskins and Robert D. Bradford, of Morgantown.

Carbondale Coals, Ltd., of Calgary Alta., has been incorporated to mine and deal in coal, with a capital of $300,000. The incorporators include Andrew L. Stevens, William Kemp and Leonard E. Cross.

The Leland Coal Co., Ltd., has been incorporated to mine coal and other minerals, with a capital of $1,000,000, by James H. Prowse, George Gray, Norman R. Shaw and others. Headquarters are at Taber, Alberta.

The Freeport Collieries Co., of Columbus, Ohio, has been incorporated with a capital of $10,000 to own, deal in and operate coal properties of all kinds as well as to deal in coal and coke at wholesale. Incorporators are E. E. Learned, B. W. Gearhart, J. R. Elder, Adam G. Innis and S. D. Doney.

The Cameo Coal Mining Co., of Whitesburg, Ky., has been incorporated with a capital of $10,000, by A. B. Ewen, T. F. McConnell and W. J. Raybould, to operate in the Letcher fields of southeastern Kentucky.



The Wabash Coal & Coke Co., 343 South Dearborn St., Chicago, has been incorporated with 1,000 shares of no par value to mine and deal in coal and other fuel products. The company was organized by E. M. Strachan, A. C. McClelland and Morris Bernstein.

New Equipment

Ace Water-Level Indicator

A type of liquid water-level indicator used for boilers, tanks, etc., known as the "Ace," with which one or more indicating panels may be used and which may be placed adjacent to or at any convenient point some distance from the boiler, has been brought out by the W. B. Connor Co., Inc., 110 West 42d St., New York City.

The indicator consists essentially of a float chamber or column *A* with a special extension tube *B* for the armature, low-voltage transformers *C* and a seven-light indicating panel. The tube *B* is made of non-magnetic metal through which the magnetic flux passes across the pole of the external armature. The low-voltage transformers *C* are located outside the apparatus in order to avoid contact with the live steam. They are also not subjected to any pressure or temperature. The armature actuated by a float in the column *A* and responding to the water level, travels through the magnetic field of seven transformers, giving seven indicating points. The armature is tubular in construction, made of magnetic material and copper plated. The rod connecting the armature to the float is Monel metal. The float is kept as small as possible, namely 3½ in. in diameter, and is made of forged steel suitable for steam pressures up to 600 lb. No guides or other internal mechanisms that would tend to cause sticking and prevent operation are used.

Water-Level Indicator

A float within the water column on the boiler actuates low voltage transformers located above it which energize a bank of remotely situated lamps. These show the level of the water in the boiler.

The transformers, located as they are, are not subject to excessive temperatures and the voltage carried on the primary is between 3 and 4 volts. The output of the secondary transformer when the armature is out of the field is about ¾ volt and with the armature in the field about 3 volts, operating a 3.8 volt light. The device can be used in connection with operating a series of lights of an indicator as illustrated or a graphic chart for permanent record or a high- and low-water alarm signal. The indicators are made for standard pressures of 150, 250, 400 and 600 lb., and the weight is approximately 175 lb. The water column or float chamber of the indicator can be used as an auxiliary to the standard water column as illustrated, or it can be furnished equipped with water gage to replace the existing column.

Switchboards Automatically Control Substation

In the accompanying illustrations may be seen the two switchboards constituting the new Cutler-Hammer automatic substation controller. This apparatus has been so designed that it starts the motor-generator set and automatically provides maximum protection without the expense of an attendant.

This controller is composed of two switchboards, one for the high- and the other for the low-tension current. These boards are interlocked both mechanically and electrically. The low-tension board is really the "master mind" of the control apparatus. It is this board which ferrets out the troubles and guards the motors, generators, machinery and control equipment from damage. It provides automatic starting, stopping and protection to all the equipment.

The apparatus can be made to start by means of a time clock, or a push button which may be located at some remote point. After it is started by either of these methods the low-tension board takes full control, responding immediately to all emergencies as well as to normal conditions.

The following controls are provided in the construction of this low-tension board: Automatic starting from a push-button station; alternating-current, low-voltage release; automatic restart after return of alternating current; dead-phase, reverse-phase, phase-failure and field-failure protection; alternating-current overload protection by means of an instantaneous trip and also by an inverse time limit; thermal protection of the transformers; automatic opening and closing control of the direct-current circuits; direct-current

Digitized by Google

overload protection by time limit and also instantaneously; direct-current, low-voltage and reverse-current protection. The board also contains an alternating-current line voltmeter, direct-current ammeters for synchronous motor field, direct-current line voltmeter and a line ammeter.

The Master Mind

This is a front view of the direct-current switchboard. It is interlocked both electrically and mechanically with the alternating-current board, the two forming the complete control. Most of the real control apparatus is, however, mounted on this board.

The high-tension board carries all of the high-tension switching equipment. It is interconnected with the low-tension board, and functions in combination with it. This board also contains a potential transformer, providing dead-phase protection and in addition furnishes low voltage for the alternating-current line voltmeter. High-tension fuses protect this transformer. This board also carries current transformers for use with the overload relays and the alternating-current ammeter. It has also oil-immersed switching equipment consisting of: A 3-pole manually operated oil circuit breaker, arranged for bell-crank operation from the front of the low-tension board; a 5-pole, oil-immersed, magnetic contactor used in starting, which connects the auto-transformer to the line, and the motor starter to the auto-transformer low-voltage tap, during the acceleration period; one 3-pole oil-immersed magnetic contactor used in running.

Alternating-Current Switchboard

Upon the board is mounted the alternating-current switches and some other pieces of equipment. Although the two boards are separate they are so interconnected that they form practically a unit control. Thus although their functions are somewhat dissimilar they operate in conjunction one with the other.

In order to prevent short circuiting the auto-transformer this contactor is mechanically interlocked with the starting contactor so that both cannot be closed at the same time. The transfer from the starting to the running contactors is accomplished by the supervisory relays on the low-tension panel.

In the design of these switchboards, particular attention has been paid to accessibility for inspection and maintenance. All high-tension wiring between circuit breaker and oil-immersed contactors and transformers is made by means of a rigid busbar. Lugs are provided for connecting incoming lines, motor leads, and auto-transformer to the board. An asbestos terminal board near the floor provides easy means of connecting the control and meter circuits to the low-tension panel.

When the control circuit is closed either by push button or time clock, the synchronous motor comes up to speed and the direct-current circuit breaker is closed, connecting the load to the generator. If any trouble exists on either the direct- or alternating-current sides of the set which may damage the apparatus, or if such trouble should occur during operation, the set will automatically shut down until this difficulty is rectified. It will then resume operation automatically.

John W. Guay, formerly sales engineer of the Fort Pitt Steel Casting Co., McKeesport, Pa., has been appointed works manager, and **H. F. Stratton**, formerly in charge of the pattern, mould and core department, has been named superintendent.

Hall-Will, Inc., Erie, Pa., is the name of a firm recently organized for the manufacture of pipe, bolt and nipple threading machines. Leslie S. Hall, formerly vice-president and general manager of the Williams Tool Corporation, who organized Hall-Will, Inc., is its president and general manager, and C. F. Williams, a son of the founder of the Williams corporation, is its vice-president.

