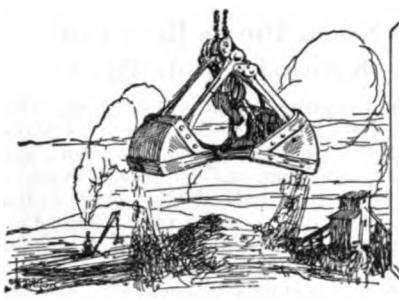
"Company" anthracite prices, announced following the resumption of hard-coal mining last week, range from $8.25 to $9.15 on broken coal, $8.75 to $9.25 on egg and nut, $9.25 to $9.50 on stove and $6 to $6.35 on pea. Specific schedules of the various companies are shown in the tabulation following:

	Broken	Egg	Stove	Chestnut	Pea
D. L. & W.	$8.25	$8.75	$9.25	$8.75	$6.00
Hudson Coal Co.	9.00	9.00	9.35	9.00	6.00
Phila. & Reading	9.15	9.15	9.40	9.15	6.25
Lehigh & Wilkes-Barre	8.25	8.75	9.25	8.75	6.00
Lehigh Valley	8.50	9.00	9.35	9.00	6.00
Lehigh Coal & Navigation Co.	9.25	9.25	9.50	9.10	6.35
M.A. Hanna & Co.	9.00	9.25	9.60	9.25	6.50

Steam sizes—No. 1 buckwheat, $3 for all companies listed except Hudson Coal Co., which is $3.50; No. 2 buckwheat (rice), $2 for D. L. & W. and Lehigh & Wilkes-Barre coals; $2.25 for other coals; No. 3 buckwheat (barley), $1.60 for D. L. & W. and Lehigh & Wilkes-Barre coals, $1.75 for others. No rice or barley quotations made by Hudson Coal Co., which offers birdseye at $2.

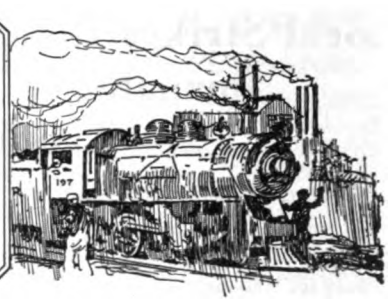
The prices named by the same companies for February, 1925, were as follows:

	Broken	Egg	Stove	Chestnut	Pea
D. L. & W.	$8.00	$8.75	$9.00	$8.75	$5.85
Hudson Coal Co.	8.75	8.75	9.25	9.00	6.00
Phila. & Reading	9.15	9.15	9.40	9.40	6.00
Lehigh & Wilkes-Barre	8.00	8.75	9.00	8.75	5.50
Lehigh Valley	8.50	8.80	9.15	9.15	6.00
Lehigh Coal & Navigation Co.	9.25	9.25	9.50	9.25	6.00
M.A. Hanna & Co.	8.80	9.15	9.85	9.40	6.75



Steam sizes—Buckwheat No. 1, $3 @ $3.15; rice $2 @ $2.25; barley, $1.50; birdseye, $1.60.

All quotations are f.o.b. mines per gross ton.



Delay Horning Report

John I. Pratt, Pennsylvania state mine inspector for the Pittsburgh district, says the blame for the explosion in the Horning No. 4 mine of the Pittsburgh Terminal Coal Corporation on Feb. 3, in which twenty lives were lost, will not be placed until his investigation is completed and a report submitted to the Department of Mines at Harrisburg.

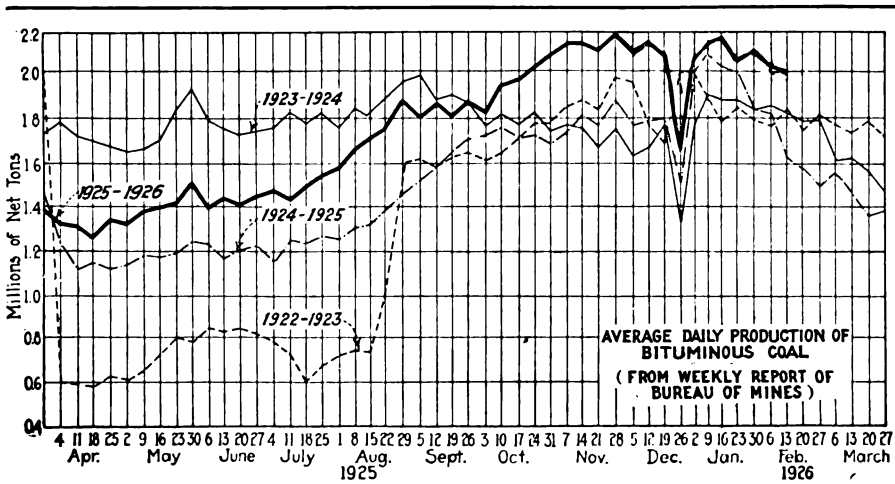
Production And the Market

Coal Market Unsettled, Due to Weather Changes And Sudden End of Strike

The bituminous coal markets of the country are still in a state of flux. Producers and distributors are trying to adjust themselves to the conditions created by the sudden termination of the anthracite strike while endeavoring at the same time to accommodate output to the fluctuations due to changing weather conditions and the uncertainties of year-end industrial requirements. This seesawing, as might be expected, has been accompanied by some upsets in prices which have further decreased average realizations at the mines.

The most cheering feature of the situation is that the decline has been more moderate than some of the pessimists predicted. *Coal Age* Index of spot prices on bituminous coal for Feb. 22 was 170 and the corresponding price was $2.06, as compared with an index number of 173 and a price of $2.10 on Feb. 15. There were some sharp losses in going prices on prepared sizes in eastern markets, both in the high- and the low-volatile grades, and these losses were reflected back in interior markets. Mine-run, too, was weaker along the Atlantic seaboard. As forecast last week, prices on slack are firmer.

Operators Trim Production



In keeping with the changed conditions operators are effecting a gradual reduction in production. For the second week in the month the output had been pulled down to 12,008,000 net tons. Part of this decrease was credited to the holiday in that week, but loadings on Feb. 15 and 16 gave evidence of the diminished demand for coal. Nevertheless, unless industrial requirements of the country have been grossly underestimated, further curtailment will be necessary before a balance has been struck between supply and demand.

Mining of anthracite was officially resumed last Thursday and some coal reached the New York harbor the next day. It will be some time, however, before there will by any accumulation of reserve stocks. Working forces at the mines have not yet been recruited to full strength, some operations require extra maintenance and repair work to put them into shape and producers are trying to make the present output cover as wide an area as possible. From the retailer's standpoint, this is very desirable, as it will give him a better chance to dispose of his yard supplies and rolling tonnage of other fuels.

Price Reductions Extremely Unlikely

Price announcements made by the big line companies show schedules on the "normal" winter basis. The first shipments of independent coal received at New York sold all the way up to $14 and $15. This basis, of course, cannot be maintained; on Saturday, for example, there were middle houses quoting $10@$12. Independent prices after the first rush probably will settle down to levels 50c.@$1 above company circulars on domestic sizes. Although no official statements have been made, there seems to be little hope that the old line companies will make any spring reduction.

Life has gone out of the Connellsville coke market. For several days last week there was practically no spot buying. New York quotations were on a $6@$6.50 basis, with some reports of offers at $4.50. Spot furnace coke was as low at $4 and some run-of-oven tonnage in small lots sold at $4@$4.25. Inasmuch as recent coke output has been at a rate about 100,000 tons weekly above normal requirements, some drastic readjustments are in order.

Middle West Hails Pessimists

Middle Western coal men are viewing the outlook with jaundiced eye. The retirement of several wholesalers and reports and rumors of pending mine consolidations convince many that the new coal year will be a bad twelvemonth for the optimists.

Further comfort for the pessimists is given in the exceedingly dull state of the current market. Shippers say there is a fair movement of Franklin County lump at the $3 level and a seasonable demand for furnace and egg, but admit that there are hundreds of "no bills" in the southern field. So serious has this situation become that railroads serving the Illinois district are complaining of depleted car supply.

Mines in the southern Illinois district proper are not averaging over three or four days a week. Many are doing less and some are down for the rest of the season. Like conditions prevail in the Duquoin district.

Commercial demand has been cut sharply in the Mt. Olive field, but railroad fuel requisitions have been somewhat heavier. There, too, "no bills" of all sizes plague. The Standard district still is held down in the same old rut of selling too near cost to be profitable. Only the exceptionally situated mine is working better than three days.

Eastern Invasion Grows Stronger

Eastern coals are invading the Middle West in increasing volume—and at decreasing prices. The termination of the anthracite strike lopped off about 50c. from the quotations on high-grade eastern coals. Choice eastern Kentucky domestic sizes are to be had at $2.25@$2.75; less favorably known 4-in. block is down to $2.

Conditions in the St. Louis local market are no better than those ruling in Chicago. Mild weather has squeezed down the domestic demand; industrial movement is light. There is some movement of steam coals to the Missouri River, but the tonnage is disappointing. Local domestic demand, limited in quantity, largely ignores the more expensive fuels.

Profiting—for the time being at least—by the bitter experiences of the past few weeks, Kentucky producers are keeping consignment coal out of the Louisville market. As a result of this self-restraint, less is heard of distress sales and the prices on screenings have shown a slight advance. This increase has had a beneficial influence upon other steam grades.

Kentucky Steam Coal Prices Up

Two weeks ago western Kentucky screenings were quoted at Louisville at 50@80c.; the present range is 80@90c. Slack from eastern Kentucky, offered ten days ago at 60@95c. in the Louisville market and at 40c.@$1.10 in Cincinnati, is now quoted at 60c.@$1 in Louisville and 65c.@$1.10 in Cincinnati. Even wagon-mine western Kentucky mine-run, which sold down to

Digitized by Google

90c., is now commanding $1.25@$1.50 for the better grades. Nut-and-slack is scarcer because many operators are screening out the nut coal.

There are some reports of sales of eastern Kentucky block at $3.25@$3.50, but $2.50@$3 is the range at Louisville. Two-inch lump is $2.25; egg, $2; nut, $1.75; mine-run, $1.35@$1.75. Western Kentucky block is $1.75@$2.10; lump and egg, $1.60@$1.90; nut, $1.35@$1.50. Retail buying is on a hand-to-mouth basis. Middle houses are starting to seek contract renewals.

The coal trade at the Head of the Lakes is debating the question of the future of anthracite in the Northwest. It is estimated that 20 per cent or more of the normal hard-coal tonnage in this territory was replaced by other fuels the present season, but anthracite dock interests hope to recover lost ground and arrangements are under way to move the normal quantities up the lakes during the navigation season.

Shipments from Docks Decrease

Compared with January, there has been a falling off in shipments from the docks this month. Nevertheless, there is a substantial reduction in the stocks on hand. Although retail buying has been reduced to a minimum, the docks do not expect to carry over any smokeless coal into the new season and prices are firmly held. Demand for coke exceeds the supply.

There is a better movement of gas and steam coals to industrial consumers. March bookings show satisfying increases over February orders, notwithstanding the fact that the iron mining companies have been buying lightly. Stocks of screenings are melting down and prices on fine coal are stiff.

Domestic trade at the Twin Cities is a weather proposition. With the end of the anthracite strike, steam coal buyers have settled back into their old rut of indifference. Prices are weakening and the appearance of distress coal has not improved the situation from the seller's standpoint.

Milwaukee Demand Light

Milder weather has slackened the demand for coal in the Milwaukee market. Retail prices on nut and range coke are off $1. This may be attributed to the end of the anthracite strike. The local trade, however, does not look for any early heavy shipments of hard coal to this territory, but the supply of other acceptable fuel for domestic consumption is ample.

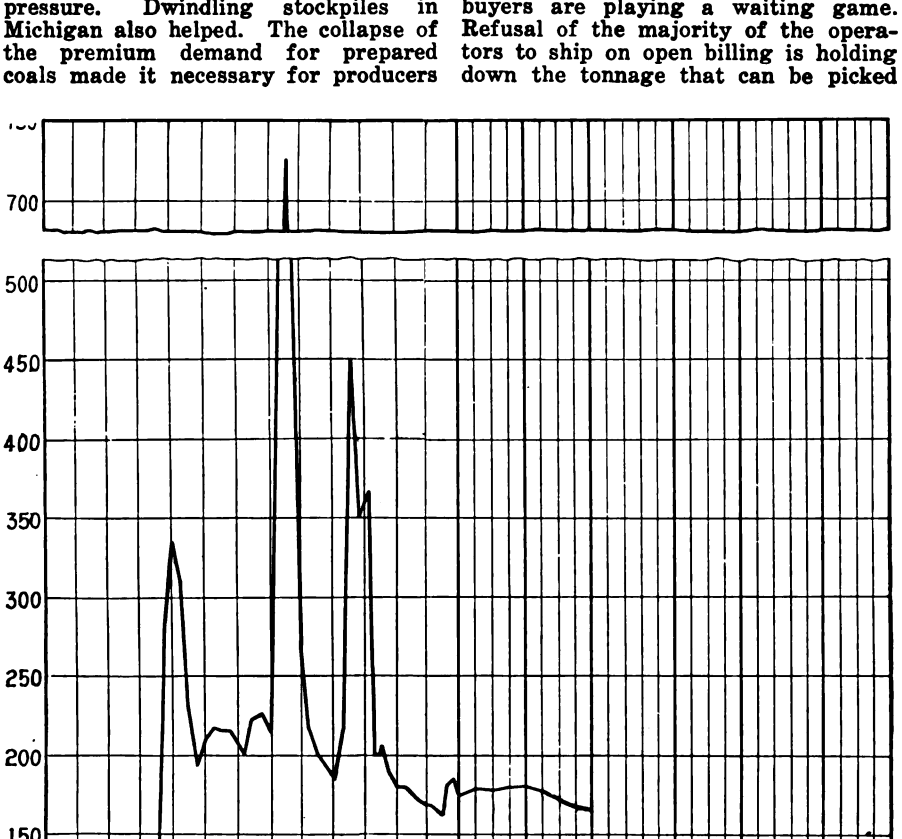
The southwestern market is growing weaker. No prepared grade of Kansas coal now brings above $4.50 and many operators are glad to receive $4.25. There are approximately 300 "no bills" of lump and nut on track and about 125 cars of screenings. Prices on the latter, however, are firm. Most shippers ask $2.35 and demand $2.50. Retail stocks are light. Few mines are doing better than three or four days a week.

There has been no increase in domestic demand for Colorado coals. Running time has been cut to an 80 per cent basis, but "no bills" continue to accumulate. Prices, nevertheless, are unchanged and no reductions are contemplated. Transportation conditions are excellent and there is an oversupply of labor.

"Rotten" is the way Utah operators describe business. There has been a heavy slump in demand for all prepared sizes, with nut the chief victim. The backbone of current movement is the consumption by the mining industries. "No bills" are a troublesome handicap, but no changes have been made in prices. Short running time is stiffening the market on slack.

Cincinnati Market Seesawing

In this period of readjustment, there is considerable seesawing of prices in the Cincinnati market. This movement has every appearance of continuing until some firm ground for future business is reached. High-volatile slack, for example, is stronger, but prepared sizes are weaker. Smokeless mine-run also is softer, but the low-volatile market as a whole seems to be holding its ground.



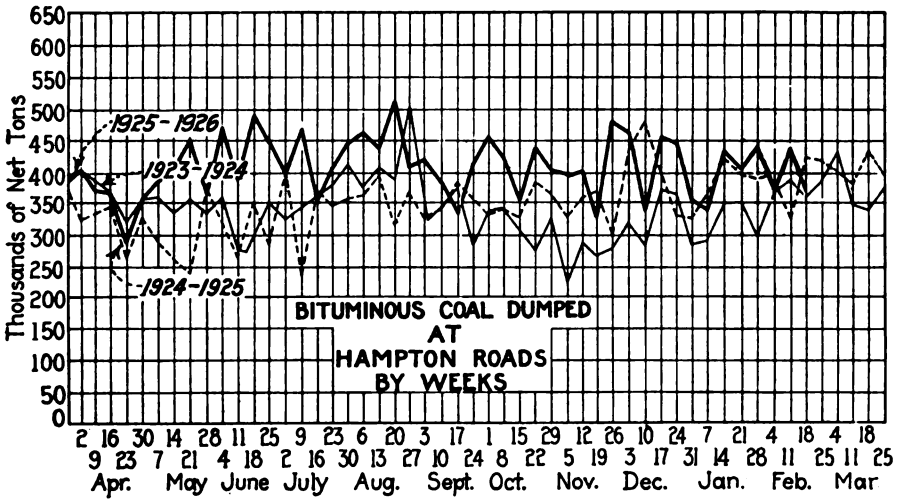
A number of factors have entered into the market on slack. The diversion of several hundred cars to Lake Erie ports for lake loading lessened the pressure. Dwindling stockpiles in Michigan also helped. The collapse of the premium demand for prepared coals made it necessary for producers to hold to higher figures for slack coal. This same necessity strengthened mine-run quotations.

The present week probably will see a change in smokeless quotations. Weakness already is in evidence in Detroit and Chicago and there is no reason to believe that Cincinnati will escape. Lump and egg toward the close of last week were offered at $4.25@$4.50. Mine-run was off 25c., but this loss was made up in the prices asked for slack.

Movement of coal through the Cincinnati gateway dropped sharply last week. The total number of cars interchanged, according to the American Railway Association, was 12,120—a decrease of 1,223 cars. The greater part of the decrease was on the Chesapeake & Ohio Ry.

No Life to Central Ohio Trade

The coal business in central Ohio is featureless. Retail trade has been less active—the result of warmer weather—retail prices, however, are well maintained. There is little distress coal to upset the market. Steam buyers are playing a waiting game. Refusal of the majority of the operators to ship on open billing is holding down the tonnage that can be picked



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	Feb. 22	Feb. 15	Feb. 8	Feb. 1	Feb. 23	Feb. 25
Index	170	173	177	178	168	184
Weighted average price	$2.06	$2.10	$2.14	$2.16	$2.03	$2.23

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

up at bargain-counter figures. A few industries are beginning to make inquiries about contract renewals.

Production in the southern Ohio field is under 20 per cent of capacity. Some of the larger mines have closed down and will not reopen until the lake season is under way.

Northern Ohio shippers, like their more southerly breathern, also complain of poor domestic demand. Nominally, prepared coal prices are unchanged, but distress offerings are having a depressing effect upon the actual spot transactions. Quotations on screenings, on the other hand, have advanced a dime as a tribute to decreased production arising from the lessened movement of prepared sizes.

The No. 8 field produced approximately 270,000 tons during the week ended Feb. 13. This was 38 per cent of capacity. Compared with the preceding week the output decreased 26,000 tons.

Pittsburgh Returns to the Husks

Predictions that the end of the anthracite strike would mark the end of eastern retail buying of Pittsburgh district egg coal have been swiftly verified. It is now forecast that the $2.75 @$3.25 range on that size will sink to $2@$2.25. Demand from regular customers also has lightened. Slack has been under increasing pressure and quotations weakened to 90c.@$1 on steam and $1@$1.15 on gas slack. Decreased lump production, however, may soon change this drift. The district as a whole is producing about 30 per cent of capacity.

Central Pennsylvania quotations have slumped and the future is uncertain. Pool 1 was offered last week at $3.10 @$3.45; pool 9, $2.60@$2.75; pool 71, $2.85@$3.10; pool 10, $2.35@$2.45; pool 11, $2@$2.10; pool 18, $1.85@$1.90. Slack is $2; prepared coals, $3.50@$4.50. District loadings the week ended Feb. 13 were 22,385 cars, as compared with 21,137 cars the week preceding.

Buffalo bituminous shippers are still struggling to recover from the effects of the sudden termination of the anthracite strike. Slack has sold at Canadian points within the past ten days at 10c. and it is difficult to get $1 at the mines. Nominally, however, the price range is unchanged from that of recent weeks.

New England Still Favors Anthracite

In spite of the official ballyhooing for bituminous coal, the anthracite settlement has taken all the starch out of the market for substitute fuels for domestic consumption in New England. Retail dealers are more anxious to unload stocks on hand than to order forward more cars. On top of this, the industrial consumer is again showing a lack of interest in the market.

Prices dropped off over night. Prepared smokeless fell from $8 net, f.o.b. mines, to $4.75, with some central Pennsylvania offerings at $3.25. All-rail Pennsylvania is back in the doldrums of last summer. Shippers, of course, will try to hold a market for screened coal, but the success of their efforts appears very dubious.

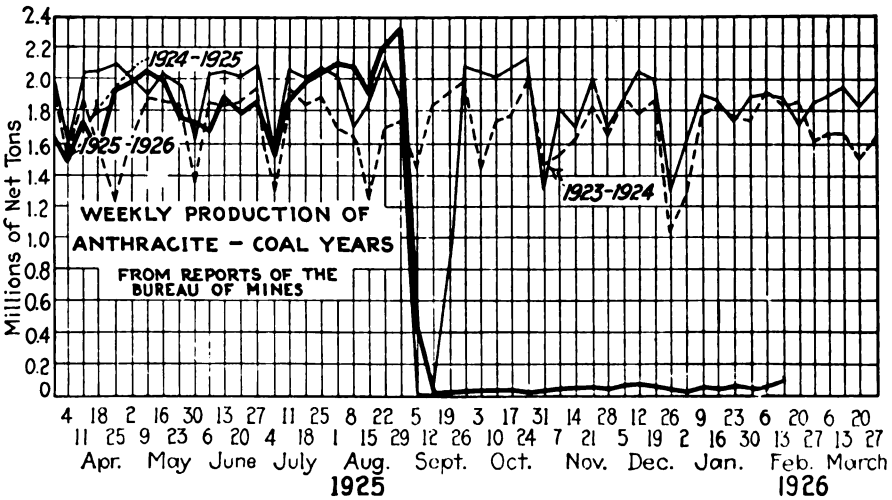
F.o.b. Hampton Roads, the prices have softened to $4.75 per gross ton for everything except Navy Standard, which is $4.85@$5. Contract tonnage is moving in fair volume, but inquiry for spot cargoes is light. For inland delivery the price on cars at Providence has dropped from $7 to $6@$6.15. At Boston, the slump has been less pronounced.

Cancellations Swamp New York

There has been such a wave of cancellations of orders received by the New York trade that some shippers question whether the retailer is not over-estimating the capacity of the hard-coal mines to make prompt deliveries. Coke has been the hardest hit. Sized coke is down to $6.50, with some reports that business could be booked at $4.50. Local retailers, however, paid $15@$18 for loaded boats in New York harbor.

Bituminous mine-run is holding its position. The best coals are well sold up and prices are steady. Cheaper grades were slightly easier. Prepared sizes of high-volatile, on the other hand, dropped $1, and smokeless nut and egg declined $2.50@$3.50. Congestion at the piers has given the tidewater market a strong tone.

Delays in transportation retarded the slump in the Philadelphia bituminous market last week. Prices declined about 25c., but further recessions are expected after the rail congestion has been cleared up. The local coke market has gone to pieces. Oven prices on sized coke are down to $5@$6, with no demand.



Interest in Contracts Revived

The end of the domestic boom has diverted the interest of the soft-coal producers to industrial contracts. Both buyer and seller, however, will do considerable sparring on prices before closing. The position of the operators on slack has been strengthened. The slump in demand for prepared sizes means less slack at bargain figures and the resumption of operations at the cement mills means a broader market.

Gas-coal shippers, who enjoyed an overflow business when low-volatile mines were unable to keep up with domestic demand, are now trying to line up railroad contracts to take care of production.

Except for a flood of cancellations of orders for sized bituminous coal, the end of the anthracite strike has had little effect upon the Baltimore soft-coal market. Industrially a moderate to fairly brisk call for ordinary runs of coal continues. Prices show no material change.

There has been a slight weakening in demand at Hampton Roads. Mine prices on prepared sizes of bituminous coal have dropped approximately $2, but retail quotations are unchanged. Foreign business is subnormal. Coastwise movement also is off. Bunker trade is about holding its own.

Feb. 7, 1925	199,210	63,561	.....	.....

Demand for the cheaper grades of steam coal in the Birmingham market is easier and some concessions have been made in prices. There is still a good movement of the better coals from the Cahaba and Warrior fields, but no overwhelming activity in any section of the trade. Contract customers are taking their full quotas. Spot bunker business showed an increase.

The most cheering news is that some consumers already have signed up contracts for the new year at prices above those written in the expiring agreements.

Domestic demand has been affected adversely by weather conditions. Medium and high-grade coals have a spotty strength, but the cheaper grades are sluggish. There has been no break in the coal market. Some reduction in price, however, is anticipated with the resumption of anthracite mining, but it is believed that demand will absorb the output for some time to come.

Rush to Unload Substitutes

The first shipment of anthracite reached the Jersey terminals in less than twenty-four hours after the whistles had blown at the mines and was soon on its way to retailers in New York and Westchester County. The retail distributors, however, were more concerned with the problem of clearing out stocks of substitute fuels in their yards than in clamoring for immediate deliveries of hard coal.

The majority of the larger old-line producers announced that their prices would be the same as the schedule in effect prior to the strike. Independent egg, stove and nut were held at $10.50 @$15; pea, $7@$8.50, and No. 1 buckwheat, $4.50@$5.50. Some of the early shipments of independent tonnage, it was reported, would be billed at March prices, as yet unannounced.

Reading prices, made public at Philadelphia last Thursday, were on the following basis: White ash steamboat, $9.50; broken and egg, $9.15; stove, $9.40; chestnut, $9.15; pea, $6.25; buckwheat, $3; rice, $2.25; barley, $1.75. Lykens Valley steamboat to nut for February shipment are held at $1 above the white ash schedule. On Lykens Valley pea, the price is $6.70; buckwheat, $3.75; rice, $2.70; barley, $2.10. Independent prices on domestic coals are 75c.@$1.25 above the Reading white ash basis; steam sizes, 50@75c.

Cancellation the Order of the Day

Philadelphia retailers were busy cancelling orders on soft coal and coke. Nevertheless there is still considerable tonnage in transit and in retail yards. Consumers are cutting down on their orders, hoping that a small quantity will carry them over until anthracite is received. Some retailers are trying to dispose of stocks of coke by forcing consumers to take it in combination with deliveries of buckwheat and pea.

Baltimore retailers who cancelled orders for prepared bituminous as soon as the anthracite strike was settled could not move fast enough to stop a flood of shipments released to forestall such action. It is doubtful whether they will be able to dispose of this tonnage before anthracite is moving in normal volume. Householders are losing no time in placing orders for their favorite fuel.

Buffalo was promised its first shipments of anthracite this week. The question now uppermost is how much of a hold substitutes have been able to get during the long suspension. Many consumers assert that they are "through" with anthracite, but these threats are discounted.

Connellsville Sinking Down to Normal

"Normalcy" is rapidly returning to the Connellsville coke market. "Normalcy" means, among other things, that the producer who had not supplied the eastern retail buyer or jobber with car numbers before the anthracite agreement was signed was out of the running.

There was no spot buying of any kind for several days. Late in the week there were some small orders for run-of-oven coke placed at $4@$4.25. A blast furnace covered for the rest of the month at $4. Crushed coke was offered at $5. There has been practically no demand lately for foundry coke except to fill out contracts.

Some operators with coal that will do for gas-making already are looking for a market. Ovens which have been enjoying the high-dollar trade, however, hardly will be able to curtail production fast enough to meet the coke situation and the possibility of coke accumulations in the field is far from remote.

The Connellsville *Courier* reports coke output in the Connellsville and Lower Connellsville regions for the week ended Feb. 13 at 120,200 tons by the furnace ovens and 124,860 tons by the merchant ovens. Compared with the preceding week, furnace oven output decreased 4,000 tons; merchant oven production, 1,780 tons.

Foreign Market And Export News

British Trade Retains Strong Position on Prices; Forward Bookings Heavy

The position of the British coal market generally is satisfactory. Exports are brisk and as orders are executed a steady replacement is taking place. An improving output, readily absorbed, testifies the underlying strength of the market. Demand from France shows revival, greatly due to the rise in native prices and the cheapness of British supplies.

Contract business is negligible, but buyers show a ready disposition to book up well over February, and also, in some cases, into March. Dry large coal supplies are adequate, but clearances are slow. Monmouthshire coals are firm. All the collieries are heavily sold over the month, particularly Black Veins.

The second week of February was not active on the Newcastle market either in actual business or in demand for forward contracts. Prices, however, remained stable, and in the case of best steam coals there has been an increase of about sixpence.

Cokes have been much quieter, but even there the quotations have not altered and are held firmly. Gas concerns both at home and abroad are inquiring freely for supplies. Though much of the inquiry is a safeguard against the consequences of a stoppage so far as home buyers are concerned, that is hardly the case in respect of foreign buyers, their business representing a genuine improvement in trade.

Output by British collieries during the week ended Feb. 6, according to a special cable to *Coal Age*, totaled 5,415,000 gross tons, compared with 5,495,000 tons in the preceding week.

Belgian Market Still Strong

The slight improvement in the Belgian market which began toward the end of January shows a tendency to steadiness, with prices still firmer. The fact that work has been resumed at Charleroi iron and steel plants has revived demand for industrial coals and the stocks of these grades are diminishing rapidly—particularly stocks of semi-bituminous and quarter-bituminous. Even in the Boringe district the situation is better owing to the continual lessening of foreign competition and the higher prices on French coals.

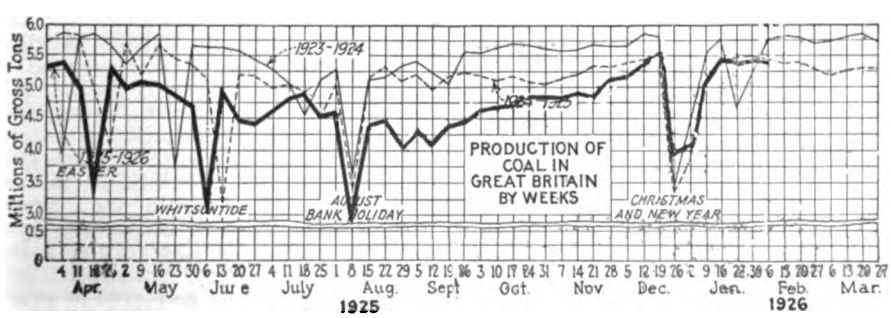
In domestic fuel, the situation remains good. Orders are still plentiful.

Greater firmness also is noticeable in coking smalls. The Coke Syndicate maintains the price of 125 fr., but it is a nominal rate as there are offers made at 115 fr. Reparation coke is quoted at 120 fr.

French Coal Market Sold Ahead; Keen Demand for Gas Coals

Paris, France, Feb. 6.—The situation from the seller's standpoint, is very satisfactory. The majority of the French works are behind in shipment. Flaming coals are particularly scarce.

The price increase on Nord and Pas de Calais fuel is accepted without difficulty. In this respect it should be pointed out that the screened 20 m/m. were quoted at 113 fr. in November, 1923; 110 fr. in March, 1924; 110 fr. 20c. in June, 1924; 119 fr. 60c. in October, 1925, 119 fr. 60c. in January, 1926.



In the Loire coal field the wage question is not yet settled. The coal owners agree to grant the increases asked, but the amount is not yet fixed. The Loire collieries, however, have raised their prices 6 fr., as of Jan. 16. Prices on Belgian graded coals to France during February will be calculated upon the basis of 82.75 Belgian francs to 100 French fr.

	Semi-bitum.	Quarter-bitum.	Lean	Anthracitic
Lump	163.15	165.15	163.15	.....
Cobbles 80/120	174.	174.	184.90	201.25
Cobbles 50/80	217.50	217.50	223.55	241.50
Nuts 30/50	229.60	229.60	235.65	253.80
Beans 20/30	161.	161.	161.	.....

For semi-bituminous, second choice, 5 fr. less than the first choice.

German reparation fuel receipts are heavier than they were some time ago, when they were delayed or impeded through the flood of the Rhine, but exact figures for 1926 are not available. During 1925 France received 8,230,220 tons of reparation fuels from the Ruhr, or a monthly average of 686,000 tons.

From Feb. 1 the price on reparation coals shipped by sea was increased 4 fr. per ton; for those delivered via Jeumont and Givet (Franco-Belgian frontier), the anthracite sorts were increased 12 and 7 frs.; sized coals (including lignite briquets) 5 frs. Industrial coals delivered through the Rhine are up 4@19 frs. and domestic coals, 5 frs.

British Coal Exports Decline

British coal exports during January, 1926, totaled 4,148,042 gross tons as compared with 4,632,051 in December, 1925, and 4,337,768 tons in November.

January exports were valued at £3,821,336, or an average per ton of slightly less than $4.50. Exports to the United States totaled 121,100 gross tons of an average value of $10 per ton, while exports to Canada were 16,000 gross tons, averaging $8.75 per ton. These figures do not reflect recent good export orders. The subvention is reflected in the low average values of exports.

The collieries of Wales are heavily sold in anticipation of price increases and a still stronger market, as the situation in the United States and the reappearance of the Paris-Orleans Rys. in the South Wales market as a purchaser of coal after a year's absence, implies other orders.

ALABAMA

Gen. T. Q. Ashburn, executive officer of the Inland Waterways, has been in the Birmingham district making an inspection of the Warrior River service and terminal facilities at Birmingport. A large amount has been appropriated by the federal government for improvements at the terminals on the Warrior River and a number of additional steel barges which are now under construction will soon be placed in commission and the embargo against Cordova and several other ports will be lifted. General Ashburn stated that the Inland Waterways Corporation probably would take over the Ensley Southern Ry., which recently was bought from the Southern Ry. by the Port of Birmingham Co. This line extends from Birmingham to Birmingport. It is understood that the line will immediately be rehabilitated and additional rolling stock and motive power provided and it will be operated for the Port of Birmingham Co. by the Tennessee Coal, Iron & Railroad Co., affording an independent rail connection between Birmingham and the river. This probably will bring about a large increase in the movement of coal from the district by water to the southern ports.

The Pratt Fuel Co., which recently purchased and took over the holding of the Alabama By-Products Co. at Dora, is preparing to mine coal on a large scale at Kershaw Mines, near Dora. A mammoth coal washer will be constructed.

COLORADO

The new mining law which requires all coal mines to install air circulating systems and have a licensed man in charge was tried out in court by Fred Sevcik of Colorado Springs, and he won the case against James Dalrymple, state mine inspector, in the lower court. The case probably will be carried to the state Supreme Court.

J. B. Marks, who for the last year has been assistant to J. F. Welborn, president of the Colorado Fuel & Iron Co., recently was appointed vice-president in charge of sales, traffic and purchase for that company. He has been with the company since 1901.

ILLINOIS

Between thirty and thirty-five coal drilling outfits are now being worked daily on two tracts of land immediately west of Duquoin, having been started the latter part of January by an Indiana concern. No official announcements have as yet been made. The coal at the location is of good quality, averaging from 25 to 55 ft. under the surface and is about 6½ ft. thick. With progress being made at the present rate of speed, it is estimated that the owners will begin to move machinery and material toward the site by April 1 or earlier.

By-Products Coke Corp., Chicago, reports for year ended Dec. 31, 1925, net income of $874,570 after taxes, charges and reserve for contingencies. This is equivalent, after allowing for dividend requirements on nine per cent preferred stock, to $7.76 a share earned on 94,953 shares of common stock, and compares with deficit of $498,222 in 1924.

Some community co-operation has meant more than a year of reasonably steady work at Mine No. 4, owned by the Illinois Fuel Co. and under lease at the present time to the Wall Coal & Mining Co., at Sparta. Through the co-operation of employees of the mine with the Randolph Club of Sparta, options were obtained the last week in January on forty acres of coal land which was necessary to continue operation of the mine. Since the option was obtained, miners and business men have advanced more than $4,000 for the purchase of the coal and will lease the land to the Wall Coal & Mining Co. for operation purposes as soon as the deal is completed. For some time the coal company endeavored to secure the coal underlying this particular forty-acre tract, but declined to buy it outright. The owners refused to sell the coal on a royalty basis and a shutdown of the mine on May 1, 1926, was threatened. The Randolph Club learned of this condition and after consulting officials of the coal company obtained an option on the coal from the owners of the land.

M. E. Pervier and C. C. Pervier, Annawan, have opened a new coal mine southeast of that town.

The Chicago Title & Trust Co. on Feb. 16 filed a foreclosure suit in the Williamson County Court under a mortgage on the property of the Sunnyside Mining Co. amounting to $450,000. The company's mine has been shut down since January, 1925. Recently its tipple was damaged by fire. The company owns more than 100 acres of coal lands.

The airshaft for the coal mine of the Galesburg Coal Co., at Galesburg, was completed Feb. 1 and is now connected up with the entry. The air shaft is 120 ft. deep and passes through a number of seams before reaching the No. 1, which is the one of commercial value. Steps will be built in from top to bottom, so that there will be a way of escape from the mine.

INDIANA

The final chapter in the history of the Rockville Coal Mining Co., which attracted considerable capital in that section some years ago, was written Feb. 11 when all the properties of the company were sold under the sheriff's hammer for $2,506. The mine, although located near the big bituminous fields of western Indiana, was a losing enterprise from the start and has been shut down for nearly a year.

Mining rights to coal seam No. 5, in Riley Township, near Terre Haute, have been granted to Donald Faulkner for a term of twenty years. The lessors are to receive 15c. for each ton of coal mined and an amount equal to at least 6,000 tons annually. The land is just northeast of the town of Riley.

Clem Richards, coal operator of Terre Haute, Ind., is expected to be a candidate for state chairman of the Republican party in Indiana. Mr. Richards always has taken an active part in politics and has held many appointive organization offices in western Indiana.

The Old Knox Mining Co., Indianapolis, which operates the Knox Mine, in Knox County, has been placed in the hands of a receiver. Jacob S. White, Indianapolis attorney, was named receiver and placed under bond of $25,000. The receiver was ordered to continue operation of the company's business. The company owns approximately 3,500 acres of land in Knox County. The petition for a receiver was filed by George B. McKibbin, a stockholder, who alleged the company to be in danger of insolvency.

KENTUCKY

Unionization activities carried on in southern Indiana during the last few weeks by the United Mine Workers will be extended to include western Kentucky about March 1, according to William Thompson, of Ft. Branch, Ind., chairman of the organization committee of District 11. Approximately 3,000 miners recruited from Illinois, Indiana and Ohio will compose the "army" which, it is planned, will march from mine to mine in the Kentucky field during the campaign, Thompson said. Similar tactics were employed in south-

Digitized by Google

ern Indiana, where all but two non-union mines, the Crescent and Sunnyside of Evansville, are now closed. Tyler Lawton, president of District 11, denies that any such unionization movement is contemplated in Kentucky.

Another effort was made in the Kentucky Legislature on Feb. 16 to bring out a coal tonnage tax bill. However, at the opening of the legislative season this year a rule was made that if a bill is defeated, no similar bill shall be taken out of committee or acted upon, and if a bill is killed in one house, the other division of the Legislature will not waste time with it, as the matter would be under the heading "Disposed of." A vote on the ruling went 68 to 20, in sustaining the rule, and the bill of Representative Strange, of Bowling Green, is dead. As usual, Representative Jones, of the Harlan-Leslie district, led the arguments favoring the coal operators.