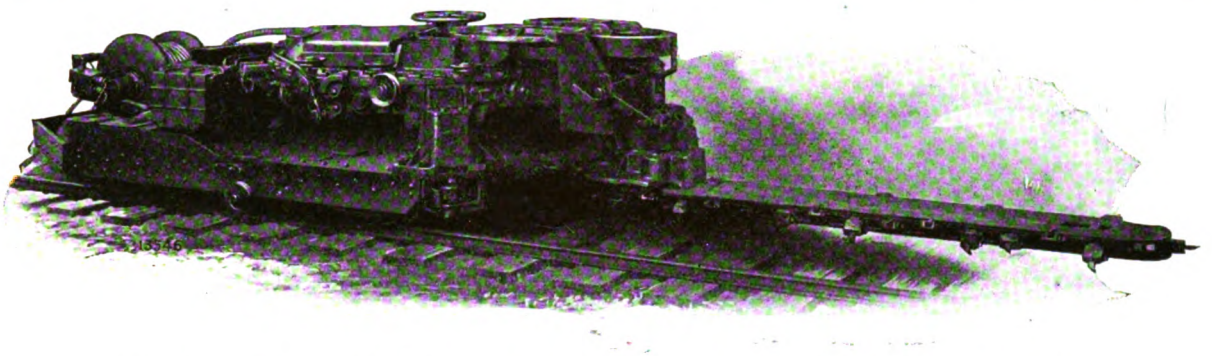
Joseph T. Ryerson & Son, Inc., of Chicago, Ill., have taken over the reinforcing bar division of the Penn Metal Co., of Boston.

Wm. L. Moorhead, of the Moorhead Electric Machinery Co., and Gust Reitmeyer, expert in repairing and rebuilding mining equipment, have consolidated their interests and formed the **Moorhead-Reitmeyer Co., Inc.**, 40 Water Street, Pittsburgh, Pa. A complete line of used mining equipment and modern repairing facilities will be available.

The Ohio Brass Co., Mansfield, Ohio, has moved its Chicago office from 1217 to 1714 Fisher Building, 343 South Dearborn St.

The Baltimore office of the **Timken Roller Bearing Service & Sales Co.** was closed May 1. The service requirements of customers in this territory will be supplied through the Richmond, Pittsburgh and Philadelphia branches. T. F. Rose, formerly assistant manager of the Chicago branch of the company, has been appointed manager of the Cincinnati branch. H. C. Sauer has been named manager of the Detroit branch. Fred G. Rumball, formerly manager of the Kansas City branch, has been promoted to the position of sales engineer, automotive division, of the Timken Roller Bearing Co. Mr. Rumball will have his headquarters at Cleveland. The position of branch manager at Kansas City will be filled by J. M. Carey.

The Knoxville (Tenn.) office of the **Sullivan Machinery Co.**, E. L. Thomas, manager, has just moved from 614 Market Street to new and larger offices at 611-15 General Building, 623 Market St.



The Tulley Equipment Co., St. Louis (Mo.) representative of the Climax Engineering Company, Clinton, Iowa, has moved to 2339 Pine Street, where offices and a service station will be maintained.

The A. F. Brown Co., 79 Barclay St., New York City, has removed its sales department and stock room to the general office and works, at Elizabethport, N. J.

The Park Manufacturing Co., makers of motors for special use in coal mines, will start a factory at Petersburg, Ind., it has just been announced. At the present time the company turns out this equipment at Terre Haute, Ind.

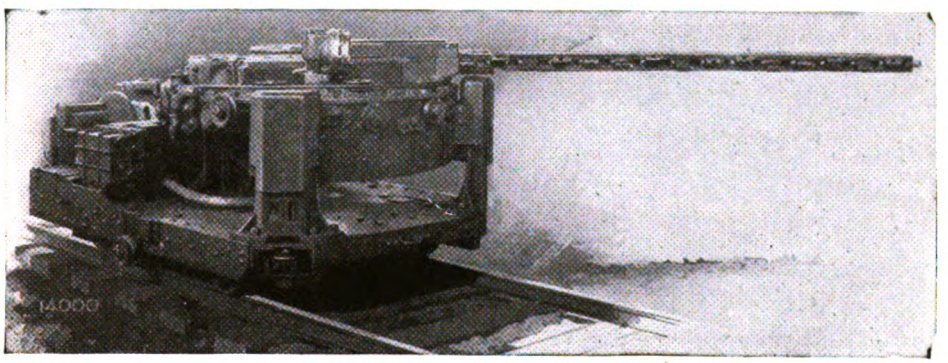
A COMPLETE LINE FOR CUTTING, LOADING, HANDLING & VENTILATING

29-C Arcwall Bottom Cutter. The swivel cutter-bar can be locked in three positions, which permits under-cutting on the bottom without interfering with the track, and leaving no wedge-shaped portion of bottom to be taken up.

29-C "ARCWALL" COAL CUTTER



Trade Mark Reg. U. S. Patent Office

THE Jeffrey Arcwall has a wide range of cutting heights —on bottom, or at any place between bottom and roof; in the coal, or in the shale bands or dirt.

Adjustable while in operation to an irregular binder and operated on a truck, which eliminates loading and unloading.

Cuts out dirt bands, insuring a clean, marketable product. Produces more lump coal because light charges of powder may be used — coal is not shattered so much.

Has an average cutting record of 20 to 30 places in eight hour shift.

Jeffrey Permissible Type Arcwall Coal Cutter. Its construction follows the general design of the Standard Arcwall Machine and is Government Approved throughout.

Your answer to— *lower locomotive costs per ton hauled!*

And how can your annual locomotive costs be reduced? Vulcan Electric Locomotives answer this question. They are designed primarily to reduce maintenance and operation costs. They embody the same long-service qualifications as the popularly used Vulcan Steam Locomotives, which have service records of thirty and forty years.

The feature which has done most to make possible Vulcan Steam Locomotive durability, and is now built into the Vulcan Trolley Locomotive, is the 3-point suspension of the chassis. This feature absorbs shock, reduces wear and strain, and cuts down maintenance costs.

Get the complete facts about Vulcan Electric Locomotives—both trolley and storage battery. It will pay you.

VULCAN IRON WORKS
WILKES-BARRE, PA.

New York Office: 50 Church St.

Established 1849

Chicago Office: McCormick Bldg.

VULCAN IRON WORKS OF Wilkes-Barre, Pa. U.S.A.
STEAM GASOLINE ELECTRIC **LOCOMOTIVES**

How and why it's built like the Vulcan Steam Locomotive

Here is the answer to the demand of the industry for a Trolley Locomotive with the same shock-resistant, long-service features as the Vulcan Steam Locomotive.

3-Point Suspension

This 3-Point Suspension of the entire chassis is an exclusive feature of the Vulcan Trolley Locomotive. One pair of springs supports the frame through one set of hangers. One end of another pair of springs is held by other hangers. The opposite ends of the springs engage an equalizing bar extending across the machine and supported in the center. By means of this arrangement shocks are absorbed, the weight is evenly distributed and the locomotive runs smoothly over any ordinary inequalities of track.