KANSAS

Contrary to early predictions of mine union officials following the recent run-off election between Pittsburg and Frontenac for headquarters for District 14, United Mine Workers, the offices will remain in Pittsburg. Early returns from the election, which was held Feb. 2, indicated the miners of the district favored Frontenac, but the final canvass of ballots, Feb. 10, gave Pittsburg a majority of 393. The run-off election followed a special election in December to choose between Arma, Frontenac and Pittsburg. In that election Arma was eliminated. Frontenac received more votes than either of its competitors, but did not obtain a majority of all votes cast, necessitating the run-off of Feb. 2.

NORTH DAKOTA

North Dakota mines produced 1,357,408 tons of lignite valued at $2,601,807.47 in 1925, it is shown in the annual report of A. Waddington, state mine inspector. This is the second largest annual tonnage mined in the history of the state. In 1923, 1,435,605 tons were produced. The production increase over 1924 is 327,959 tons, and the valuation increase is $325,985.47.

OHIO

At a meeting of the stockholders of the Peerless Elkhorn Coal Co., which had headquarters in Columbus, held Feb. 11 the company was dissolved. The property has been taken over by the Hatton, Brown & Co., Inc., of which concern it was a subsidiary. The property consists of an operating mine in the Elkhorn district of Kentucky. F. G. Hatton was president and George F. Schwartz, secretary of the corporation. No change is being made in the management of the concern and the mine will continue to operated as in the past.

Following a cave-in in the main entry of the Union Mine, near Pomeroy, work has been resumed by about 100 miners. None was injured and work was suspended for about 10 days.

Orders have been given by the Sauters Coal Co. for the cleaning up of the Gaylord mine, near Martins Ferry, preparatory to starting operations after a long idleness. It is planned to give employment to about 175 men and to operate at full capacity.

W. K. Field, president of the Pittsburgh Coal Co., who had been confined to his home in Columbus for a few weeks, owing to a severe attack of influenza followed by a heart attack, is recovering and again able to be out. He will soon take up his duties at the company's main office in Pittsburgh.

Jerome Watson, head of the Ohio Department of Mining made a personal investigation of the explosion in the shaft of the Powhatan mine, near Bellaire, which occurred Feb. 15 causing the death of one man and injury to 18 others. He was assisted by several deputy inspectors in the eastern Ohio district. The results of the investigation have not been made public but it is believed that a short-circuit was responsible. The main shaft and tipple were wrecked by the explosion, which occurred soon after the day force went to work. The men had gone on a strike because the Powhatan Coal Co., the owner, paid by check, but had voted to return to work. The mine was formerly owned by the Cleveland & Western Coal Co. Several of those injured, principally burned, are not expected to recover.

PENNSYLVANIA

The Clearfield Bituminous Coal Corporation will launch a large reforestation program this spring with the planting of 1,030,000 seedlings in Indiana, Cambria and Clearfield counties, under the direction of R. D. Tonkin, the coal company's forester. Several years ago the company established a forestry department on a large scale. Since the spring of 1920, including last year, approximately 1,115,550 trees have been planted on lands of the corporation, which owns the surface rights of some 26,000 acres suitable for the growing of timbers. The state forestry department has furnished about 50 per cent of the trees planted thus far.

Jones & Laughlin is completing the construction of 122 new byproduct coke ovens at its Aliquippa works and hopes to have them in operation by March 1. This will add 1,800 net tons to the daily capacity of the plant. By May 1, Jones & Laughlin hopes to have completed the erection of 60 other ovens at the Pittsburgh works, these to have a daily capacity of 600 tons.

The Lehigh Coal & Navigation Co. reports for the year ended Dec. 31, 1925, net income of $1,794,796 after charges and taxes, equal to $3.06 a share. This compares with $2,548,067, or $4.35 a share, in 1924. There was a deficit of $544,676 against a surplus of $208,595 the preceding year.

The Buffalo & Susquehanna Coal & Coke Co. is in a queer lawsuit. Some time ago an agreement was made with the miners in one of its mines at DuBois that they should continue to work at unchanged wages till a certain contract was filled and they should forfeit $1 a day if they quit work previous to that. Some of them did leave and were docked in their pay. Now two of them, Harry Carns and Dominic Stephanowski, are suing the company for the recovery of $20 each so withheld.

In a suit just filed in federal court at Scranton, Warren T. Acker asks for an injunction to restrain the South Penn Collieries Co. from proceeding with a $2,000,000, bond issue, alleging that a contract he has with the concern has been broken in that he has

Pennsylvania Coal & Coke Corp. Starts No. 18 Mine After Two-Year Shutdown

This mine, at Barnesboro, Pa., was opened in 1917 as colliery No. 3 of the Watkins Coal Mining Co. It is in the Lower Kittanning or Miller seam. The picture at the left shows an empty trip about to enter the mine. The stone building in the background is a combination office, shop, substation and lamp house. The tipple, shown in the other picture, is about 2,000 ft. from the mine opening. The cars are handled in a cross-over dump, and the coal is elevated by an apron conveyor.

Digitized by Google

been virtually forced out as general manager. The local man asks the court to order the company to restore his former rights to him, that he also receive permission to inspect the books of the company and that the court order the company to pay him for whatever money damage it deems he is entitled to. Mr. Acker at one time was owner of the Von Storch mine, in Scranton, which he sold to the South Penn company for more than $2,000,000 several years ago. He alleges that in this deal the company unloaded much worthless stock on him and that coal holdings of the concern in other parts of the anthracite field were misrepresented. Former Governor Sproul of Pennsylvania is president of the South Peen company, and R. H. Buchanan, for years identified with the Hudson Coal Co., is general manager.

UTAH

George W. Evans, consulting coal mining engineer, of Seattle, declared in a recent address at Price that Utah coal fields are 100 per cent overdeveloped at present both in mines and man power. He said, however, that just as soon as Carbon County coal can be placed on the Northwest market at a price less than crude oil, there will be a huge demand and production will be greatlv increased. It is understood that Mr. Evans was in the Utah field for the purpose of looking over the situation on behalf of certain interests of Seattle that will open mines there as soon as they feel the demand justifies such action.

Five coal companies in nearly as many cities in the state have been awarded reparation by the Public Utilities Commission in connection with coal shipped in 1921 and 1922 in intrastate commerce. The payments were made on domestic lump coal which had been charged at the straight lump rate. The commission held that the mine-run rate should have been charged.

WEST VIRGINIA

More general development of coal lands in Nicholas County is presaged by the organization of the Camp Fork Coal Co., with chief works at Greendale. Only recently the Gauley Fuel Co. was organized to operate in the same county. Organizers of the Camp Fork Coal Co., which is capitalized at $200,000, include George C. Backus, E. M. Johnson, C. D. Burgess and G. R. Krebs, all of Charleston.

The Supreme Court of West Virginia declined on Feb. 11 to issue a writ of error in connection with the fines and jail sentences imposed on certain union miners in Barbour County for contempt of court in picketing after an injunction had been granted. The men appealed to the higher court on technical grounds, declaring the picketing was done in connection with their membership in the United Mine Workers. Plaintiffs in the case where the Bear Valley Coal Co., Tresler Coal Co., Cambria Coal Co., Brown Coal Co., Grier Gas Coal Co., Bear Mountain Gas Coal Co. and the Blocky Pittsburg Coal Co.

More than 100 employees of the Wood Sullivan Coal Co. were present at a safety rally of the company at Vanwood on Feb. 12, held in connection with the general safety campaign now being inaugurated by the West Virginia Department of Mines. District Inspector Rumberg outlined the program of the state department and asked for the co-operation of the men in the mines. Co-operation on the part of officials of the company was assured and it was pointed out that safety rules were being placed in effect at the several plants of the company.

The plants and property of the Wake Forest Mining Co., operating on Cabin Creek, have been purchased by the Wyatt Coal Co., headed by John Laing. The transfer of the property became effective Feb. 1. The Wake Forest company was owned by J. C. Grimm, Charles Cabell, John L. Dickinson and the late J. R. Thomas, Mr. Grimm being the president of the concern. The company owned two mines on the line of the Chesapeake & Ohio. These mines had a capacity of 400 tons a day, but it is planned by the purchasing company to increase the capacity to 1,000 tons a day and James Martin, who has for some time been the manager of the Wyatt Coal Co., will take over the management of the two additional mines.

Among the new equipment to be installed at the Fordson Coal Co.'s mine at Nuttallburg, W. Va., is an automatic feeder to the crossover dump.

The New England Fuel & Transportation Co. is installing an automatic scale and dump feeder at the No. 3 mine, Lowesville.

CANADA

The Rocky Mountain branch of the Canadian Institute of Mining and Metallurgy is supporting Lewis Stockett of Calgary for president for the Institution year 1926-27. Mr. Stockett is a mining engineer of over forty years' active experience. He has been associated with the mining industry of Alberta and southeastern British Columbia for over thirty years and for the past twenty-one years has had the direction of the development and operation of some of the largest mining projects in Alberta and southeastern British Columbia.

British Columbia produced 2,438,052 gross tons of coal in 1925, compared with 1,964,469 tons in 1924. The output of Crow's Nest Pass increased from 273,170 tons in 1924 to 853,502 in 1925.

The Royal Commission appointed to inquire into the conditions leading to the recent strike of the miners employed by the Minto Coal Co. at Minto, N. B., held its first sittings at Frederikton on Feb. 10. In a statement of the miners' grievances they complained of long working hours and requested the adoption of legislation providing for an 8-hour day. A minimum wage scale also was requested.

Traffic

Illinois Intrastate Rates Cut

The Illinois Commerce Commission on Feb. 16 announced reductions in coal freight rates amounting to 11c. per ton to East St. Louis, Ill., from all Illinois points except from Group No. 2 mines, within a twenty-mile radius. On the latter mines the reduction is 21c. per ton.

The decisions were in the Perry Coal Co. and the Illinois Coal Traffic Bureau against the Alton & Southern R.R. et al. The new rates are to be established within forty-five days from Feb. 8, or on or before March 25. The interstate rates to St. Louis, Mo., will not be disturbed, thereby increasing the differential from 25c. to 33 to 46c. per ton.

The coal affected originates principally in the Nos. 2, 6 and 10 groups of mines.

The new rates, the reduction and the interstate rate to St. Louis, Mo., follow:

	New Rate	Reduction	St. Louis Rate
No. 2 (Belleville) within 20 miles	.70	21	$1.16
No. 2 beyond 20-mile zone	.80	11	1.16
No. 5 (Nilwood-Taylorville)	.84	11	1.16
No. 6 (Duquoin)	.90	11	1.27
No. 7 (Centralia)	.90	11	1.27
No. 8 (Chatham)	.90	11	1.24
No. 9 (Murphysboro)	.96	11	1.35
No. 10 (Herrin-Zeigler)	.99	11	1.385
No. 15 (Springfield)	.93	11	1.26

Association Activities

The Fayette-Greene Coal Producers' Association will hold its third annual dinner meeting at the White Swan Hotel, Uniontown, Pa., Saturday evening, March 6, when U. S. Senator David A. Reed, of Pennsylvania, will be the principal speaker. Charles W. O'Neill, secretary-treasurer of the Central Pennsylvania Coal Producers' Association, also will speak. About 300 coal and coke producers of western Pennsylvania are expected to be present. G. Carl Areford is president of the Fayette-Greene Coal Producers' Association; J. Fred Shean is secretary, and T. J. McClernan, chairman of the meeting committee.

Obituary

John Robertson, Labor Member of the British Parliament for the Bothwell division of Lanarkshire since 1919, died at Glasgow, Scotland, Feb. 14. He went to work in a coal mine at the age of 13 and followed that calling for many years before he became one of the champions of labor in British politics. He was chairman of the Scottish Miners' Union and a strong advocate of nationalization of the mines.

Frank Nichter, 69, who for 20 years was mechanical engineer for the D. L. & W. Coal Co., now the Glen Alden, died Feb. 10 at Scranton, Pa., after a brief illness. During his long service with the Glen Alden he supervised the construction of many modern breakers, among them the Truesdale, the Taylor and the Diamond. He retired from the service of the coal company a few years ago to go into business for himself, and met with much success. He was born in Austria-Hungary, but had lived in Scranton 42 years.

M. C. Walker, 45 years old,—for many years superintendent of the Pittsburgh & West Virginia Coal Co.'s Echo Point mine, near Wheeling, W. Va.,—died suddenly at his home Sunday, Feb. 14. Heart trouble was given as the cause of his death. He is survived by seven brothers and four sisters. Mr. Walker came to Echo Point from Galley Valley, near Charleston, W. Va., several years ago.

Coming Meetings

Canadian Institute of Mining and Metallurgy. Twenty-eighth annual and general meeting, March 3-5, at the Windsor Hotel, Montreal, Quebec, Canada. Secretary, G. C. Mackenzie, 603 Drummond Bldg., Montreal, Que., Canada.

New England Coal Dealers' Association. Annual meeting at the State Armory, Worcester, Mass, April 7 and 8. Secretary, E. I. Clark, 141 Milk St., Boston, Mass.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, in conjunction with the annual meeting of practical operating officials. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. The fourteenth congress will be held in Madrid, Spain, commencing May 24, 1926. From May 5 to 22 excursions of interest to the visiting delegates will be arranged. Information concerning the congress can be obtained from the secretary of the organizing committee, Enrique Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

American Wholesale Coal Association. Annual meeting, June 7-9, at Toledo, Ohio, Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

New Companies

The Colson Coal Co. was incorporated early in February in Denver, Colo., with a capital stock of $250,000, by H. W. Colson, Bessie Colson, George Stewart and others.

The Coal & Clay Producers, Inc., has been incorporated at Terre Haute, Ind., with a capital stock of 7,500 shares of no par value, to do a general coal and clay mining business. The incorporators are A. J. Beasley, L. M. Springer and H. Derby.

The Gauley Fuel Co., which was incorporated late in January, with a capital stock of $50,000, by S. M. Auston and John B. Laing, both of Lewisburg, W. Va., will operate in Nicholas County, Kentucky.

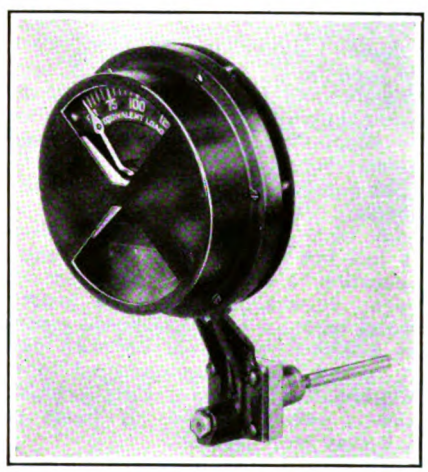
Publications Received

Superpower, by William S. Murray. McGraw-Hill Book Co., Inc., 370 Seventh Ave., New York City. Price, $3. Pp. 237; 6 x 9 in.; illustrated. Some of the points discussed are the benefits to be expected from a national adoption of superpower, the economic aspects of the movement, its effects upon transportation.

True Value of Reading Coal Stock and Effect of Coal Asset Upon Reading Stocks and Bonds. Philadelphia Company of Philadelphia, Huguenot Park, New York City. Pp. 16, 6 x 9 in.

Sampling and Examination of Mine Gases and Natural Gas, by George A. Burrell and Frank M. Seibert; revised by G. W. Jones. A revision of Bulletin 42. Bulletin 197. Pp. 108; 6x9 in.; illustrated. Price 25c. Bureau of Mines, Washington, D. C.

Organization and Courses of Study in Anthracite Coal Mining for Mine Foremen and Assistant Mine Foremen. Department of Public Instruction, Harrisburg, Pa. Bulletin No. 6. Pp. 24; 6x9 in.



Discovery Depletion in Relation to the Mining Industry. General Tax Committee of the American Mining Congress, Washington, D. C. Pp. 76; 6x9 in.; illustrated. A discussion of the history, economic base and justification for the discovery depletion principle.

New Equipment

New Thermotel Registers Transformer Conditions

Accurate knowledge of the conditions under which electrical equipment is operating is always important. The type B-2 thermotel as manufactured by the General Electric Co., of Schenectady, N. Y., is a new load indicator for 60-cycle, 2,300-volt current. It is applicable to the subway type distribution transformers ranging in size from 15 to 200 kva. inclusive. It is similar to the thermotel for the pole type of transformers and was designed as a convenient and reliable means of making load surveys.

This instrument is designed to evaluate the sum of all of the several

The Transformer Watchman

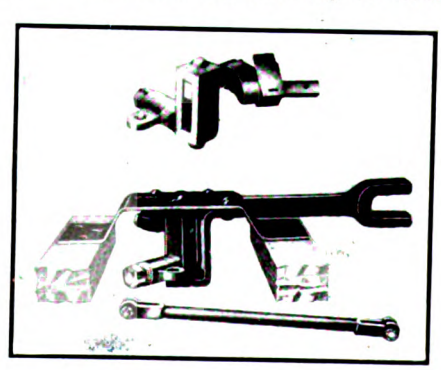
This little instrument which may be attached to the side of the transformer shows the percentage of capacity which the unit is carrying and also indicates when the full capacity is exceeded. This latter indication constitutes virtually a danger signal.

variables on which the output of a transformer depends. These include the kva. rating of the transformer, the load, the duration of the load, and the temperature of the surrounding air, usually referred to as the ambient temperature. The percentage of available transformer capacity being utilized is also indicated.

This instrument shows when the transformer is underloaded as well as overloaded, together with the load conditions existing at the time of resetting. Furthermore, it exposes an easily distinguishable danger signal when safe load conditions are exceeded. An important detail of its construction is its ability to accurately differentiate ambient temperature variations.

This device consists essentially of two thermometers connected in series. One is of the capillary tube type and is immersed in the oil of the transformer; the other is of the bimetallic type and is located in the external case and acts as a corrective for the ambient temperature. The combination of the two actuates an index and danger signal.

The external case is of brass, finished in black japan and thermally insulated from the radiant heat of the transformer by a metal screen and air space. This case is riveted to a bronze casting through which the capillary tube passes. Installation requires only the removal of the lower oil-sampling plug, after which the thermotel, which is provided with the necessary fitting, is screwed into place. An auxiliary sampling plug is provided on the instrument to permit the checking of the oil level in the transformer.



The index is of the maximum reading type and records the maximum percentage of the transformer's capacity that has been utilized since the last resetting, the scale being graduated to read between 50 and 100 per cent of transformer capacity. The semaphore indicating an overloaded transformer is normally not visible until 100 per cent of the capacity has been exceeded. When this occurs, it drops into view.

Low Parallel-Throw Switch Stand Is Adjustable

An inexpensive, double-bearing, parallel-throw switch stand called the "Durabil" that is claimed to be positive in action and smooth in operation recently has been developed and patented by the L. A. Green Railway Equipment Co., of Pittsburgh, Pa. The accompanying illustration shows this switch throw in some detail.

All parts of this switch stand are below the housing and thus are protected from damage. The entire stand is compact, rising only 2 in. above the ties. The throw of the lever is parallel to the track assuring safety to the operator. The stand is non-automatic and self locking, being on dead center when in normal position.

All parts of this device are made of rolled or die forged steel. The length of throw is adjustable, being capable of variation from 3 to 5 in. by the mere transference of shims or washers Thus this stand can not only be used

Details of the Switch Stand

It is built entirely of forgings no cast parts being employed. It is low and compact and the movement of the hand lever is in a direction parallel to the track assuring safety. Actual length of throw may be adjusted to suit local requirements.

Digitized by Google

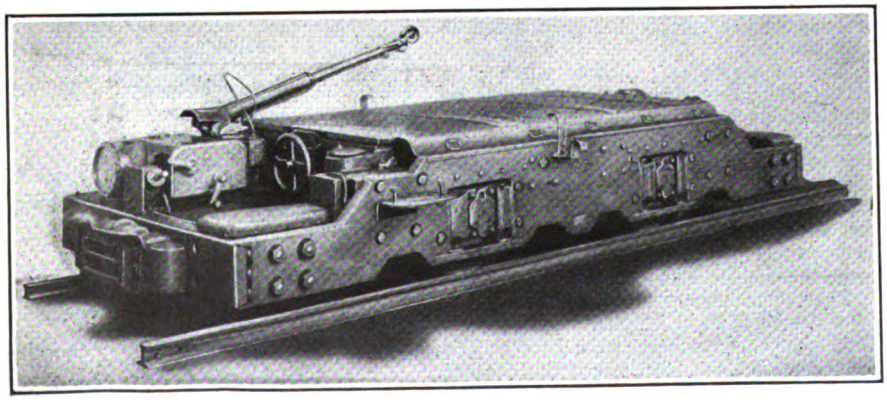
with switches of differing lengths of throw but by changing the position of a shim or two it can be adjusted for worn switch points thereby obtaining positive contact of these parts. The connecting rod may be either made rigid or be fitted with a spring.

Saves Time in Splicing

Trolley lines have a way of failing at inopportune moments. In the accompanying illustration is shown the type SL bronze, set-screw splicer as recently developed by the Westinghouse Electric & Mfg. Co., of East Pittsburgh, Pa. This splicer permits repairs to the trolley wire to be made in a minimum of time, thus saving both direct and indirect losses, the latter frequently far overshadowing the first in magnitude. The approach lips point upward forming a firm yet gentle underrun. The wires may be inserted without bending and each is held firmly in place by two set screws.

Firm Grip is Assured

In this 10-in. splicer which accommodates all sizes and cross sections of trolley wire, the four set screws hold the two ends of the wire firmly. The greater the tension on the wires, the tighter will the set screws bind.



These set screws are inserted in a slanting direction and are mounted in square nuts that are capable of rocking. Each nut thus acts like the fulcrum of a pinch bar to which the set screw forms the active end. As soon as tension is applied the set screws wedge tight and take hold of the wire so that it cannot slip. This splicer is 10 in. long and one size will accommodate all trolley wires from 1/0 to 4/0 round, grooved or of figure-8 section.

New Cable-Reel Locomotive Is But 25 In. High

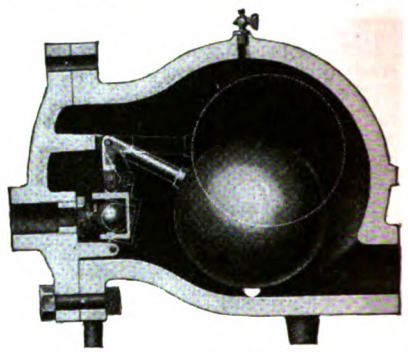
In the accompanying illustration is shown the low, cable-reel locomotive recently placed on the market by the Jeffrey Manufacturing Co., of Columbus, Ohio. This machine is built with either inside or outside drivers. The overall height of the inside wheel type is 26 in. with a trolley pole mounted on an outrigger. The overall height of the outside wheel type is 25 in.

This low type of locomotive permits the trolley pole to be placed on top of the machine, yet keeps the minimum height of the trolley wire down to 29½ in. The motor equipment consists of two low speed motors giving a maximum traversing speed of 4 m.p.h. at full load. The machine may also be built for a speed of 6 m.p.h.

The cable reel diameters for the inside-wheel type of locomotive range from 42 to 48 in. They are fitted with 850 ft. of No. 3, single-conductor cable. This reel is motor driven. The motor equipment on this locomotive was designed especially for it, and is much more liberal in dimensions than has formerly been the case on similar machines. The frame is of the plate type 2½ in. thick, and the controller is of the non-stubbing finger variety, on contact cylinder as well as on the reverse. All fingers have renewable burning tips.

Low Cable Reel Locomotive

The total height of this machine ranges from 25 to 26 in. depending upon whether the drivers are outside or inside the frame. The height of the trolley wire may be as little as 29½ in. The motor-driven reel will hold 850 ft. of cable, permitting the locomotive to proceed this distance beyond the end of the trolley line.



Trap Prevents Wire Drawing

When a steam trap is open it should be wide open, and when it is closed there should be no leakage. Furthermore, any device of this kind should be simple in construction and readily accessible.

In the accompanying illustration is shown a steam trap that is said to embody these three important requisites. It has but few working parts and in operation is either shut tight or wide open. It was designed by a practical steam engineer to overcome the troubles he had experienced in his own plant. It is now being manufactured by the Williams Gauge Co., of Pittsburgh, Pa., and is known as the "Williams new ball-seat trap No. 4B."

This trap is held closed and tight when the float is in the position shown in the accompanying illustration. This float is made of welded chrome nickel, and is tested to a pressure of 600 to 1,200 lb. As the water in the chamber rises the float, of course, rises with it, but the trap does not open immediately. The ball cage is purposely made sufficiently large so that there is approximately ⅛ in. of lost motion or play between the ball valve and the cage. Consequently, the ball is held in place by the pressure within the trap until the float rises to the position shown by the dotted line. When this position is reached the cage pulls the ball away from its seat, and the trap is wide open.

As soon as the ball leaves its seat the pressure is equalized and the ball moves to the back of the cage, leaving the outlet fully open so that discharge is quickly accomplished. No wire drawing across the seat can occur. As the water is blown out, the float sinks, and when the water level reaches a point 3 or 4 in. above the outlet the float has assumed the position shown in the picture. This tips the cage forward to a point where the ball is caught by the water being discharged and the valve closes with a snap. Once closed there is no possibility of leakage. Inasmuch as the ball and seat fit each other accurately, and both are made of Monel metal, tightness is assured. Both the ball and the seat are removable and may be easily renewed. Every part is quickly accessible and although there is but slight possibility that repairs need be made, the time and cost of making them should they ever be necessary will be only trifling.

Part Section of Trap

This device is intended to overcome the usual failings of steam traps, chief of which is a liability to steam cutting. When this trap opens it opens wide; when it closes it closes tight. There is thus small danger of its developing a leak.

Industrial Note

A merger of the financial interests of the **Hewitt Rubber Co.**, of Buffalo, N. Y., with the **Gutta Percha & Rubber Mfg. Co.**, of New York and Brooklyn, recently was effected. At a reorganization meeting held in Buffalo, F. E. Miller was elected president of the Gutta Percha & Rubber Mfg. Co.; John H. Kelly and Amadee Spadone were elected vice-presidents, and W. J. Magee, secretary and treasurer. The reorganization is the first step in the removal of the company's plant, office and other facilities to Buffalo.

Trade Literature

W. C. Lipe, Inc., Syracuse, N. Y., has issued an 18-pp. 8½x10½-in. bulletin illustrating and describing its products, among which are its speed reducer, electric hoists, flexible couplings, internal geared conveyor pulley, gear tooth rounding machine and coil winder.

Measurement of Water. Republic Flow Meters Co., Chicago, Ill. Bulletin No. W-31. Pp. 15; 8½x11 in.; illustrated. Describes the metering of water electrically.

Standard Chain Drives. Hans Renold, Ltd., Didsbury, England. Pp. 47; 4x6 in.; illustrated. Describes both the Bush roller and inverted tooth type chain drives up to 50 hp. Prices are included.

Metallo Gaskets. Metallo Gasket Co., New Brunswick, N. J. Catalog 26. Pp. 32; 6x9 in.; illustrated. Describes the styles of gaskets manufactured by this company and gives price lists.

COAL AGE

The World's Accepted Authority on Coal Mining

McGraw-Hill Publishing Company, Inc. **March 4, 1926** Price Twenty Cents per Copy

The Conveyor with the Wave-Motion which cuts power consumption in half

Send for the new Eickhoff Catalog— just off the press.

The distinctly different curvature of its Roller Cradle, together with correctly designed drives, make possible the extraordinary grade-overcoming capacity, and the amazingly low power consumption of the Eickhoff Wave-Motion Jigging Conveyor.

Twenty years of experience in the perfection of its design and materials assure its unrivalled mechanical efficiency and long enduring service.

17,000 installations abroad and a rapidly increasing number in America bear witness to the dependability and adaptability of this revolutionary conveyor.

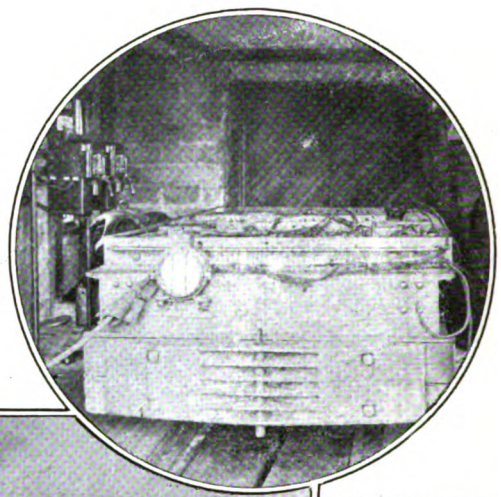
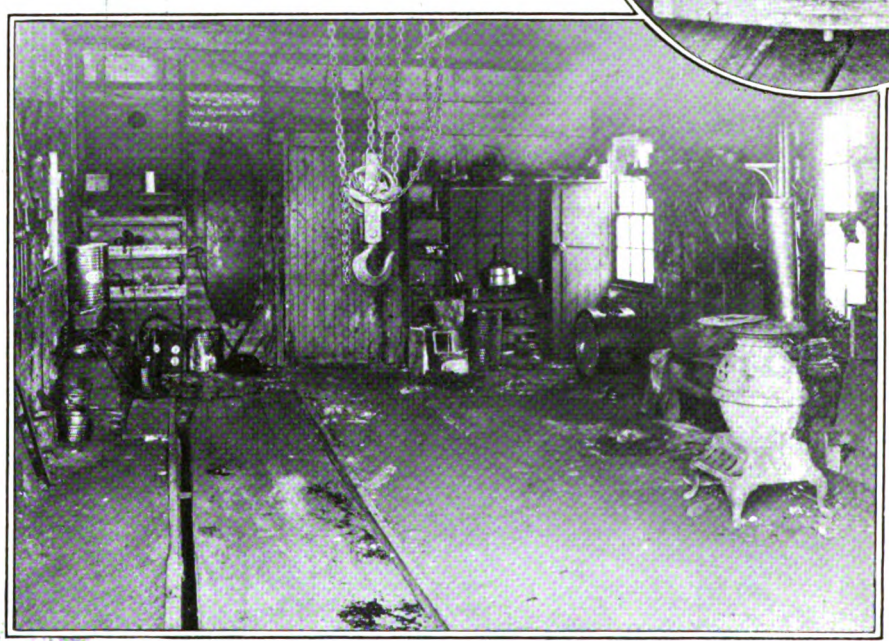
For Better Haulage



YOU want a haulage system that runs like clockwork; one that gets the coal out smoothly and steadily day after day without any fuss or trouble.

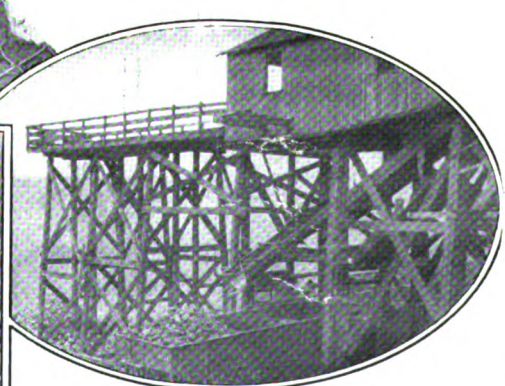
If you haven't got such a haulage system now, one of the biggest steps you can take toward attaining it is to install Exide-Ironclad Batteries in your battery motors.



An Exide-Ironclad has lots of pep and speed; plenty of power for grades; it rarely gets out of order; its charging efficiency is high; it lasts for years and costs only a reasonable amount in the beginning. Send now for a copy, of our booklet, No. 1791, entitled, "Facts for Consideration in Selecting a Battery for Locomotive Service."

THE ELECTRIC STORAGE BATTERY COMPANY
Philadelphia

Exide Batteries of Canada, Limited, 153 Dufferin Street, Toronto



An Exide-Ironclad takes its charge—eagerly, thirstily, wasting hardly any current.

When miners have to wait for cars it's bad for their morale and it's bad for company profits. When Exide-Ironclad Batteries are on the job to hustle the empties in and the loads out, there's very little waiting for empties done. The speed and pep of this battery holds up all day long.

An Exide-Ironclad is so ruggedly built it hardly ever spends any time in the repair shop. It stays on the job day after day and year after year.

How quickly the car will be loaded and how many loaded cars there will be at the day's end depends largely upon the speed with which the haulage motors can haul the coal. If there are Exide-Ironclad Batteries in those motors, more cars are going to pass under the tipple each day.

How do your motors come back to the charging barn at night? Do they breeze in like this Exide-Ironclad-equipped motor, with still a lot of pep left at the shift's end? An Exide-Ironclad Battery always has lot of stamina.

To Lower Haulage Costs

WE USUALLY think of a shoveling machine as a mechanical device used for loading coal into mine cars. These machines, however, may and frequently do find other application underground.

Next week Frank H. Kneeland will describe how shoveling machines are being used to load out cuts and fills on the main haulage entries of a group of mines in Kentucky. By this means the work of bringing an undulating bottom to grade is greatly simplified. Furthermore, this dead work can be performed at a less cost by shovel than the same work could be done by hand.

Best of all the shovel does the work rapidly. Changing grades on a main haulage may be an extremely expensive operation, because in most cases such a change entails a more or less pronounced interference with haulage operations. With two power shovels, one at either end of the cut, such changes can frequently be made over a week end and with no interference with haulage.

* * *

ALABAMA is making headway with rock dusting, as is the rest of the country. The Alabama engineers are thinking the problem out for themselves, and J. H. Edwards during his visit to that state recorded what the outcome of this thinking has been. His observations will appear in next week's issue.

* * *

ANOTHER article will describe the results of investigations as to liquid oxygen as an explosive. This rock-shattering material familiarly known as LOX, can be used by coal men only in surface work. It seems well adapted to employment in strip pits.

The Bulldog tackles another task

The Daddy of the Bulldog Family with the alining feature.

The New Bulldog Clamp — popular as pay-day in the mines.

The Bulldog Cable Clamp for feeder cable suspension from insulated hangers.

Using inverted angle iron as a trolley, doesn't eliminate Bulldog from the picture. Not by a long shot! In fact the Bulldog Clamp is just as much at home with this type of overhead as with a wire trolley.

Pairs of hook type jaws, made to fit standard $2\frac{1}{2}$-inch angle, are adapted to the Bulldog clamping principle. Screwing down on the nut tightens the grip of the jaws in identically the same way as the familiar Bulldog wire clamp functions.

It pays to stock and standardize on O-B Bulldog Clamps for all trolley and feeder cable hanging, because the work is expedited and the job is permanent.

Coal as an Ice Remover

NONE of the modern problems in cities is more perplexing than that of removing snow and ice. In one storm in 1920 New York City spent $5,500,000 for the service and yet did not do the work either speedily, thoroughly or without hindrance to traffic. The ideal way to remove the ice would be by heat. By this method the snow would in fact not be removed, it would melt as it falls and the sidewalk would be kept clear, saving labor and the suits that follow falls on the icy pavements, keeping the walks free for loading operations or for business and making trading at the stores attractive.

A foot of snow just freshly fallen weighs from 5 to 12 lb. per cubic foot. The latent heat of fusion for snow is about 143 B.t.u. per pound, and as snow may fall at a temperature of 10 deg. below freezing 165 B.t.u. of heat will serve to raise the temperature enough not only to assure melting but the transfer of the water over the curb or to cause it to evaporate into the dry air. Taking the heavier weight of snow per foot of fall and assuming a foot of precipitation, the number of British thermal units needed to melt the snow and give it a final temperature of 10 deg. above freezing, having fallen at 20 deg., would require 1,980 B.t.u. per sq.ft. Assuming that there is a waste in heat such that twenty times as much coal is used as the thermal capacity of that fuel would indicate, the quantity of heat needed would be 39,600 B.t.u., or about the heat in three pounds of coal. If the cost of the coal as stoked into the furnace was $10 per ton the cost of melting by steam in the manner indicated would be 1½c. per sq.ft. and a pavement 16 ft. wide and 100 ft. long would be cleared for $24.

Probably in most cities there would be but three such storms in a year and a cost of $72 would not be excessive. Such a pavement would supply enough snow to fill five wagons for a precipitation of one foot, and the cleaning of the sidewalk, the loading of the snow on the wagon and the transfer of it over slippery, drifted streets to the wharf might easily cost $25, or $75 for three such snows. However, as the municipality pays for the cartage there probably would be an apparent total loss in such melting because the city would be relieved at the cost of the owner.

Perhaps municipalities might be disposed to allow a reduction in taxes where such cleaning by steam pipes is provided. It might be arranged also that the owner would keep the snow off the street to its center and thus help in the general clearing of the roadway. Perhaps it would not be unconstitutional to require newly constructed buildings ten stories or more in height or buildings of over five stories constructed for manufacturing purposes to provide pipes and boiler capacity for the removal of snow on the sidewalk and in the road. Such high buildings create an unusual density of traffic and an obligation rests on the owners to relieve in part the congestion which the intensive use of their building space makes inevitable.

What an assistance to communication it would be if, at least, two main thoroughfares in New York City were provided in some such manner with complete equipment for removing the snow as fast as it fell.

High Discovery Depletion Builds Up Oil Competition

THE NEW TAX LAW revises the depletion clauses relating to "discovery" of mines and of oil and gas wells. In the case of metal mines more liberality is shown than in the past in that the law requires that "discoveries" shall include ore in commercial quantities contained in a vein or deposit discovered in an existing mine or mining tract if the vein or bed thus discovered is not merely an extension of a vein or bed already known to exist. In other words, a disconnected commercial orebody in a known mineralized zone is eligible for discovery valuation for depletion purposes, provided it has not been included in a former valuation.

The revision of the discovery depletion allowances in no way benefits the coal industry. The only depletion that this industry can get is based on cost, or March 1, 1913, value. The coal beds of the United States have been accurately mapped by state and federal surveys, and this fact is held to preclude discovery, coal lands being purchased or leased only when commercial coal is known to exist.

The discovery depletion allowed oil in 1921 to 1923 averaged 70c. per barrel (30 per cent) on the total production, while the total depletion on coal (based on cost and March 1, 1913, value) was approximately 6c. per ton, or only about 2 per cent of the selling price of coal. This disparity is still greater when it is realized that the heating value of a barrel of oil is only a quarter to a third that of a ton of coal. The wide variation in tax-free allowances for those two competing industries is a question that the National Coal Association might well consider.

In the amount of depletion allowable in the case of oil and gas wells the new tax law is definite. Discovery depletion, as such, is not mentioned, but the law specifically states that "In the case of oil and gas wells the allowance for depletion shall be 27½ per centum of the gross income from the property during the taxable year. Such allowance shall not exceed 50 per centum of the net income of the taxpayer (computed without allowance for depletion) from the property except that in no case shall the depletion allowance be less than it would be if computed without reference to this paragraph."

As between the discovery depletion allowable for

Digitized by Google

mines, and the 27½ per cent deduction for oil wells, the oil industry has by far the greatest advantage, for the depletion deduction will cover an entire pool even more effectively than did the discovery clause in the earlier laws. The average percentage of discovery depletion for oil wells in 1921 to 1923 was approximately 30 per cent of gross income. There is, therefore, a slight reduction, but the rate is entirely too high, for it means that practically 50 per cent of the net income will be tax-free. The average depletion on cost is about 5 per cent of gross income, leaving 40 to 45 per cent of net income as development appreciation to be written off as depletion, after all exploration and production costs have been deducted.

Mine Mapping Reduces Dangers

MINE maps should always be kept up to date. By this means only can the superintendent and other general operating officials make frequent eye-surveys of mine workings to determine the degree of safety of new development. These men do not have the time to make personal inspections of a mine as thoroughly or as often as might be desired. Between times they must rely upon the mine map to convey knowledge of extensions of workings. To serve this purpose, consequently, the map must be reasonably accurate.

A daily extension of the map will aid in the avoidance of many dangers. A weekly correction will reduce the probability of an impending danger. No working map should stand uncorrected for periods greater than a week.

The importance of accurate map-keeping has been proved by private and state investigations of a number of explosions which have taken place in the past few years. Entries have been driven far ahead of fresh air, crosscuts outby of the last have been left open, doors omitted, etc., unknown to the superintendent and more frequently to the general management.

Not so long ago a number of men worked under conditions more dangerous than they at the time realized, while taking part in the rescue after an explosion in a mine in which a "bleeder" entry was allowed to remain open long after it had ceased to serve a specific and safe purpose. The opening was not plotted on the map nor was the management aware of its existence. The oversight might have caused a second explosion.

A danger or an approach to such a condition ought to be indicated on the map on the day it is noted. Underground officials could facilitate this procedure by jotting down in a notebook abnormal conditions in any place, which at the end of each shift should be indicated so far as possible on the map in the outside mine office.

Those Fortunes in Anthracite

IN THE year 1925 the reports made by the several anthracite companies to the Treasury showed the aggregate of the net incomes in the previous year, fiscal or calendar, as the case might be to total $28,611,281. They also showed a total of the net losses sustained to be $6,791,469. Deducting net losses from net income the whole of the anthracite industry made a net earning, excluding Federal taxes, of $21,819,812.

No wonder when the secret was revealed by the publication of the tax returns, the public was convinced that the producing of anthracite was a poorly compensated business. The United Fruit Co., for instance, in which no one but the stockholders are interested showed a profit of $26,218,015.55 before payment of income tax. It would be futile to compare that twenty-two million made in the anthracite industry with the $120,982,-531.89 made by General Motors or the $165,000,000 and more made by the U. S. Steel Corporation. Still less will it stand comparison with the earnings of Mr. Ford.

The output of anthracite in 1924 deducting what was used at the mines for steam and heat was 80,291,438 net tons. So the profit per marketed ton was 27.1c. and for whole tonnage produced 24.8c. Truly a lot of pother has been made about a most niggardly profit, and the pity of it is that many who if they were in the business would want a return four or five times as large are among the persons who have been most voluble in criticism. If industry generally was conducted on margins comparable with those on anthracite the cost of living would make a notable decline.

Diesel-Electric Transportation

JUST what place the Diesel-electric engine, with its replacement of oil for coal, is going to take in the railroad industry remains to be seen. The disposition is to say that it is any man's guess, but back of it all is a belief that as means are adapted to ends it may have an increasing place in the transportation industry, especially for yard work and for traffic not dense enough for true electrification but near enough to cities to make smokelessness important. It has good powers of acceleration because of its high horsepower at low speeds, but it is not suited for use where stops are frequent because it constitutes such a huge weight to be accelerated. This all seems to be conceded. What is not clear is what place it has in main-line operation, especially for freight service.

The Diesel-electric engine in itself alone is not exceedingly heavy but it needs heavy foundations and therefore a heavy truck beneath it. Much electric equipment goes with it, also adding seriously to the weight and to the weight of the carriage. A steam locomotive will weigh 140 lb. per horsepower, but the present Diesel-electric equipment will weigh from 250 to 300 lb. per horsepower. Some are hoping that 200 lb. will be the figure ultimately obtained.

The cost of the Diesel-electric unit is three or four times that of the steam locomotive, but the fuel cost is only 30 per cent as large and the Diesel-electric engine should easily work twice as many hours as a steam locomotive, for it fuels seldom and takes water even less frequently, runs without repair and has no firebox to clean out. For these reasons, as C. A. Stein, the general manager of the Central Railroad of New Jersey, has said, its cost of operation should be one-fifth that of the steam engine working on anthracite and one-third of the same prime mover working on bituminous coal.

The large outlay, the weight on the drivers and conservatism will hold back the Diesel-electric locomotive. Samuel M. Vauclain may have been right when he said at the Midwest Power Conference at Chicago, Ill.: "It is my opinion that considerable time must elapse and many millions of dollars be expended in the development of an oil-electric power unit in the shape of a locomotive before machines of this type will figure to any great extent in transportation service."

Recent Improvements in Automatic Centrifugal Pump Control Simplify Apparatus

Time-Delay Relay Takes Place of Notching Type—Adjustments Are Made to Suit Pumping Conditions—In Case of Trouble Pump Is Locked Out of Service

By R. S. Sage*
Schenectady, N. Y.

THE DRAINAGE problem of a coal mine is one of the most important the operator has to solve. In the anthracite field there are many instances where an average of twenty tons of water must be pumped for every ton of coal produced and this ratio in some cases is much greater. It is highly important, therefore, that the pumping apparatus be adequate in every particular and, at the same time, its operation should be carried on as economically as possible. Mine pumps usually have to operate intermittently over long periods and therefore require either manual attendance or an automatic system which accomplishes the same results with complete reliability.

Rapid progress has been made during the past two or three years in the application of automatic control equipment to mine pumps, and the system has now been brought to a point which assures success in handling all operating conditions which arise in such service. Manual attendance, where automatic apparatus is used, has been almost completely dispensed with, and best of all, without in any manner compromising the dependability of the plant. As a result large savings in operating expense have accrued to the operators. Fortunately, the automatic system involves no excessive capital outlay for additional apparatus and yet is not complicated.

Some publicity already has been given to the automatic pumping systems which have been adopted with great success in the anthracite fields. Therefore, the present article will deal with a recent improvement in the control equipment, particularly in the manner of securing successive restarts of the pump.

Automatic control equipment described in this article refers to centrifugal pump installations only, there being no particular problem attending the automatic starting and stopping of plunger type pumps. When centrifugal pumps are operated with a suction lift, it is necessary that the pump be primed before it will deliver water. The use of foot valves often makes priming unnecessary, but such valves are not always considered dependable, as they are likely to leak from one cause or another. Therefore, in automatic installations operating under a suction lift, a priming pump is an essential part of the equipment.

The sketches in Figs. 1 and 2 are included so as to illustrate the apparatus involved and the functions they perform. Referring to Fig. 1, the apparatus comprising the complete equipment will be found listed in the drawing. Fig. 2 is a simplified wiring diagram reference to which should be made in connection with the explanation which follows.

When the sump fills with water to a predetermined height, the float switch, *5*, closes its contacts and establishes a circuit through contact *b* of the time relay and the interlock *a* of the master contactor, *A*, to the solenoid-operated valves *9* to the contactor starter, *8*, of the priming pump motor, and to the motor, *M*, of the time relay, *B*. The priming pump then starts and proceeds to exhaust the air from the main pump casing through the valves, which are held open by the energized solenoids.

The air is drawn through the vacuum breaker, *6*. As the air is being exhausted, water rises into the pump casing and eventually is drawn through the priming pipes and into the vacuum breaker. As the water level in the vacuum breaker rises, a float causes electric contacts mounted thereon to close.

The closing of the contact, *6*, completes a circuit through the operating coil of the master contactor, *A*, which closes its contacts, *e*, and opens its interlock contacts, *a*, with the following results:

(a) A shunt circuit around *6* is made through *10* and *11* (when these latter are closed).

(b) A circuit is made to the magnet, *S*, of the time relay, *B*, and its timing action begins to function from this instant. The energizing of this relay magnet causes the contact, *d*, to close at once, establishing for itself a holding circuit.

(c) A circuit is made to the starter, *7*, for the main pump motor, which is brought up to its normal running speed.

(d) Contacts *a* open, thereby de-energizing the starter, *8*, shutting down the priming pump and de-energizing the solenoid-operated priming valves, causing them to close.

As soon as the main pump has reached a sufficient speed high pressure is developed which closes the contacts of the pressure regulator, *11*, which completes the parallel circuit to the coil of the master contactor. When the priming of the main pump is completed and the solenoid valves are closed, no more water is drawn over into the vacuum breaker. This device is so con-

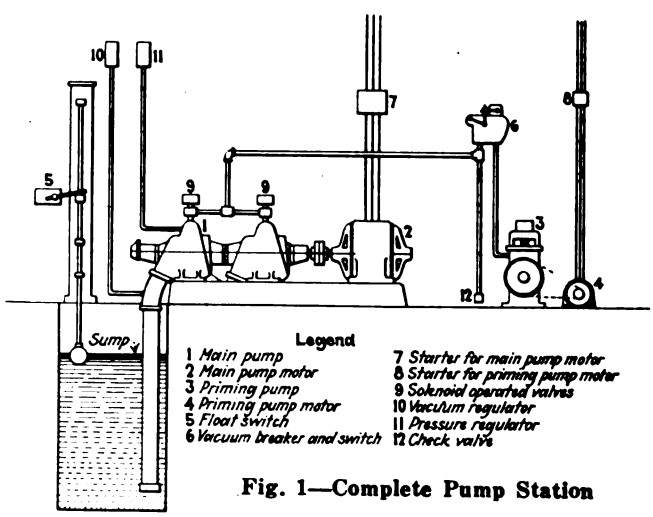

Fig. 1—Complete Pump Station

*Mr. Sage is of the industrial department, General Electric Co.

Digitized by Google

structed that, when its compartment is filled, the rising of its float opens a valve to atmosphere, thereby allowing the water to drain out through the pipe and check valve shown in Fig. 1. This also causes the switch *6* to open again, but not until *11* has closed so that a circuit to the master contactor coil is maintained.

The interval between the closing of the solenoid-operated priming valves, indicating completion of the priming operation and the opening of the vacuum breaker switch, *6*, is approximately fifteen seconds. This is normally ample time for the main pump to build up pressure and close the pressure switch *11*.

The timing relay, usually set for a period of about two minutes, releases its contact *b* after a predetermined time delay and closes the contact *c*. Normally this operation has no result whatever, as the master contactor is already closed and the opening of contact *b* does nothing except disconnect the small motor *M* or relay *B*.

The starting cycle is now completed and the main pump continues to run until the level of water in the sump has been lowered to a predetermined level, when the float switch *5* opens and the apparatus stops.

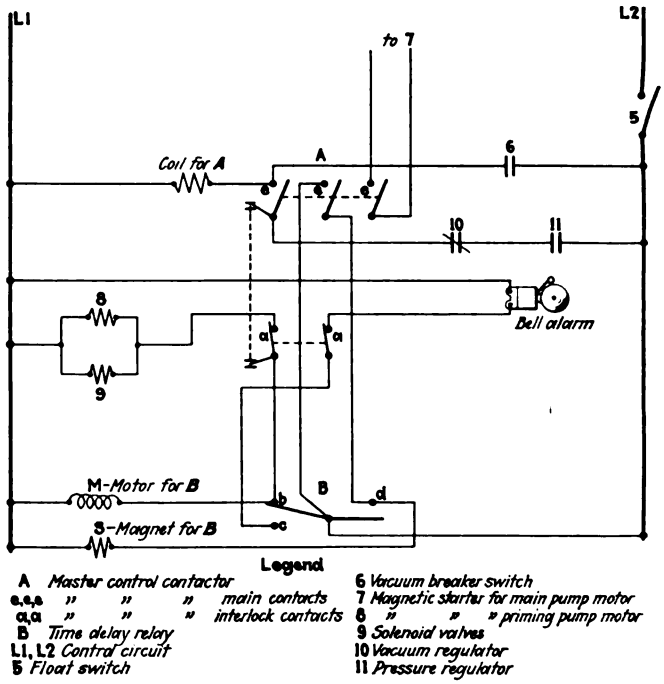
Consideration should now be given to the way in which the apparatus functions when, for some reason, the pump does not go into service as intended. If, for instance, the pressure switch *11* fails to close, indicating that the pump did not build up its proper pressure—as would be caused by a broken discharge pipe, leaks in the suction pipe, etc.—the master contactor will be de-energized when the vacuum breaker switch opens and the pump will be shut down. The pump would then be reprimed and the starting procedure would be repeated as previously explained. Such starts and restarts would occur until the time relay *B* opened the circuit at *b*. This happens at the expiration of the period for which the relay is adjusted. The timing of this relay may be adjusted to allow three, four or more restarts before it will permanently disconnect the pump control apparatus from the power supply. When the circuit is broken at *b* a circuit is established at *c* for the alarm bell which serves to indicate that inspection of the equipment is necessary.

It may frequently be the case that more than one start is necessary before the pump is properly brought into operation. For instance, if a long discharge line must be filled, the vacuum breaker switch may open before the pressure regulator closes on the first trial, or enough air may remain in the pump casing on the first attempt to prevent the pressure regulator from closing before the vacuum breaker switch opens and thus shuts down the main pump.

The vacuum regulator *10* protects the pump against operation with an excessive suction lift such as could result from a clogged intake on the suction pipe or failure of the float switch to stop the pump when the predetermined low water level is reached. In some cases the operation of the vacuum regulator instead of the float switch is relied upon to shut down the equipment at low sump level. Also, some outfits are installed so that they may be stopped or started by a push button located at a remote point instead of by a sump float switch. In such instances a throw-over switch may be used to permit operation by the float switch or from the push-button station, as desired.

It is common practice to provide reverse-phase and phase-failure protective devices in the main motor circuits in addition to overload and under-voltage relays, thus insuring against improper electrical conditions. It is also recommended that all equipments include bearing temperature relays for the main motor and the pump. These relays would then be connected into the control circuit to stop the machines in case bearing temperatures became excessive. With the installation of these simple devices practically every conceivable emergency is provided against.

If the priming pump fails to prime the main pump, the vacuum breaker will not close the master contactor, with the result that the priming pump will continue to operate unless some means is supplied to prevent it. This can be taken care of by providing an additional time-delay relay so adjusted as to open the circuit to the priming pump motor after the lapse of 20 or 30 minutes. If this relay is not provided, no harm can result, as the type of priming pump generally used is suitable for continuous operation. Moreover, such a condition would soon be brought to the attention of someone by the ringing of another bell alarm indicating a high sump level.



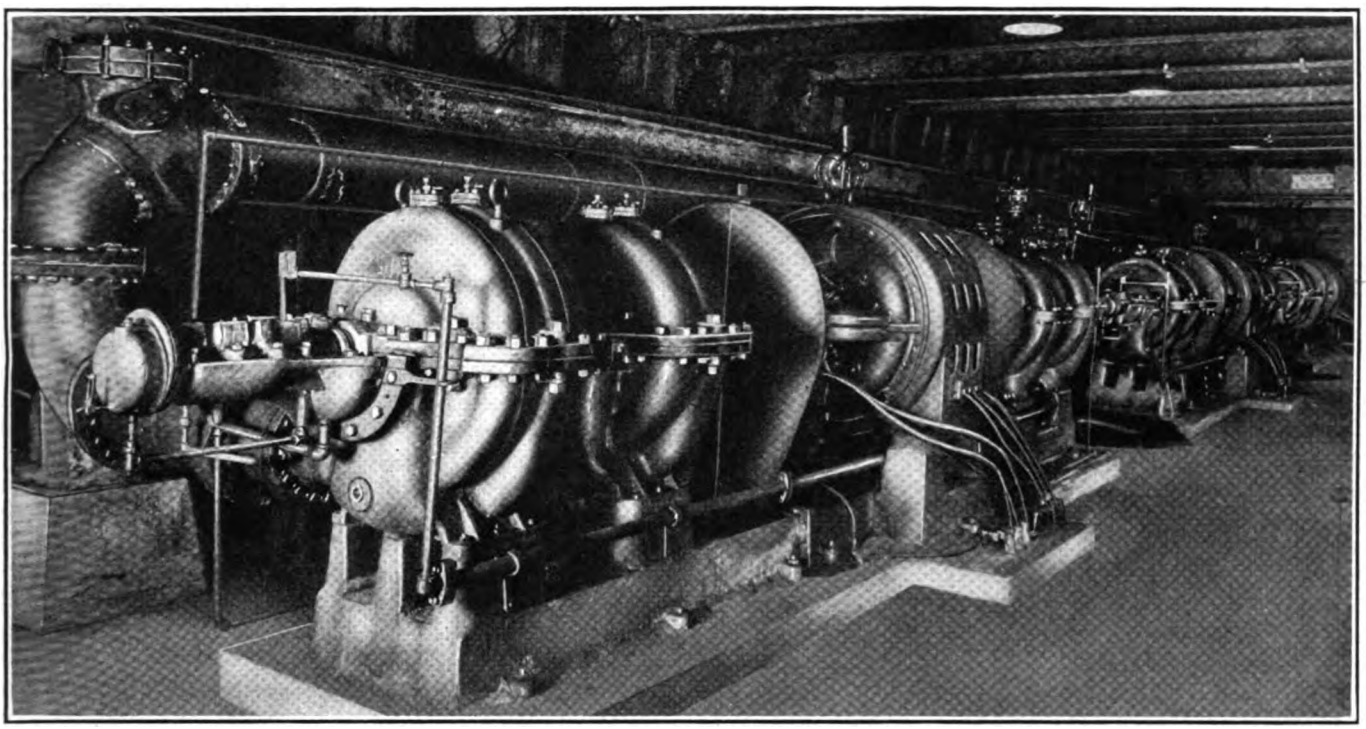


Fig. 2—Wiring and Control Devices Used With Automatic Apparatus Are Simple and Reliable

A time-delay relay is used to limit the number of restarts the equipment will make before the control circuits are automatically locked out. This simplifies the protective and control apparatus.

In case the automatic equipment is shut down by the action of either of the time-delay relays it is necessary for the operator, after he has corrected whatever fault exists, to reclose the time relay so that automatic operation can be resumed. A reset push button is provided for this purpose.

It is by the application of relay *B* that this system differs from the original control equipment developed for this service. Previously, the system included a form of notching relay which permitted the apparatus to make a definite number of restarts, usually three, before permanentlty locking out the control devices. The substitution of the time relay somewhat simplifies the circuits and increases the dependability of the system as a whole, because the relay employed is a standardized product used in large numbers on motor starters and other control apparatus.

A Few New Minor Changes Improve Automatic Pumping Service

By E. J. Gealy
New York, N. Y.

IT IS a remarkable fact that ever since the first complete automatically primed, started, protected and stopped centrifugal pumping outfit was designed and put in operation only a few minor changes or improvements have been found necessary. Most of the installations recently made are primarily the same as those described in the Sept. 13, 1923, issue of *Coal Age*. However, a few improvements have simplified and perfected the operation of the original automatic features.

Where a single centrifugal pump is primed by an automatic motor-driven priming pump a spring-operated valve illustrated in Fig. 1 may be used. The valve itself is constructed the same as the original solenoid-operated type but is actuated by means of a spring instead of a solenoid.

The spring-operated valve is held closed against a spring by the pressure developed in the centrifugal pump. When the pump is stopped the power of the spring is sufficient to open the valve.

Air easily passes through the passages of the valve, but when the centrifugal pump is primed and develops pressure the valve closes. Once closed in this manner it stays tight and does not leak, because the plunger is held on its seat by the pump pressure.

Headpiece
These three eight-stage 2,000-gal. per minute centrifugal pumps at the Greenwood Colliery of the Lehigh Coal & Navigation Co. automatically come into service as required. When the water level in the sump rises to a predetermined level one of the units starts. If the water level continues to rise, another unit automatically steps in to help. Should these two pumps fail to prevent the water from rising further, the third unit gets under way. As the water recedes each unit is stopped in its proper sequence. All these operations are automatically controlled without any manual attendance whatsoever.

A leather washer on the end of the valve stem is used to seal the valve against air leaks while it is open. This feature obviates the necessity of packing the valve and also reduces its friction.

Equipment For Two or More Pumps

The electric control equipment of automatic pumping outfits has been slightly improved by changes designed to handle two or more pumping outfits from one priming pump. Fig. 2 shows a wiring diagram of a two-pump control system operated from two float switches. The second pump is prevented from coming into operation by means of a timing relay in the circuit of the first pump. A triple-pole, double-throw switch is provided to make the starting sequence of the two pumps selective.

Quite similar control apparatus has also been designed to start, as required, any number of pumps in the same station. If the water level in the sump unduly increases after the first pump has operated for a time, the second pump is automatically put into service. If the water still continues to rise, a third pump is automatically started and placed in operation. As the water level recedes the pumps go out of service in their proper sequence. Such a station located at the Greenwood Colliery of the Lehigh Coal & Navigation Co. near Lansford, Pa., is shown in the headpiece.

Another feature of control relating to the rate at which the starting contactors of the motor controller are closed has been improved. In this connection when sufficient time was not permitted before the pump motor was thrown directly on the power line for the motor

Digitized by Google

to come up nearly to full speed, the pump seemed to lose its water. The column of water in the suction line or in the pump appeared momentarily to part when the motor speed was suddenly increased from a low value to full speed. Lately this difficulty has been removed

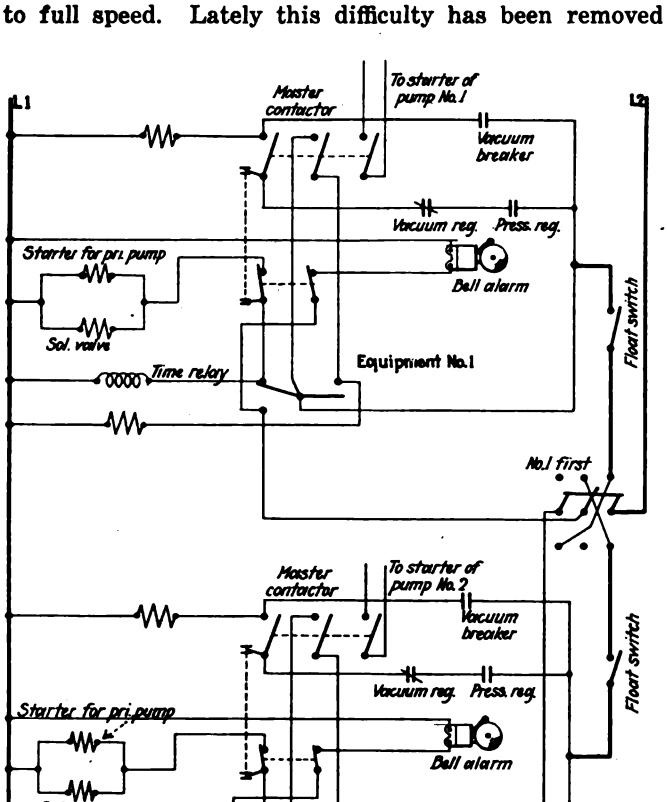

Fig. 1—Two-Pump Control System

This diagram shows the wiring circuits used when two pumps are primed by one motor-driven priming pump. Each centrifugal unit is controlled by its own float switch

by adjusting the contactor switches on panels connected to wound-rotor induction motors so that the motor nearly reaches full speed soon after the first contactors are closed. Thus there is no sudden jerk when all the motor resistance is cut out and the motor brought up to full running speed.

Economies of operation, maintenance and repair are rapidly popularizing these recent innovations in centrifugal pump control and interest in the system is already spreading to other industries.

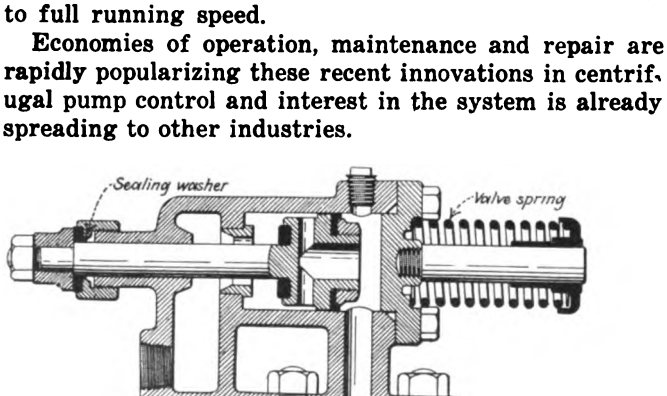

Fig. 2—Spring-Operated Priming Valve

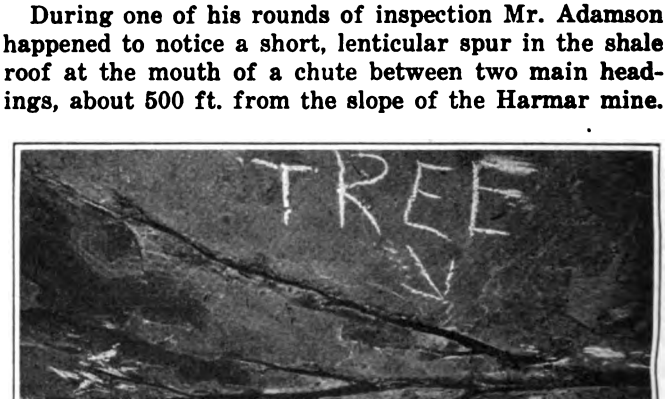

The valve itself is the same as the solenoid type. The spring is connected to the valve through a crosshead and tie rods

Mine Roof Reveals Unusual Fossil of Carboniferous Tree

A COALIFIED fossil, which from a scientific point of view is probably the most valuable specimen of a tree of the Carboniferous period ever discovered, because it combines so many hitherto unknown or only suspected characteristics of the tree it represents, is now on exhibit at the Carnegie Institute of Technology, Pittsburgh, Pa. The U. S. Bureau of Mines classifies this fossil as that of the extreme tip of a *Lepidodendrum lanceolatum* (meaning a family of ancient, fern-like trees with a bark composed of overlapping scales and leaves which are lance-shaped). The fossil was discovered recently by Superintendent James Adamson in the Harmar mine, in the Double Freeport seam, of the Consumers Mining Co., Harmarville, Pa.

Back about 200 million years ago a fern-like forest grew in a bed of mud which lay over a thick deposit of peat-like material in the vicinity of what is now Harmarville. The tip of one of these trees fell undamaged into this mud which later was submerged by a sea and then covered by a thick deposit of limestone. During a later period these deposits were uplifted and in subsequent years eroded to the topography of the region in the present day. The pressure subjected by the heavy overburden changed the peat deposit into coal, which is now known as the Double Freeport seam, and coalified the tip of the tree in the mud above the bog without changing the surface structure of the tree tip, such as the leaf scars and bark patterns.

During one of his rounds of inspection Mr. Adamson happened to notice a short, lenticular spur in the shale roof at the mouth of a chute between two main headings, about 500 ft. from the slope of the Harmar mine.

Mine Chief Found This Fossil

Carboniferous period tree imbedded in the roof above the Double Freeport coal seam in the Harmar mine near Pittsburgh, Pa. The fossil is somewhat distorted because of the angle at which the photograph was taken.

Suspecting that the exposed spur might be a projection of a large fossil body hidden by a slab of shale, he pried down the latter and uncovered a fossil roughly measuring 4 ft. in length from tip to tip. A *Coal Age* camera was focused on the fossil as it hung in place in the roof, with the result shown in the accompanying illustration.

Mr. Adamson appreciated the scientific value of his find and set a crew to work removing the fossil. This was finally accomplished by drilling close together a series of holes on a rectangular border. The slab was then reinforced with cement in a protecting box and loosened.

Artificial Storm of Air-Sand Floats Coal on Its Upper Surface, Leaving Refuse to Sink

By Thomas Fraser* and H. F. Yancey†

THE air-sand process is one in which inferior material is removed from coal by means of a body of dry sand artificially fluidized and maintained in that condition by a continuous stream of air bubbles flowing through the sand body. By proper regulation of the rate of air flow, this fluid air-sand body may be maintained at such a density that coal will float near its surface and the refuse, which is heavier, will sink through the sand to the bottom of the container. This separation is a float-and-sink operation similar to the separation of wood chips and stones in water; the one floats and the other sinks, irrespective of the size of the pieces. This was the objective sought in the development of this method of cleaning coal—a dry process which requires no preliminary sizing. Fig. 1 shows the cast-iron cell used for testing at the Central District Experiment Station of the Bureau of Mines, Urbana, Ill. This consisted of two castings: a rectangular box 12 in. square in cross section and 18 in. tall, open at both ends and flanged on the bottom and a cubical box also 12 in. square inside, with a closed bottom and flanged top. A porous diaphragm is bolted between the flanged ends of the two castings.

SO FAR the air-sand process is in its laboratory stages, but it seems to have possibilities on a commercial scale. The efficiency of its separation is 87.3 per cent on laboratory tests. The coal does not need close sizing before treatment, as the process is practically a "float-and-sink" determination based on gravity alone and in no way dependent on size. The coal floats on the sand cloud.

The upper part of the cell above the diaphragm is filled with river sand that has been passed through a 20-mesh screen without the removal of the dust. Air under suitable pressure is admitted to the lower part of the cell below the diaphragm, passes through the diaphragm and bubbles up through the sand, distending the mass and throwing the sand particles into motion.

Obviously the diaphragm is the essential feature of this machine. It must act as an air-diffusing medium to distribute the rising air bubbles evenly over the cross section of the cell so as to agitate the sand body uniformly and produce thereby an homogeneous fluid. For this purpose perforated metal plates, Filtros plates and porous concrete slabs have been used successfully. The last named have been given preference in the experimental work because of facility with which special shapes may be made.

The sand bath, when correctly adjusted, "boils" uniformly on the surface and feels much like a fluid; it is easily penetrated and stirred with the hand, and offers little resistance. When ordinary silica sand is used, just enough air to produce a free flow makes an air-sand bath of about 1.45 specific gravity, as indicated by a spindle hydrometer. Coal will float in this medium in the upper part, but almost entirely submerged. Refuse material such as shale and pyrite sink to the bottom of the cell and accumulate on the diaphragm. An accumulation of coarse material 2 or 3 in. deep apparently does not interfere with the operation but helps to break up and distribute the air; a thicker bed is disadvantageous.

To obtain a specific gravity of 1.45 with silica sand, a pressure equal to the weight of 1½ to 3 in. of mercury is required in the air chamber. This depends primarily upon the porosity of the diffusing medium. No measurements of air consumption have been made, but the volume used is comparatively small; the function of the air is to agitate and distend the sand body, not to lift the coal load by impact. No irregularity of flow is observed in the sand chamber as might be expected on a cell of such shape. This is probably because of the small quantity of air used and the low velocity through the diaphragm. The simple apparatus by which the operation of the process may be demonstrated, can be assembled in a few minutes in any laboratory where the material is available. It consists of a 3-in. porcelain Büchner funnel, and an open glass cylinder of approximately the same diameter as the funnel and 12 in. or more long. The two are fitted together, sealed by wrapping the joint with electrician's tape and supported by an upright ringstand. Sand is placed in the cylinder, and air is introduced through the stem of the funnel. Any source of air the pressure of which is fairly constant, is suitable. In a small tube of this kind only a small quantity of air should be admitted the admission being controlled by the "cracking" of the valve.

As an example of the separation made by the method Table I gives the results of a test on coal from No. 6 bed in central Illinois. The coal was of nut size (2 by 3 in. round-hole screen) and was taken from a 10-ton sample collected at the mine. It contained the natural proportion of impurities, as it had not passed over the picking table in the tipple. The cast-iron cell shown in Fig. 1 was used to make the separation.

Table I—Results of Air-Sand Cleaning Test

Products	Weight, Pounds	Yield, per Cent	Ash, per Cent	Sulphur, per Cent
Raw coal	62.3	100.0	14.3	6.09
Cleaned coal	54.4	87.3	9.9	4.57
Refuse	7.9	12.7	44.9	16.56

The results of this trial are very satisfactory, as may be judged by comparing them with a test made of a much larger but identical sample of the same lot of nut coal in a two-compartment jig. In the jig test 82.6 per cent of washed coal was recovered containing 10.3 per cent ash. A specific-gravity analysis, made by the

This article was presented at the New York meeting, American Institute of Mining & Metallurgical Engineers, Feb. 16.

†Associate chemical engineer, U. S. Bureau of Mines, Seattle, Wash.

Digitized by Google

float-and-sink method on another part of the 10-ton sample used in all the work, showed it to contain 90.4 per cent of float coal with 9.9 per cent ash, the same quantity of ash as that of the cleaned coal obtained in the air-sand test. The efficiency of the separation between coal and refuse in the air-sand cell is, therefore, 87.3, which is the yield of cleaned coal, divided by 90.4, the yield theoretically possible under ideal conditions, or 96.6 per cent. The ash content of the refuse obtained may appear on casual inspection to be too low, but considering that nut coal 2x3 in. was treated, and that the refuse contained about 30 per cent of pyrite, which loses about one-third of its weight on incineration, the 44.9 per cent ash in the refuse is quite acceptable.

In the development work on this problem, only the cast-iron cell shown in Fig. 1 was used. A gravity method suitable for the removal of refuse from the machine was developed. A bar screen made of sheet iron was placed in the cell just above the porous diaphragm and inclined at an angle of 45 deg. to it. One side rested on the diaphragm.

The slope was continued outside the cell by making an opening through the side of the diaphragm frame, constructing a special diaphragm of porous concrete, and providing an outside chute that reached to the same level as the bottom of the air chamber. When in operation, the opening of this chute is sealed with sand so that it does not act as a bypass for air. This arrangement provided a satisfactory means for removing refuse with no interference with, or alteration of, the air-sand medium within the cell.

The transition of this process from the laboratory test unit to regular plant operation will require the solution of various problems. Trials with various laboratory units have reached a stage of development wherein the main factors governing the separation between coal and refuse by the air-sand process have been satisfactorily controlled, and apparently no problems incapable of solution stand in the way of full-scale application.

Fig. 2 shows a cross section of the arrangement for a proposed general plant using this process. The operation is more or less self-evident. The air-sand medium is produced with 20-mesh river sand in the cell, which might be from 8 to 24 in. deep. Air is supplied by a high-pressure blower through the expanding approach to the diffusing slab that forms the bottom of the air-sand cell.

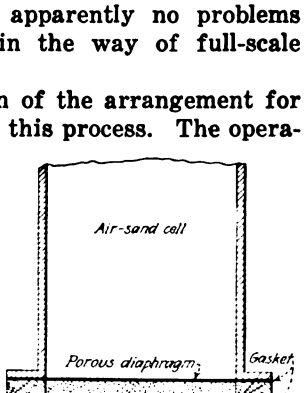

Fig. 1—Air-Sand Coal Cleaner

Apparatus as used at Central District Experiment Station, U. S. Bureau of Mines, Urbana, Ill.

This slab is inclined to one side to facilitate the discharge of refuse and avoid the use of a moving element for that purpose. The tendency of the rising air to favor the high side is compensated by increasing the resistance of that part of the diffusing medium. Refuse is swept out by a continuous slow movement of sand over the cell bottom and out through the refuse chute as shown. The rate of discharge is controlled by the outside revolving gate.

Coal is fed to the upper part of the air-sand cell, dragged across it and discharged by an endless chain scraper line. Discharge of coal is also aided by continuous rise and overflow of sand, any excess over the quantity removed by the slate gate being supplied from the sand storage tank. A stirring device to promote uniform agitation of the sand may be found advisable

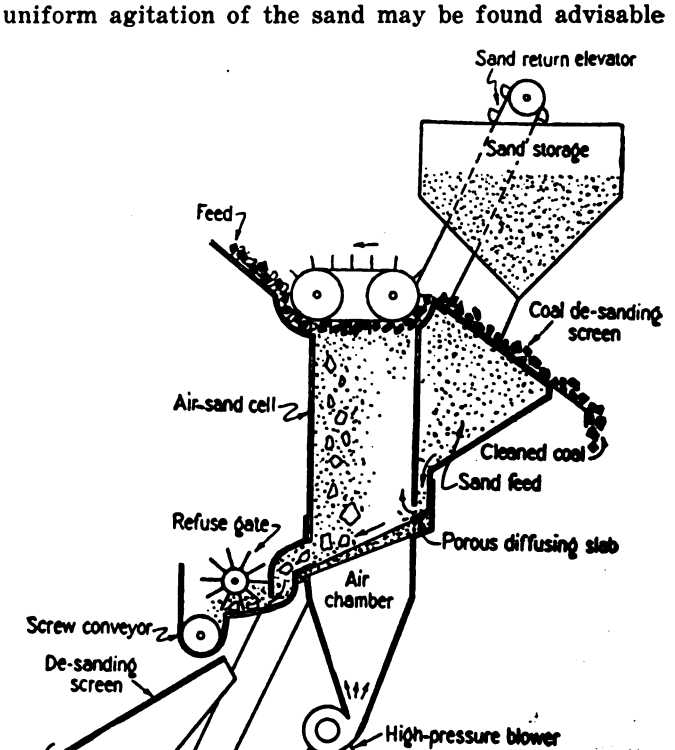

Fig. 2—Proposed Plant for Air-Sand Process

This shows plan for supplying sand to the air-sand cell, floating the coal on the sand, removing it by a conveyor, de-sanding it, removing the refuse and collecting what sand passes out of the refuse gate.

in a large-scale operation, although it has not been necessary in the experimental cell.

Heavy refuse such as shale, pyrite and bone particles drop out of the coal stream as it traverses the separating cell, and fall through the sand to the inclined cell bottom. Cleaned coal and overflow sand pass immediately over a de-sanding screen, and the sand returns directly to the sand feed chute. The refuse, which carries a larger circulating sand load, is gathered by a screw or drag conveyor to a central point where it is de-sanded by a screen and the sand is returned to the general sand storage bin by an elevator.

Suction dust hoods are not shown in Fig. 2, but will probably have to be placed over the separators and screens in order to keep the plant clean. However, on account of the small quantity of air used to agitate the sand, the air load on the dust-collecting system will not be heavy.

The only preparation that the feed will require is de-dusting or removal of fine material of the size of the sand or finer. Obviously the cleaned coal could not be de-sanded by a simple screening operation if the contained coal were as fine as the sand. Bypassing of the fines is coming to be almost standard practice at many coal-mining plants.

It is expected that the coal dust produced by attrition in the system after preliminary de-dusting of the feed will be taken up by the dust-collecting system, as there is a classifying action at the suction hood favoring the

Digitized by Google

induction of the light coal particles; the position of the hood and direction of air flow at the top of the separating chamber especially favor this action.

Degradation of the sand, if appreciable, may form a dust that will be difficult to separate from the coal, but it is expected that the quantity will be so small that it can be absorbed by the coal dust product without contamination of the latter. In tests made with new sands containing slime, it has been observed that the dust that is finer than desired for the air-sand bath is carried away by the air so that after a few minutes operation the sand mass becomes free of dust.

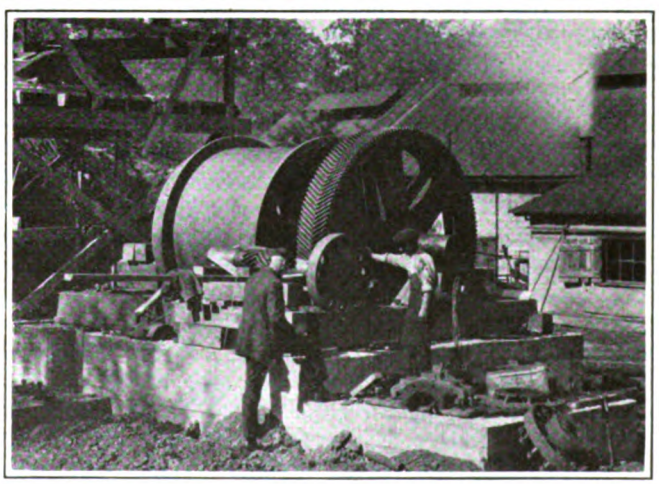
The objectives sought in the design of a plant for cleaning coal by this method should be simplicity and low cost, in order to take full benefit of the three outstanding advantages of the process, which are: (1) dry operation; (2) positive and immediate float-and-sink separation; (3) the treatment of an unsized feed.