Other Features

Cast Steel Bar Frame

Each side frame is cast in one piece and of steel bar design, thus combining maximum rigidity as well as accessibility. The open spaces permit ample ventilation and simplify inspection.

Brake Rigging

The powerful, easily operated brakes, like the other two features, have been adopted in a large degree from Vulcan Steam Locomotive practice.

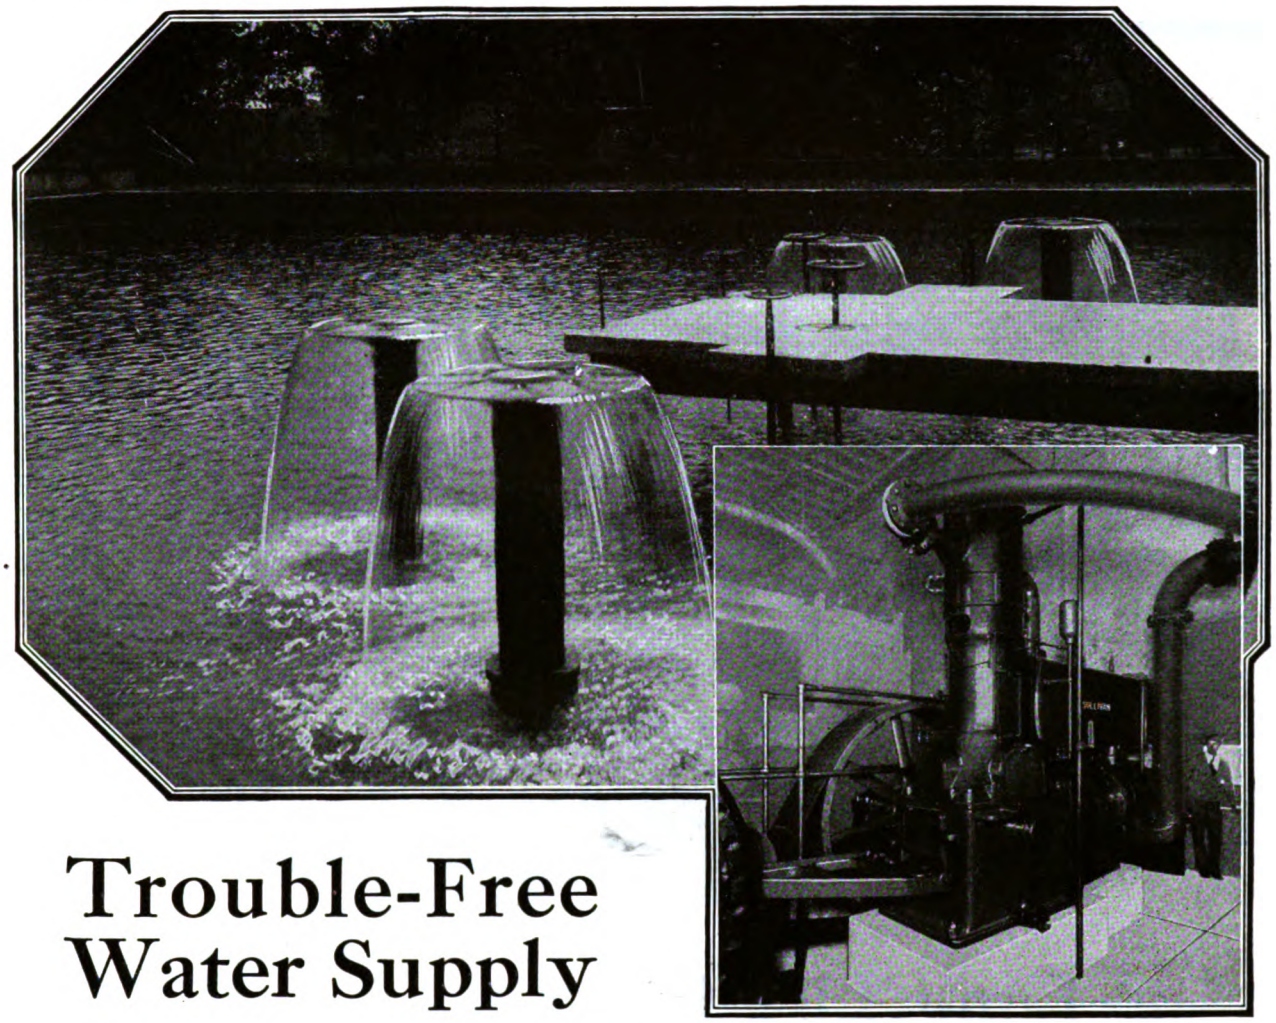
You Can't Stop This

But You Can Replace the Switch —Quickly

BURNED out contact jaws and blistered blades are inevitable. Equally unavoidable are bends and twists caused by abuse. The huskiest switch is not sufficient protection from such conditions.

The remedy is a switch that is readily accessible and quickly installed. To install the new switch the insulator need not be removed from the line. The switch is readily accessible on top of the insulator.

The new switch always fits. The seats upon which the switch parts rest are machined after assembling on the insulator. Switches are interchangeable.



Sturdy ash side bars and a heavy all-bronze under-run give assurance of long life to the rest of the Double-Gap Section Insulator.

Trouble-Free Water Supply

Whether your water strata are deep or shallow, rock or gravel or sand, you can assure a continuous trouble-free supply from your wells by adopting the

SULLIVAN AIR LIFT SYSTEM

Sullivan Air Lift is dependable, because the wells may be cleaned, and then kept free permanently from mud or sand.

It maintains its efficiency over long periods.

There are no wearing parts in the wells to require inspection or repair.

A number of wells may be pumped from a central station, with full control of each.

More water may be obtained from wells by air lift than by mechanical pumping.