It may be added that the air-sand process was developed to its present stage by the Bureau of Mines, but it is patented (U. S. Patent No. 1,534,846, April 21, 1925, a process of separating loosely mixed materials), and the patent is privately owned.

Drill Rig Mounted on Auto Truck Does Fast Work

In stripping operations where the overburden must be drilled and shot before it can be removed, rapidity in moving the drill rig from one hole to another is important. The accompanying illustration shows the drill rig which W. N. Chandler, Jr., of Tulsa, Okla., placed on the body of an old White truck. The drill rig proper is operated by a kerosene engine.

With this outfit Chandler and his father are now sinking shotholes on contract for the Hinde Mountain Coal Co. Such shotholes are drilled 45 ft. deep and are placed 30 ft. apart each way. They are shot ten at a time. There is no loss of time in starting a new hole as it is merely necessary to drive the truck with the drill equipment from one hole location to the next. The speed and convenience of this method are important factors in this class of work and it is said that Chandler and his automobile outfit are much in demand. The equipment may also be employed in drilling oil or other wells where the depth does not exceed 800 to 1,000 ft. It is most advantageous, however, in work on shallow drillholes where frequent moves are necessary.



It Moves Swiftly

This drilling rig, mounted on an automobile truck, shifts rapidly over a track to be drilled ahead of a stripping operation enabling the owner to drill the overburden at several strip pits within a few miles of each other. This speed of transport seems to work to the advantage of everybody concerned and removes some of the cumbersomeness of the process of sinking shot holes. Naturally this rig would speed up drilling for any purpose.

Cost Keeping—at a "Super's" Desk

Orderly detailed records of mine operation costs from day to day may be computed and filed in such manner as this. The "super" is so well acquainted with each phase of his operation that a vast array of figures may mean something to him. But if the most is to be derived from them, through his own studies and those of his superiors, the figures must be grouped and condensed on graphic charts.

Big Alabama Hoist Under Construction

This is said to be the largest electric hoist in the Alabama coal field south of Birmingham. It has been installed by the Montevallo Coal Mining Co., at Aldrich, to replace the steam hoist now used to pull cars up the slope. The new hoist, which is driven by an 800-hp., 2,300-volt wound-rotor induction motor, will wind 3,600 ft. of rope at a speed of 1,250 ft. per minute. B. C. Moore (left), master mechanic and outside foreman, is discussing with C. H. Brill, the mine electrician, some point regarding the installation.

Rocky Mountain Men for Three Long Days Steep in Their Safety Problems

Concentrated Mining Conceded to Enhance Safety but Canvas Tubing Is Warmly Attacked—Harrington Condemns Open Switches—Stray Currents a Hazard—At Acme Accidents Decreased with Mechanicalization

MEATY and intensely interesting discussions of coal-mine problems marked the twenty-second meeting of the Rocky Mountain Coal Mining Institute at Denver, Colo., Feb. 23, 24 and 25. The dangers attending the use of electricity underground and what can be done to offset them, the ventilation of workings opened under modern mining methods, safe shot-firing and other subjects were treated at length during the three days of technical sessions and "good time gatherings." The meeting brought 300 members from the four mountain states of Colorado, Wyoming, New Mexico and Utah. This was the largest attendance the Institute has ever assembled at any of its conclaves.

After members had renewed acquaintance President John B. Marks called the first morning meeting to order. The question of a division of the membership into active and associate members was discussed and later referred to a committee for study. E. H. Weitzel of the Colorado Fuel and Iron Co. and W. F. Murray of the Coal Leasing Division of the U. S. Geological Survey as founders of the Institute were elected life members. The convention then, upon the suggestion of George B. Pryde of the Union Pacific Coal Co. and James Dalrymple, Colorado chief mine inspector, decided to change its official emblem from a replica of the old miner's oil lamp to that of an approved magnetically locked safety lamp.

A paper entitled "Spiralizing Plant of the Spring Canyon Coal Co." by George A. Murphy, general superintendent of this company at Spring Canyon, Utah, was read by Mr. Gibson. This plant is one of only two installations of the sort in the West. It was installed to clean the smaller coal of the refuse made by a 2-in. bony band near the bottom of the seam which necessarily gets mixed with the coal in mining. By its use approximately 90 per cent of the refuse is separated and the ash reduced from an original content of 8 per cent to approximately 5 per cent.

The plant is a 5-unit spiral capable of handling from 35 to 40 tons per hour of pea coal (through 1¼ in. and over ¾ in.). Four of these units handle coal from the distributor and a fifth a re-spiralizer handling the "middlings." In operation it was found that after the surfaces of the spiralizer flights and chutes attained the necessary smoothness from wear, the chief difficulty encountered was from wet coal which tends to clog the chutes. One attendant runs the plant. Mr. Murphy considers the installation now a success.

Discussion developed the fact that the spiralizing plant proper cost about $50,000 when it was built with the new tipple of the Spring Canyon Coal Co. In a country where water is not readily available such a spiralizing plant takes the place of a washery.

C. H. Trik of the Jeffrey Manufacturing Co. next

The panorama at the top of the page shows the members of the Rocky Mountain Coal Mining Institute lined up before the photographer. The man on the bottom step with his hands clasped on a perfectly good Fedora and his feet spread to assure entire stability is Horace Moses, the new president.

Digitized by Google

presented a paper on the "Ventilation of Working Faces Under the Various Systems of Concentrated Mining." Nobody questioned Mr. Trik's conclusion that concentrated systems of mining offer opportunity for much better ventilation of working faces than do the old scattered system of workings but sharp exception was taken to his advocacy of the use of canvas tubing and auxiliary blowers for the ventilation of narrow work preliminary to the mining of blocks.

Line Brattice vs. Blowers

Mr. Trik declared that there were two methods of sending air to the face of dead ends: one by the use of line brattices and the other by auxiliary blowers with canvas tubing. Blowers and tubing permit the ventilation of headings 100 to 1,000 ft. long and when such headings are finally connected some operators move the blowers up to the face and use them to blow fresh air along the face. Concentrated systems of mining, if successful, he said, show a reduction in cost of production per ton over former systems. Any additional saving in cost of ventilation is just so much velvet and the mine operator may expect, if his permanent airways are kept clean and wide, to have a decreased cost of total ventilation because of lowered mine resistance and consequently a decreased use of power.

Inspector Dalrymple said that thus far in concentrated systems of mining the main consideration seemed to be cost reduction with no thought of safety. It seemed to him little short of murder in a gaseous mine to place electrically driven blowers along the working faces. In his opinion these blowers presented a serious hazard when used to ventilate headings 200 ft. or more in length, due to recirculation. He said they would not be allowed in a gaseous mine in Colorado. He also opposed carrying air such distances by line brattice.

William Littlejohn of the Utah Fuel Co. and James Struthers and G. D. Jones of the Victor American Fuel Co. also felt such auxiliary fans to be a distinct hazard. E. H. Denny of the U. S. Bureau of Mines said that the Bureau considered that the use of such electric-driven fans whether intermittently or for the full 24 hours of a day involved grave hazards from air recirculation if fans were not truly placed in intake air. They also created a certain amount of fire hazard. He said that the Bureau accordingly had withdrawn its approval of the proposed American Engineering Standards Committee Code. Anemometer readings showed measurable velocities in places ventilated by line brattice only for 50 to 75 ft. from the outer end of the brattice.

Daniel Harrington declared that auxiliary fans had no place in a coal mine and cited cases to prove the hazard from gas ignition involved in their use. He declared inadequate ventilation from a health standpoint was also possible due to a rechurning of the air. He had found a working place supposedly ventilated by fan so deficient in oxygen that a match would not burn and men could not work properly.

Glenn Knox of the Gunn-Quealy Coal Co., Rock Springs, Wyo., discussed the concentrated system of mining with conveyors as described in Oct. 15, 1925, issue of *Coal Age*. He pointed out that by driving three entries in this system no use of blowers or of narrow work without crosscuts was necessary.

Crosscuts Suited to Any Method

Mr. Harrington voiced an apparently general sentiment when he said that it was possible to work any of the concentrated systems which he had seen or heard of without violating the law or safety practice with reference to crosscuts, and the elimination of crosscuts and consequent use of blowers was merely a cost-saving scheme not vital to the systems themselves.

At the Wednesday morning meeting, discussion of Mr. Trik's paper of the previous day on "Ventilation of Working Faces Under the Various Systems of Concentrated Mining" was resumed. Mr. Trik pointed out that the manufacturers of the small auxiliary fans

Digitized by Google

could furnish with them a right angle connection which would permit of the fan being placed in fresh air. He thought that the installation of these fans should not be necessarily condemned just because the mine officials did not place them in the proper position.

Mr. Harrington's paper on "Danger from Electricity in Coal Mines" was then taken up and occupied the attention of the Institute for the balance of the morning and a good part of the afternoon session. Mr. Harrington declared that electricity was a growing source of danger as a cause of mine explosions and that accidents from contact with exposed wiring and the like were only a small portion of the sum total properly attributable to it.

He said that, over a 25-year period, 30 disasters and approximately 100 serious mine fires involving a total loss of 1,660 lives have been caused by electricity. In 1924 and 1925 eleven out of the twenty coal mine disasters were of electrical origin. All electrical equipment used in coal mines has inherent dangers. Even 110 volts alternating current has killed men by contact. Explosions have been caused by the rupture of pick-proof cable in a coal dust cloud, by trolley arc and gas, by incandescent globe, by mining machines at the face, by machine nips, by pump and hoist motors, by electric drill, by open switch, by booster fan, by face conveyor motor and by stray currents, all in the presence of gas, as well as by trolley line and black powder. New intensive systems of mining with the increased use of loading, scraping and conveying machinery at or near working faces means a heavy increase in the amount of electrical equipment underground.

Mr. Harrington stated that continued and increased use of electricity in coal mines is a necessity and therefore that the problem is to formulate and make use of safe electrical underground practice. He then raised thirty-five specific questions relating to underground electrical practice with his viewpoint on these.

D. C. McKeehan, electrical engineer of the Union Pacific Coal Co. whose new electrical and other safety standards have been published recently in *Coal Age*, discussed Mr. Harrington's questions in detail. He favored the use, for power lines, of lead-covered, armored cable properly grounded supported on a steel messenger wire. He would keep these out of returns of gaseous mines. He understood that a receptacle with plug is now in use by one company to replace the usual "nips" for attachment of machine cables to power lines.

No Open-Type Switch Safe

He is of the opinion that no open type of switch is safe in any mine and that in nongaseous mines a safety type with quick-make-and-break blades, the box of which cannot be opened except when switch is out, should be suitable. In gaseous mines oil circuit breaker switches should be used.

Mr. Harrington brought up the danger of stray currents in electrical blasting. Mr. McKeehan thought the use of rubber-clad shooting wire and the keeping of lead wires short circuited and away from coal and rock would minimize premature shots. Mr. Harrington and Mr. McKeehan both believed that new systems of mining presented an extra electrical hazard of gas ignition and the latter advocated the use of totally enclosed motors. They also favored keeping of mining machines and trolley line voltages down to 250 volts d.c. and 220 volts a.c. Frequent inspections of underground electrical equipment by competent persons are desirable. While there is a considerable variety of approved electrical equipment available, careful supervision and inspection are essential to see that it remains in a safe condition.

C. B. Officer of the Sullivan Machinery Co. submitted written discussion of Mr. Harrington's paper. He thought that with the concentration of mine work it was entirely possible for mines to make their electrical installations more carefully and more permanently. He believed that under certain conditions an open type electrical switch was safe for mine use. He thought that there was little choice as to safety between direct and alternating current. He knew of many mines using pressures of 500 volts or more without, in his opinion, increased hazard, as men paid more respect to such higher voltage installations and were more careful around it.

Underground Wires Removed

Regarding storage battery equipment in mines he cited an eastern mine in which all underground wires have been removed and all electrical equipment operated by storage batteries, every part of the installation being of approved type. A careful study would have to be made in a gaseous mine before the feasibility of replacing wiring by storage batteries for the transporting of electrical energy can be decided, he said. In mines using or contemplating mechanical loading the placement of loading machine storage battery track would be a difficult problem.

Mr. Jones of the General Electric Co. thought Mr. Harrington's paper very much overdrawn and that the dangers cited were more attributable to carelessness than to electricity. Suitable electrical equipment was on the market and rules for good practice in its installation had been formulated. He believed that some of the accidents for which electricity was blamed were really from other causes.

The discussion of Mr. Harrington's questions by L. C. Ilsley, electrical engineer of the Bureau of Mines, was read by K. H. Marshall of the Bureau. In the main, Mr. Ilsley's views as to safe practice coincided with those of the previous speakers. He believed that in general power lines should be installed in intake entries and that rooms should not have power lines in them other than the properly designed trailing cables. Greater safety could be obtained by the use of junction boxes in place of "nips" or by the use of storage battery power trucks but with "nips" designed so that there was no likelihood of electric shock when attaching them seemed to have no special hazard.

Neither weatherproof wire nor rubber-covered wire should be relied upon in mines to prevent shock; all conductors except metallic armored coverings should be given the same respect as bare wire. Poor rail bonding is one of the greatest causes of stray electric currents in mines. Unless the amount of the stray current exceeds ½ of an ampere there will be little danger of premature firing of electric detonators; if stray currents of dangerous amperage are present the only remedy would be the hunting out of their source and the improvement of the return.

He believed that multiple shot-firing has a tendency to weaken the roof and that gas liberated by one shot might be ignited by a second shot. The danger from missed shots was reduced. Incidentally the Bureau of

Digitized by Google

Mines knows of no multiple-shot electric battery of the magneto type which cannot ignite gas. The ordinary mine telephone can ignite gas through the ringer. He said two types of loading machine have already been approved by the Bureau of Mines as well as a large variety of electrical equipment.

Mr. Littlejohn thought that the dangers of power lines in intakes in the presence of coal dust overbalanced those of such installations in returns. He also thought the dangers from blowing up of long trailing cables in rooms were greater than those from the use of machine wires in rooms.

Edward Bottomley's paper on "Mechanical Loading at Acme, Wyoming" pointed out some of the difficulties and changes necessary when such a system of loading is installed. Results now being secured from production, cost, and lump coal standpoints were highly satisfactory. The mechanizing of the 3,500 ton Acme mine was described in the Jan. 28, 1926, issue of *Coal Age*.

Discussion developed that the good results obtained in this mine by the Goodman shoveling machine and Joy loaders were in 11 ft. of coal with coal roof and bottom and that no timbering was required in the working places. In the nearby mine of the Hotchkiss Coal Co. similar mechanical loading was being employed. To secure more lump in mechanical loading a 7-ft. undercut had been made. The mining machine was then set up on ties and a second 5-ft. cut made. When the slack from this double cutting was removed the effect of the old-time snubbing practice was secured and in 13-ft. coal with 7 holes in a 26-ft. room lump coal production was increased 12 per cent. There also was a saving of one-third in powder consumption as a result of careful supervision.

Mr. Bottomley stated that accidents per ton had been materially reduced in the Acme mine since mechanical loading was introduced.

Mr. Johnson of the Coloder Co. believed that mechanical loaders offered much opportunity for accident reduction on a man-day tonnage basis. He described the use of a breast type cutting machine mounted on a turret truck and cutting at an angle with the horizontal to produce a snubbing effect. A shot in the bottom below the beginning of the cut resulted in the desired snubbing.

Big Cars Help Hand Loading

Mr. Struthers believed that in the figures presented mechanical loaders were given none the worst of it, and that if cars were rebuilt to increase the capacity to three or more tons for the benefit of the machines that a similar enlargement might work to the advantage of hand loading. Mr. Dalrymple observed that the dependent shots involved in the shooting system and the lack of timber would be a violation of the mining law in Colorado. Although Mr. Bottomley found that an increased mine car supply or the equivalent in larger capacity was desirable, Mr. Knox found at Sweetwater, Wyo., that the concentration of working territory made fewer cars necessary.

A letter from F. N. Cameron, general manager of the Utah Fuel Co., was read, following Mr. Bottomley's paper, enclosing a description by Superintendent Jones of the new system of shooting and gas inspection at the three Castlegate mines. For nine months the fire bosses in the Castlegate mines have been taking charge of all shooting and gas inspections.

Under this system the fire bosses meet at the lamp room at 9 p.m. to prepare their lamps and receive their powder and caps. The foreman thus knows before he goes to bed that his fire bosses are on the job. The fire bosses have the opportunity and sufficient time, if the number of shots they have to handle is kept within reason, to examine the places before and after shooting, giving them more time and smaller districts to cover in the most important part of their work—the final examination of the mine before the men start in the morning.

By this system there is no powder or caps in the mine during the day shift. Powder and caps are handled only by certified men and there is an absolute check on all explosives. Every hole is loaded and tamped by qualified men and the fire bosses know, before they leave the mine for the electrical shot-firing from the surface, the condition of each place to be shot. After a little time these men know how to use the powder so as to get the maximum proportion of lump or maximum tonnage.

Cap Distributors Really Salesmen

In nearly all coal mines now there are the so-called shot inspectors whom Mr. Jones thinks could better be termed "cap salesmen" inasmuch as they are merely cap distributors. The system described by Mr. Jones is said to make for real safety and efficiency in the handling of powder.

Average cost of explosives at the three Castlegate mines, subject, Mr. Jones believes, to improvement, is as follows:

Tonnage 45,229		Cost per ton Cents
Powder	$1,906.25	4.2
Caps	436.56	1.0
Labor	1,401.45	3.1
	$3,744.26	8.3

	No. 1 mine	No. 2 mine	No. 3 mine
Tons per lb. of powder	9.33	5.47	4.31
Lb. powder per shot	.724	1.3	1.08

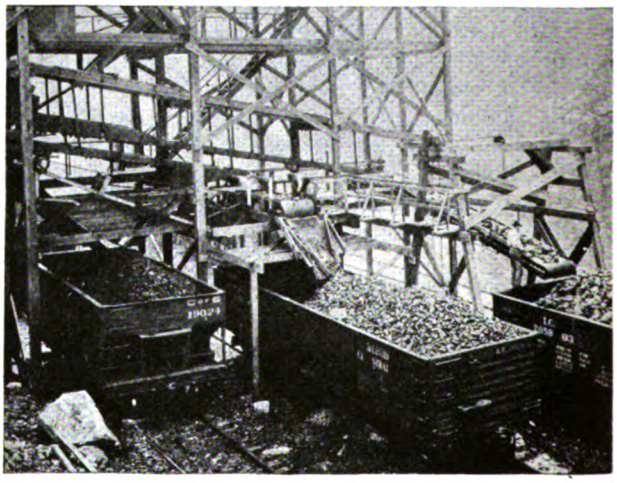
Mr. McLeod, chief mine inspector of Wyoming, thought there was possibility of fire boss passing up an unshot place on his last inspection under this system chalking it on his first round. Mr. Dyer of the coal leasing division of the U. S. Geological Survey and Mr. Harrington both thought the new system a good one. Mr. Dalrymple and Mr. Harrington, however, both took a crack at the system now in use at Castlegate and in other Utah and Colorado mines of paying fire bosses, upon whom the safety of every man in the mine depended, on a day basis.

At the Wednesday evening banquet the 600 guests forgot coal mine hazards and costs when confronted with the "Parisian Follies" by the Rocky Musicoal Players. A black face cast under the direction of Mr. Veatch and Mr. Krippner caroled and jested in an orange grove on the banks of "Bitter Creek, Wyo." Walter Tripp as "Private Sambo Bottomley" with a monologue on the late war was featured. Pliny F. Sharp officiated most efficiently as toastmaster. The principal speaker was the Rev. Wilson P. Ard of Denver whose eloquent address "The Challenge of a Great Adventure" held the undivided interest of his audience.

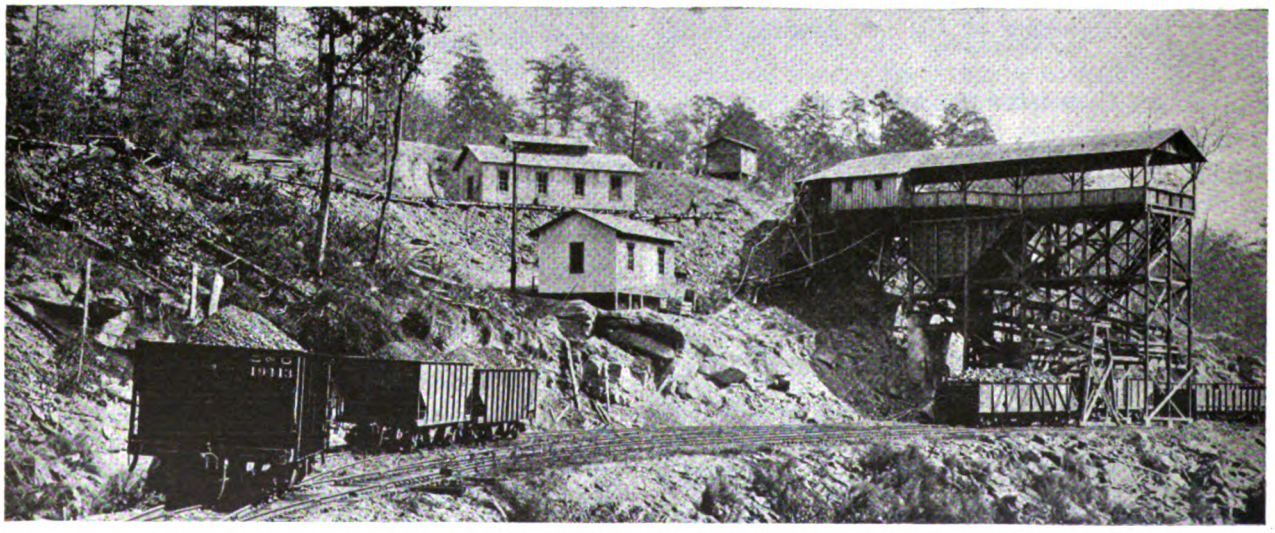
At the meeting of Thursday morning C. M. Billington criticized the new system of combined fire bossing and shot-firing described the previous day, declaring that it was inadequate because of the absence of fire bosses in the mine during the day shift. In case of a

Digitized by Google

disaster, he said, the result would be similar to that of a shipwreck in which captain and crew escaped by boats but the passengers lost their lives. Daniel Harrington replied that the Castlegate mines had foremen and assistants on duty and that in general, in his opinion, there were in any event too many flame safety lamps in a mine on the day shift.



T. H. Butler, of the Union Pacific Coal Co., presented the suggested changes in the report of the Safety Committee of the Institute together with other additions suggested by George W. Pryde, chairman. Discussion at the afternoon meeting developed that some of the changes in the report did not meet the approval of various members of the safety committee itself. The recommendations that 500 volts direct-current be barred from underground installations; that mines having traces of gas be termed gaseous; that permissible powder and electric detonators be used exclusively in gaseous mines; that open lights be barred from all underground workings; that no dynamite be used in coal mines; these recommendations were among those causing little or no discussion. The recommendations that no gas accumulation be moved during the working shift aroused much question as to what constituted a dangerous gas accumulation; likewise a proposal that all men working about underground wiring wear rubber shoes brought criticism of the value of such shoes, rubber gloves, rubber mats, etc., as protective devices. The proposed changes in the safety committee report were finally referred back to the committee for further study and discussion at the next meeting.



The final business of the session consisted in the election of officers for the year 1926. The new officers of the institute are as follows:

President—Horace Moses, general manager, Gallup American Coal Co., Gamerco, N. M.
Vice-Presidents—Robert L. Hair, Colorado; Virgil R. McKnight, New Mexico; A. E. Gibson, Utah; Thomas Foster, Wyoming.
Secretary-Treasurer—Benedict Shubart, Colorado.
Executive Committee—J. B. Dick and C. M. Billington, Colorado; W. C. Holman and Robert Wyper, New Mexico; R. R. Kirkpatrick and George Schultz, Utah; Edward Bottomley and Quince Rice, Wyoming.

Tipple Has Belts on Picking Tables and Loading Boom

No. 3 Mine, Alabama Fuel & Iron Co., in the Cahaba Field, at Acton, Ala.

The workings of this mine are in the Helena seam, and the coal is about 66 in. thick. Contrary to the impression conveyed by the name, the coal mined by this company in the Cahaba field is not utilized in the iron-and-steel industry. Of the 1,250,000 tons production about 1,000,000 tons goes for steam purposes, mostly to railway and steamship companies, and about 250,000 to domestic use. In the upper left-hand corner is the mine mouth and exterior slope. The coal cars are hauled up the slope in five-car trips by a single rope hoist. In the upper right-hand corner and in the bottom illustration will be found two views of the tipple. This structure was built about two years ago. It utilizes belts for the picking tables and loading boom. The smaller sizes are shipped to some of the central washeries of the company.

Book Reviews

What Rock-Dusting Costs

Steady progress in the movement for the rock-dusting of bituminous coal mines as a means of preventing or limiting disastrous coal dust explosions is indicated as the result of an investigation conducted jointly by the Bureau of Mines of the Department of Commerce and Carnegie Institute of Technology, Pittsburgh, Pa. and recorded in Bulletin 18, Coal Mining Investigation Series, entitled "Methods and Costs of Rock-Dusting Bituminous Coal Mines." Whereas at the beginning of 1924 few coal mining companies operating in the United States had done thorough rock-dusting, by September, 1925, 102 companies in 12 states had rock-dusted 211 miles. The tonnage annually produced by these rock-dusted mines according to the bulletin, represents approximately 11 per cent of the annual production of all bituminous mines in the United States.

Rock dust has been found useful not only in preventing explosions but in subduing mine fires. Some mine operators are storing material at strategic points for fire fighting.

Limestone Dust Purchased

Limestone and shale are used almost exclusively for rock-dusting. Most of the purchased material is limestone, but shale from the mine roof, in which the free silica is less than 25 per cent, is used by the mine operator who has equipment to pulverize it at the mine. There are suitable materials such as gypsum and dolomite, also adobe clay and talc, where these contain less than 25 per cent free silica. The cost of rock dust, sacked, and unloaded, including freight, at the mine has ranged from $4.85 to $7.70 per ton, with an average of about $6. The cost of rock dust, chiefly shale dust, mined and pulverized at the mine, has ranged from $2.60 to $5.50 per ton, with an average of about $3.50.

Most of the rock dust used is purchased, but a few coal companies have their own pulverizing plants. Five types of pulverizers have been used for this work. These cost from $2,000 to $5,800 and pulverize 1,500 to 3,500 lb. of rock per hour at costs varying from $2.09 to $4.96 per ton.

There are two classes of rock-dust distributors—fixed discharge nozzle and flexible discharge nozzle. These machines must be adaptable to mine conditions, apply an effective coating to the roof, ribs, and floor, and be easy to operate. The machines cost from $370 to $4,800, and can move from 1,700 to 4,200 ft. per hour. Commercial machines distribute 1.28 to 3.5 lb. of dust per linear foot of travel.

Don't Omit Barriers

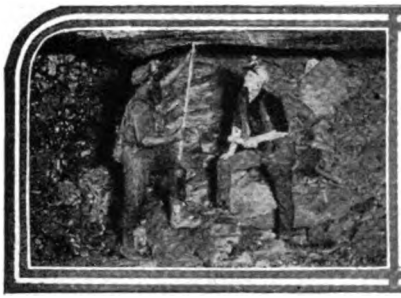
Rock-dusting, say the authors, C. W. Owings, assistant coal-mining engineer, U. S. Bureau of Mines, and C. H. Dodge, research fellow, Carnegie Institute of Technology, should be supplemented with effectively designed barriers, which are considered to be a secondary line of defense. Mines should be divided into zones and the barriers placed at strategic points. V-trough and concentrated barriers erected in the mine in sets of from 10 to 24 have cost from $1.75 to $5.70 per trough. However, experienced investigators of the Bureau consider that many V-trough barriers that have been erected in mines do not carry enough rock dust to extinguish an explosion unless supported by generalized rock-dusting in the vicinity. Concentrated barriers have cost $64.50 for a wooden barrier and $74.50 when of steel construction.

Further information is given in Bulletin 18, Coal-Mining Investigations series, "Methods and Costs of Rock-Dusting Bituminous Coal Mines." Copies of this bulletin may be obtained from Carnegie Institute of Technology, Pittsburgh, Pa., at a price of $1.50.

Making the Orsat Accurate

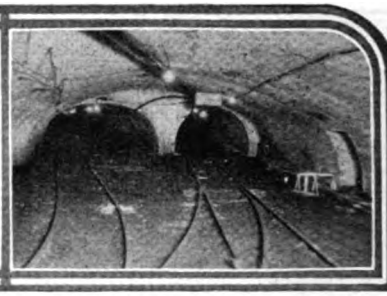
From an extremely simple rough-and-ready apparatus the Orsat is becoming rapidly an instrument both elaborate and accurate. It is also widening its sphere of usefulness. But without all this elaboration and accuracy it will serve many useful purposes, and perhaps only a few will have to use the exact methods that A. C. Fieldner, G. W. Jones and W. F. Holbrook describe in Technical Paper 320, of the U. S. Bureau of Mines, entitled "The Bureau of Mines' Orsat Apparatus for Gas Analysis."

The Orsat is operated by combustion and therefore there is a change in temperature and pressure to be corrected or eliminated. The water-vapor content changes, and the gases are dissolved in part by the confining liquid. Then there is the capillary error of the apparatus. "A change of 2.7 deg. C. during a determination makes a difference of about 1 per cent in the volume. As a gas analysis" say the authors "is actually a series of observations of changes of volume during treatment by different absorbents, a temperature change may indicate the presence of certain constituents which in reality are not present."



Early History of D. & H. Co.

To the coal-mining man the book entitled "A Century of Progress" published by the Delaware & Hudson Co. will be a great disappointment. He will feel that the coal industry on which the progress and success of the transportation department of the company has rested has been given inadequate consideration. Apparently the author, whose name is suppressed, is a railroad man. He has written a conservative but intensely interesting book—on the history of a railroad. Rarely does he have anything to say as to the mines or as to coal selling.



Romance of Selling

In the early days the selling of coal was a romantic enterprise. The coal company did not elbow itself into other coal markets, but it made new ones of its own. Anthracite, when it first came to New York, was regarded as a worthless product fitted for nothing except for filling or ballasting. Gradually it found itself, despite opposition, in places which everybody thought it could never attain. The imagination of the Wurts family, the pioneers in its marketing and in the building of the means of transportation to New York, proved sound, and the scoffers were silenced. To many, today, the new uses for coal being proposed seem as unwise and improbable as those advocated by Jesse Fell, the Delaware & Hudson Canal Co. and the Lackawaxen Coal Mine and Navigation Co. A little of the imagination and pluck of the Wurts family is all that is needed today to make the coal industry progressive instead of stagnant.

Underground Operation

Choosing Tie and Rail Sizes

Ties and rails are the very backbone of any mine track. Not only must the right size of rail be chosen to carry the required load, but ties of adequate size must be used under it, the ties must not be set too far apart, the proper number of spikes should be used, and the rails must be adequately fastened together at the joints. Concerning this phase of mine work James L. Libby says in the Union Pacific Coal Co. *Employees' Magazine:*

Ties furnish the bearing for the rails, as well as a means of fastening and holding the rails in place. Good, well-tamped ties are necessary in maintaining the alignment and grade on track work. It has been proved in practice that hewed ties are more satisfactory than those that are sawed, as the latter have a woolly surface which permits the retention of moisture and encourages fungus growth. Furthermore, in the shaping of the sawed tie the saw cuts in part across the grain and thus weakens the tie, giving it a tendency to split easily.

The dimensions of ties vary according to the importance of the haulage. Long ties give greater stability to the track and do not split as easily. On slopes or any main haulage a 6-in. hewed tie of a length sufficient to give at least a 12-in. projection on either side of the track should be used. The spacing of ties should be 18- to 24-in. centers. In secondary haulage and rooms 4x5-in. sawed ties spaced on 24-in. centers and with an 8- to 12-in. projection give satisfaction because of the short life of these working places.

Steel ties have not been extensively used, but will doubtless be improved in design and their use become more general as the price of wood ties increases. With the panel system of mining, they have the following advantages in room work: (1) They lower the height of shoveling and increase headroom from 2 to 4 in., (2) they lower the lift in replacing a car in case of derailment, (3) they keep the track always in proper gage, (4) they enable the miners to lay their own track, and (5) they have long life and can be used over and over again, whereas wooden ties become split and full of holes and consequently are useless.

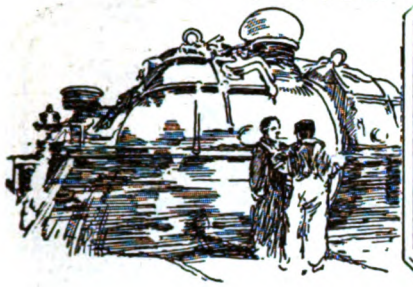
Their disadvantages are: (1) Their higher initial cost, (2) the fact that they are ill suited for animal haulage because the hoofs of the animal slip on the steel, and (3) the track does not stay on grade or in alignment. The last objection can be remedied by lugs, or turning down the ends of the ties, and then cutting holes in the floor to hold them in place. Much grading or leveling of floor is necessary even when wood ties are used, so that the use of steel ties may not be so objectionable.

In the selection of rails for mine track it is false economy to skimp on first cost; too light a rail, while showing a saving in original outlay, will require an expenditure of the initial saving over and over again in repairs and maintenance. The life of the haulageway, the tonnage to be handled during this life, the type of haulage and the system of mining determine the weight of rail to be used.

Most manufacturers estimate the necessary weight of rail in pounds per yard to be numerically equal to twelve times the weight in tons on each wheel. It is better to use sixteen times this weight, and with four-wheel locomotives this equals four times the weight of the locomotive. Thus a 6-ton locomotive would require a 24-lb. or say a 30-lb. rail; a 10-ton machine a 40-lb. rail and a 15-ton machine would require a 60-lb. rail. A good rule to follow is to use 60-lb. rails on main slopes, 40-lb. rails on planes, 40- to 60-lb. rails on main haulages, 30-lb. rails on ordinary entries and 20-lb. rails in rooms.

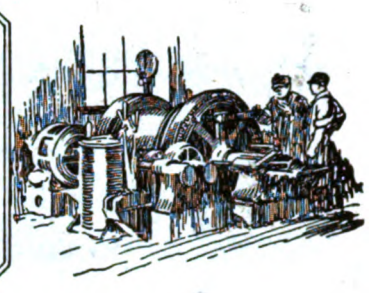
If straight face arc wall machines are used, however, the minimum rail weight to employ will be 30 to 40 lb. Heavy rails are advantageous because of their greater rigidity. They thus retain their alignment and surface grade better, have a long life and a low maintenance cost.

A track is weakest at the joints where the rails have no vertical strength. The joints, therefore, require good fish plates or angle bars. Bolts should be used in all the holes in the angle bars or fish plates and lock washers employed to keep the bolts tight. Angle bars should be used where possible as they give a stiffer joint. Ties should be laid and firmly bedded on each side of the joint so as to give a short suspended joint. When cross ties are insecurely bedded so that track is allowed to move up and down under the wheels, the strongest and most effective fastenings soon become comparatively inoperative.



All rail sections for the different weights used should be standardized; this also applies to the fish plates or angle bars. The drilling of the rails and fish plates or angle bars should all conform to a definite standard made up for the different weights of rail.

The rails should be fastened to the ties with ample sized spikes; four spikes should be used to each tie. The two spikes on the inside of the track should be driven on one side of the tie, and those on the outside of the track on the other side of the tie, in order to keep the ties in the proper position with reference to the rails. This is necessary to preserve the gage.



Cars Smaller in Gassy Mines

Mine cars must not only be small enough to leave a safe passing width on one side of the roadway but in gassy mines must be of such size that an adequate airway can be provided by a brattice cloth hung so as to take air back from or to the face. This consideration often determines the width of the car where the roof is so poor that the span of the roadway is limited.

Practical Pointers For Electrical And Mechanical Men

Crossarms Are Installed Upside Down

Standard flat braces installed in the regular way on the under side of a wood crossarm add but little to the strength of the arm. Such braces will buckle under a comparatively slight compression. The chief use of flat braces, as generally installed, is to keep the arm in a horizontal position. It is true that if a heavy load is hung on one end of a crossarm the brace on the opposite end will be in tension, but the strain tending to break the arm at the center is not lessened by reason of the brace.

Supports a 1,500,000-Circ.Mil Circuit

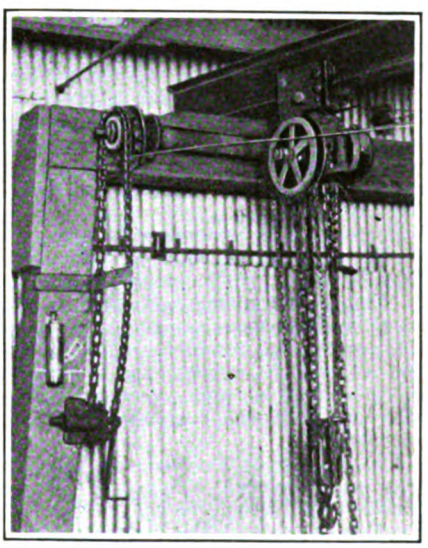
With this construction, placing the braces above the crossarm and attaching the heavy cables close to the braces, there is but little tendency to bend or break the arm. The braces are in tension and the arm under compression

These facts were taken into consideration by J. F. MacWilliams, electrical engineer of the Pennsylvania Coal & Coke Corporation, when he was building a pole line to carry two 1,500,000-circ.mil copper cables of a 275-volt direct-current circuit. This line is shown in the accompanying illustration. It extends from a substation to the top of a borehole entering No. 3 mine, which is located at Ehrenfeld, Pa.

The normal weight of the circuit is close to 1,000 lb. per 100 ft. The cables are hung on the under side of the crossarms and flat braces placed above the arms. The suspension fitting is a Type C mine feeder wire insulator with a plain ⅝-in. bolt substituted for the expansion bolt. The point of attachment is close to where the brace is fastened to the arm. There is then but little bending moment on the arm, and the flat brace is in tension.

Double crossarms are used and there is a suspension insulator on each arm. On the upper side, a 2-wire, 2,300-volt circuit is carried on ordinary pin insulators and below, on pole brackets, is a telephone circuit. The line has been in use for several years and has survived heavy sleet storms.

Device Moves Chain Block With Ease and Safety



Often it is inconvenient and none too safe to move a loaded chain-block trolley by pulling or pushing directly on the load or its fastenings. This is especially true where the I-beam, supporting the trolley, is above a motor pit. An illustration of how easy it is to remedy such a condition can be seen in the machine shop and motor barn of the Fordson Coal Co., at Nuttallburg, W. Va. The accompanying illustration shows the trolley-moving mechanism which was built from odds and ends picked up about the shop and from the scrap pile.

Protects Unwary Heads

It is hard for a heedless person to get into contact with the trolley wire running into the main slope of the Pennsylvania Coal & Coke Co.'s No. 18 mine at Barnesboro, Pa. The board guards are bolted to straps depending from the trolley bracket. This mine was recently reopened after having been down for more than two years.

Mounted at one end of the I-beam is a small drum or windlass. From one end of this drum a ¼-in. wire rope goes directly to the trolley. From the other end a rope of the same size is carried over a sheave mounted at the other extremity of the I-beam, thence passing back to the trolley. In other words, the trolley is moved by means of a headrope and a tailrope, one unwinding from the drum as the other is wound onto it.

Windlass for Moving Trolley

The parts are odds and ends picked up on the job. With this device there is no struggle or danger in moving a heavy weight suspended by the chain block as the person doing the moving is at all times in the clear.

The trolley can thus be moved in either direction depending on which way the drum is rotated. The drum is turned by means of a crank which is mounted at a convenient height above the floor. An ordinary detachable-link chain connects this crank to the drum. With this windlass attached to the I-beam trolley, heavy or unsecurely attached loads can be moved with ease and safety.

News Of the Industry

Sentiment for Coal Legislation Has Cooled in Congress Since Settlement of Anthracite Strike

By Paul Wooton
Washington Correspondent of *Coal Age*

Interest in coal on Capitol Hill seems to be evaporating. Just after the settlement of the strike the authors of coal bills in each house professed relief on the ground that they at last could go ahead deliberately and carefully to work out legislation when the situation was not surcharged with emotion.

Despite these professions no progress has been made, at this writing, since the settlement. Chairman Parker of the House Committee on Interstate and Foreign Commerce has not made good his promise to conduct coal hearings, and as this is written the committee has heard of no plan or approximate date on which the coal bills are to be taken up.

The display of fireworks in the District of Columbia Committee of the Senate was interrupted by the dawn of plentiful supply. Even the sub-committee of the Senate Committee on Education and Labor—consisting of the redoubtable Borah, with Senators Copeland and Metcalf as fellow members — admittedly has done nothing. This sub-committee was charged specially with the duty of examining and passing upon the merit of all coal bills pending in the Senate. Senator Borah himself stated on the floor of the Senate that his own coal bill soon would be forthcoming, but his office says other matters have been claiming his attention.

Administration Still Lukewarm

Senator Oddie has found the administration's interest in coal legislation to be quite as lukewarm after the strike as was the case while it was pursuing its popular hands-off policy. To his request for a report on his coal bill Senator Oddie received this reply from Secretary Hoover:

"The President has recommended to Congress that action should be taken on the report of the U. S. Coal Commission. In order to work out the details of your draft it would seem to me desirable that the members of that Commission, the various representatives of employers and employees, and the experts in the different government bureaus be called before the committee to give information to the committee rather than to attempt to anticipate in advance what the result of such an inquiry would be.

"I will be glad to appear before the committee if it is desired."

Since the Senate referred the Robinson bill to the Committee on Education and Labor, and since Senator Phipps, the chairman of that committee, has indicated that his committee will study the Robinson bill and all other coal bills now before the Senate, Senator Oddie will wait until that committee has concluded its work or has indicated that it will do nothing before he launches hearings. He sets forth his views in a letter to Secretary Hoover, which follows:

Oddie States Position

"I am in receipt of your letter of Feb. 13 in answer to mine of Dec. 10 last, in which I referred to you a copy of the bill S. 3 [for the creation of a Bureau of Coal Economics, and for other purposes] and asked that the Committee on Mines and Mining be furnished a report thereon.

"Your letter states it to be your judgment that, as the President has recommended to Congress that action should be taken on the report of the U. S. Coal Commission, it seems to you to be desirable, in order to work out the details of the above mentioned bill, that the members of that Commission, the various representaives of coal operators and employees, and the experts in the different government bureaus should be called before this committee to give it information, rather than to attempt to anticipate in advance what the result of such an inquiry would be.

"Inasmuch as the Senate, on the 6th instant, decided to refer to its Committee on Education and Labor a bill introduced by Senator Robinson of Arkansas, which undertakes to deal with the question of national emergencies arising in the production and distribution of coal, I am of the opinion that all interests would be best served if that committe should, in connection with its consideration of Senator Robinson's bill, hear yourself and those whom you have suggested with respect to Senate bill No. 3 and any other bills pending in the Senate relating to the general subject.

"The holding of hearings on this subject by two committees of the Senate at the same time is unnecessarily expensive and time-consuming and would greatly tend to confuse the issue in the public mind. Any provisions of the bill S. 3 failing to receive adequate attention in hearings before the Committee on Education and Labor could be covered in supplemental hearings before the Committee on Mines and Mining. If, after completing hearings on S. 3, the Committee on Education and Labor shall have become convinced that the merits of that measure are such as to make action by the Committee on Mines and Mining desirable, a recommendation to the Senate to that effect could be made. I have every reason for believing that such a recommendation would be promptly acted upon by the committee of which I am chairman."

The most casual survey of the legislative situation shows that coal merely is a subject of speculation among political wiseacres and professional specialists.

Chief interest centers on details now leaking out concerning the alleged under-cover agreement between the anthracite operators and the miners. At its face value this agreement with its provision for a modified check-off, to be worked out by the Board of Conciliation, seems to be a substantial concession to the miners. The miners' leaders, at least, are busy assuring their followers that the operators have promised the check-off.

Study New Agreement

Most observers, however, are very skeptical on this point. They point out that since the plan depends on joint agreement by the two sides and the Board of Conciliation, it is no more certain to be acted on than the provision for arbitration. The arbitration machinery in the agreement will work only if the miners want it to work. Similarly the Board of Conciliation will act on the check-off only when the operators want it to act. In view of the oft-repeated refusal of the operators to consider the check-off, it seems unlikely that they will accept it now through the Board of Conciliation until they feel assured the arbitration feature of the agreement can be made to work.

In short, the producers seem to feel that the arbitration provision is worth as much to them as the check-off is worth to the miners. Any other supposition would admit the defeat of the operators and victory for the men.

All of this tends to strengthen a growing impression that the fight was close to a draw and to confirm the conclusion that the real victor was the anthracite-consuming public.

Fan and Foreman Not Needed in One-Man Mine, Colorado Judge Rules

District Judge Arthur Cornforth made permanent a temporary injunction in the case of Fred Sevcik, one-man mine operator of Colorado Springs, Colo., against State Coal Mine Inspector James Dalrymple, on Feb. 16. The court held that Dalrymple could not force Sevcik to install a fan in his property or to employ a foreman at the rate of about $225 per month.

The effect of the decision is to declare the state law requiring such things unconstitutional, and J. S. Breitenstein, of the Attorney General's office, representing Inspector Dalrymple in the case, said he would appeal to the Supreme Court.

The court holds that the law should not make the same provisions for a mine operated by but one man or employing only a few men as for a mine where a large number of miners are employed.

Favorable Report on Bill Expanding I. C. C. to 13 Appointed by Regions

Regional representation on the Interstate Commerce Commission is provided in a bill reported favorably by the Senate Committee on Interstate Commerce. The measure provides for increasing the membership from eleven to thirteen, eventually to be apportioned as follows:

New England Group—Maine, New Hampshire, Vermont, Massachusetts, Connecticut, Rhode Island, one member.

Middle Atlantic States—New York, Pennsylvania, New Jersey, Delaware, Maryland, Ohio, District of Columbia, two members.

Lake Group—Michigan, Indiana, Illinois, Wisconsin, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Kansas, Nebraska, three members.

South Atlantic Group—North Carolina, South Carolina, Georgia, Florida, Virginia, West Virginia, Kentucky, two members.

Gulf Group—Alabama, Mississippi, Louisiana, Arkansas, Oklahoma, Texas, Tennessee, New Mexico, two members.

Mountain Group—Montana, Wyoming, Colorado, Idaho, Nevada, Arizona, Utah, two members.

Pacific Group—Washington, Oregon, California, one member.

The committee's report has this to say by way of justifying regional representation:

"The object of this legislation is to bring together in the Commission as near as may be a personal knowledge of the transportation conditions and problems that exist in the different sections of the country. The combination of the local conditions produce the national conditions and proper administration of the national conditions must rest upon the intimate and accurate personal knowledge of the various local conditions.

"The very structure of our government is based upon local self-government and local representation in the general government.

"The several states are represented in Congress, bringing together the problems that arise in the several states that are to be solved under the federal Constitution.

"This vital principle is recognized and applied in the appointment of federal judges.

"It is applied in the appointment of the various boards and commissions created by Congress.

"The vastness of our territory and the varied forms and character of our articles of freight, the varied topography of the country, the differing degrees of development in the several parts of the country, the different degrees of possible development, the presence of actual and potential water competition in the form of river, lake and ocean transportation makes it the more imperative that there shall be represented in the semi-judicial body known as the Interstate Commerce Commission intimately and accurately these various factors. That these very vital differences exist is evidenced by the fact that the Interstate Commerce Commission has divided the country into what is called rate-making groups. This because it was imperative to treat each according to the condition therein existing."

Coal Stocks for 49 Days In Industrial Bins

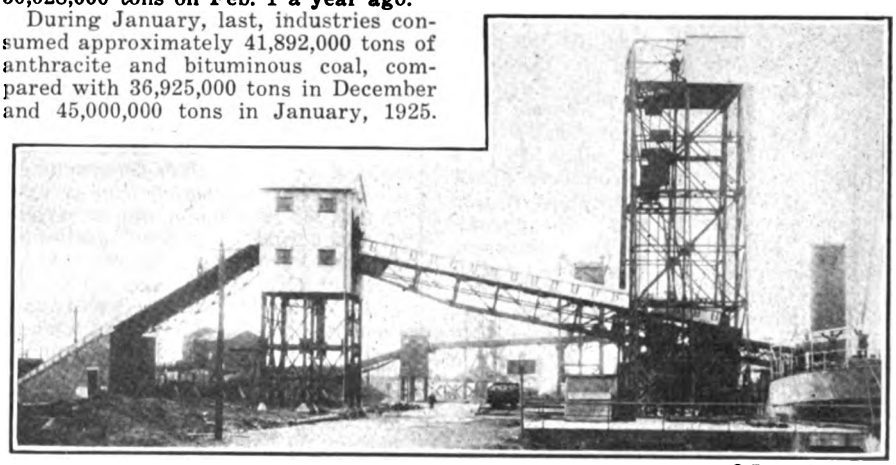
Stocks of anthracite and bituminous coal in the hands of industrial consumers on Feb. 1, according to the National Association of Purchasing Agents, totaled 66,190,000 tons, or sufficient to last 49 days at the January rate of consumption. This compares with 68,399,000 tons on hand at the beginning of the preceding month and 50,028,000 tons on Feb. 1 a year ago.

During January, last, industries consumed approximately 41,892,000 tons of anthracite and bituminous coal, compared with 36,925,000 tons in December and 45,000,000 tons in January, 1925.

British Empire Corporation Agrees to Check-Off

The British Empire Steel Corporation has agreed to restore the check-off at its coal mines in District 26, United Mine Workers (Nova Scotia), in a proposal submitted to the union executives late last week. Another proposal made by the miners' executives will be passed upon by the directors of the steel corporation this week, when an agreement is expected to be reached. The proposals were not made public.

Signing of a two-year contract under wage rates agreeable to both parties was prevented two weeks ago because the corporation insisted upon abolition of the check-off. The district union rejected the agreement by a majority of 3,735 votes. The contract was drawn up on the basis of the recent report of the Sir Andrew Rae Duncan Royal Commission.



Distribution Census Plan May Be Tried in 1928

Before any effort is made to induce Congress to authorize a census of distribution, which would require a large appropriation, it is proposed to select two or three important lines for the purpose of giving the plan a trial.

The first opportunity for the experiment will be when the manufacturers census is taken in 1928. If the trial demonstrates the value of this expansion of the census statistics, the appeal then can be made to Congress for the full census of distribution or the work can be undertaken gradually. This plan will require legislation, but no large amount of money.

Union Gives Up in Kanawha

The United Mine Workers ceased to pay relief to strikers on Big and Little Coal River, in the Kanawha (W. Va.) field on March 1. The order affects 2,500 miners and probably 4,500 dependents in the entire Kanawha field. At the present time there is no union mine south of the Kanawha River. Ten or eleven union mines continue to work in northern West Virginia, chiefly along Scotts Run, but otherwise the union ceases to be a factor.

Loading Welsh Coal for Export to the United States

This belt conveyor system at the Port Talbot docks, Wales, transports coal from railroad yards at the left, across the street and down to a vessel's hold. The elevating structure at the right, with its counterweights, enables an operator to hoist or lower the end of the delivery conveyor to meet the height of the vessel.

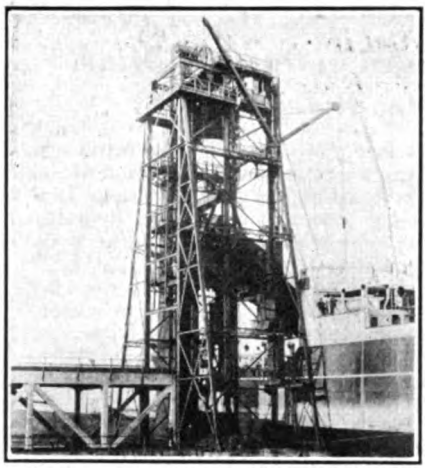
U. S. Steel Corporation Observes 25th Birthday; Has Remarkable Record

The United States Steel Corporation, the world's greatest industrial organization, was 25 years old on Feb. 25. Judge Elbert H. Gary, chairman of the board of directors of the corporation, has been its chief executive officer since its formation.

During its corporate existence the Corporation has done a gross business of approximately $23,000,000,000, has disbursed to stockholders dividends aggregating $1,279,253,784, and has paid out in wages something like $6,496,-268,920.

When the corporation began business in 1901 it had fifty subsidiary and sub-subsidiary organizations, fifteen of them main subsidiaries. Now there are 130 subsidiary and sub-subsidiary companies, twenty-seven of them main operating companies.

The Steel Corporation was the first billion-dollar corporation to be formed in the United States and it has consistently held its position as the premier industrial enterprise. The balance sheet shows that it has total assets of $2,500,000,000. At the close of 1924 it had 246,753 employees, and the wages paid out in that year totaled $442,458,577.



The net working capital at the end of 1924 was $427,661,627. The capital surplus provided at the date of organization was $25,000,000, and in the twenty-five years of the corporation's existence this has been increased to $517,061,308.

Charles M. Schwab, now chairman of the Bethlehem Steel Corporation, was the first president of the Steel Corporation, having served from April 6, 1901, to Aug. 4, 1903. He was succeeded by W. E. Corey, who served from Aug. 4, 1903, to Jan. 31, 1911. James A. Farrell, the present incumbent, succeeded Mr. Corey.

The original executive committee comprised some of the most prominent men of the time, including Judge Gary, Daniel G. Reid, William Edenborn, Edmund C. Converse, James Gayley, Charles Steel, Charles M. Schwab and George W. Perkins, the last two being ex-officio members.

The most important of the ten companies originally merged into the giant Steel Corporation was the Carnegie Steel Co., dominated by Andrew Carnegie and producing practically one-fifth of all the steel made in the United States. This company itself had earned in 1899 a profit of nearly $24,000,000, and in 1900 of approximately $40,000,000. The Carnegie Steel Co. represented a consolidation of the Carnegie and Frick interests, and in absorbing this combination the new corporation acquired control of the most successful steel organization of the time.

The steel-producing equipment controlled by the new corporation consisted of 149 steel works with an annual capacity of 9,400,000 tons of crude and 7,700,000 tons of finished steel; 78 blast furnaces with a pig iron capacity of 7,400,000; more than 500,000 acres of coking coal lands, more than 1,000 miles of railroad, and a fleet of 112 vessels engaged in traffic on the Great Lakes, in addition to extensive holdings of undeveloped ore-yielding property, docks, natural gas, limestone properties and so forth.

English Car Dumper in Action

This is a machine at the Alexander Docks, Newport, England. The hoist can lift railroad "wagons" up to 20 tons capacity, dumping them at any height up to 76 ft. into chutes delivering into ship's holds or bunkers.

Sayers to Succeed Read

Dr. R. R. Sayers, Chief Surgeon of the U. S. Bureau of Mines, will likely serve as Acting Safety Service Director for a month or so after the present Director, Dr. T. T. Read, leaves the service. Dr. Read takes up his new duties with the American Institute of Mining and Metallurgical Engineers in New York March 8.

Stover's Smokeless Coal Bureau is now located at 858 Earle Building, Washington, D.C., the transfer from the Chicago offices having been made March 1.

Foresees Coal Economies In Britain

George E. Learnard, of New York, a manufacturer of boiler room equipment who has been a close student of the British fuel situation, is quoted in an interview with *Electrical World* as saying:

"Legislation will shortly be passed by the British Government forcing the development of a national power supply from a series of large and economical stations. As large water supplies are infrequently found at the mines, I believe the government will cooperate in the development of a plan to distill coal at the shaft mouth. The motor spirits, tar and oils will be removed and used in industry and the residual fuel sent to power plants and coal users in pulverized form in which it can be stored and transported. England now imports motor spirits to the value of sixty million pounds sterling."

Plan New Union Drive in Northern West Virginia

One of the most intensive drives ever attempted will soon be launched in an effort to unionize northern West Virginia, according to a statement issued last week by Van A. Bittner, international representative of the United Mine Workers in that district. This follows closely a recent announcement by R. M. Williams, international representative in Monongalia County, that the union would issue another strike call to open-shop miners some time between April 1 and May 15. John L. Lewis, president of the miners' international union, declared a short time ago that Mr. Bittner had full authority to direct the union's efforts toward organizing the field.

Declaring that the recent anthracite settlement was "a great victory for the miners, their families and the United Mine Workers," Mr. Bittner added that "for the time being the entire efforts of the United Mine Workers will be centered on northern West Virginia, and, with our plans perfected, our policy will be to go onward and forward and not rest until every contract-abrogating coal operator reaffirms the union wage scale."

The proposed strike call will be the third issued in this region since the beginning of 1925. The first call was effective April 1 and the second on Sept. 26.

National Guard Keeps Peace In Southern Indiana

Peace reigned unbroken in the southern Indiana coal field last week following the dispatch of national guardsmen to Evansville as a result of a demonstration against non-union miners by unionists Feb. 16, in which one man was seriously injured and scores beaten and clubbed.

Detachments from four units of the Indiana National Guard are on duty in Evansville, where they are being held ready for emergency calls. Two aeroplanes, one mounting a machine gun and both equipped for bomb dropping, make daily reconnaissance flights over the field. The infantry units are completely equipped with chemical warfare appliances.

Non-union mines in the region have practically all resumed operations since the arrival of the troops. The only activity on the part of union workers reported was the holding of a mass meeting at Boonville on Sunday at which T. N. Taylor, Indianapolis, president of the state Federation of Labor, was the principal speaker

Hudson Coal Co. to Erect $2,000,000 Breaker

The Hudson Coal Co. has decided to erect a breaker costing $2,000,000 at Olyphant, Pa., and in the near future the plans for the structure will be ready. The new breaker, it is said, will do the work that is now handled at three other breakers in the Olyphant field. The new plant will be even larger than the Hudson's Marvine operation in Scranton, one of the biggest in the anthracite field.

Did Electric Arc in Firedamp Cause Jamison Blast?

An arc from an undercutting machine, from a defective cable or from the breaking of the circuit between the cable and the power line flashing in an accumulation of gas, probably was the direct cause of the explosion that occurred on Jan. 14 at the No. 8 shaft mine of the Jamison Coal & Coke Co., Farmington, W. Va. The presence of the gas in turn was probably due to interrupted ventilation, an open door being a likely cause.

Whatever the initiating agents, the opinion is held that coal dust propagated the explosion, which finally was stopped by the water contained in the swags on the main headings. When the explosion occurred the company was engaged in a big program for reconditioning this mine to make it more safe and already had spent a large sum of money toward this end. These are deductions from the testimony of witnesses at the inquest of the disaster, which was held in Fairmont on Feb. 26. The verdict rendered was that the nineteen victims "came to their death by an explosion of gas ignited by causes unknown to the jury."

The explosion took place in the Seventh Right section, a new development which is turned off the main heading at a piont about 3,000 ft. from the hoisting shaft. This section consists of a right and a left side, each of which was being ventilated by an individual split of air. At the time of the explosion two shortwall machines were at work in each of the two splits, or four in all in the section.

Prosecuting Attorney N. W. Ogden, counselled by R. M. Lambie, chief of the West Virginia Department of Mines, first of all tried to establish the fact that sufficient coal dust could not have been stirred up by the cutting machines to cause the initial ignition. This as an approach to the finding of the real medium, which was gas.

Deprecate Influence of Dust

Several other witnesses discounted any possibility of dust being the initiating cause, seeing that only two machines were on each of the splits and that these two were 500 to 1,000 ft. apart, intervals which would give ample opportunity for the dust caused by the first machine to settle in some degree before it could be carried by the air to the place where the second machine was at work.

William Leeper, fireboss, and Walter Brown, the mine foreman, remarked that under normal conditions the section would not have accumulated sufficient gas to cause the explosion, but the former declared that gas could have collected in sufficient volume had a door been left open, particularly in the No. 1 Right Butt entry of the section through which No. 4 machine had to pass. Assistant Mine Foreman William Beuglass visited the section on the day of the explosion. He found ventilation good and detected no gas.

One of the doors in the section was not destroyed by the force of the explosion, and an exploration crew found it standing open. This door might have been opened by the pioneer waves of the explosion, for which reason too much significance should not be attached to the position in which the door was found.

The fact that, as disclosed by Mine Foreman Brown, little gas was detected in the section after the explosion, with ventilation more or less impaired, led to the belief that an abnormal condition was set up prior to the explosion. State Mine Inspectors Kramer and Griffith were of the opinion that the piercing of a gas pocket by a cutting machine was the remote cause of the explosion. Many years ago the latter had served for eight years as foreman at this mine—in fact he held that office when the mine was first opened—and he recalled that the gas, emitted from pockets when punctured by drill holes, often made a loud whistle which at times frightened the men. This indicated gas under a high pressure. This gas would bleed off in two hours to three days.

A screw driver and hammer were found near No. 3 machine and the lid on the starting box was found lifted from its position. The body of an electrician was found in a chute of No. 1 butt heading, perhaps on his way to make repairs. However, there were no indications that this machine had anything to do with the explosion, which is believed to have started on the opposite side of the section.

Machines Ten Years Old

The four machines that were working in the section were installed about ten years ago. These were undercutters bearing approval plates of the West Virginia Department of Mines. (The department has long since ceased to issue such approvals.) The machines had no U. S. Bureau of Mines approval plates; in fact they were too old for that. All four machines were under coal in some stage of cutting, but all the controllers were in the off-position when found. However, one of the controllers might have been on at the time of the explosion. If the runner had his hand on the starter at the time, the force of the explosion would have caused him to pull the starter to the off-position as he was flung backward. The machines were not equipped with an automatic closing device on the starter.

Thomas Jarret, state mine inspector, said the force of the explosion was most markedly manifested in the Seventh Right section and thought that the most likely place for the starting of the explosion was the tight end of a crosscut which was being driven between Rooms 8 and 9 on the left side, from which point the force seemed to radiate. Machines Nos. 1 and 2 were at work on that side. A small piece of metal was broken out of the starting box casing on the first machine. The second machine was partially covered by a fall of slate. He testified that the rescuers encountered a number of small fires which were quickly extinguished.

State Inspector W. B. Riggleman, in whose district the mine is located, testified that quick liberation of gas from feeders is a comparatively common occurrence in this mine. He concurred with Mr. Jarret in the latter's belief as to the location of the seat of the explosion.

P. D. Costello, superintendent, on the stand outlined the measures his company had been putting into effect for greater safety. In the early part of 1925 the company decided to discontinue the use of electricity for cutting. Accordingly, prior to the explosion it had installed air compressors and air lines at a cost of approximately $60,000. The compressor station had already been built in the Twentieth Right section (about 2 miles inby of Seventh Right section) and was supplying motive power to ten punchers in its section at the time of the explosion. Two electric machines were still in service in the section due to the difficulty of training men for the job of running the punchers. A similar compressor room in Seventh Right section was near completion. The additional cost of cutting by air punchers as against electric machines in this mine is 9c. per ton.

The mine was sprinkled every day. The use of water cars had been discontinued. Water lines were laid along entries at a cost of $12,000. The intention was, and is, to extend sprinkling to the face of the rooms. No. 9 mine of the company in the same district was being rock-dusted and a rock-dusting machine was on order for this mine.

To Urge Higher Duty on Coal Imports to Canada

Two motions for increases in the duty on coal imports are to be made in the Dominion House of Commons. R. K. Smith (Conservative, Cumberland) intends to move for "an early enactment of a substantial increase in the customs tariff on the importation of coal and steel products of all grades and kinds into Canada from foreign countries." Mr. Smith takes the ground that such action "is essential to the well-being of the province of Nova Scotia and this Dominion."

T. L. Church (Conservative, Toronto Northwest) intends to move that the time has arrived for Canada to have a national policy in relation to its coal supply, and that no part of Canada should be left dependent on the United States for such supply. In his motion Mr. Church takes the ground that the government should immediately consider the initiation of an all-British and Canadian coal supply; that a duty should be placed on coal from the United States, to insure an all-British supply for Canada, and that coal should be carried on a preferential toll basis by the railways, on the same basis as grain and flour.

318 Killed in January Mine Accidents; High Rate Due to Explosions

Accidents at coal mines in the United States in January, 1926, caused the death of 318 men, according to information received from state mine inspectors by the U. S. Bureau of Mines. All but three of the fatalities occurred at bituminous coal mines. The unusually large total for the month was due to four major explosions that caused the death of 142 men. In January a year ago only one major explosion occurred, with a loss of 6 lives. Because of the four disasters, the death rate for bituminous mines was 5.87 per million tons, based on a production of 53,662,000 tons, as compared with 3.47 for January last year based on an output of 51,930,000 tons. The non-disaster rate for January, 1926, for bituminous mines was 3.22 and that for January last year was 3.35.

The most disastrous explosion during the month was that which occurred at Wilburton, Okla., on Jan. 13, which resulted in the death of 91 men. On Jan. 14 an explosion in a mine at Farmington, W. Va., killed 19 men. Five lives were lost in a mine explosion at West Frankfort, Ill., on Jan. 29. The death of only 5 men out of more than one thousand men in the mine at West Frankfort at the time of the explosion is attributed to the use of rock dust, which localized the effects of the blast. The fourth explosion was at Helena, Ala., on Jan. 29, and resulted in the death of 27 men.

The figures for all mines for January, 1926, when compared with those for the same month last year, indicated reductions in the per-million-ton death rates from falls of roof, haulage, explosives and electricity. Only explosions showed an increased death rate, and this rate was more than ten times the rate for January, 1925, and nearly five times the average rate for the year 1925. The following figures show the death rates per million tons for the principal causes of coal-mine fatalities:

	Year 1925	Jan., 1925	Jan., 1926
All causes	3.811	3.959	5.906
Falls of roof or coal	1.842	1.971	1.876
Haulage	.615	.859	.724
Gas or dust explosions	.590	.270	2.823
Explosives	.174	.337	.074
Electricity	.144	.152	.130

Urges Body to Maintain Industrial Peace

Creation of an industrial Relations Commission of nine members "to discover the laws of industrial peace and effect a uniform compliance with them by capital and labor in all industries engaged in interstate commerce" was proposed in a resolution introduced in Congress, at Washington, Feb. 20 by Representative Browning, Democrat, of Tennessee.

Note Issue to Finance New Hazle Brook Breaker

An issue of $2,000,000 6 per cent gold notes of the Hazle Brook Coal Co., dated March 1, 1926, and maturing serially from March 1, 1927, until March 1, 1936, is announced by Brown Brothers & Co. and Edward B. Smith & Co. The Hazle Brook company operates seven anthracite collieries under leases covering about 8,913 acres of coal lands in Schuylkill County near Pottsville, Luzerne County near Hazleton, and in Columbia and Northumberland counties, Pennsylvania. Over one-third of its coal is produced by modern stripping methods. The company also owns five breakers of modern design with all necessary equipment and has begun the erection of a new breaker which will increase its productive capacity to 1,525,000 tons per year. The proceeds from the sale of these notes will be used for the erection of the new breaker with improvements, for the retirement of all mortgage indebtedness and for other corporate purposes.

State Mine Chiefs to Confer

The semi-annual conference of the heads of the state mining departments of Pennsylvania, Maryland and West Virginia will be held in Pittsburgh on March 5. J. J. Walsh, secretary of the State Department of Pennsylvania; Dr. J. J. Rutledge, chief engineer of the Maryland Bureau of Mines, and Robert M. Lambie, chief of the state Department of Mines of West Virginia, will attend.

Coal-Mine Fatalities During January, 1926, by Causes and States

News Items From Field and Trade

COLORADO

The State Coal Mine Inspector's report for January, just released, shows a decrease of 245,000 tons in Colorado's coal output compared with the same month a year ago.

ILLINOIS

The Knox Consolidated Coal Co., of Indianapolis, Ind., operating mines in the Indiana Fourth and Fifth Vein fields, has taken over the business and personnel of the Great-West Coal & Lumber Co., Fisher Building, Chicago. R. E. Barr, formerly president of the Great-West company, has been appointed Northwestern manager, and with him will be associated practically the entire force of the old Great-West company.

The Majestic mine of the Crerar-Clinch Coal Co. broke its output record in the month of January, 1926, with 83,500 tons of coal. The mine has worked full time every day since Oct. 1, 1925. It has been in operation for twenty years.

INDIANA

The Fort Branch mine, Fort Branch, is cleaning up its property preparatory to closing down indefinitely. About 160 men are employed when the mine is operating at capacity.

Agents representing C. W. Willis, of Sullivan, Ind., are obtaining options and leasing 2,000 acres of stripping coal lands east of Hartwell, near Petersburg, with the intention of opening another big stripping mine in southern Pike County. The tract under option is connected with the Southern Ry. by a switch.

The machine shops and supply rooms of mine No. 28 of the Vigo Mining Co., at Sullivan were burned Feb. 13, causing an estimated loss of more than $50,000. The flames were discovered late at night and had gained such headway that they could not be controlled. The storerooms contained much valuable mine machinery and equipment. The origin is not known.

KANSAS

Work was resumed Feb. 23 in the Newlands-Haynie mine, in the southeastern Kansas field, where a strike was called Feb. 2 in protest against penalties imposed by the company on three miners for dirty coal. Officials of district 14, United Mine Workers, insisted responsibility for dirt in the three protested cars could not be determined, as others than those whose names appeared on the cars assisted in loading them. The penalties were set aside in the agreement reached.

The district board of District 14, United Mine Workers, called a strike, effective Feb. 19, at Katy mine, No. 2, southeastern Kansas field, operated by Jim Price, Joe Lafayette and George Mercz. The union officials said the operators refused to recognize a committee appointed by the miners. Twenty-seven men walked out.

KENTUCKY

Green River mine, located between Hebbardsville and Curdsville, will open soon, according to Ollie Keach, of Evansville, Ind., president of the Green River Kentucky Coal Mining Co. The mine recently was auctioned at a commissioner's sale, the owners buying in the stock and Keach succeeding himself as president.

The H. T. W. Coal Co., organized a short time ago to take over the mines of the Alma-Thacker Coal Co., which was forced into the hands of receivers in 1925, is operating the mines with a daily output of about 600 to 800 tons. The product is being sold through the Central West Coal & Lumber Co., of Columbus, Ohio. J. W. St. Clair is at the head of the company.

The West Kentucky Coal Co. and St. Bernard Coal Co. for the year ended Dec. 31, 1925, shows surplus of $372,378 after taxes and charges, but before depreciation, against $676,028 in 1924.

Coal men and other business interests of the Whitesburg section are endeavoring to bring pressure to bear on the Louisville & Nashville R.R. to force the road to carry out an alleged promise to build a connecting link from Whitesburg to Elkhorn City, there connecting with the Carolina, Clinchfield & Ohio Ry. It became known recently that, because of the heavy cost of construction in rough country, the road had decided not to build a connection through from its eastern Kentucky division, and would merely connect up from the Cumberland Valley division, in the Harlan section.

MISSOURI

Joseph Landreth, 57, proprietor of the Landreth coal mine, at Marceline, was instantly killed by a fall of rock in his mine, Feb. 12. Frank Ellis, a miner, was dangerously hurt and is in a hospital.

The Central Coal & Coke Co. and subsidiaries for the year ended Dec. 31, 1925, show net profit of $74,144, equivalent to $3.95 a share. This compares with $364,035, or $5.27 a share, in 1924.

OHIO

Preliminary figures given out by various railroads in Ohio covering coal production during 1925 show that a total of 479,553 cars, or about 23,977,000 tons, of coal was mined as compared with 581,300 cars, or about 29,000,000 tons, in the preceding year. It is estimated that only about one-fifth of the tonnage used in Ohio is produced in the Buckeye State, the remainder coming from West Virginia and Kentucky to a large extent. Of the total output in the state in 1925 the southern Ohio field produced 115,289 cars, or about 5,764,000 tons. Of that production 57,023 cars, or about 2,851,000 tons, was commercial coal; 53,907 cars was railroad fuel, and 4,359 cars, or 217,000 tons, shipped to the lakes.

Owing to the depression in the coal industry, with less than one-half of the 17,000 miners in the eastern Ohio field at work, members of the Fifth sub-district of the United Mine Workers have voted to postpone the twenty-eighth annual convention until March, 1927.

Advanced training in mine rescue work was given at Nelsonville last week by the U. S. Bureau of Mines and half of the force of inspectors of the Ohio Department of Mining were in attendance. The other half will receive the training next week.

M. A. Hanna Co. reports for the year ended Dec. 31, 1925, net income of $123,294 after interest, depreciation, depletion and federal taxes, equivalent to $1.10 a share, on the first preferred stock. This compares with net loss of $1,651,572 in 1924.

The New Pittsburgh Coal Co., of Columbus, a subsidiary of the Pittsburgh Coal Co., has purchased a large tract of coal land in the Pomeroy Bend district. The acreage had been under lease by the company for some time. The purchase price was in the neighborhood of $100,000.

PENNSYLVANIA

The increased value of coal-mine dumps in the anthracite field was brought out recently when the ownership of a bank at New Philadelphia was disputed before an alderman in Schuylkill County. The plaintiff in the case was H. R. Seligman, president of a coal mining concern in Lackawanna County, who charged J. O. Ulrich and

Digitized by Google

J. E. Kirby with taking a bank worth $100,000. Seligman also charged that Ulrich had made threats against him unless he kept away from the coal dump. In their reply Ulrich and Kirby contended they had been worked out of the lease on the mine dump through improper methods, but a counter suit brought against the Lackawanna man was dismissed. The alderman held Kirby and Ulrich for trial on Seligman's allegations. The bank in question is said to contain thousands of tons of burnable culm, yet ten years ago it was deemed of no great value.

Court in Schuylkill County has been asked by trustees of the Stephen Girard estate to put a stop to juicy fees being collected by the treasurer of the school district in West Mahanoy Township, in which nearly all of the assessable property is owned by the Girard estate. Court is asked to limit the treasurer's fees to $500 a year. It is alleged that if the tax collector in the township is allowed to collect the usual commissions he will receive $7,000 a year for little or no work and that such a procedure would mean a waste of the taxpayers' money. Much interest is being manifested in the case due to the fact that in many other districts coal companies pay from 70 to 90 per cent of the taxes.

The preliminary report of the Pennsylvania Coal & Coke Corp. for the year ended December 31, 1925, shows a deficit of $461,294 after depreciation, depletion, etc., as compared with a deficit of $428,376 in 1924. Deficit for the fourth quarter last year was $3,760, against $129,720 in the fourth quarter of 1924. December net income was $320 before federal taxes, against a deficit of $42,770 in December, 1924.

Operations will be resumed soon at the Buck Ridge mine, at Johnson City, according to an announcement last week. This mine formerly was owned by the Puritan Coal Co. This concern went into the hands of a receiver and it is now understood that the Buck Ridge operation is to be taken over by one of the largest independent producers in the Pottsville area. Former Governor Sproul of Pennsylvania is mentioned as being interested in the deal. Mr. Sproul is heavily interested in the South Penn Collieries Co., which has several operations in the Scranton field.

A commission composed of Dr. J. J. Rutledge, of Baltimore, chief engineer of the Maryland Bureau of Mines; S. A. Taylor, of Pittsburgh, president of the American Institute of Mining and Metallurgical Engineers, and Robert M. Lambie, chief of the West Virginia Department of Mines, will investigate the cause of the mine blast at Horning mine of the Pittsburgh Terminal Coal Co., in the Pittsburgh district, beginning March 4.

No giant power legislation will be enacted by the special session of the Legislature at Harrisburg, the Senate corporations committee last week having reported out with a negative recommendation all the Pinchot giant power bills. These eight measures took the place of twenty-two that met a similar fate during the regular legislative session last year.

From proceedings originating in Allegheny County, the Fayette courts on Feb. 25 ordered the sale of the Albany and Ferry mines by the receivers of the Forsythe Coal & Coke Co. to the Albany Coal Co., both Pittsburgh corporations. The Albany mine is located near Brownsville, and the Ferry plant, near East Millsboro. The consideration was withheld. The receivers of the Forsythe company are Connie C. McGregor and R. L. James.

A new seam of anthracite 16 ft. thick was discovered recently by diamond drill men of the Dodson Coal Co. near Hazleton. Development will begin at once, the coal being prepared at the Beaver Brook mines. The seam is thought to be a merger of the thick mountain strata which "pinch out" in other properties of the company.

TENNESSEE

J. H. Mitchell, H. C. Kivett and the Frost interests, of Corbin, Ky., recently purchased the Queen & Crescent coal properties at Moreley, at a price of $27,000. Mr. Mitchell has been named president of the company; Mr. Kivett, vice-president; Charles Frost, Sr., general manager and Charles Frost, Jr., secretary-treasurer.

UTAH

The Standard Coal Co. has laid off 105 men at its mine, one-third of the entire force.

Application for the appointment of a receiver for the Great Western Coal Mines Co., of Salt Lake City, has been made. The application is made by a Mr. A. Strebel, who claims to have a secured judgment against the company for $6,487.36, and it is stated that so far but $100 has been paid. It also is alleged that the company has certain assets which it could dispose of or utilize for the benefit of its creditors, but refuses to take any steps in this direction.

The Denver & Rio Grande Western R.R. has applied to the Utah Public Utilities Commission for permission to construct a railway from Spring Canyon Junction to Kenilworth, which would reduce the grade from 6.10 to 3 per cent. The company also asks permission to abandon the old line between the same points. The improvement would cost, it is estimated, $500,000.

The Utah Public Utilities Commission has dismissed the application to build a branch line up the Huntington Canyon for coal purposes. The application had been pending since 1922 when it was originally filed by Arthur and James H. Mays under the name of the Central Railway Co.

It is announced that plans will be made to rush development work on its properties in Salina Canyon by the Sevier Valley Coal Co., of Richfield. The shaft is now being sunk through solid rock, it is stated. It is expected that the branch line to the mines will be completed by the coming summer.

Register Eli F. Taylor of the federal land office will offer 40 acres of coal land for lease on March 31. It is located near Emery, in Emery County. The property was operated once by the Black Diamond Coal Co., but was taken back by the federal government on the ground that the terms of the lease were not fulfilled.