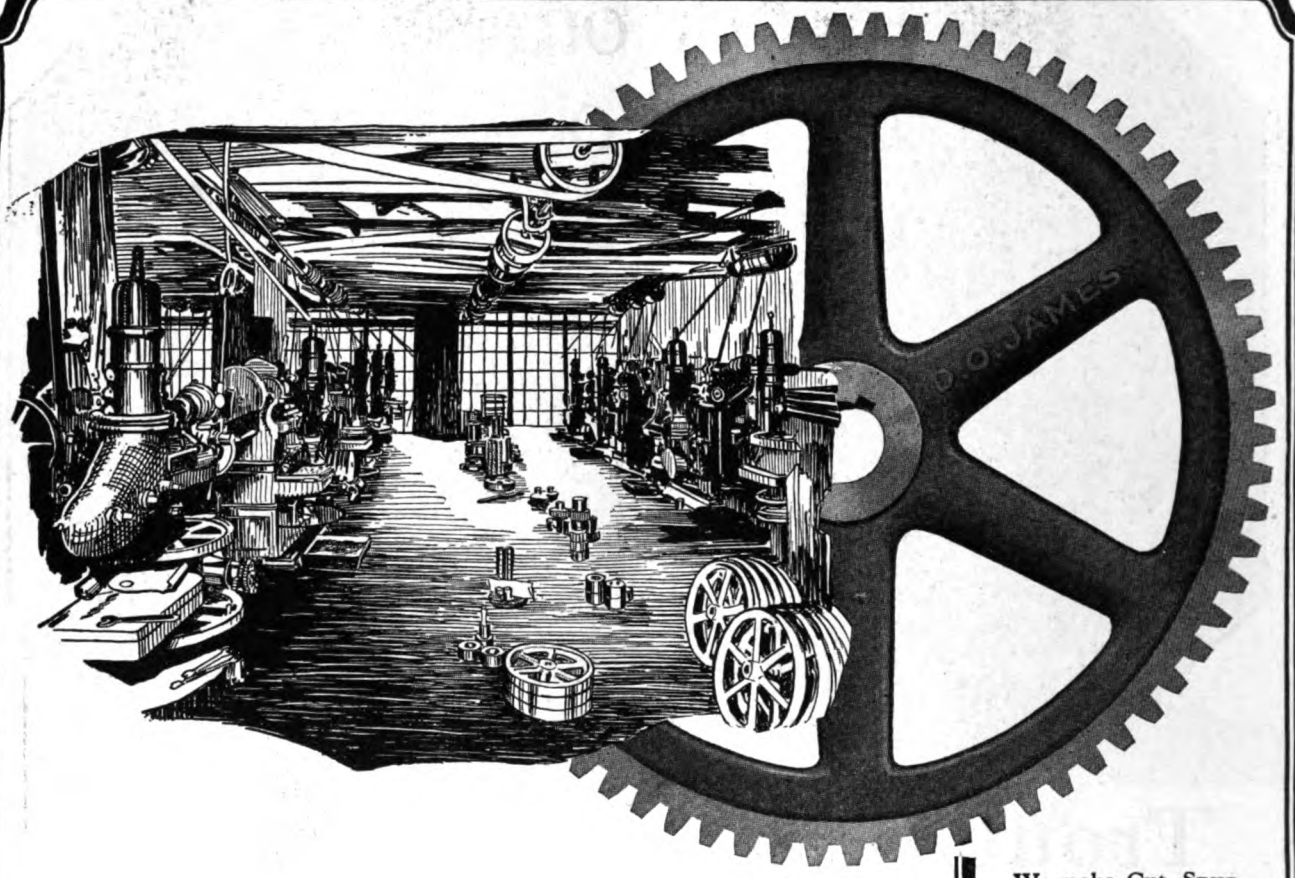
The most economical power equipment is available for operating the system.

Sullivan air lift installations have a reputation for economy and reliability. They are backed by 30 years' experience.

The pictures show one of the Sullivan Air Lift installations at Carthage, Missouri, the Angle compound motor driven compressor supplying air to pump two wells. There are two discharges from each well to the reservoir.

These plants are practically automatic. A second Sullivan angle compound compressor and air lift pump supplied most of Carthage single handed throughout last Winter, with only two daily inspections, morning and evening.

Tell us about *your* water problems.



Ask for Air Lift Catalogue No. 71-H

The Sullivan exhibit at Buffalo will show an operating model of an "air made" well, showing how the air lift gets rid of fine sand and secures a permanent supply. Don't miss it.

Long Life Gears

James "Long Life Gears" have quality in-built — a habit with us rather than a special effort. Made of the best materials — by men of long experience — and according to standards dictated by more than 40 years of specialization — they are a guarantee of long time, trouble-free operation.

Our facilities are most complete for making Spur, Bevel, Mitre, Helical, Herringbone, Spiral and Internal Gears of any material and in any quantity. Our prices are as low as is consistent with quality. Our service, because of our enormous capacity, is beyond competition.

Let us make your next order of gears. If they are standard size buy from our Catalog No. 99 (* have you a copy?) If they are special — let our Engineering Department help you with their design. The services of this department are gratis.

*Where shall we send the catalog?

15 repeat orders – the test of satisfaction given by this big tonnage car

This big tonnage car was first designed and built by "Car Foundry" for a large mining company in 1908. And repeat orders have been coming in for it ever since. On March 15th the 15th order was received.

All of which speaks well for the ability of "Car Foundry" Engineers to design and build the car best suited to the job.

Whatever the conditions of your mine or whether you are mining bituminous or anthracite coal, "Car Foundry" Engineers can supply you with the car best suited to lower your loading and haulage costs. High as well as low cars; automatic drop bottom cars, end dump or rotary dump cars; big or small capacity cars; two-truck cars of ten-ton or more capacity for hauling long distances;— whatever your car needs, "Car Foundry" is equipped to fill them.

Get a "Car Foundry" quotation before you buy.

These "Car Foundry" Service Plants, each in the heart of a great mining region, enable us to render a national service with "localized" advantages—no matter where your mine is located.

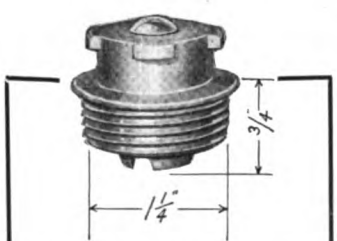
Compare the ease of greasing cars the Lincoln way, with the difficulty encountered when plugs have to be re-removed, grease gun inserted, an imperfect greasing done, and the plug replaced. The Lincoln way is not only much easier, but takes only a fraction of the time.

Grease 'em this way and you know they're greased!



You can tell just by looking at a Lincoln Grease Plug **if it has been greased recently.** And when done by the **Lincoln System, you know** that grease, under 200 pounds **pressure has penetrated every** part of the bearing.

Slip the Coupler Nozzle over the grease plug and give it **a quarter turn. This locks** it in place with a grease tight **grip. One stroke of the hand** pump shoots a full quarter **pound of grease through the** plug into the bearing. The **plug is opened by the nozzle,** not by the grease pressure, **thus the pressure is not diminished** but applied in full.

Every Lincoln Grease Plug always admits grease, they **never rust, clog, or require** replacing. Hence there is **never any reason for slighting** a single wheel equipped **with a Lincoln Plug.**

Our introductory offer makes possible a thorough trial at very little expense. Write today for details.

Lincoln Plugs are made in sizes and threads to fit all types of mine cars. Write for our circular showing all types, or better still, send us one of your present pipe plugs and we will send you a rustproof Lincoln plug to replace it.

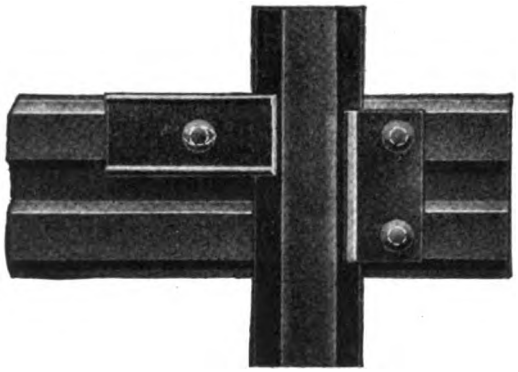
A Tie for Every Purpose

DESIGN NO. 3

A rugged but convenient tie for universal service.

DESIGN NO. 5

A tie designed to especially meet the needs of those who desire to ball the jumper rail. Note how the clip holds the rail securely in place.



DESIGN NO. 7

This tie with the clips placed alternately is designed to permit of easy installation in existing track. By merely sliding the tie under the rails, raising, moving slightly so that fixed clips engage the rail flange and hammering the rotary clip a quarter turn, it is put into use. By reversing the procedure ties may be easily removed from the track.

West Virginia Mine Ties—

are made to meet any requirements

For new track—For "balling" jumper rails
For easy installation in existing track

Hammer the rotary clip. That's all you have to do to fix the rail to the West Virginia Steel Tie. A certain one of our three designs may be best adapted to your needs, but they are all rugged, convenient and hold the rails in place. No tipping or spreading of rails. Pressure on rails cannot loosen the tie.

West Virginia ties are quickly installed and reinstalled. They are easily carried. They save head room. They are shock resistant and rigid.

Complete facts about West Virginia products sent to you immediately upon your request.

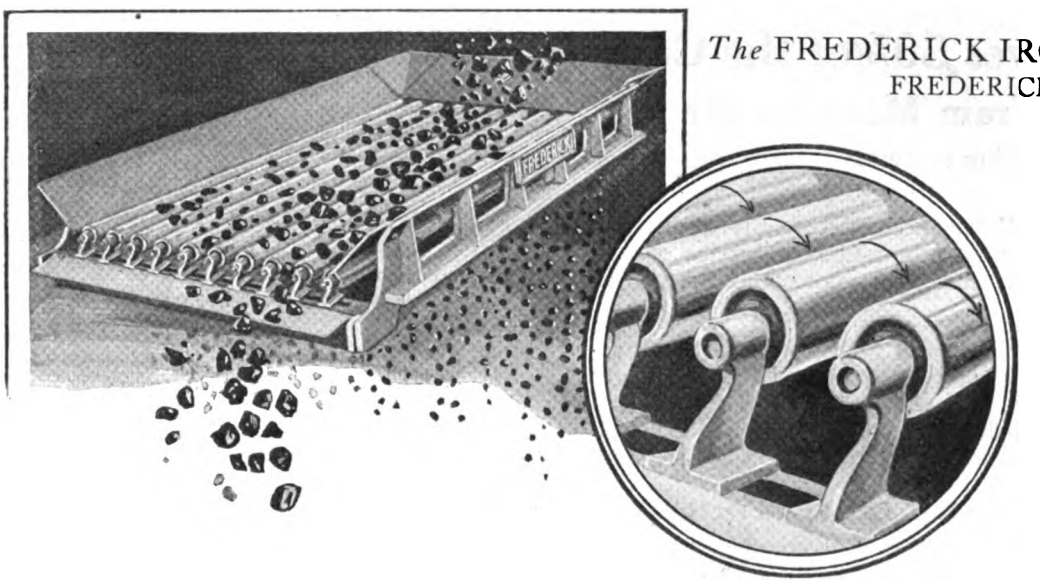
"At the mine where I installed your Frederick Separator and other equipment last year the season netted us $25,000 profit: At our other mine, under same conditions, in same district, working the same seam but not using your equipment we lost money."

Perfect Screening without Breakage



$25,000 profit or loss!

$25,000 profit in one mine and a loss in another — both mines operated by the same company, under the same conditions, in the same district, in the same seam! How was this possible? The Frederick Separator made all the difference between profit and loss!

If you want the name of the operator who sends us this report regarding the profits made possible with the Frederick, write us.

The Frederick makes profits possible by increasing your percentage of prepared sizes and decreasing your percentage of screenings, by cutting your power, labor and maintenance bill and speeding tonnage.

If you don't know the complete story, send for it.

MINE METHODS-SCRAPING, LOADING and HAULING Revolutionized by "LITTLE TUGGER" HOISTS

"Slushing" Saves 50% of the Costs

Muck and Tram Mechanically

Hand mucking or shovelling consumes 35% to 45% of the *total* mine working time.

"Little Tugger Slushing" has been successfully applied in practically every method of modern mining without any change in the original mine layout and with appreciable savings in mucking and loading time.

However, if in planning the layout for a new level, arrangements are made to take the greatest advantage of "Little Tugger Slushing," the latter can be counted on to reduce the time to from one-half to one-fourth the time consumed by hand shovelling methods and with a corresponding reduction in labor.

6-H "Little Tugger" Hoist

From prehistoric days until within the last few years no great improvement was made in that important major mining operation of mucking and loading.

The necessity for lower costs and greater production has finally and definitely replaced hand shovelling by "Little Tugger Slushing" in many mines throughout the world.

Knowledge of your industry

A Few Facts From The Experience Index

Going through the McGraw-Hill experience file at random you will find such facts as these:

5 McGraw-Hill men formerly in automotive engineering.

8 McGraw-Hill men formerly in material-handling engineering.

2 McGraw-Hill men formerly in subway construction.

12 McGraw-Hill men formerly with process (chemical) industries.

9 McGraw-Hill men formerly in electrical merchandising.

4 McGraw-Hill men formerly consulting engineers.

16 McGraw-Hill men formerly with central stations.

9 McGraw-Hill men formerly with electric railways.

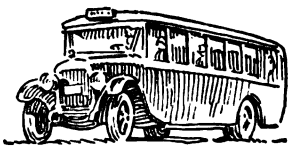
6 McGraw-Hill men formerly machinery designers.

And so on.

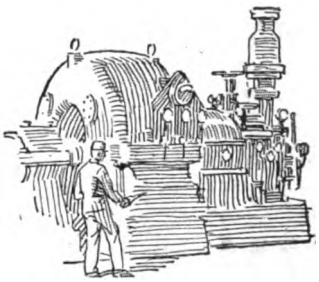
From shop and mine, from factory and generating station, from chemical laboratory and construction job, from jobber and dealer, have come the men who make the McGraw-Hill organization. Production men, operating experts, specialists in selling from many industries have come to develop the McGraw-Hill Publications as authorities in industry..... authorities, first, to their subscribers, the creators and builders of industry.....authorities, next, to the men who are selling to industry.

As editors, department heads, service men, marketing counselors and field representatives, these men have become essential units in the McGraw-Hill organization, absorbing its purpose and spirit and devoting their fine attainments to carrying forward its tradition of over a half-century's service to industry.

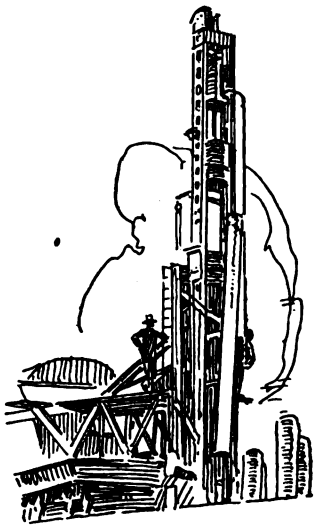
The experience of these men has been cataloged, classified and filed for instant reference. That file is the nerve center of the organization. Thumb over the index tabs and it will be strange if you do not find a man, or twenty men, who have a working knowledge of the industry to which you sell, or the equipment which you make.