VIRGINIA

Chesapeake & Ohio Ry. suits aggregating $400,000 are affected by a recent decision of the Virginia State Supreme Court of Appeals granting a writ of error to the Smokeless Fuel Co. in an appeal from the Circuit Court of Newport News, involving a suit for $7,093.56. The suit was one of a number of cases in which the railroad is seeking to recover alleged demurrage due on shipments of coal. Request for a writ was presented Feb. 9.

Increasing its total output of soft coal by nearly 2,000,000 tons over the preceding year, the state of Virginia easily maintained its position last year as eighth among all of the coal-producing states of the country. Virginia's total production for 1925 was 12,455,000 tons, as compared with 10,693,000 tons in 1924.

Substantial Dwellings Erected by the Kingston Pocahontas Coal Co.

These dwelling are of modern brick construction and each building houses two families. Large windows and sufficient space between each dwelling provide plenty of light and fresh air for the occupants.

Digitized by Google

WEST VIRGINIA

Ignition of a small pocket of gas in the Arnettsville mine of the Fort Grand Coal Co. recently caused a fire which caused minor damage, as the blaze was quickly extinguished by W. B. Riggleman, and other safety experts. Six miners, in the mine at the time of the explosion, were unharmed.

Miners in three Elm Grove mines, near Wheeling, have been provided with safety lamps to replace the open carbide lights formerly used. The new electric safety lamps were recommended by Robert M. Lambie, chief of the State Department of Mines.

The Crozer Coal & Coke Co. of Crozer, near Elkhorn, McDowell County, recently installed a 3,000-ton screening and coal preparation plant.

The Davis Colliery Co., at Jontee, Gilmer County, recently installed a $60,000 tipple.

The Davis Creek Land & Coal Co., Charleston, has installed screens to prepare nut sized bituminous coal.

The C. H. Mead Coal Co. has awarded a contract for the erection of a new tipple at its No. 2 operation. The structure will have four tracks and be equipped with the latest screening machinery for the preparation of coal. The Mead company has started putting in a slope to the No. 3 Pocahontas seam and the coal from the new mine will be run over the new tipple in addition to that from the No. 2 mine operating in the Beckley seam. The tipple will handle 2,500 tons in eight hours and will be one of the best equipped in the Winding Gulf field.

Robert M. Lambie, chief of the state department of mines, presented each of the 20 survivors of the explosion at mine No. 8 of the Jamison Coal & Coke Co. with "self rescuer" chemical masks, which is a protection against the fumes of carbon monoxide.

Gordon B. Late, Clarksburg coal operator, recently acquired a lease on the Austin Coal Co.'s coke ovens in Preston County and has put the plant in condition for immediate operation. This is one of the oldest plants in the state, but it has been idle for several years.

More rigid enforcement of the state mining laws is being sought by Robert M. Lambie, of Charleston, chief of the Department of Mines, who declares that too many accidents have been occurring in the mining fields. As a means of reducing the number of accidents, the head of the department has directed all state mining inspectors to prosecute all offenders who do not comply with the law. In line with this order, three prosecutions recently were instituted in the Panhandle section by A. E. Lafferty, of Moundsville, the penalties varying from $50 to $150 and costs.

Reconstruction of the Baltimore & Ohio R.R. bridge across the Guyan River at Huntington, is contemplated, the company having made a request of the War Department to approve the plans, according to Major H. M. Trippe, U. S. District Engineer at Huntington.

Plans are being made by the Superior-Pocahontas Coal Co. to open a new mine at Davy, along the Norfolk & Western Ry. The company will develop a tract of 2,300 acres of virgin smokeless coal land, and it is planned to expend $65,000 in making improvements as soon as the weather conditions are auspicious.

The Portsmouth By-Products Co. has awarded a contract for the erection of a $250,000 tipple at its Freeburn mine, near Williamson, to cost approximately $250,000. When completed, the loading capacity of the mine will be increased to 4,000 tons of coal every eight hours. At present the loading capacity is 2,500 in 12 to 13 hours. It is expected that construction work will begin within 30 days and will be completed in September.

The Winding Gulf Colliery Co., at Winding Gulf, is preparing to spend $50,000 for a new tipple and screening outfit. Work will be started as soon as the weather permits.

The Scotts Run operations of the Connellsville By-Product Coal Co., of the J. A. Paisley interests, of Cleveland, will be rock-dusted soon. According to reports the machinery has arrived.

WYOMING

P. J. Quealy, president of the Kemmerer Coal Co., has just announced that work will be started immediately on the opening of a new mine by that company on the Sublet No. 5 vein, four miles northeast of Kemmerer. The program calls for an expenditure of $400,000. The first work will be the construction of a 1,500-ft. slope to the coal seam, practically all of which will be rock work. A 660-ft. ventilating shaft is to be sunk to this slope. It is expected that actual production will be possible within another year. The mouth of the slope will be near the old Susie, or No. 4, mine of this company.

CANADA

Canada's production of coke in 1925 totaled 1,471,116 net tons, an increase of slightly more than 100,000 tons over the year preceding. Trade Commissioner Lynn W. Meekins, Ottawa, reports to the Department of Commerce. In addition to the amount produced locally, 852,427 tons was imported. In the production of the domestic product 660,760 tons of Canadian and 1,581,466 tons of imported coal was used.

Imports of coal into Canada from the United States during 1925 were as follows: Anthracite, 3,225,398 tons valued at $26,996,042; bituminous, 12,501,096 tons, valued at $26,758,170, as compared with imports of anthracite 3,878,721 tons, valued at $34,804,748, and bituminous 12,500,616 tons of the value of $29,431,661 during 1924. Imports of coal from Great Britain during 1925 consisted of 558,259 tons of anthracite of the value of $5,100,467 and 46,858 tons of bituminous valued at $213,722 as compared with 273,277 tons of anthracite valued at $2,472,737 and 43,835 tons of bituminous of the value of $188,483 during 1924.

Traffic

Ask Extension of Emergency High-Voltatile Rates

Operators of the Williamson field and other southern West Virginia high-volatile regions have filed a plea with the Interstate Commerce Commission asking continuance of the emergency rate granted by the Commission on prepared coal to New England and the Atlantic Coast states. Shippers believe that it will be possible to retain the Eastern market if rates are reasonable. When the present through rate was granted as an emergency measure during the anthracite strike, April 30 was set as the date for restoring the former rates.

N. & O. to Penalize Shipment On Consignment

Information has been received by coal operators along the Norfolk & Western Ry. that beginning March 15 this road will penalize operators shipping unconsigned coal loads to either the Bluefield or Portsmouth scales. A penalty of $2 a car will be imposed on the shipper, which will carry for a 48-hour period, after which the regular daily demurrage rates will apply. The order is similar to the one issued by the Chesapeake & Ohio Ry., according to coal operators.

C. & O. Adjusts All-Rail Rates To Northwest

The Chesapeake & Ohio Ry. has issued freight tariff No. 1160-C, I.C.C. No. 10,218, reducing rates on coal to northern Illinois to the extent of 15c. per ton and establishing joint through rates to southern Wisconsin on an adjustment similar to the one made to trans-Mississippi River territory. This final adjustment in "Northwestern All-rail Rates" establishes the same rates from northeastern Kentucky mines to destination territory as those in effect from mines on the Louisville & Nashville R.R., which are substantial reductions from the combination of local rates, which were the only rates the northeastern Kentucky or Big Sandy district had in effect. The new rates become effective as of March 15, 1926.

Association Activities

At the annual meeting of the **Pittsburgh Vein Operators' Association**, held Feb. 24, at the Hotel Cleveland, Cleveland, Ohio, the name of the organization was changed to the **Eastern Ohio Coal Operators' Association.** This change was made in order to promptly describe the mining location of its membership and more clearly indicate that the mine properties were located in the State of Ohio. The following officers were elected: President, Ezra Van Horn, general manager, Clarkson Coal Mining Co.; Vice-President, W. L. Robison, vice-president, Youghiogheny & Ohio Coal Co.; Treasurer, H. R. Sullivan, treasurer, Central Coal Mining Co.; Secretary, D. F. Hurd.

Personal

There is an opening on the editorial staff of *Coal Age*. Please address J. E. Spurr, *Coal Age*, 10th Ave. and 36th St., New York, giving such information as would be of interest.

J. C. Myers has resigned as superintendent of the Wisconsin Coal Co., at Anco, Ky., effective in a few weeks. He has not announced his plans for the future.

Simon Levy, president of the Boylston Coal Co., Chicago mail order coal house, was held on a $10,000 bond recently, charged with using the mails to defraud.

J. P. Routh, president of J. P. Routh & Co. and the Riberena Fuel & Chartering Co., announces the opening of offices in the Bankers Trust Building, Norfolk, Va., with J. H. Tonkin in charge.

G. R. Krebs, of Charleston, W. Va., is among those interested in the Camp Fork Coal Co., a recently organized corporation with headquarters at Greendale, Nicholas County, W. Va.

George Wolfe, formerly secretary of the New River Coal Operators' Association, with headquarters at Beckley, W. Va., has moved to Norfolk, Va., and is engaged in the general investment business.

Harry A. White has been appointed district manager at Norfolk for the Pocahontas Fuel Co., Inc., succeeding Edwin O. Parkinson, who died several weeks ago. Mr. White formerly was assistant manager of the Norfolk office of the company.

Daniel F. Gallagher, who for several years was New York manager for Campbell, Peacock & Kinzer, is now connected with the Shanferoke Coal & Supply Corp., 120 Broadway, New York City. The Shanferoke corporation recently became representative for Campbell, Peacock & Kinzer in New York State and northern New Jersey.

E. C. Pratt, president of the Republic Coal Co., of Minneapolis, Minn., recently started on a three weeks' trip which is to include a stop at Herrin, Ill., where the Pratt Brothers Co., of which he is the head, has a mine.

John A. Howe, of Minneapolis, Minn., vice-president and general manager of the Carnegie Dock & Fuel Co., says that indications point to 1926 being a good year in the coal trade in the Northwest. Consumers would do well, he said, to contract for coal in sufficient quantities this season to provide against a possible suspension of mining in union bituminous fields when the Jacksonville agreement expires, April 1, 1927.

William Bartrim, combustion expert for the Midland Coal Co., Kansas City, Mo., recently received a letter from H. E. Shrack, Topeka, assistant manager of the Board of Administration of Education, Charitable and Correctional Institutions of Kansas, announcing that the state will save about $60,000 this year through improvements and alterations in heating equipment.

E. W. Davidson

E. W. Davidson has resigned as managing editor of *Coal Age*, effective March 1, to take charge of publicity for the Society for Electrical Development, 522 Fifth Ave., New York City. Mr. Davidson had been on the editorial staff of *Coal Age* for five years, four years as Western editor, stationed at Chicago, and one year as managing editor. The good wishes of the editorial staff and doubtless of the readers of *Coal Age* accompany him.

Obituary

John Finger, 93 years of age, founder of the Finger Brothers Pittsburgh & Kanawha Coal & Coke Co., at New Albany, Ind., large handlers of river and rail coal, died at his home in New Albany, on Feb. 23, following a short illness. A native of Germany, he came to America as a boy, and founded the coal company about thirty-five years ago. He is survived by three sons, four daughters and his widow.

Frank A. Schneider, for many years in the coal trade of St. Paul, Minn., died last week, after an illness of a few weeks. He was 48 years of age and left a widow, a son and a daughter. When but 15 years old he started with the North Western Fuel Co., of St. Paul, and continued in various positions until about 1912, when he went with the C. Reiss Coal Co. with which he remained until his death. Funeral services were conducted under Masonic auspices.

Trade Literature

Blasters' Handbook. E. I. duPont de Nemours & Co., Wilmington, Del. Pp. 198; 4x7 in.; illustrated. Describes practical methods of using explosives for various purposes.

Common Sense in Steel Dollars. Heintz Mfg. Co., Philadelphia, Pa. Pp. 16; 6x9 in.; illustrated. Describes the steel welding operations of this company.

Crowding the Blasting Crew is the title of Bulletin 317, issued by the Marion Steam Shovel Co., Marion, Ohio, describing its shovel operations. The book has 16 pp., is 8½x11 in., illustrated.

The United States Distributing Corporation, New York City, has issued a 39-pp., 8x10½ in. book illustrating and describing the activities of its subsidiaries.

Industrial Notes

George E. Cullinan has been elected vice-president in charge of sales and a director of the **Graybar Electric Co.**, which has just been organized to succeed the supply department of the Western Electric Co. **Leo M. Dunn** has been appointed vice-president in charge of merchandising and accounting.

Allis-Chalmers business in Continental Europe will be handled through an organization recently incorporated as Allis-Chalmers (France), with headquarters at 3 rue Taitbout, Paris. H. I. Keen, who has been manager of European sales through the company's district office in Paris, will be the managing director of the new organization. The company has maintained for many years an office in London at 728 Salisbury House, London Wall, E. C. 2.

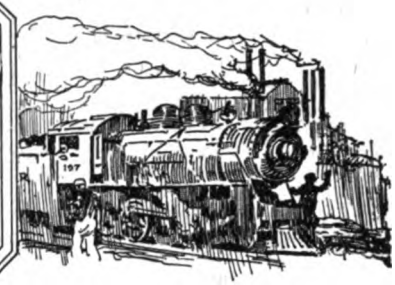
W. C. Adams, member of the firm of **Allen & Garcia Co.**, Chicago, will hereafter be located at Birmingham, Ala., in the Birmingham Age-Herald Building, as resident engineer of the company.

The Cutler-Hammer Mfg. Co., of Milwaukee, Wis., has opened a new sales office in the Healey Building, Atlanta, Ga., to take care of the trade in the states of North Carolina, South Carolina, the eastern section of Tennessee, Georgia, Florida, southern Alabama and Mississippi. A. C. Gibson, formerly of the Philadelphia office, is in charge. The General Machinery Co. of Birmingham, Ala., will continue to serve the northern half of Alabama.

The Superheater Co., of New York and Chicago, recently elected M. Schiller vice-president in charge of accounts and purchases, and W. F. Jetter, treasurer and assistant secretary. Bard Browne was appointed assistant to the vice-president in charge of sales and service, and T. F. Morris, assistant secretary and assistant treasurer.

S. C. Ebbert, who was connected with the Birmingham offices of the General Electric Co. for a number of years, has formed a connection with S. L. Morrow, 720 Brown-Marx Building, Birmingham, Ala., sales representative of Link-Belt Co. and H. W. Caldwell & Sons Co. Mr. Ebbert is a mechanical and electrical engineer of recognized ability and is thoroughly acquainted with the industrial needs of the district.

Publications Received



A Century of Progress. A history of The Delaware and Hudson Co., 1823-1923. Pp. 755; 5 x 8 in.; illustrated.

The Bureau of Mines Orsat Apparatus for Gas Analysis, by A. C. Fieldner, G. W. Jones and W. F. Holbrook. Bureau of Mines, Washington, D. C. Price, 5c. Technical Paper 320. Pp. 18; 6 x 9 in.; illustrated. Describes the apparatus used in the gas laboratory of the Bureau of Mines at Pittsburgh, Pa., for the complete and partial analysis of gases.

Production And the Market

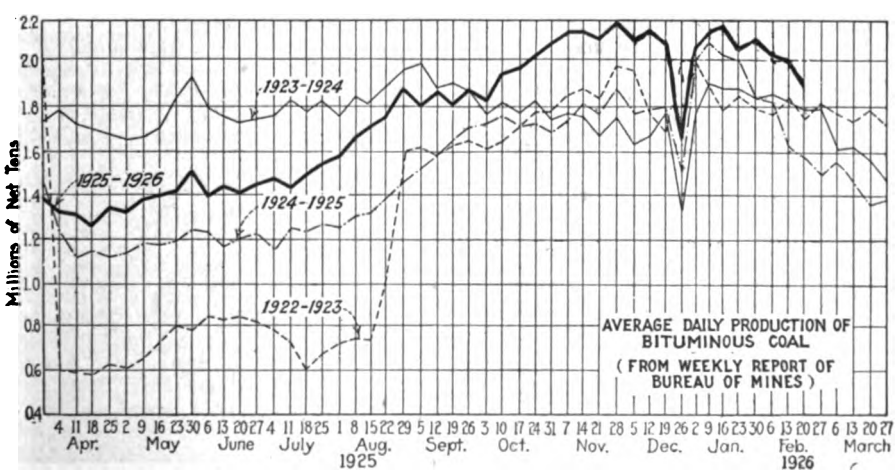
Liquidation Process Rules Soft-Coal Market; Anthracite Situation Parodoxical

The process of liquidation in the bituminous coal markets of the country still continues. The process is marked more by sharp recession in demand than by sharp breaks in spot prices. The latter are still working to lower levels, but the descent is not abrupt. The decline is moderate because prices as a whole have been so low that pronounced declines would throw more companies into operations at a substantial loss.

Coal Age Index of spot prices on bituminous coal for March 1 was 169 and the corresponding price was $2.04, as compared with an index number of 170 and a price of $2.06 on Feb. 22. This week's index number is the same as that in effect a year ago, when the outlook for the industry was anything but promising. During the past week West Virginia low-volatile coals in Eastern markets and southeastern Kentucky block in the Middle West were the chief victims of the price decline.

Production Still on the Downgrade

Bituminous production is being curtailed to meet the new conditions. The output for the week ended Feb. 20 was estimated by the Bureau of Mines at 11,513,000 net tons, as compared with 12,011,000 tons the week preceding. Preliminary figures for last week indicate a further decline. Notwithstanding these drastic cuts, there is still considerable coal on wheels which can be sold only at bargain-counter figures. And "no bills"are the common lot of most producing fields.



The greatest danger in connection with this unsold and rejected tonnage is not the losses that will be suffered to effect disposition, but the false basis of values such distress sales will establish in the minds of many buyers. Coming at the time when the question of contract renewals is pushed to the front, such a false basis may have a disastrous effect upon next year's business. As a matter of fact, in some cases buyers are holding off from renewing contracts apparently with just such an idea in mind.

Look to Lake Trade for Relief

To the Appalachian Region the most favorable factor in the present situation is the approach of the opening of navigation. One or two troublesome accumulations of tonnage have been moved to boats tied up at the lower ports. This has been a great help to the high-volatile coals. The low-volatile producers, however, have not been able to arouse the interest of lake buyers. In both high- and low-volatile fields, jockeying for prices between buyer and seller already has started.

The anthracite situation is paradoxical. The householder is eager to take in hard coal, but the eastern retailers, particularly in the metropolitan areas, are more concerned with getting rid of the stocks of "substitute" fuels still in their yards. The result is that, while shipments are readily absorbed—possibly because the tonnage is spread so thinly over a wide territory—there is no pressure upon the producers for quick deliveries. In fact, some representatives of the producers complain that the market lacks life. Extravagant premiums on independent tonnage are fading out of the picture, although the range over company circulars is still high.

Domestic interest in beehive coke is largely history. Production in the Connellsville region is declining in spite of increased buying by industrial interests. Some of the byproduct ovens which stepped into the market during the hard-coal strike, however, are laying plans to hold part at least of the business then enjoyed.

Estimates of Production

(Net Tons)

BITUMINOUS

	1925	1926
Feb. 6	10,910,000	12,167,000
Feb. 13 (a)	9,758,000	12,011,000
Feb. 20	9,464,000	11,513,000
Daily average	1,577,000	1,919,000
Coal yr. to date (c)	424,651,000	483,706,000

Middle Western Mines Closing

With winter demand apparently on its last legs, the number of mines in Illinois and Indiana closing down or reducing running time is on the increase. An unofficial check of the situation shows more mines down in the two states than at any time, barring general strike periods, in the past five years. "No bills" are no respecters of sizes in either state.

According to present plans, most of the southern Illinois operators will try to hold to the $3 base on lump this month. Pressure from outside coals, however, is severe. West Virginia and eastern Kentucky high-volatiles are easy at $2.50. Smokeless lump is reasonably firm at $3.50@$3.75; egg and nut, $4@$4.25, and mine-run, $2@$2.35.

The Middle Western steam market is exceedingly quiet. Neither the reduced output of coal as a result of the resumption of anthracite production nor the shutting off of tonnage by strikes in southern Indiana has strengthened steam coal prices. Railroad buying in southern Illinois is light. Stripping operations are gathering in some spot orders for locomotive fuel as these mines are willing to compete on a price basis with non-union western Kentucky.

There is no change in the situation in the Duquoin and Jackson County fields. Railroad buying is the mainstay of current business in the Mt. Olive district. With that exception, conditions are on all fours with those in southern Illinois. Mines in the Standard area still pursue a ruinous price policy, but this has little effect upon the accumulation of "no bills" and some operations plan to shut down for an extended period.

The St. Louis local market is "flat, stale and unprofitable." High-grade coals lag in demand. Many retail distributors have been forced to enter into the building materials business to keep out of red ink. Country domestic trade is no better than that in the city and steam movement is light.

Undigested Surplus Pains Kentucky

The collapse of the Eastern market for domestic coal leaves the central states with an undigested surplus of Kentucky and West Virginia high-volatile tonnage. Although consignment shipments are held down to a minimum, the potential capacity of the mines depresses spot prices—particularly upon prepared sizes. The chances are that there will be little advance until the opening of the lake season.

Screenings, on the other hand, are moving to higher levels under the influence of curtailed production. Industrial consumers are showing more interest in the market. Eastern Kentucky slack commands 90c.@$1.10 and screenings from the western part of the state sell for 10c. less. High-grade eastern Kentucky block is easy at $2.25@$2.75; lump, $2@$2.50; egg and nut, $1.75@$2; mine-run, $1.35@$1.50. Western Kentucky block is $1.75@$2; lump and egg, $1.50@$1.75; nut and mine-run, $1.25@$1.50.

Digitized by Google

Mild weather the last half of February cut into shipments from the docks at the Head of the Lakes to such an extent that some of the plants were on a part-time basis. Industrial demand did not wholly escape the slump, but the slackening in this department of the trade was attributed to heavy buying in earlier weeks. An expansion in steam-coal business is expected this month.

"Substitutes" Still Moving from Docks

The end of the anthracite strike has had little effect upon the movement of Pocahontas and other "substitute" fuels from the docks. Present stocks are large, but dock operators still believe that there will be little left unsold when navigation opens. Docks, however, are planning to bring up the normal quantities of hard coal the coming year.

Dock quotations on all coals are firmly held. There is a real shortage in screenings. Some operators have been compelled to buy from competing docks to take care of contracts. Stocks of all sizes on hand on March 1 were estimated at 3,232,000 tons.

The market at the Twin Cities is colorless. Supplies are free and there is no rush to accumulate tonnage. Consumers, both domestic and industrial, are going on the theory that, with the hard-coal strike over, there will be plenty of coal for everybody. All-rail southern Illinois lump is quoted at $3 mines; central Illinois, $2.50; western Kentucky, $1.90.

Milwaukee in a Slump

Bituminous demand is easing up at Milwaukee. Prices on low-volatile coal are softening, but this weakness has not, as yet, extended to retail quotations. Some anthracite has been received and is being sold at pre-strike prices.

The domestic market in the Southwest has faded away and Kansas operations now are down to two and three days a week. There has been some reduction in the number of unbilled loads of screenings and about one-third of the "no-bills" of prepared have been moved. Arkansas industrial demand is light; domestic business is a closed incident. Less than a dozen mines in the Henryetta field are working.

Decreased domestic buying has cut Colorado operations to a 70 per cent basis. Conditions otherwise are unchanged. Utah, too, suffers from mild weather, but the predicted acute shortage in slack coal has not made its appearance although the situation is tight. Prices, generally speaking, are well maintained. The number of idle miners is growing.

Look to Lakes for Relief

High-volatile producers with headquarters at Cincinnati are looking to the lakes for relief from existing unsatisfactory market and production conditions. Some orders for 2-in. lump and slack already have been placed—principally with southeastern Kentucky mines. Quotations still show a wide spread, lump ranging from $2 to $2.50 and slack from 60c. to $1.

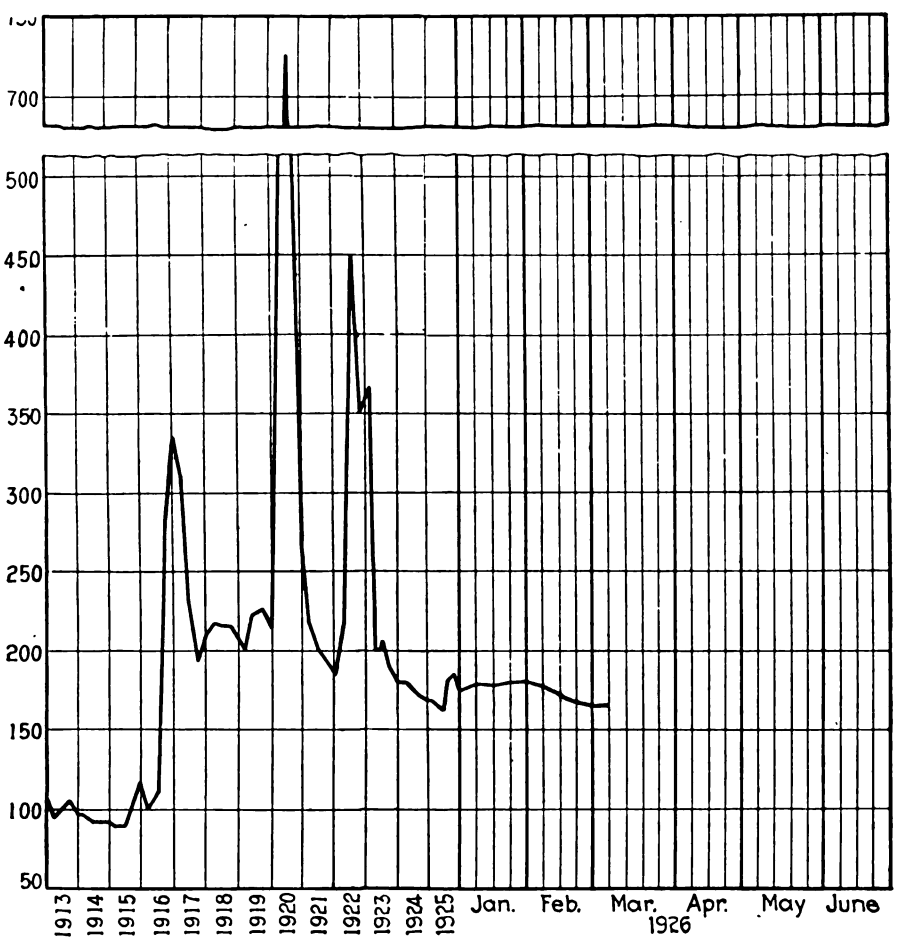
On the other hand, lake buyers are turning a cold shoulder to offerings of low-volatile coals at prevailing quotations. These figures, released last Saturday, show Pocahontas lump at $4; egg, stove and nut, $4@$4.25, and mine-run, $2.25. Some spot New River lump is available at $3.75@$4.

Movement through the Cincinnati gateway has increased only slightly. The latest car interchange report of the American Railway Association shows 12,357 cars interchanged, or 227 loads more than in the preceding week. The number of empties sent to the mines declined 2,122.

Cincinnati retail business is off with a good start for March. Prices show no material change from February levels. Smokeless lump is $8.50; mine-run, $6.50; high-volatile lump, $6.25@$6.50; slack, $4@$4.50. River business is coming back into its own with warmer weather. Most of the boats are back on their regular schedules.

Central Ohio Trade Marks Time

Basic conditions in the central Ohio trade are unchanged. Domestic demand is affected adversely by weather conditions. Retail prices, however, are firm and Columbus dealers have enjoyed one of the best years in their history. The spot steam market is extremely sluggish. Unsold tonnage at mines and junction points has reached uncomfortable proportions. No real relief is expected before the opening of the lake season.



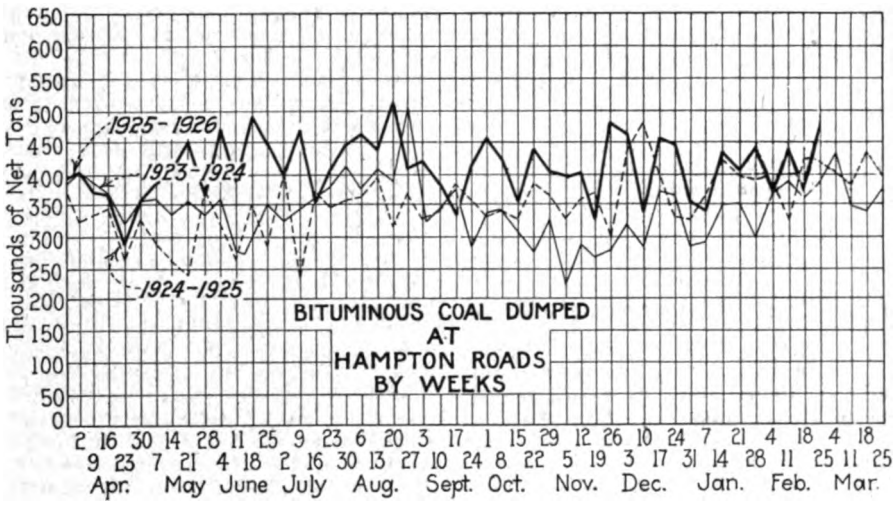
Contracting is still in the inquiry stage, except for a few short-term agreements. It is not considered likely that contract figures will show much change from last year, when mine-run was signed up at $1.35@$1.75.

Southern Ohio production is not averaging over 18 per cent of capacity. As for several months past, the Pomeroy Bend district has been the most favored.

Depression rules in the Cleveland market, but prices are unchanged, except for distress lots of prepared sizes. Screenings, however, are in fair demand because of declining production. Output from the No. 8 field during the week ended Feb. 20 approximated 248,000 tons, or 35 per cent of capacity. This was 12,000 tons under the output for the preceding week and 5,000 tons less than in 1925. More mines are closing down.

Pittsburgh Market Weakens

"No bills" have been added to the woes of the Pittsburgh producers. Egg and nut are offered as substitutes for mine-run and domestic lump is seeking lower levels. Industrial buyers are



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	Mar. 1	Feb. 22	Feb. 15	Feb. 8	Mar. 2	Mar. 3
Index	169	170	173	177	169	183
Weighted average price	$2.04	$2.06	$2.10	$2.14	$2.04	$2.21

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

holding back orders, presumably in the hope that non-union offerings will break the market.

Three-quarter Youghiogheny gas is off 20@25c. Competition from the Connellsville field is the explanation advanced for this weakening. Slack prices, however, are growing stronger as production declines. Steam slack is up 10c. and gas slack, 15c.

Central Pennsylvania Loadings Off

Daily loadings in the central Pennsylvania field have dropped from 3,800 to 3,600 cars since the resumption of hard-coal mining. This loss is much less than was expected. "E" and "D" seams in Huntingdon, Bedford, Cambria, Blair and Somerset counties are quoted at $1.95 on contract and $2.25 for spot sales. "C" prime is $2 on contract and $2.30 spot. "B" Miller Seam is $2.30 on contract and $2.65 on spot.

In Clearfield, Centre and Clinton counties, "E" and "D" seams bring $1.90 on contract and $2.15 on spot sales. "B" seam is $2.25. Indiana County "E" and "D" seam coals are $1.85 on contract and 15c. higher on spot sales. "B" seam brings $2 and $2.30.

The Buffalo market is still in a watchful waiting mood. Business is unusually quiet. Nominal quotations are unchanged.

New England Turns to Anthracite

A full week of anthracite mining has sapped the New England bituminous market of the last traces of strength. Mine-run, as well as prepared coals, has settled into a rut and no early improvement is in prospect. There still is considerable prepared bituminous en route, which probably will go at a sacrifice. Recent quotations: Egg is offered well under $4 and $3.25 seems to be the top obtainable on lump.

Navy Standard coals command $4.70 @$4.85 gross f.o.b. Norfolk and Newport News. Less favorably known coals sell down to $4.60. With the outlet for screened sizes more restricted, reductions in the accumulations of tonnage at the piers will be in order. Industrial and railroad consumption show little change. Coal on cars at Providence and Boston is weaker, recent quotations being off 25c. or more.

Coke, ovoids and Welsh anthracite are still arriving, but the cargoes are received with no great enthusiasm. Several of the Boston retailers are trying to get rid of stocks of foreign fuel already on hand. Price cuts have not been potent in persuading the householder to buy freely of these fuels.

Distress Coal Rules New York

How to dispose of distress coal is the chief problem of the New York bituminous market at the present time. Long Island R.R. tracks are crowded with low-volatile coal and coke, many cars of which have been refused. The market for screened bituminous has practically disappeared, but retailers say that the cargoes of British and German coal and coke still arriving are being readily absorbed.

Mine-run also is inactive. Receipts at tidewater piers have been heavy enough to maintain a daily average of nearly 4,500 cars of coal on tracks, but deliveries have been so slow that serious congestion has ensued.

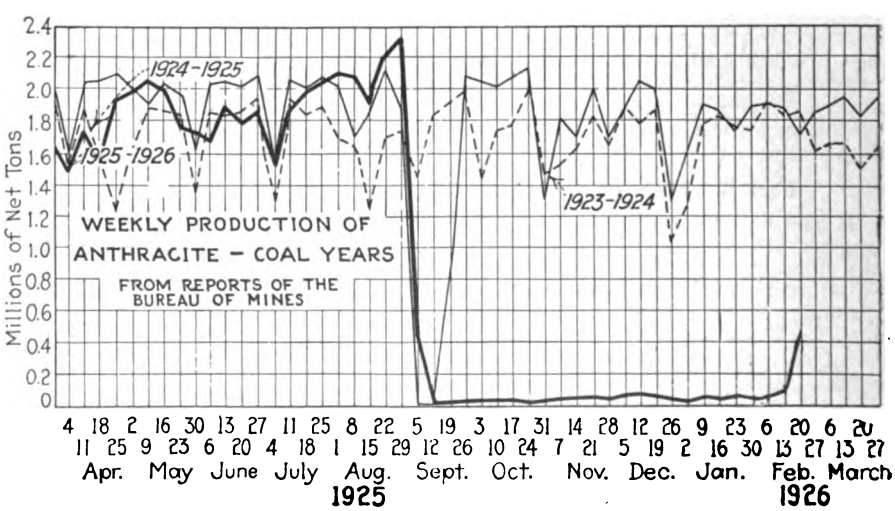
Coke is gradually dropping both in demand and in price. Sized coke, which was held at $14 f.o.b. ovens before the anthracite strike was settled is now offered at $5@$6. Retail prices have dropped from $25 to $15 per ton. Some ovens are planning educational campaigns to hold part of their strike trade.

Philadelphia Market Lethargic

The Philadelphia bituminous market is soft and slow. Spot buyers seem determined to force a bigger break in prices—notwithstanding railroad congestion and delayed deliveries. Producers are turning their attention to contract renewals. Some of the larger operators are asking $2.65@$2.75, but others are willing to take $2.35. Buyers, however, are indifferent. The railroads have been able to pick up so much distress tonnage at bargain figures that contract solicitation finds them cold.

Baltimore Market "Flat"

"Flat" is the way the Baltimore bituminous market is described. Prices on the better grades of steam coal show no real change; gas coals have weakened under light demand. Tonnage at tide and in transit is too great to arouse the industrial consumer to buying activity. Prices on prepared sizes are off $2@$3 per ton since the anthracite strike ended. Bunker demand is weak and there is no export business to ease the strain.



Prices at Hampton Roads slumped 50@75c. last week in belated tribute to the anthracite strike settlement. This slump affected the regular pool classifications. Lump, egg and nut for domestic purposes have dropped $3.25@$3.50 since the strike ended. Dumpings at the piers for the week ended Feb. 25 were 431,980 gross tons, as compared with 322,899 tons the week preceding. The usual month-end rush to avoid demurrage was reflected in this increase.

Fairmont Fears Overproduction

Overproduction is the bugaboo of the Fairmont district. Some sharp reductions in output have been effected, but the market continues to sag. Slack and mine-run are the weakest. The former is quoted at $1@$1.20 on the Monongahela Ry. and mine-run is $1.25@$1.55. Three-quarter lump holds at $1.60@$1.75. Prices at mines on the Western Maryland and Baltimore & Ohio railroads are lower, with slack at 50@90c.

Conditions in the Birmingham coal market last week were a repetition of those controlling the preceding week. Poorer grades of coal moved slowly; higher grades were readily absorbed. Contract consumers took liberal tonnages. On the whole, industrial movement was better than domestic as the latter was hit by the warm weather. General mine quotations were unchanged.

The rising mercury and the end of the anthracite strike have left their impress upon the coke market. Demand still takes care of output, but the prices have weakened. Egg and nut are to be

had at $5.50 ovens, as compared with $6.50@$7 three weeks ago. Foundry coke is $6.50@$7 for spot tonnage, with consumption and production about balanced.

No Pressure on Anthracite

The anthracite market at New York is a paradox. Retailers are so anxious to rid themselves of the substitute fuels still on hand that they are making no frantic demands on hard-coal shippers. Nevertheless, independent operators experience no difficulty in selling domestic sizes at $12@$14 in straight lots and at $12 for egg, stove and chestnut in combination with broken coal. Pea coal is still somewhat scarce and is held at $7.50@$9. Retail prices range from $14.95 on egg and nut to $15.50 for stove.

Spot demand for steam sizes is held down by the surplus of bituminous mine-run available at low prices. Most of the steam tonnage coming in is being applied on existing contracts. Free independent No. 1 buckwheat is quoted at $3.65@$5; rice, $2.50@$3; barley, $2@$2.50, mines. Culm was quoted at $4.30 f.o.b. piers the close of last week.

Receipts of domestic anthracite at Philadelphia last week exceeded expectations. Independent prices, too, are working lower. Starting out in some cases $6 above company circular, prices have come down to $1.50@$3 above company figures, with little moving at the higher premiums. Retail prices are still an uncertain quantity, but the average basis is around $15.75 for egg and nut, $16 for stove, $12 for pea and $8 for buckwheat, curb delivery.

Cut Retail Prices on Substitutes

In an effort to move stocks of screened bituminous coal and coke on hand, Philadelphia retailers are offering these fuels to the consumer at $2@$3 under cost prices. Demand, however, has dropped off sharply. The wholesale market in the buckwheats presents no unusual feature.

Baltimore dealers are fighting shy of independent domestic anthracite at $9.50 @$14.50, mines. Although the householder appears to have little coal of any kind on hand, the retail distributors are hopeful that company tonnage will be coming in in normal quantities before any pinch develops.

Anthracite demand at Buffalo has been less heavy than local representatives of the shippers had banked upon. But the steady flow of hard coal has ended the dreams of the bituminous producers and bargain prices induce no buying. Coke prices have dropped $6 in the fight of the ovens to hold on to some of the business they had.

Connellsville Seeks Its Level

Optimists in the Connellsville region are trying to convince themselves that the price liquidation program has been completed. There are so many operators who have not blown out their ovens, however, that an awkward accumulation of crushed coke seems unavoidable. There has been a light demand from eastern retail interests and some of the industrial buyers have come back into the market.

Straight furnace coke dropped 25c. last week, bringing the price level to $3.75@$4. Yard crushed coke is $4.50 @$5. Foundry coke is $5@$5.50, with a fair volume of buying.