For more than fifty years the McGraw-Hill Company has known industrial America. Its contacts have been inside contacts; its fund of experience is the composite gained in shop, factory and field.



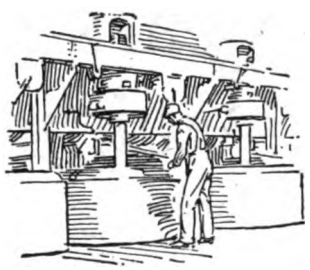
Through this intimate knowledge and constant contact, McGraw-Hill seven years ago sensed the step that industry is now taking in applying to its selling the same science and caution that have advanced industrial production and reduced costs. The service of McGraw-Hill Publications was extended to embrace not only the publishing of technical information on production and engineering but counsel on scientific, waste-free selling. This counsel is epitomized in the following McGraw-Hill Four Principles of Industrial Marketing which today are bringing country-wide endorsement from industry, bank, advertising agency and university.



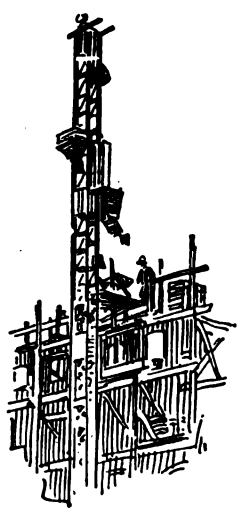
MARKET DETERMINATION—An analysis of markets or related buying groups to determine the

Digitized by Google

is here!



potential of each. With a dependable appraisal of each market, selling effort can be directed according to each market's importance.



BUYING HABITS—A study of the selected market groups to determine which men in each industry are the controlling buying factors and what policies regulate their buying. Definite knowledge eliminates costly waste in sales effort.

CHANNELS OF APPROACH—The authoritative publications through which industries keep in touch with developments are the logical channels through which to approach the buyer. In a balanced program of sales promotion these publications should be used effectively and their use supplemented by a manufacturer's own literature and exhibits.

APPEALS THAT INFLUENCE—Determining the appeals that will present the product to the prospective buyer in terms of his own self-interest or needs.

These Four Principles are more than a formula. They are a method, repeatedly tested by practical application, backed by a half-century of intimate acquaintance with industry. Any manufacturer selling to industry can apply them to advantage in his own marketing program. Our Marketing Counselors will be glad to lay the details before you or your advertising agent. A conference can be arranged by communicating with our nearest office.

Dragged from one location to another, it still stands the gaff.

Two years use— *without a bit of trouble*

DURING the last two years considerable construction work has been done in this great middle west oil refinery. Addition has followed addition. And Super Service has played its part in this work.

The foreman in charge writes—"In the two years I have used Super Service Cords and Cables on Electric machinery in construction work, we have never had a single shut-down due in any way to their use."

A clean record made possible by the special process under which Super Service is built. Every foot is vulcanized in steel molds under tons of pressure—a special process used in the manufacture of no other wire.

A process that compresses the outer jacket of rubber into a tough, dense, yet flexible covering that protects the conductors from wear and abrasions and gives it many times the life of ordinary cables. It is absolutely waterproof and highly resistant to the action of oils and acids.

If you would like detailed information about these portable cords and cables with the long life, we will be glad to send you a catalog and price list.

Modern Mining—Timken Bearings

When modern methods are emphasized today two things are well understood—more satisfactory profits—and Timken Tapered Roller Bearings. A clear lesson is being pointed by the most progressive operators. They are strikingly in agreement on Timken Bearings, in the entire coal handling equipment, including mine cars.

Timkens are heavily preferred for their *plus* characteristics, over and above the anti-friction properties* which save so much lubricant, man-power, animal-power or electric current.

Timkens also provide higher load area, inherent thrust capacity and *POSITIVELY ALIGNED* bearing rolls. This makes it possible to absorb all stresses scientifically within the bearings themselves. No motion is carried on extra parts or on the axle surfaces. Supremely enduring Timken-made electric furnace steel carries all the load, with rolling motion always.

Every form of self-destruction in the journals is overcome. Cars stay at work continuously and make more hauls per day at less cost per haul. Changing over to this high-efficiency basis is thoroughly practical. Ask Timken or leading car and equipment builders to outline a program which will pay its own way.

THE TIMKEN ROLLER BEARING CO., CANTON, OHIO

*Tests by U.S. Bureau of Mines prove Timken Bearings lower in friction—starting, running, and on curves

The LENIX DRIVE

(TRADEMARK REG.)

OIL-ENGINE-DRIVEN 6-KW. EXCITER

Driving pulley 40-in. dia., 6½-in. face, 300 R.P.M.
Exciter pulley 8-in. dia., 7-in. face, 1500 R.P.M.
Pulley centers 4-ft. 0-in.

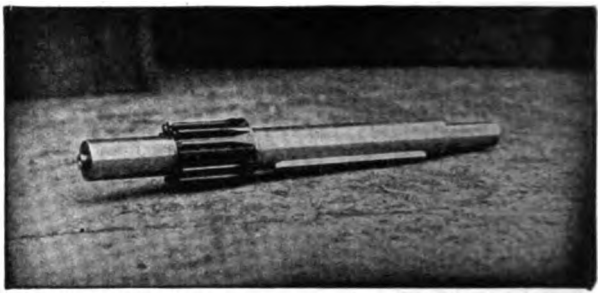
"Beyond our fondest hopes"

That's the expression used by the superintendent of the Palmyra, Missouri, Light and Water Department, in referring to the Lenix Drives used by him on 12½ and 6 kw. exciters, with oil engine-generator units.

And good reason, too. Belt slippage is positively eliminated even on extremely short pulley centers and the automatic action of the Lenix causes it to maintain sufficient tension on the slack side of the belt to transmit the load.

In the words of the superintendent:

"Replying to yours of the 25th ult., as to the satisfaction we are receiving from the LENIX drives on our 12½ and our 6 kilowatt exciters, would say that they have been in daily use for over five months and we are satisfied with the service they are giving beyond our fondest hopes. In fact, I much prefer LENIX drive over a direct belt drive on account of the great reduction in belt tension and the reduction of heating in the exciter bearings."



Make no mistake about the Lenix. It is not an idler. Rather, a "belt-wrapper" applied to belt drives for saving floor space, eliminating belt slippage and increasing the general capacity of the drive.

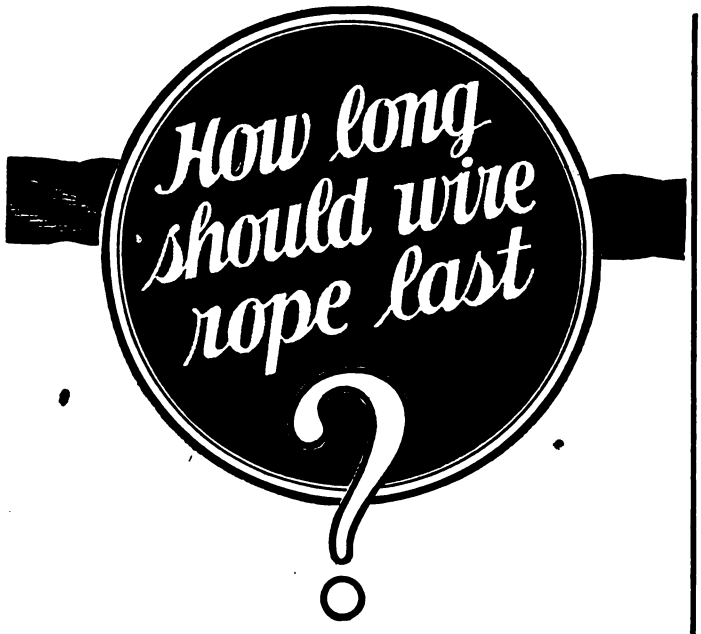
Reserve Power in Shays For The Heaviest Grades

AS THE shovels cut deeper and deeper, the grades, up which coal must be hauled, become heavier.



If Shays are hauling your loads, the heavier grades will not hinder your production.

For in the Shay is reserve energy for the heaviest grades. Its multiple cylinder engine and all wheel drive provide the requisite power.

Digitized by Google

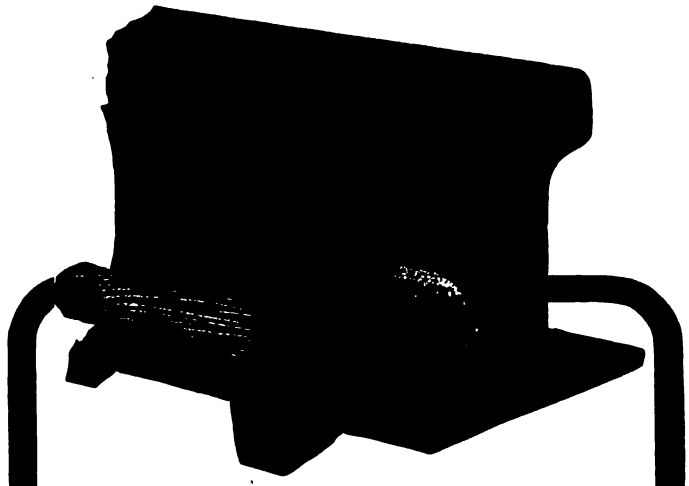
answer: The life of wire rope will always depend on the conditions under which it operates—plus the kind of rope used.

With the advent of Tru-Lay Brand, the disadvantages inherent in ordinary wire rope were eliminated and new records for length of service and economy established.

The ability of Tru-Lay Brand to decrease wire rope mortality is due to exclusive construction features that may be obtained in no other make.

It is made on a totally new principle that preforms each wire and strand to the shape it will take in the finished rope. This means longer service, less expensive lay-ups for replacements, a greater ease in handling with an added factor of safety, the ability to resist unstranding — to distribute strand loads equally, to eliminate seizing and resist kinking.

Users of Tru-Lay Brand know the answer to "How Long Should Wire Rope Last?"



Write for a sample and interesting literature.

UNA Metmold Mine Bonds

In this type of UNA Bond each bond head is provided with its own individual mold. There are no separate molds to be carried from joint to joint.

In positioning the bond, merely slip the lug under the base of the rail. A slight blow drives it home ready for welding.

The original UNA Process of Copper to Steel welding is used. The UNA Metal electrode melts under the heat of the arc. As the mold fills up the individual strands of the bond are welded into the bond head and the molten copper welds both to the base and web of the rail.

The welded bond provides a continuous path of copper from rail to rail.

The simple, positive and highly conductive copper to steel weld, make every UNA Bond a good Bond.

LUNKENHEIMER

Globe, Angle and Check Valves

Globe Iron Body Bronze Mounted | Swing Check Bronze | Angle Iron Body Bronze Mounted

are standard equipment in thousands of plants because of their economical performance over long periods of time. Once installed they require very little attention; they stay tight and maintenance expense is negligible. Procurable in bronze, iron or steel, in all standard sizes, for all prevailing pressures and temperatures. The extensive line provides a selection of the correct valves for any service.

Lunkenheimer Distributors are located in all commercial centers, and render prompt service right from stock. Call on them for your requirements.

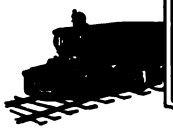
Marion Soot Blowers Save Coal

Soot insulated boiler tubes resist heat transfer and defeat the purpose of tube design.

Clean boiler tubes help to secure maximum effective use of the fuel energy.

Always-clean boiler tubes are easiest obtained by installing Marion Soot Blowers. Operation is so simple, and completely effective, that it is easy for firemen to clean the tubes as frequently as is needed to maintain maximum efficiency.



There is a type and size adaptable to every boiler. *Send for catalogue.*

The new "Baby" CEMENT-GUN (TRADE MARK) for a one-drill compressor

(just what you wanted!)

All the advantages of its big brothers—but it's small, compact, convenient. Runs 100% efficient on a one-drill compressor, 60 cu.ft. actual air a minute. Weighs only 200 lbs. Just what you want to have around handy for the repair and maintenance of furnace linings, patching, stack-repairs, "Gunite" application generally.

Let us tell you all that "Gunite," applied by the "Cement-Gun," will save in your mine. Write for Bulletins.

Cement-Gun Company, Inc.
Allentown, Pa.

New York Pittsburgh Phoenix Chicago
Seattle Salt Lake City San Francisco

Sole representative for TRAYLOR MINE TYPE COMPRESSORS. The ideal compressor for all mine work. Large capacity, high efficiency and smallest overall dimensions of any mine type compressor on the market.

The CEMENT-GUN (TRADE MARK) IS NOT A RESTRICTED ARTICLE AND MAY BE PURCHASED AND USED BY ANY ONE.

We have a separate department which does "Gunite" work under contract. Let them make suggestions, estimates and bids on any of your work.