The Connellsville *Courier* reports coke output in the Connellsville and Lower Connellsville regions the week ended Feb. 20 at 110,700 tons from the furnace ovens and 121,460 tons from the merchant ovens. Compared with the preceding week furnace oven output decreased 9,500 tons; merchant oven production, 3,400 tons.

Imports Into United States Almost Double

Coal and coke imports into the United States last year were nearly double those of 1924, but little more than half the total reached in 1923. The greatest proportionate increases were in imports of anthracite coal and coke from the United Kingdom. Sharp increases in movement the last quarter of the year swelled the totals. In December alone, the United States imported 146,700 gross tons of anthracite from Great Britain, as compared with a monthly average for the year of 28,500 tons.

Exports of anthracite from the United Kingdom to Canada also have increased, as shown by figures obtained from Consul A. B. Cooke, Swansea, Wales. Exports from Swansea consular district to Canada in 1925 totaled 364,073 tons, as compared with 215,995 in the foregoing year. Exports to the United States, as stated by Consul Cooke, amounted to 230,388 tons in 1925 and 79,641 in 1924.

Foreign Market And Export News

Welsh Industrial Coals In Keen Demand; Tyne Spot Market Sluggish

The outlook in the Welsh steam coal industry continues to improve and prices are firmer, but operators are not ready to sell forward on current rates. Orders are plentiful until late March or early April. Steamers have been somewhat delayed by the recent stormy weather, though tonnage is now arriving regularly.

Shipments have been helped by the improvement of dock facilities, chiefly the reconstruction of the coal hoists to take the new 20-ton cars of the Great Western Ry. In addition to this the trippers and trimmers are working better than for some time past.

A favorable impression has been created by the return of the Paris & Orleans Ry. to the use of Welsh coal and this railway has ordered 150,000 tons of Monmouthshire Black Veins large and Cardiff smalls for shipment up to the end of August. France and Italy are both buying better, and the hope exists that the Italian State Rys. will return to the use of Welsh coals. Inquiries from the United States are few and from South America moderate.

The improvement in Wales is having the opposite effect on the Newcastle market. The collieries are well booked, but merchants are finding some difficulty in getting rid of their stocks and in many cases are selling below colliery quotations. There are few contracts at Newcastle worth reporting, though several orders have come through from European gas works for gas coals up to around 2,000 tons.

Output by British collieries during the week ended Feb. 13, according to a sepcial cable to *Coal Age*, totaled 5,400,000 gross tons, compared with 5,415,000 tons in the preceding week.

Belgian Market Still Gaining

The slow but steady progress in the Belgian coal market continues unchecked, according to reports from Brussels under date of Feb. 11. Domestic coals are holding their position and the industrial coal market is improving more rapidly than had been anticipated.

The greatest improvement is in the Borinage. Increased prices on French coals, decreased receipts from Holland, lessened competition in coke from Germany and the resumption of metallurgical operations in the Charleroi district all have contributed to quickening activities in the Borinage.

No decision has been reached on prices for small coal consumed by the Belgian State Railways since Nov. 1, 1925. Patent fuel prices, however, were set at 97 fr. for November and December and 100 fr. since Jan. 1, 1926.

February indemnity fuel prices are 5 to 10 fr. above January figures, except on unscreened 25 per cent semi-bituminous coals, which are off 10 fr.

French Domestic Coal Demand Outstrips Production

Paris, France, Feb. 11.—There has been no break in the French market. Industrial orders are filled without difficulty, but production cannot take care of current domestic demand. Screened flaming gas coals seem to be the shortest in supply. Stocks are being supplemented by purchases of British coal, D. C. B. sorts (corresponding to screened No. 4 of the Pas de Calais), which have jumped 9 fr. in one week.

Wage increases have been granted in the majority of the French producing districts and prices at the pit mouth have been advanced to cover the increase.

French receipts of indemnity fuel from the Ruhr in December were: Coal, 482,700 tons; coke, 288,800; lignite briquets, 32,300 tons. During the first twenty-three days of January, 242,200 tons of coal, 203,700 tons of coke and 25,100 tons of briquets were received. Average daily receipts were approximately 20 per cent less than in the preceding month.

Last year this country produced 48,033,564 metric tons of coal and lignite, as compared with 44,954,567 tons in 1924 and 40,844,218 tons in 1913. The 1925 total includes 5,213,000 tons from Lorraine, which in pre-war years was credited to Germany's output.

Coming Meetings

Fayette-Greene Coal Producers Association. Annual meeting March 6, at Uniontown, Pa. The third annual banquet will be held in the evening at the White Swan Hotel. Secretary, J. Fred Shean, Box 450, Uniontown, Pa.

American Mining Congress. Southern industrial development conference, Hotel Peabody, Memphis, Tenn., March 15-17. Acting secretary, Henry M. Payne, Southern Division, American Mining Congress, Memphis, Tenn.

New England Coal Dealers' Association. Annual meeting at the State Armory, Worcester, Mass, April 7 and 8. Secretary, E. I. Clark, 141 Milk St., Boston, Mass.

American Welding Society. Annual convention at 29 West 39th St., New York City, April 21-23. Secretary, M. M. Kelly, 29 West 39th St., New York City.

National Retail Coal Merchants' Association. Ninth annual convention at the New Willard Hotel, Washington, D. C., May 17-19. Resident vice president, Joseph E O'Toole, Transportation Bldg., Washington, D. C.

Electric Power Club. Convention at The Homestead, Hot Springs, Va., May 24-27. Secretary, S. N. Clarkson, B. F. Keith Bldg., Cleveland, Ohio.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, in conjunction with the annual meeting of practical operating officials. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. The fourteenth congress will be held in Madrid, Spain, commencing May 24, 1926. From May 5 to 22 excursions of interest to the visiting delegates will be arranged. Information concerning the congress can be obtained from the secretary of the organizing committee, Enrique Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L Hutchinson, 29 West 39th St., New York City.

American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

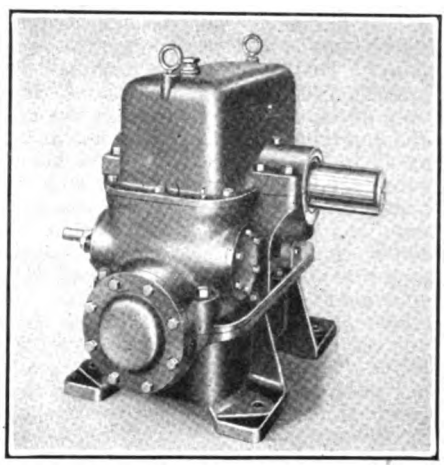
American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

New Companies

The Reichert Coal Co., Freeburg, Ill., has been incorporated with capital of $20,000 to acquire coal and coal rights and to operate coal mines. The incorporators are W. C. Reichert, Elmer W. Reichert and William J. Reichert.

The Bidge Coal Co., of Mulberry, Kan., with a capital of $16,000, has been incorporated.

Papers of incorporation for the **Boulder Coal Co.**, Boulder, Colo., have been filed of record by W. J. Quinlan, Melvin G. Gelwicks, C. M. Goddard, and others. The capital is $50,000. The new coal company will operate mines, including the Black Hawk mine, which will be developed.



The Monroe Coal Co., Greenville, Ky., capital $25,000, has been chartered by Henry B. Lee, George T. Collamore, and O. S. Roberts.

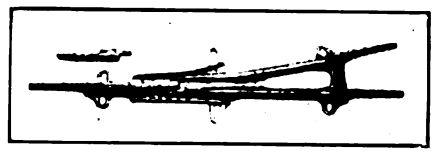
New Equipment

Two-step Worm Reduction Gear for Driving Conveyors

Recently the De Laval Steam Turbine Co., Trenton, N. J., has developed a two-step worm reduction gear to provide ratios of from 100 to 1 to 8,000 to 1. The unit which is shown in the accompanying cut is designed for driving conveyors, stokers, heat-treating furnaces, escalators or similar devices. Its gearing consists of an initial worm turning a wheel mounted on the end of an abutting shaft. This shaft carries a second worm which drives the low-speed wheel and shaft.

A single casing carries all bearings

This new two-step worm reduction gear is intended for driving stokers, conveyors, heat-treating furnaces and other similar devices



for the high-speed worm shaft and the low-speed worm shaft, which also carries the high-speed wheel and shaft so as to insure accurate alignment and meshing. The construction is rugged to enable the use of the unit for heavy-duty work. End thrust and bending strains from the driving and the driven machine are taken on flexible couplings of the pin and rubber bushing type.

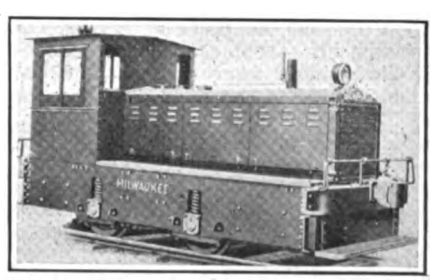
The casing serves as an oil reservoir, in which oil is maintained at a sufficient level to touch the high-speed wheel and the low-speed worm at all times. In addition to this, the unit is equipped with a positive oil pump by means of which oil is drawn from the reservoir and forced through passages to the low-speed shaft bearings.

Improved Trolley Frog Assures Good Tracking

The type CF overlapping runner trolley frog made by the Westinghouse Electric & Mfg. Co., of East Pittsburgh, Pa., offers several improvements over previous designs. In this improved frog the trolley wheel rides on the runner continuously and never touches the pan. Current is thus always collected in the groove of wheels and not on the flange. The life of both frog and the trolley wheel are thus greatly increased.

This frog possesses exceptionally good tracking qualities as the wheel will follow through without the necessity for slewing the trolley pole by the

Plenty of Clearance Is Assured



Ample wheel clearance is provided in this design of frog and the wheel makes continuous contact in the groove and not on the flanges. The life of both wheel and frog is thus prolonged.

locomotive driver. It is equipped with renewable bayonet type approaches so that there is an easy transition of the trolley wheel from the wire to the frog body. This is made in either 15- or 20-deg. angles for right-or left-hand turnouts, thus adapting it to practically all points of application in and about the mines.

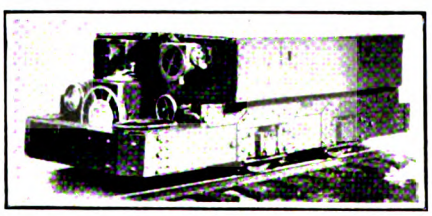
Two Gasoline Locomotives of 18 and 20-Ton Sizes

The latest addition to the line of gasoline locomotives manufactured by the Milwaukee Locomotive Manufacturing Co. consists of two locomotives of 18 and 20 tons' capacity respectively. These machines are of the four-speed gear and chain drive type, and are geared for four speeds of 2, 4, 6, and 12 m.p.h. both forward and reverse. The machines are built for all gages of track from 30 to 56½ in., and the design of the frame is such that the center of gravity is very low, to steady the locomotives on poorly surfaced track.

It is claimed that the design of the transmission eliminates all possibility of stripping the gears, and as the gears are always in mesh there can be no clashing. All the gears have exceedingly wide faces and are made of chrome-nickel steel forgings, except the

New 18-ton gasoline locomotive

final driving gear and pinion, which are made of steel castings. Removal of the various covers and housings for inspection of the gears and the entire dismantling of the transmission without removing the case proper from the locomotive are features of the design. Driving sprockets on the final drive shaft in the transmission are centrally



Digitized by Google

located between two bearings, thus providing a rigid and sturdy construction and eliminating the use of a separate jack shaft. Chrome-vanadium roller chains are employed for power transmission.

The locomotive is equipped with hand-operated four-wheel brakes as standard, but also can be equipped with straight or automatic air brakes when specified. A 12-volt electric lighting and starting system consisting of a generator starter and Westinghouse storage battery is used. The engine is a Beaver six-cylinder heavy-duty type, having overhead valves, forced feed oiling, and a maximum speed-regulating governor.

Two Battery Locomotives Put On Permissible List

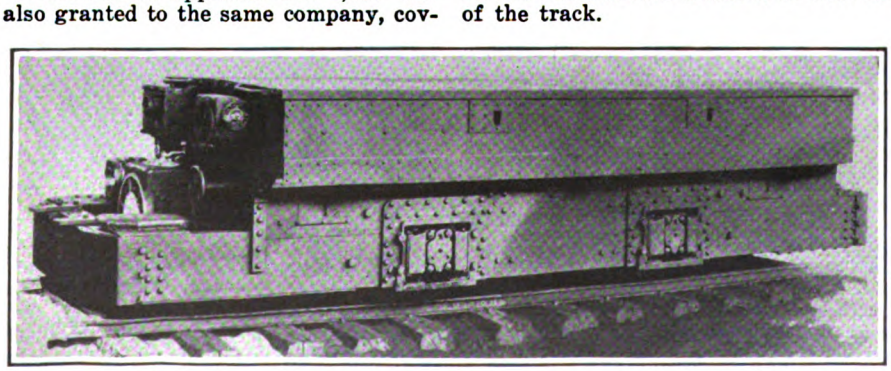
Two more new type of storage battery locomotives have won the right to bear the official stamp of permissibility. Government approval No. 1,510 was recently granted by the Bureau of Mines to the Jeffrey Manufacturing Co., of Columbus, Ohio. This approval covers a large permissible storage battery locomotive intended for main line haulage. This machine is equipped with two 60-hp., 250-volt motors. The battery consists of 110 lead-plate cells, and has a capacity of 120 kw.-hr.

Permissible Gathering Locomotive

This machine is similar in general construction and appearance to the main line haulage locomotive, except that it is smaller. It is fitted with a battery of 64 cells, having a capacity of 60 kw.-hr. It is intended for gathering purposes only.

This new haulage locomotive is built for a 44-in. track gage. The overall width is 78 in. and the overall length 19 ft., 2½ in. The total height is 50½ in. above the rail, and the wheelbase is 70 in. The drivers are 26 in. in diameter and are carried upon 4½-in. axles. The total weight of the locomotive is 18 tons. Machines of this type have a haulage capacity sufficient to permit them to take the place of several compressed air machines.

Government approval No. 1,507 was also granted to the same company, covering a permissible storage battery gathering locomotive. This machine is equipped with two 15 hp. motors, and the battery consists of 64 lead plate cells having a capacity of 60 kw.-hr.



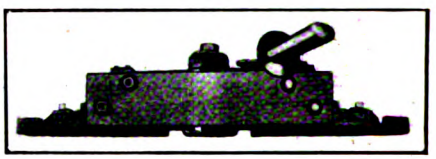
The dimensions of this machine are as follows: Track gage, 48 in.; total width 72 in.; length 12 ft., 3 in.; over-all height 45½ in.; wheelbase 44 in.; diameter of driver 20 in., and diameter of axle 4 in.

Machines of this type are intended for gathering purposes taking the coal to and from the working faces and making them up into trips to be hauled to the tipple or shaft bottom by means of the main haulage machine.

Improved Shoveling Machine With Low Headroom

The new shoveling machine (No. 2-25) recently developed by the Myers-Whaley Co., Knoxville, Tenn., embodies several points of design that make the shovel different from those designs of shovel introduced earlier by the company. This machine is designed for operation in very low headroom. It is only 39 in. high over-all from the rail, and can be operated in headroom as low as 42 in. from the rail. It is a heavy, substantial machine, however, and embodies all improvements which the company has developed up to this time. A roller chain drive is used from the motor to the first shaft instead of a spur-gear drive. This drive is enclosed in oil casing and is noiseless, and the designers think that it will prove very durable. The first machine has been in service for loading rock a short time, and in that service has developed the same capacity as the company's Special No. 3 or Standard No. 3, and is said to have required no repair parts. Indications are that the upkeep on the machine will be low.

Another machine recently developed by the company is an auxiliary turntable conveyor which is used back of the shovel, for delivering material to the side. This conveyor swings 360 deg., and is adjustable in and out and up and down at the discharge end. Its extreme reach is 13 ft. to each side from the track center. This auxiliary conveyor is built with the same care as its other machines, the company says, and is applicable for loading of rock or ores where it is desired to load on parallel track or to discharge the material at considerable distance to one side of the track.

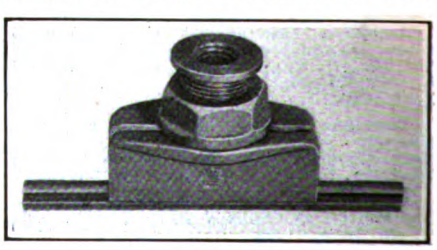


Large Permissible Storage Battery Haulage Locomotive

This machine weighs 18 tons and is intended for main line haulage. It is provided with 110 lead plate cells and has a capacity of 120 kw.-hr., this being ample for all ordinary haulage purposes.

Double Insulating Gap Proves Efficient

In the accompanying illustration appears a 600-volt double gap section insulator as recently developed by the Westinghouse Electric & Mfg. Co. of East Pittsburgh, Pa. This insulator has a double beam with two air gaps as insulating media. These gaps take the shape of arcing horns and consequently there is no tendency to carry the arc over if the motorman happens to overrun the insulator when the switch is open. A short rugged blade is attached under the box in such a manner that the insulator will remain continuously in alignment.



Wires Inserted Without Bending

This type of section insulator possesses many advantages over its predecessors. It has a double insulating gap and the trolley wire may be inserted in either end without deformation. It is thus easy to install and efficient in use.

This insulator has bronze end castings and renewable arcing tips. It is equipped with the SL type of approach which permits insertion of the wires without bending. A rotating board makes installation and removal easy. The plate can be locked open thereby complying with the requirements of the bituminous coal mine compensation rating schedule.

Great Holding Power Assured

Line material for use in mines is constantly being improved. The heavy duty trolley clamp shown in the accompanying illustration and designed by the Westinghouse Electric & Mfg. Co., of East Pittsburgh, Pa., is so constructed as to afford a maximum holding power on any size of wire from 1/0 to 4/0 grooved or figure-8 section. This clamp is easy to install and affords a maximum wheel clearance in the jaws.

Low Height and Sure Grip

This trolley clamp will hold any size of wire either grooved or figure-8. It possesses several improvements over previous designs and is particularly adapted to mines affording low headroom.

Suspension of this clamp is secured by means of a ball on a stem casting which is hung in a recess in the jaws. This eliminates excessive loads on the fulcrum pin. On account of its compact design and minimum overall dimensions this clamp is particularly adapted for use in mines where the headroom is small.

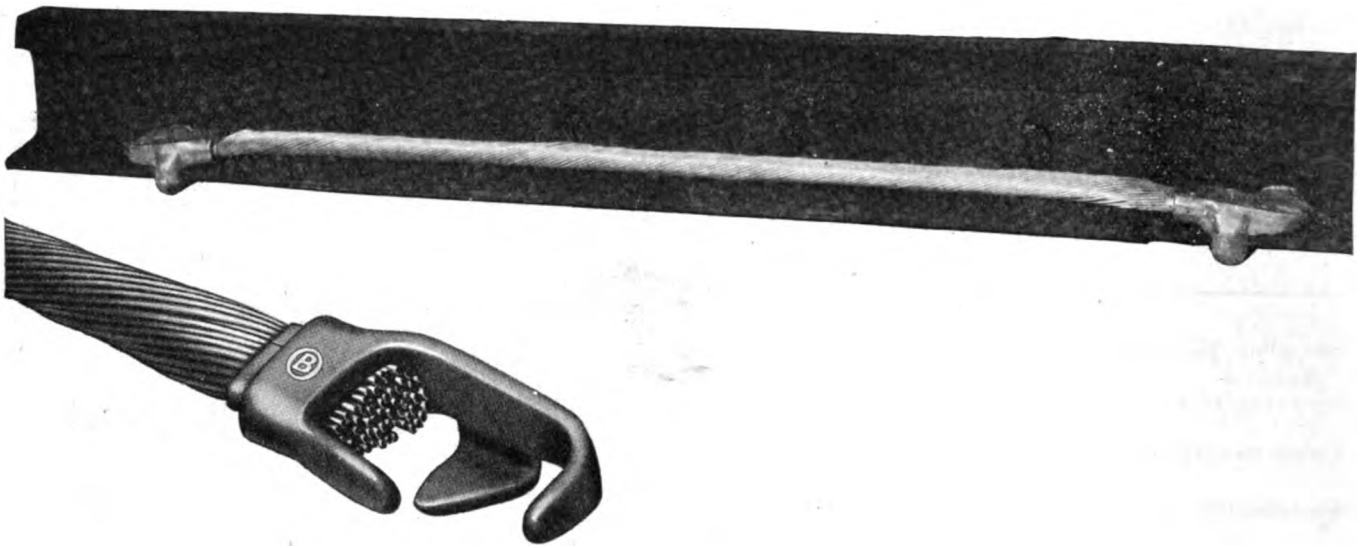
Lake Rate War Revived

THE LAKE CARGO coal cases, in which a decision was handed down last summer, have been reopened by the Interstate Commerce Commission. Interested parties are given until March 22 to say whether they desire to submit additional evidence. That advantage will be taken of the Commission's offer is a foregone conclusion.

These rates have been before the Commission in one form or another since 1912. Involved in the question is the bitter struggle between Ohio and Pennsylvania, on the one hand, and southern West Virginia and eastern Kentucky, on the other, to dominate the coal tonnage of the Northwest. In the background hovers the spectre of union vs. non-union labor.

A simple transportation question has become a big economic issue, clouded by political manouveuring. The issues in these cases, their transportation, economic and political background, will be reviewed in next week's issue by Sydney A. Hale.



Light on Fan Construction

VENTILATING engineers say that our coal-mine fans are behind the times. Experience in the ventilation of factories and schools and in the supply of air to furnaces has resulted in wonderful progress in the theory and practice of ventilation.

L. W. Huber will discuss next week the fan that has blades so turned that it seems as if the designer desired them to avoid moving the air. But such fans when driven at high speed are efficient and give unusually stable conditions. They use almost the same horsepower and give almost the same quantity of air despite changes in pressure such as would entirely unbalance a fan with forward-curved blades. That uniformity of horsepower is good for the fan, and the uniform air flow is an essential factor in promoting safety. But as to the desirability of these high-speed fans for mine use there is much difference of opinion.

Introducing AW-12

Something new and better, in rail bonding

Four distinguishing features make this new bond a distinct improvement. Each feature affords a substantial advantage to the user.

FIRST—The terminal hook clamps the bond to the rail base. A tap of a hammer sends it home. This holds the bond firmly in place while welding.

SECOND—The terminal itself forms a sort of a cup in which the molten welding metal is retained. The opening in the wall of the terminal permits starting the weld outside and working it inside. This insures development of welding heat on the rail base preparatory to the complete fusion of wire strands, rail base and the terminal.

THIRD—Every wire strand extends through the terminal and becomes an integral part of the actual weld. Insures perfect conductivity.

FOURTH—A soft copper sleeve protects the strands where they enter the terminal. Bending and vibration will not break them off.

Use O-B Copper Alloy Welding Rod, especially prepared for rail bonding. It contains the necessary elements, including fluxing material, for proper fusion of the metals to be welded.

Read over these points again! They mean better bonding, fewer breaks and less up-keep cost as soon as you get this new type bond in service.

Ask for O-B Type AW-12 Rail Bonds.

The Coal Myth

WHAT everybody believes is likely to be in the main untrue, for, when all are agreed, then exaggerations are inevitable, statements are not questioned or examined and no one fears to give rein to his imagination. So it has been with the coal industry. It has been declared the worst of all the world's institutions. It has been the prey of masters of superlatives. Is it sick? There is none more sick. Is it overdeveloped? None is more so. Is it irregular in operation? None works more irregularly. Is it deficient in mechanicalization? None is more deficient.

Some time when coal has partly re-established itself by a superhuman effort we shall begin to see it in its right light. Day laborers at mines, for instance, who get $7.50 for an eight-hour day will be seen to be better paid than snow shovelers who work for ten hours and obtain a wage one-third lower, paying also more for shelter, transportation, food and comfort than the laborers at coal mines. Some day the irregular trades will be examined, and coal will be seen to be nowhere in the running. Some day the primitive industries will hold a congress and refuse to recognize such a well-developed and highly mechanicalized industry as coal mining. Some time the miner will be seen not as a feudal serf but as one of the more independent of artisans. There will come a day also when we shall see the industry as one in which the operators are grossly undercompensated. The world is happy in having a myth, a scapegoat for simple minds to discuss. We have so many difficult problems to solve. Here is something we all agree on —a story which we can believe without doubt or question. Why then trouble about the facts!

Talleyrand de Périgord said history was "a fable agreed on." That expression will serve to describe the coal industry until someone comes to shatter our faith and to convince us once more that the more superlatives there are in an assertion the more unsafe it has become. If all that has been said of the coal industry is true there is no certainty in human nature.

Snap Judgment

AT A MEETING of the Chamber of Commerce of the State of New York on Feb. 4, its committee on public service was asked to investigate coal prices in New York City. On March 4, the committee reported that it was "quite apparent that profiteering is and has been going on" and that this price-gouging "is not confined to the cellar dealer or peddler." Mark-ups of 54 to 106 per cent by those distributors of fuel in bag lots did not impress the committee as exorbitant. Large retailers, stated an appendix to the report, "must bear some share of responsibility for oppressive prices."

The mandate to the committee was "to ascertain the facts concerning the relation between the cost of coal delivered in New York and the price demanded by retail dealers *of all classes*." Yet, nowhere in the report is there any evidence that the committee had any accurate knowledge either of mine prices, prices at tidewater or the cost of handling coal through the retail pockets. The text of this document reveals a clouded conception of the different agencies of coal distribution and their respective functions. The only statement purporting to represent wholesale prices made on the committee's authority is a hopeless jumble of mine prices on domestic anthracite, tidewater quotations on bituminous mine-run and retail delivered prices on coke.

The committee excuses its failure to develop all the facts called for in its instructions by pleading that the task was difficult and that it lacked authority to compel the submission of pertinent data. The evidence gathered, it says, was conflicting—but the imperfect record did not deter it from pronouncing judgment and from making recommendations for legislative action. Just how difficult it would have been to gather the necessary information is lost in mystery. There is, however, nothing in the report to indicate that the committee or its paid investigators unduly exerted themselves to carry their studies beyond the peddler to apportion responsibility and, if need be, condemnation.

For seventy-five years it has been the proud boast of the Chamber that it has taken no action upon questions "we confessedly do not feel ourselves qualified to judge." In the present case, however, the Chamber has seen fit to accept and indorse a report the imperfections of which are patent and in the face of a request from the chairman of the state relations committee of the New York State Coal Merchants' Association that the retail trade be heard before the Chamber committed itself. This departure from well-seasoned tradition hardly adds to the glory of the Chamber of Commerce of the State of New York.

Liquid-Oxygen Explosives

DURING the past few years much interest has been shown in this country concerning the use of combustible matter soaked in liquid oxygen as an explosive for use in industrial blasting. Perhaps it would be more proper to say "curiosity" than "interest," because up until quite recently everybody was mildly anxious to know more about this explosive, its possibilities and limitations; yet nobody seemed to be doing anything in particular about it.

As is well known, explosives, from the chemical standpoint, are of two general types—compounds and mixtures. High explosives are usually compounds while the mixtures are, as a rule, slower in their action because they evolve their gases from actual combustion which progresses from particle to particle. Common black gunpowder is an excellent example of a mixture explosive.

Digitized by Google

Liquid-oxygen explosives partake of the nature of mixtures although in many respects they behave much like dynamite which is a good example of a chemical compound. We print elsewhere in this issue an abstract of the extremely valuable paper on this subject recently presented before the American Institute of Mining and Metallurgical Engineers. This will be of keen interest to many mining men.

Several characteristics of the new explosive recommend it for strip pit mining and tunnel work in rock although its heat of explosion and quickness of action unfit it for shooting coal. The rigidity of the cartridges and the fact that the smaller sizes, in order to even approximate their possibilities must be fired within 10 to 15 min. after their placement in the shot hole are detrimental qualities.

It is in the strip pit and rock quarry, therefore, that the new explosive can be used to best advantage. Here the 4-, 6-, or 8-in. drill holes used permit the employment of cloth-bound cartridges of large diameter which may remain in place as much as 2½ hr. before firing and yet evolve a large proportion of their maximum possible energy. Another interesting feature of the liquid oxygen cartridge is the fact that it is entirely successful in wet holes or may be used with water stemming. Such stemming soon freezes after insertion of the cartridge.

Other excellent characteristics of the new explosive are its freedom from detonation by impact and the fact that it must be used practically as soon as it is manufactured. The cartridges may be made up at any time and can be safely stored in any quantity as they do not become explosive until soaked in the liquid oxygen. Atmospheric conditions have small effect upon them when either soaked or unsoaked. Furthermore their total cost as used is somewhat less than that of dynamite.

An operation using this explosive needs neither magazine nor thaw house. In its stead a suitable place must be provided for the storage of detonators, fuse and cordeau. Similarly a small oxygen plant must be installed as well as a place for soaking cartridges. However, in addition to a decreased expense all or practically all of the danger incident to storing, transporting and handling high explosives is eliminated while the useful effects realized are approximately the same.

It is reported that liquid-oxygen cartridges are being used at a large coal stripping operation in Indiana for blasting the overburden ahead of the stripping shovels. The progress of this work will be watched with more than usual interest by the rest of the coal industry.

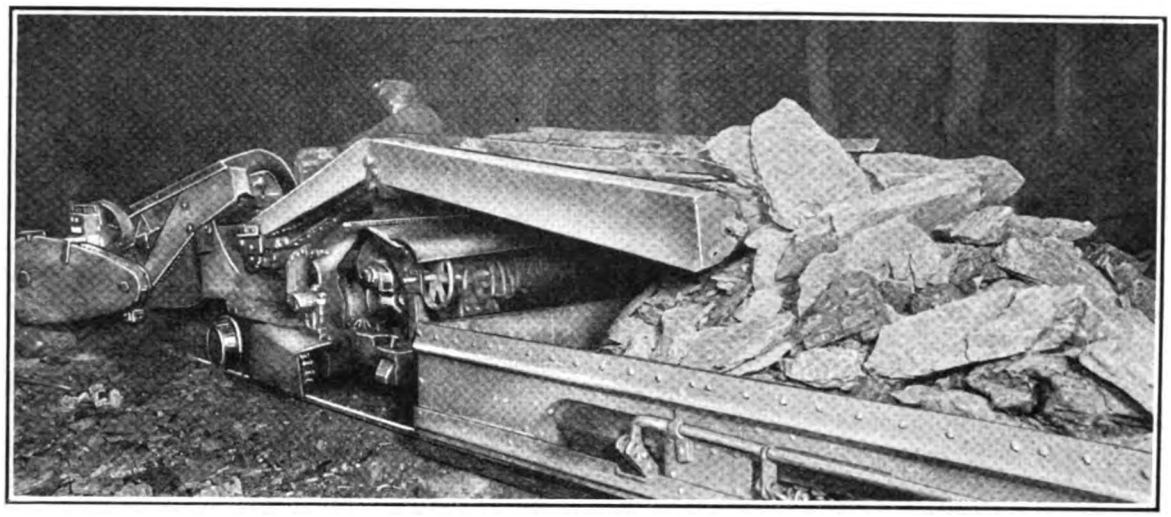
"Bootlegging" Coal

SOME have wondered how the miners met the long strike without any large withdrawal of savings funds and without any extensive measure of relief from the public, the trades unions in general or their own union. Many of them wandered to the big centers of industry such as New York and Pittsburgh and obtained work there. Perhaps in all 20 per cent of the workers left the anthracite region.

Some were reported in the bituminous mines, and, in one case at least, they were willing to perform more dead work without compensation than were the miners of the locality they invaded. A room had caved in, and the anthracite men consented to clean it up without charge in order to get the opportunity to mine the coal after the face was reached. Being away from their own homes they did not hesitate to create conditions that they were unwilling to introduce or afraid to practice in their home mines. Their action was equivalent in character to the "dumping" policy of manufacturers who relentlessly demoralize distant markets but are careful of their own.

Many miners, however, did not move away but lived on the earnings of wives and daughters employed in the silk mills. Silk manufacturing is a great industry in the anthracite region, because the air is not sullied with soot and because there is an abundance of female labor.

But there was another industry available and that, strange to say, was coal mining—"bootlegging" coal. The miners would not work for the companies, but they were willing to extract coal from the culm banks. Great activity was shown in this industry. The miners, each for himself, paid a high royalty on this coal to the owner of the culm bank. Teamsters hauled it short distances, and even into New Jersey. These "snowbird" operators made $7 or $8 a day, and the coal, improperly prepared and containing large quantities of slate and bone, was sold at premium prices. These men, so long as the winter lasted, did not find their strike unprofitable. The distant cities had to do without anthracite but the home towns and those around the region had hard coal—of a sort.



The operators made no complaint. It is usually found that when these disagreements occur the owners of mines have a sympathetic eye to the sufferings that the men have brought and are bringing on themselves. They find it difficult to distinguish those who are the mere victims of circumstances that they cannot control from those who have invited misfortune by advocacy of a dogged resistance.

Many years ago a bituminous strike occurred during which one company, having a large store and being obliged to refuse credit to the idle miners, was importuned to lend the services of its mules and teamster to the miners. This was conceded and the men were soon scouring the surrounding country for farmers ready to supply them with food. In most instances the aid was afforded, and much provender was brought in as the farmers were at that time more friendly to the miners than today, partly because wages were lower but more because the farming population had furnished many recruits to the coal industry. Even the company stores have not infrequently extended credit to the friendly miners and those whose financial difficulties appealed to the store management; and then when the bars were let down it was difficult to separate deserving from undeserving.

A Gambler's Chance

NOT a few mines covered with untreated, combustible dust are in operation. It must be true that mine officials and the higher executives are now thoroughly aware of the degree of inflammability of coal dust. With little doubt therefore those who allow combustible dust to accumulate in large quantities without attenuating it with rock dust, or even so much as soaking it with water, are deliberately taking a gambler's chance in hoping for freedom from disaster.

Shoveling Machines Reduce Costs and Speed Rock Removal

Particularly Useful With Uncertain Roof and Rolling Bottom—Can Clean Up Rock Faster Than All the Men That Can Be Gotten Around a Fall

By Frank H. Kneeland
Associate Editor, New York, N. Y.

MANY mines are afflicted with a rock problem more or less severe. Sometimes the thickness of the coal is such that the roof must be brushed in order to secure the necessary headroom on haulageways and entries. As a rule all such rippings must be removed from the mine and disposed of outside. Again, in many cases the bottom must be lifted either to give the necessary headroom or to afford a reasonable grade for the haulage. Particularly where the coal is thin and its contour uneven either or both of these methods must be followed if anything resembling favorable haulage conditions are to be approximated.

Such are the conditions encountered in a certain group of mines in Kentucky. The thickness of the coal in these operations ranges from approximately 3 ft. 6 in. to about 5 ft. Local dips and rolls are numerous, and there is scarcely a haulage road to be found in these mines anywhere that does not require grading. In many places, also, the roof caves, sometimes to a height of 20 ft. or more, necessitating the removal of large quantities of rock.

Shoveling machines have been adopted for this purpose, not only because they cheapen the process involved but also because they do the work more rapidly than all the men that could possibly be used to advantage. In a typical instance as will be described later the bottom was lifted to a maximum depth of 3 ft. throughout a distance of 245 ft. along one of the main haulage headings and all the material from this cut, amounting to 166 cu.yd. in the solid was loaded out over a week end.

Rock work on haulage roads is always expensive, not alone because the material handled is worthless but also because only a limited number of men can be employed. Furthermore a fall on a main haulage blocks traffic on this roadway and may thus cause an indirect loss that may far exceed the direct loss represented by the expense of rock handling. It is in such places that mechanical means of loading, inasmuch as they are far more rapid than hand methods, are especially advantageous, and such means are accordingly employed in the mines to which reference has been made.

It has now been practically eighteen months since the first Myers-Whaley type of shoveling machine was started to work. The savings made by this loader, however, were such that a second machine of the same kind, size and model, was installed in January of 1925.

Typical examples of the work done by these machines are shown in the accompanying illustrations, Figs. 1 to 7. In Fig. 1 practically all the work was lifting bottom. The grade was made uniform from *A* to *E* with two cuts and two fills between these points. The first cut extended from *A* to *B*, a distance of 280 ft., the maximum depth of this cut being 3 ft., the total yardage being 202½ cu.yd. in the solid. The yardage of loose material or spoil handled would be roughly twice this amount or approximately 400 cu.yd. From *B* to *D* a short fill had to be made, material for which was obtained by shooting the roof at *C*. Only enough roof was shot down to make the required fill and the material thus obtained was allowed to remain where it fell, no work being done upon it other than leveling the surface sufficiently to enable the track to be laid satisfactorily.

Digitized by Google

From *D* to *E* the cut measured 295 ft., its maximum depth being 3 ft. The volume (in the solid) was 252.2 cu.yd., making nearly 500 cu.yd. of loose rock. It was not necessary to shoot top to secure material for the little fill from *E* to *F*. The maximum depth of this fill was about 1 ft. and material for it was readily obtained from the end of the cut from *D* to *E*.

Fig. 2 shows how an abrupt dip was straightened out and excessive grades avoided. It represents another case of both brushing top and lifting bottom. Here the maximum fill was 15 ft. and the maximum cut was only 2½ ft. The total length of the fill was 630 ft. and of the cut 220 ft. The material blown down from the roof was 2,100 cu.yd., of which the shovel loaded out 942½ cu.yd., both figures representing material in the solid. The volume of rock removed from the cut was 150 cu.yd. measured in the solid.

Fig. 3 represents a case similar to Fig. 2 in that both a cut and fill are involved. The maximum depth of fill here was 10 ft. and its length to 470 ft. The volume of material shot down was 1,332 cu.yd. in the solid, of which it was necessary to move with the shovel 642½ cu.yd. also in the solid or roughly 1,280 cu.yd. of loose rock. The cut was about 130 ft. in length and its maximum depth approximately 2 ft.

Fig. 4 shows a long cut, so long, in fact that its extremities are omitted from this drawing, only 850 ft. of its length being shown. The maximum depth of this cut was 5 ft. 6 in. The spoil amounted to 1,108 cu.yd. in the solid, or approximately 2,200 cu.yd. of loose rock. As may be seen, however, the track grade obtained was excellent, the many humps and hollows originally existing being replaced by a level stretch of track and a uniform slight grade over which heavy trips can be hauled with comparative ease.