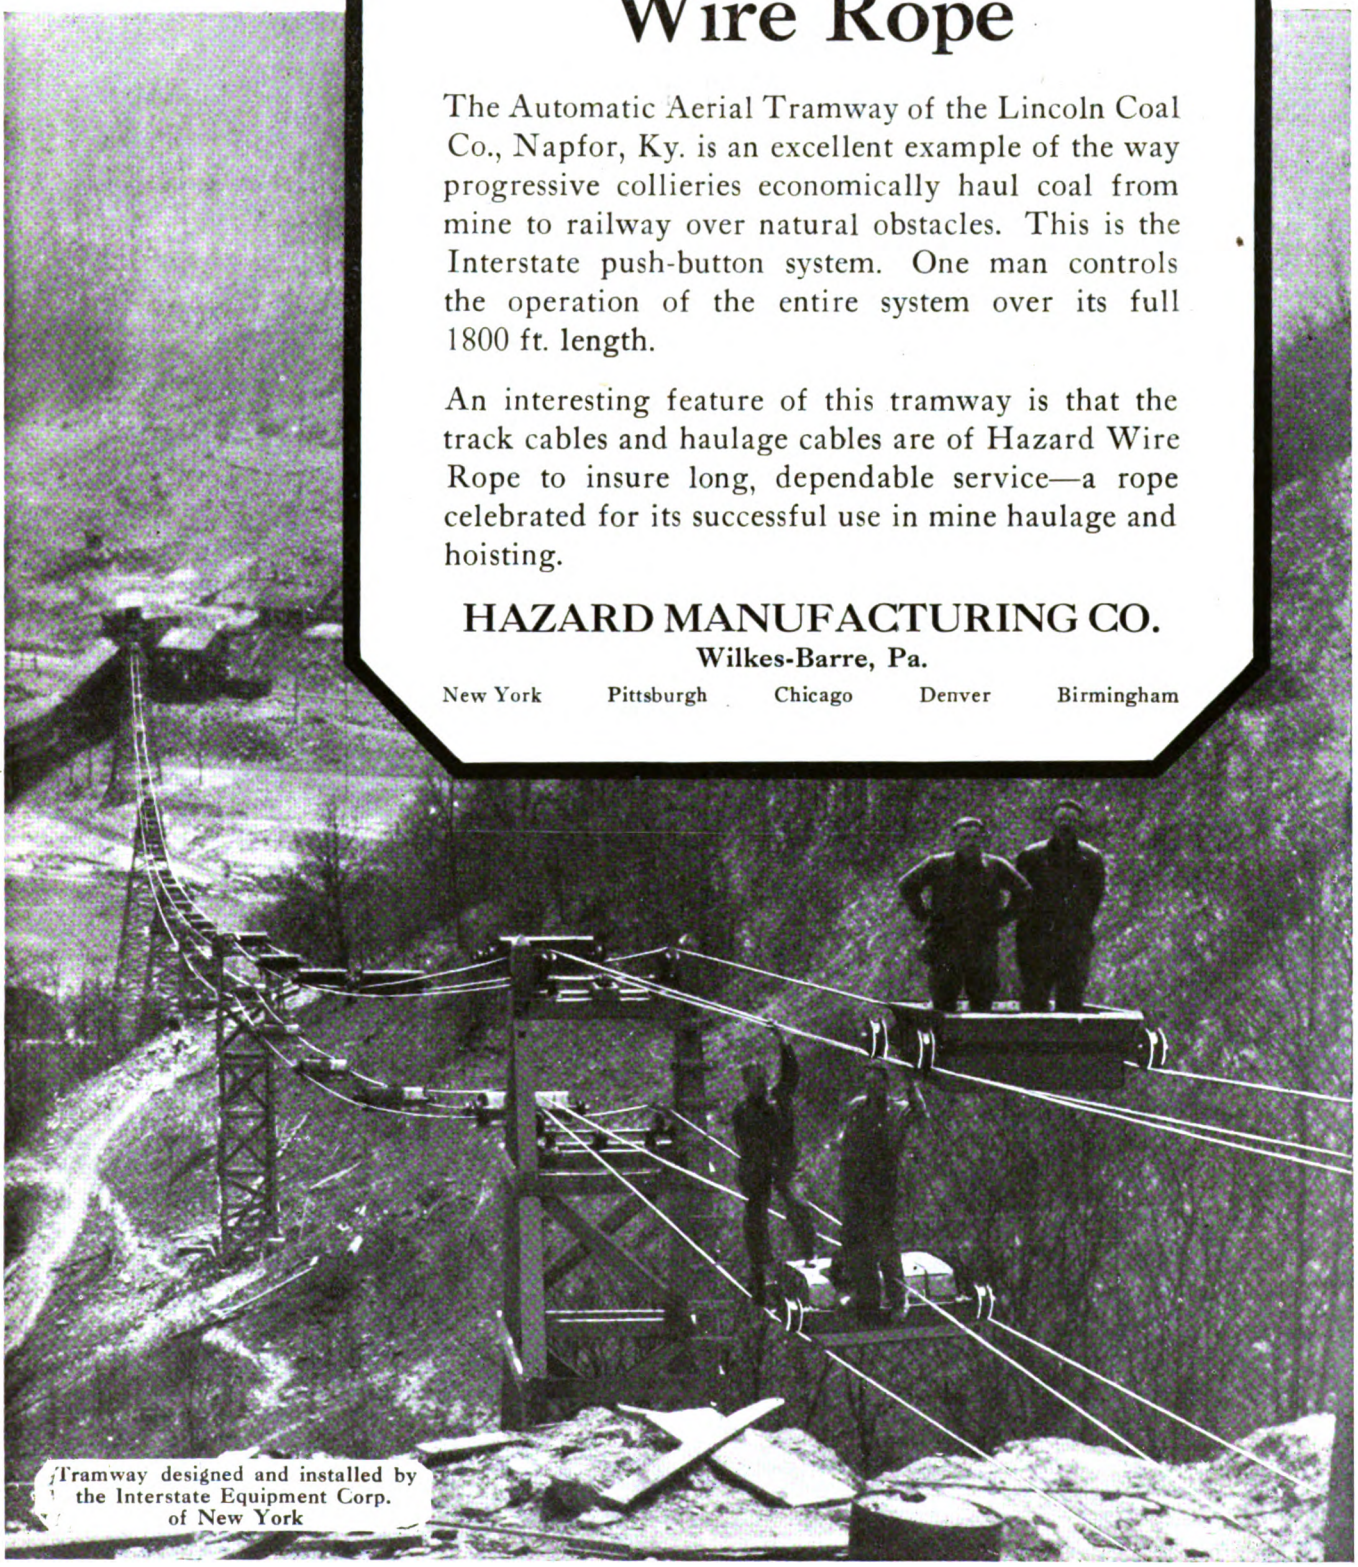
Tramming 150 tons per hour across river and valley on



HAZARD Wire Rope

The Automatic Aerial Tramway of the Lincoln Coal Co., Napfor, Ky. is an excellent example of the way progressive collieries economically haul coal from mine to railway over natural obstacles. This is the Interstate push-button system. One man controls the operation of the entire system over its full 1800 ft. length.

An interesting feature of this tramway is that the track cables and haulage cables are of Hazard Wire Rope to insure long, dependable service—a rope celebrated for its successful use in mine haulage and hoisting.

When is oxygen cheap?

CHEAPNESS is relative and depends entirely on how much material, quality and service you get for your money.

Linde Oxygen—for years industry's standard—is sold on a basis of ultimate economy. Linde service, which goes with Linde oxygen, is designed to give to every customer the latest and best information on the use of the oxy-acetylene process. Service men, engineers, consultants, research men, are constantly at work and always at your service to show the latest methods, new applications and greater economies in welding and cutting.

NOT ONLY can you build new tanks advantageously by welding, but old tanks that have given way on the bottom or on the crown can be repaired and reconditioned. Linde Methods tell you how to replace a bottom or a crown by the oxy-acetylene process and Linde engineers can give you suggestions even on design.