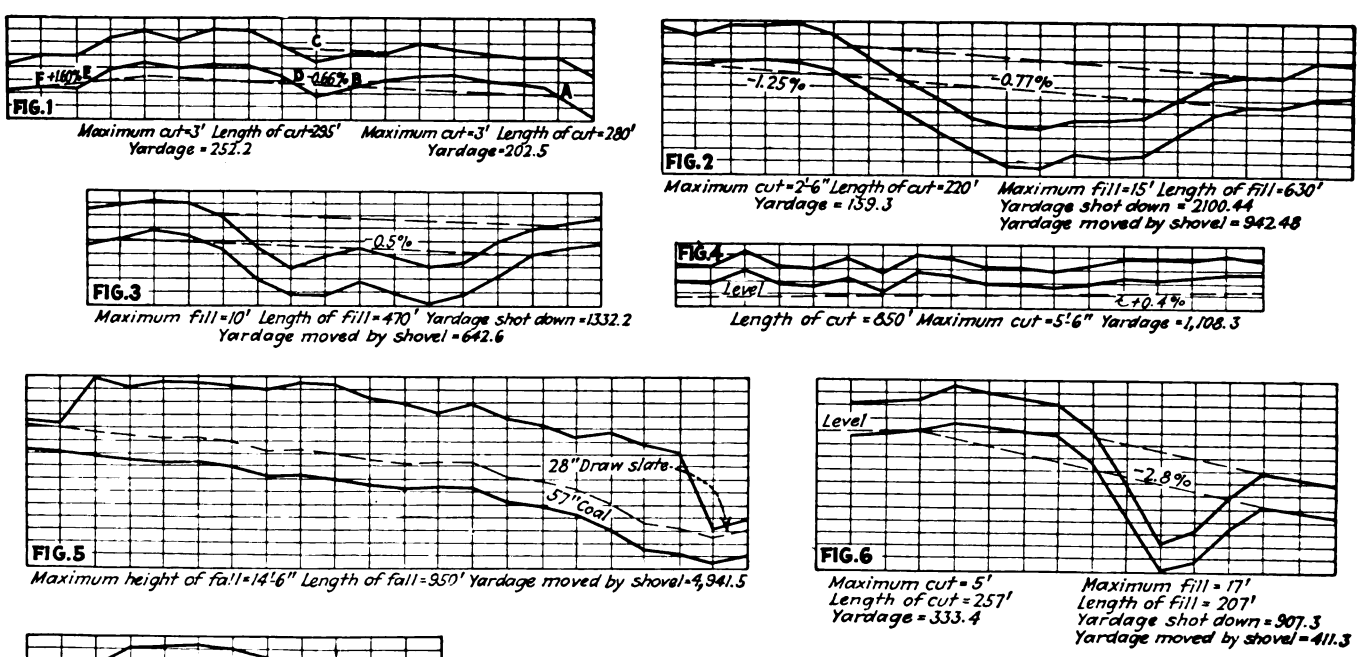

Fig. 5 shows a long heavy roof fall. For a distance of 950 ft. the top of this entry fell to a maximum height of 14 ft. 6 in. The above statement is misleading in that the fall did not take place entirely unaided. When the timbers along this heading began to show signs of distress and failure, the roof was drilled and shot, bringing rock and timbers down together. The rock was then loaded out, many of the timbers being reclaimed in this process for use elsewhere. In this particular fall 4,941 cu.yd. of material in the solid were loaded by the shovel, slight inequalities in the floor being filled in the process. The actual yardage of loose material loaded and hauled away thus amounted to almost 10,000 cu.yd.

Fig. 6 is another case of both a cut and a fill, but in this instance the fill was unusually thick and heavy. It was made in a sharp local dip where the pitch of the coal at one end was so steep that a locomotive could not ascend with more than one or two cars and not even then unless it had a running start. To overcome this difficulty the roof was shot down to a maximum depth of 17 ft. and over a distance of 207 ft. A total of 907 cu.yd. of solid rock was thus brought down, of which 411 cu.yd. were loaded out.

Bordering this dip on the left was a roll. Here the bottom was shot up over a length of 257 ft. and to a maximum depth of 5 ft. All of this material amounting to 333 cu.yd. of solid rock was loaded out by the shovel. The resulting grade now has an inclination of 2.8 per cent against the loads, whereas originally the maximum grade had been one of 22 per cent against them.

Fig. 7 shows how a hump or roll was cut down. This was on one of the main haulage roads and was causing much trouble. The improvement was accomplished in two operations, the first from *A* to *B* and the second from *C* to *D*. The total length of the entire job was 380 ft. and the yardage moved 322 cu.yd.

Probably the chief interest in this cutting down of a bothersome hump centers in the first cut made because of the rapidity with which the work was accomplished. The first cut was approximately 245 ft. long, its maximum depth about 3 ft. and its cubical contents 166.6 cu.yd. in the solid. Work of tearing out track was begun after the day's run on Friday. The track was removed, the place drilled and shot and all loose material loaded

Mine-Grade Adjustments in a Kentucky Coal Mine

Mechanical loading of rock, with an inexpensive means of removing it from the mine cars and disposing of it on the surface, made the work, though expensive, a notable economy in operation. The removal of the fissured rock shown in Fig. 5 eliminated heavy timbering and some danger from falling rock.

Digitized by Google

out by Sunday afternoon. The track was then relaid and was ready for traffic by Monday morning. In this case, however, the cut was accessible from both ends. Accordingly, one shovel started at *A* and the other at *B*, the shovels working toward each other. Thus, starting to shovel on Saturday morning, they met on Sunday afternoon, after loading as stated, 166 cu.yd. of solid, or approximately 325 cu.yd. of loose, bottom rock.

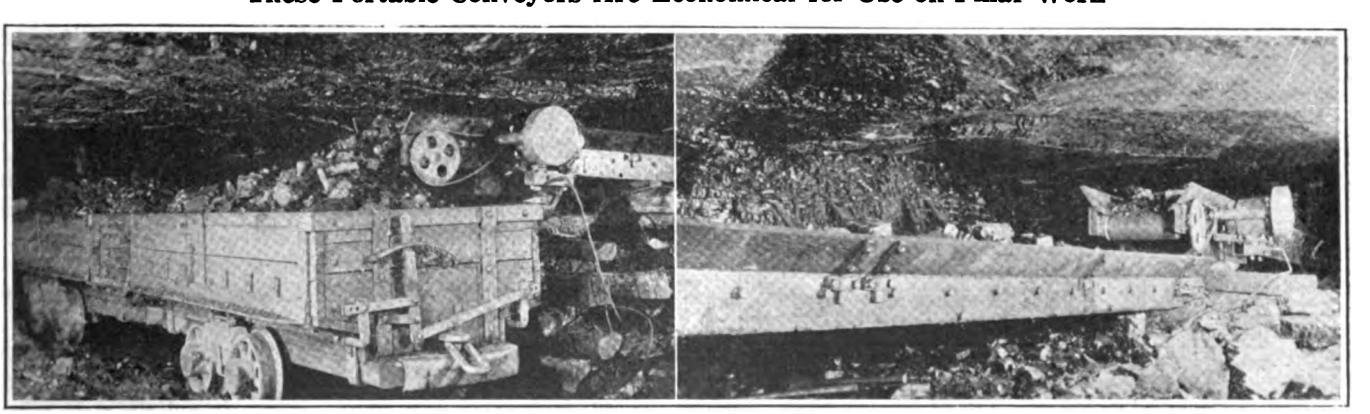
Rock shoveling in these mines is done mostly at night. Where no track is laid in the place ten 7-ft. sections of 40-lb. rail laid on steel ties have been provided. These can be laid section after section in front of the machine as it advances. Each of these sections is provided with fish plates which may be slipped over or a-straddle the webs of the rails of the track already in place and quickly bolted fast. At the first opportunity, usually the next day, this temporary track is replaced with one of a more permanent nature. Of course if permanent track is already in place and only the roof is to be brushed, the top is shot down directly onto the rails and the fall cleaned up without recourse to temporary track of any kind.

Speed of loading depends largely upon the conditions of the material to be handled and the distance over which both the loads and empties must be hauled. A car containing about 5 tons of rock can be loaded in about 5 min. This might be taken to indicate that 140 to 145 cars of this material could be loaded in the course of a 12-hr. night shift. As a matter of fact shifting cars and the breaking down of big lumps either with sledges, by hand or by mud capping consumes so much time that especially when cleaning up falls only about seventy cars are normally loaded out per shift. Chunks much larger than 1-ft. cubes cannot be readily handled in the car dump employed at the tipple. As a result pieces of much larger size must be broken down. This is done either by hand sledges or by explosives.

In shooting roof the same explosive is employed as for bringing down the coal. For lifting floor 40 per cent dynamite is sometimes used, although here also a permissible will do the work. Sticks 1x6 in. are employed, all firing being done electrically using a low-voltage battery instead of a blasting machine.

For drilling the holes jackhammers are used. These are operated from a portable compressor that is electrically driven from the trolley wire. Steel 8 ft. in length is about the longest that is used with these machines, so that if a fill is of greater depth than this the rock must be taken down in lifts. However, it is seldom necessary to do this.

Inasmuch as a cut in the bottom can be shot harder and can thus be broken up much more thoroughly than a cut in the roof it represents a much better condition for the machine. The worst condition encountered in machine operation is what might be termed a natural fall or a roof that breaks and comes down of itself. Most such falls can be anticipated and the roof shot before the timbers are crushed. Even this latter procedure, however, results in bringing down the roof in such large pieces that it is sometimes necessary to mud cap and shoot after each two or three cars are loaded. This means much delay.



ROCK IS WASTED OUTSIDE

In these mines practically all the rock that is loaded by power shovel underground is hauled to the outside. Here it is discharged in the same dump as the coal being segregated from it by means of fly valves in the chutes. The rock takes a course through the tipple that is separate from that taken by the coal and after being joined by the slate and refuse picked from the mine product is conveyed by belt to the slate bin. Thence it is taken by slate larries, hauled around a small spur on the hillside and dumped.

Direct savings made by the use of power-operated equipment, even though they may be large, are frequently far outshadowed by and become a secondary consideration when compared with the indirect savings obtained. In the specific case of the power shovel as used at the mines mentioned, although it makes a large saving in the cost of handling rock, yet its chief advantage probably lies in the speed with which its work is accomplished.

At best only two hand shovelers can work to advantage in a 12-ft. heading—any more would be in each other's way. On the average two such men would load out about five cars of rock each, or ten in all during a shift. The shoveling machine on the other hand, operated by a crew of from two to five men, depending upon the condition of the material to be handled, as has been stated, can load an average of about seventy cars per shift. Thus a machine removes roughly seven times the quantity of rock that could be handled by the gang that it supplants. It is this speed of operation that particularly commends its use.

These Portable Conveyors Are Economical for Use on Pillar Work

These conveyors are in the mines of the Phelps Dodge Corp. at Dawson, N. M. They are used exclusively in retreating room stumps and chain pillars. This process saves considerable brushing and relaying of tracks according to W. C. Holman, chief engineer at the Stag Canyon Branch operations of the company. The illustration shows two 20-ft. conveyors in tandem retreating on a chain pillar. The left-hand picture shows the delivery end with coal being deposited in a car.

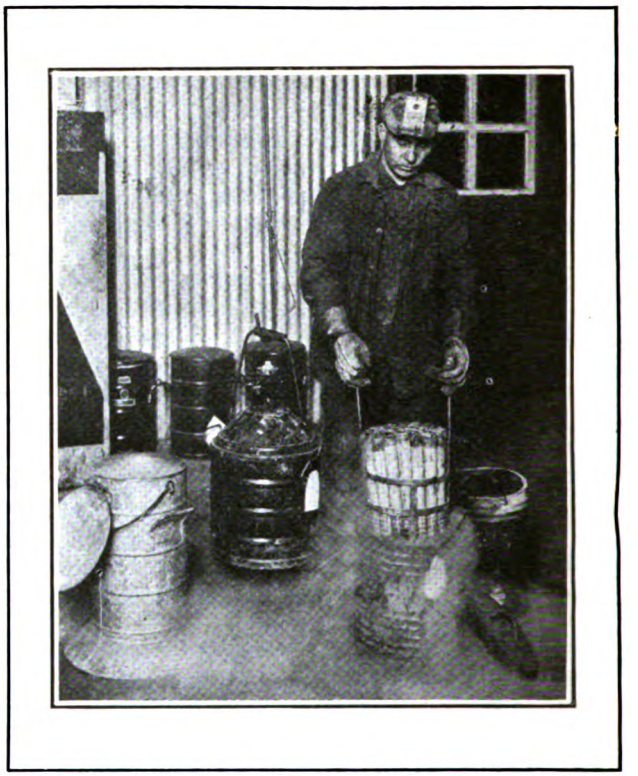
Liquid Oxygen Desirable For Strip-Pit Work

Being Combustible But Not Subject to Detonation Flame or Light Concussions the Cartridges Are Safely Handled

THAT liquid-oxygen cartridges are not suitable explosives for use in coal mines, because of the long flame that results from their detonation and because they are quite readily combustible, is conceded now by everyone. They have, however, been proved advantageous for use in open-pit work including in that designation coal and other strip pits.



During the past few years much has been heard in this country concerning the possibilities of using as an explosive for mining some form of combustible saturated with liquid oxygen. Such an explosive commonly known as L.O.X., has for some years been used in blasting down ore in the iron mines of Lorraine, France. An investigation of this substance, its possibilities and limitations has been conducted by Frederick W. O'Neil, chief engineer of the Ingersoll-Rand Co. and Herman Van Fleet, vice-president of the Air Reduction Co. The following is an abstract of their paper as presented before the winter meeting of the American Institute of Mining and Metallurgical Engineers, Feb. 17, 1926, by Mr. O'Neil.

Reliable apparatus for the production of liquid oxygen has been fully developed and perfected. Operating on the so-called Claude system, which requires compression of the air to only about 900-lb. pressure, liquefaction of the air and fractional distillation with recondensation of its oxygen content, commercially pure oxygen can be produced at an estimated cost of 2.29c. per pound.

Pouring Liquid Oxygen on Cartridges

This is done at the central charging station. Note the cartridges in a basket, the soaking container on the left and the dry carriers on the right. The cut in the upper corner of the page shows the attendant transferring the soaked cartridges to a dry carrier at the same station.

Theoretically the oxidation of pure carbon to carbon dioxide (CO_2) requires 2.67 units of oxygen by weight for each unit of carbon. Similarly, its oxidation to carbon monoxide (CO) requires 1.33 units of oxygen. As commercial carbons are not chemically pure, and as the cartridge wrapper is cellulose and not carbon, it has been assumed that 2.5 times the weight of the cartridge is required for its oxidation to CO_2 and 1.25 times the weight of the cartridge for its oxidation to CO.

Ideal requisites for a cartridge of this kind are as follows: (*a*) Maximum density in order to provide a maximum of explosive in a given volume. (*b*) Ability to absorb liquid oxygen in excess of all requirements for complete combustion so as to provide for oxygen evaporation prior to detonation. (*c*) The physical properties of both the filling material and the wrapper should be such as to render the soaked cartridge mechanically strong in order that it may be handled without breakage. This applies particularly to the wrapper which must not be too brittle at the low temperature of the liquid. (*d*) The price of the filling material must be low enough for commercial use. (*e*) The soaked cartridge must be firm and dry. With some filling materials, especially when lightly packed, liquid oxygen readily squeezes out of the cartridges making them difficult to handle.

It should be noted that a material giving maximum requirements of density tends to give minimum capacity for absorption. The commercial cartridge, therefore, will be a compromise between these two requirements.

Approximately 400 varieties of carbon blacks, lampblacks, hydrocarbons and various mixtures were investigated. Many of these materials were rejected in the laboratory because of their high cost, low densities or low absorptive qualities. Several varieties of carbon blacks and lampblacks of satisfactory cost (from 6 to 9c. per lb.) and of satisfactory density and absorption qualities were selected. From this list of possibles

Digitized by Google

a lampblack and carbon black were finally chosen as the best absorbents, and further laboratory tests and practical experiments were confined to these materials. Both of these absorbents are procurable in large quantities and at reasonable prices.

Cartridge wrappers must possess the following qualities: (*a*) The material should be combustible; (*b*) it should allow liquid oxygen to permeate it readily and (*c*) it must not be brittle or fragile during soaking, in order that the soaked cartridge may be handled without breakage. It is desirable also that it should retain liquid oxygen while at the same time allowing sufficient evaporation to prevent rupture of the cartridges by expansion of the gas. After experimentation and testing, the material finally selected was a pure rag-stock paper varying in thickness from 0.007 to 0.010 in. Papers which are filled or sized are unsuitable because of their brittleness at the low temperature of soaking.

Considerable difficulty was experienced in making a suitable cartridge. Gumming or gluing the wrapping paper renders it impervious and brittle, and a spirally wrapped ungummed cartridge is liable to sift filling material. A satisfactory cartridge was finally developed, rolled from a piece of paper of rhomboid shape. A machine gums this paper along one edge, so that when rolled into shape this edge circles the cartridge spirally. One end of the cartridge is crimped by this machine and the other is crimped by hand after filling. Both ends are then immersed in paraffin to a depth of about ¼ in., thus preventing sifting.

It was soon discovered that hand filling of cartridges was unsuccessful, and a simple machine was developed for this purpose. In this machine a spiral screw acting within the storage hopper causes the filling to exude from a nozzle at its lower extremity. The cartridge is placed on a weighted platform below this nozzle, and the carbon is forced into it against the pressure exerted by the weight. Any desired density of filling may thus be attained. The term density as here used indicates the mean apparent density obtained by dividing the gross weight of the cartridge by its gross volume.

The cost of unsoaked cartridges is about as follows:

7 x 20 in. 8 lb. cartridge, cost per lb. 15 c.	—	cost per cartridge	$1.19
4½ x 18 in. 3 lb. cartridge, cost per lb. 14 c.	—	cost per cartridge	.42
1½ x 12 in. ½ lb. cartridge, cost per lb. 24 c.	—	cost per cartridge	.04

In the accompanying illustrations Fig. 1 shows the relation between the weight of large cartridges that have been soaked and the time that they have been exposed after absorbing oxygen, and Fig. 2 shows the same relation for small cartridges. Fig. 3 shows the time in minutes taken by cartridges of different densities but of the same composition for the evaporation of excess oxygen down to the quantity necessary for complete combustion to carbon dioxide. This graph would at first indicate that the low-density cartridges are preferable as they give a longer life. As a matter of fact, however, the quantity of carbon present is smaller and their strength per unit of volume is thus decreased. The selection of the proper density, therefore, becomes a compromise between long life (low density) and explosive strength (short life and high density). Cartridges of extremely low density are unable to hold the liquid oxygen and some of it runs out when the cartridge is removed from the soaking bath.

From Europe has come many reports of the excellent results secured from the use of a substance known as carbene. This is made from acetylene gas and not much difficulty is found in its manufacture. Little hope is seen for the use of this material as an oxygen absorbent because its cost is prohibitive, and the tests already made show it to be inferior to lampblack.

Liquid oxygen may be stored and transported in Dewar flasks or vacuum bottles. These consist essentially of an inner and an outer shell with a vacuum space between them containing a compartment in which is placed a small quantity of activated charcoal. The outer vessel is provided with a lead tube which is connected to an air pump and by this the vacuum space is exhausted. When the required degree of vacuum has been obtained this pipe is pinched off and the end soldered over. At the low temperature existing in the flask when filled with oxygen the activated charcoal absorbs the residual air in the vacuum space. The whole flask is then surrounded by a sheet-steel case, the space between it and the outer container being filled with excelsior or similar material. Such flasks have shown themselves to be highly efficient in the shipment of liquid oxygen by combined railroad and motor-truck transportation, the entire journey taking three or four days. The average loss in transit from eighty 15-liter containers amounted to 10 per cent per 24-hr. day. At rest these same flasks had a loss from evaporation of 7.6 per cent per 24-hr. day.

It is believed entirely feasible in liquid-oxygen plants to store the oxygen in double receivers large enough to hold a 24- to 28-hr. supply. Although no data are available concerning the evaporation that would take place from vessels of this capacity, it is believed that owing to the large ratio between the volume and radiating surface as compared with small flasks, vacuum insulation would probably be unnecessary and hair felt or mineral wool could be used instead. Such receivers should, however, be made of copper or of a copper alloy; steel is unsuited to this purpose because it is liable to develop fine cracks at the low temperatures encountered.

Experience concerning the maintenance of vacuum equipment has not extended over a period sufficiently long to give satisfactory data. Out of 55 such containers fifteen had to be re-evacuated at the end of one year. Loss of efficiency in containers of this kind arises less from a loss of vacuum than from the fact that the inner and outer shells come into contact from rough handling. The re-evacuation of vessels of this kind is not difficult and can be readily performed at the mine.

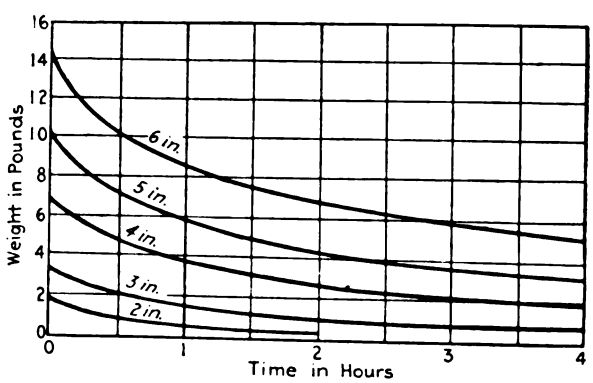


Fig. 1—Typical Time-Evaporation Curves for 12-in. Cartridge of Large Diameter

The cartridges of 6-in. diameter after two hours have less than half and after four hours about one-third of their original charge still left. The carbon is in a cotton bag. The exposure is made to the open air.

Digitized by Google

A suitable vacuum gage and a small 2-stage oil-immersed vacuum pump are all the equipment required.

Cartridges are soaked in straight-sided Dewar flasks. These are built on the same constructional principles as the transportation containers. In order to facilitate handling, the cartridges are placed in copper-wire baskets which fit easily within the container. Before starting to use a flask of this kind a small quantity of oxygen should be placed in it so that it may become chilled before the soaking of cartridges begins. In containers of this kind hair-felt insulation gives almost as good results as a vacuum.

In soaking, the cartridges are placed in a copper-wire basket which is lowered into the soaking container after which the oxygen is poured in. Fig. 4 shows the results of tests, setting forth the time required to soak cartridges of various diameters. It will be noted that when a cartridge sinks it is practically saturated and that the time required for complete saturation is from 15 to 18 min. A 5-in. cartridge requires about 30 min. for complete saturation.

Because vacuum soaking containers are rather awkward to handle and liable to damage, and inasmuch as hair-felt insulation has practically the same efficiency, what is termed a dry carrier has been developed. This consists of a double-wall vessel with about 1½ in. of hair-felt insulation between the walls, the inner vessel being made of copper and the outer one of steel. After the soaked cartridges have been removed in their basket from the soaking container, they are placed in a dry carrier into the bottom of which a little liquid oxygen has been poured. The cartridges then tend to remain saturated through capillarity from the oxygen in the bottom of this carrying vessel. Tests to determine the ability of the cartridge to take up liquid oxygen by capillarity are set forth in Fig. 5, which gives the effect of standing a dry unsoaked cartridge on end in one of these dry carriers in which a little liquid oxygen has been placed, this liquid being maintained at a constant level. This test shows that the dry cartridge is able by capillarity alone to absorb enough oxygen to reach a point between its carbon-monoxide and carbon-dioxide requirements.

Fig. 6 shows the evaporation that takes place when soaked cartridges are placed in a dry carrier with a little liquid in the bottom. This sets forth conclusively that it is entirely practicable to keep cartridges in this way 1½ hr. after soaking before use. The results shown were obtained with cartridges of rather low density and with the carrier only two-thirds full. With cartridges

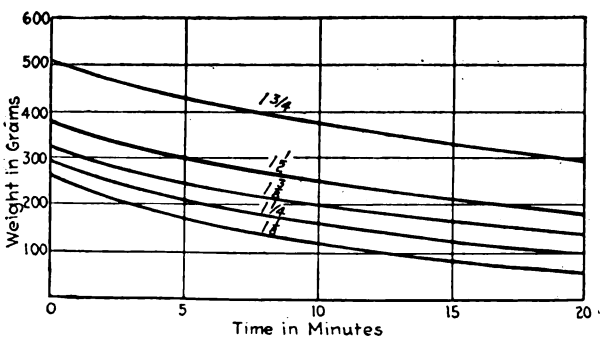

Fig. 2—Typical Time-Evaporation Curves for 10-in. Cartridges

Curves show that the weight of the liquid oxygen decreases rapidly in the cartridges as time passes. The carbon is held in a paper wrapper, and the cartridges are exposed in the open air after soaking. Note this graph has a different time scale from that of Fig. 1.

of higher density, such as are usually employed and with the carrier well filled, the loss of oxygen would be reduced about one-half. The vacuum soaking container thus need not be carried into the working places, but the cartridges may be prepared at a convenient central point. This permits a large saving in labor and trans-

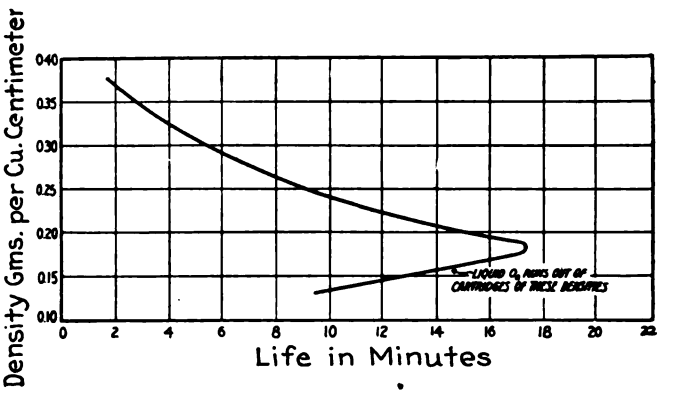

Fig. 3—How Cartridge Life Varies with Density

Dense cartridges hold but little liquid oxygen and have a short life. Loose cartridges take up a lot of oxygen but leak badly when they are no longer immersed and so they are undesirable. A happy mean is to be preferred.

portation as well as a reduction in wear and tear on the vacuum equipment. It also allows the use of larger containers and makes possible the saving of a large quantity of oxygen which would otherwise be lost.

The strength of any explosive is a function of the total energy it develops and the rate at which this energy is liberated. The methods most commonly used for determining the total energy are the ballistic pendulum and the Bichel gage. Many tests carried out in the explosives laboratory of the Bureau of Mines at Pittsburgh indicate that carbon is the best absorbent for liquid oxygen of all the materials tested and when properly soaked is practically equivalent to 40 per cent dynamite.

In the Bichel gage, or closed bomb, various cartridges were tested. As the insertion of the cartridge, closing of the bomb and getting ready for firing requires about 10 min., the soaked cartridges cannot be fired in this device at the theoretically correct time. The conclusion could be drawn from these experiments, however, that carbon L.O.X. cartridges are superior to those made from other substances volume for volume.

Comparisons with rate of detonation of trinitrotoluol cordeau by the Dautriche method showed that the rate of detonation of L.O.X. cartridges when fired at the CO_2 point, ranged from 5,520 meters (18,100 ft.) to 5,950 meters (19,400 ft.) per second. This rate varies somewhat with the length of time that the cartridges have been removed from contact with the liquid oxygen before firing. The longer the cartridges are exposed to the air the slower their rate of detonation. With 1½x8-in. carbon cartridges this rate of detonation changed from approximately 4,850 meters (15,900 ft.) per second at 5-min. exposure to the air to 4,150 meters (13,600 ft.) per second after an exposure of 30 minutes.

Tests were also made on the continuity of detonation. For this purpose a string of 1¼x12-in. cartridges 40 ft. long, was laid with the cartridges end to end and in contact. This was detonated by a cap in the end cartridge. All cartridges in this string detonated uniformly. Cartridges of the same size were then laid on the ground end to end with an air gap between adjacent cartridges. It was found that straight carbon car-

Digitized by Google

tridges would detonate in this way across an air gap of from 5 to 7 in. By the addition of suitable hydrocarbons, or metallic powders, the gap across which they could be made to detonate could be increased to 20 in. or more. Tests conducted on 1¼x12-in. cartridges in a drillhole, placing one cartridge in the bottom and detonating another at the collar, demonstrated that the bottom cartridge can be detonated across a gap of 3½ ft. or more. Evidently no difficulty will be experienced in mining because of failure of the cartridges to touch each other in the hole.

It was found impossible to detonate any of the carbon L.O.X. cartridges in the open air by flame alone, that is, by a fuse inserted in the cartridge. Caps in this case were necessary in order to assure detonation. When confined in a drill hole, however, the cartridges can be detonated by a fuse without cap, this being the standard practice in the iron mines of Lorraine. The tests on different strengths of detonators showed that they all had a like effect upon this explosive and that one strength of cap was as effective as another.

Tests were also conducted to determine how small the quantity of oxygen in the cartridge could be and still secure detonation. Cartridges were exploded that contained only 3.3 per cent of the oxygen necessary for their combustion to carbon dioxide. As the oxygen evaporates from one of these cartridges there is a tendency to leave a saturated core in its center, and detonation can be obtained as long as this core is present provided the cap is in contact with it. A 4-in. cartridge was detonated after the lapse of four hours in the open air.

Sensitiveness of the new explosive to impact was also tested. In the large impact testing machine at the Bureau of Mines laboratory the explosive was placed between steel disks and a weight of approximately 440 lb. dropped on it from varying heights. The explosive can be fired in this manner without difficulty. Many attempts have been made to detonate it by throwing cartridges against rock faces in stopes at distances of from 60 to 80 ft. In every case the cartridge failed to detonate. Dropping a miner's acetylene lamp that had previously been lighted into a container full of prepared cartridges was also tried. The cartridges did not detonate but were set on fire, producing a large flame of intense heat. A high-power rifle bullet fired through the container detonated its contents.

Tests made in the friction-testing machine in the Bureau of Mines laboratory showed that L.O.X. would not detonate under either the fiber or steel shoe. These and numerous other experiments have demonstrated

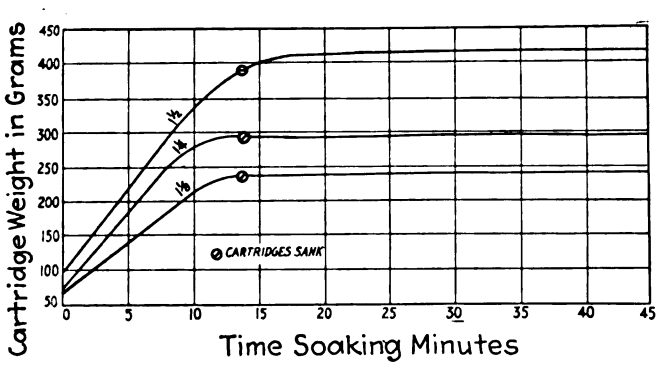

Fig. 4—Time Required to Soak Carbon Cartridges Beginning with Pouring

Note that the large cartridge is soaked almost as rapidly as the smaller cartridges. After sinking the latter gain little, if any, weight, but the large cartridge makes a slight absorption.

that with the smaller cartridges having densities of approximately 0.3, fired within 10 to 12 min. after soaking, L.O.X. is equivalent to 40-per cent dynamite, volume for volume. For the larger cartridges, the same holds true for firing at 30 to 45 min. These firing

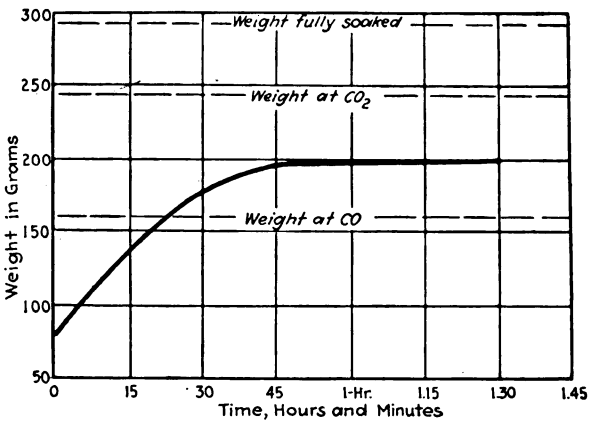

Fig. 5—Capillarity Test, 1¼x12-in. Cartridge

The dry cartridge is set on end in 1-in. of liquid, the liquid being maintained at constant depth. The dry weight of the carbon cartridge is 69 g.

periods are based upon the loss of oxygen taking place in the open air and are extended considerably when the cartridges are confined in a drill hole. This extension in the smaller diameter of cartridges ranges from 15 to 20 per cent.

One of the chief disadvantages in the use of L.O.X. in highly abrasive rock lies in the fact that the gage of the drill is appreciably decreased during the drilling process with the result that the holes are tampering. Inasmuch as the cartridges are practically solid they will not deform and fill the hole perfectly in loading. Their effectiveness in breaking rock is thus somewhat decreased.

In practical operation electric firing was found to be effective but under the conditions where the explosive was tried better results were obtained by shooting with fuse. This was crimped into an ordinary cap which was placed within a brass tube, into the other end of which a piece of ordinary cordeau was inserted. The brass sleeve protected the detonator during loading, and the cordeau acted somewhat as a booster.

All practical tests with these explosives tend to verify the work done in the laboratory and the conclusions drawn therefrom. In the light of the work done at Mineville, the following conclusions may be drawn so far as underground mining is concerned—(1) Where the ground is heavy and abrasive, causing the drillholes to be considerably tapered, L.O.X. costs more than dynamite. (2) Where the method of mining involves drilling of comparatively shallow holes without a large loss of gage, this explosive may be commercially profitable, especially where the price of dynamite is high. (3) The use of L.O.X. does away with the necessity of maintaining a stock of explosives at the mine and renders the powder supply independent of interruptions in transportation. (4) It has been shown that there is no danger from the premature detonation of this new explosive. There is, however, a danger of premature ignition resulting in violent long-flame conflagration, which would be dangerous in confined spaces underground. In loading holes, there is some danger of the liberated gas blowing out the stemming, and, perhaps, of ignition of carbon-laden gas by miners' lamps. The danger of drilling into missed holes is

Digitized by Google

eliminated, and upon this score the new explosive is safer than dynamite. (5) The use of the new explosive for shooting down coal is not recommended because of its long hot flame. (6) When firing must be done simultaneously in a large number of adjacent places, it is much more difficult to synchronize this work if L.O.X. is used than if dynamite is employed. (7) More holes are lost with L.O.X. than with dynamite because the fuse is not held as firmly. Also, inasmuch as the cartridges fit the hole loosely, they are sometimes jarred out by the detonation of adjacent holes. If a cartridge jams in loading, because of the hole being crooked, there is no time to remedy it, and there is usually no time to reload a hole that blows out its stemming by evolved gas.

While operations were going on at Mineville, oxygen was shipped to various quarries and such highly satisfactory results obtained that the liquid-oxygen plant was moved to Lebanon, Pa. From this point many quarries and open-pit operations could be reached. Tests were then made in a wide variety of rocks. These trials were mostly conducted in 6-in. holes, there being a few 2-, 4- and one 8-in. hole. The depths to which these holes were drilled varied from 6 to 106 ft., and the number of holes fired simultaneously ranged from 1 to 40. From the plant at Lebanon oxygen was shipped over long distances sometimes being held in the transportation container as long as 96 hr. For this purpose containers of 50-liter capacity, with a loss of about 3 per cent in weight per 24-hr. at rest, were employed. The loss was about twice this quantity when the containers were agitated during travel.

Most of the cartridges used in this work measured 4½x18 in. and a few were 7x24 in. These were made of the straight carbon black but were incased in cylindrical cotton bags, instead of in paper, as the large paper containers were found to be too fragile to withstand handling. Because of the large size of the cartridges and the necessity for soaking a great number at a time, large soaking tanks were developed. These were merely copper-lined boxes insulated with hair felt.

A continuous length of cordeau from the bottom to the top of the hole was used in these large blasts. This was first placed in the hole and all the cordeau from the various holes were spliced to a common trunk line which was detonated electrically by a single cap.

In introducing the cartridges into the hole a flared copper funnel, about 6 ft. long was used. This both guided the cartridges and kept surface material from falling into the hole. The stemming used was generally loose earth merely shoveled into the hole without tamping. As a rule each hole was filled to the collar. In no instance was the stemming blown out. Neither was difficulty experienced in loading wet holes, and some were fired that were filled with water to the collar. In forty-nine blasts of this kind only four encountered difficulty, and investigation of these disclosed the fact that they were not charged or fired properly due either to miscalculation or to inadequate facilities at the time of charging the hole. With these exceptions all the shots were successful in every respect.

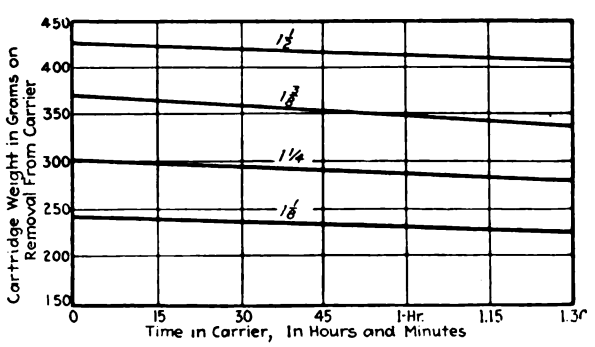

Fig. 6—Oxygen Loss in Dry Carrier

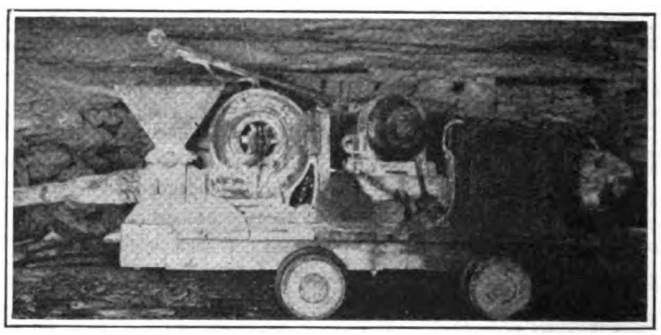
Here the fall in the oxygen content is much slower, of course, than in open air. Compare this with Figs. 1 and 2 where the evaporation is unhindered. Note also the difference in the time scales. The cartridges are stable enough that they can be made in a central loading station.



From the total quantity of dynamite replaced, as well as from the quantity of oxygen and dry cartridges used in all of these blasts, it would appear that 1 lb. of dynamite could be replaced by 0.935 lb. of oxygen, measured as produced at the liquid-oxygen plant. This, therefore, includes all losses of every sort. It also appears that 0.201 lb. of dry cartridge are required to replace 1 lb. of dynamite.

As to cost, to replace 1 lb. of dynamite for this class of service, 0.935 lb. of oxygen is required at 2.29c. per lb., making a cost of 2.14c., also 0.201 lb of. cartridge at 14c. per pound, or 2.83c. This makes a total cost of 4.94c. to replace 1 lb. of dynamite.

Rock-Dusting Gains Slowly In Alabama Coal Mines

Eleven Companies Now Dust Fifteen Mines—Powdered Dolomite is Used Exclusively—Most Machines For Applying It Are Home-Made

DURING the past calendar year rock-dusting did little better than hold its own in the coal mines of Alabama. It was inaugurated at a number of mines in 1924 awakening wide interest throughout the state but gathered only two converts in 1925. The Woodward

This One Is Electric

Rock-dusting machine used at Sayre mine of the Gulf States Steel Co. The motor at the right does the propelling. Push-Button control makes the machine simple and safe to operate. When not engaged in emptying bags of dust into the hopper the operator sits on the platform beside the hopper and directs the flexible leather nozzle.

Iron Co., which has been recognized as a leader in safety measures has not yet seen fit to slacken its intensive water sprinkling program in favor of rock dust.

The present status of dusting in the state is as follows: Approximately 1,700 tons of rock dust has been applied by eleven companies in fifteen mines. Practically all of the dust used was powdered dolomite. At least six of the eleven companies are using dusting machines of their own design and manufacture. Some are scattering the dust by hand. Few dust barriers have been installed.

The Gulf States Steel Co. and the Galloway Coal Co.

Digitized by Google

were the pioneers in Alabama rock-dusting. The former company has dusted 64,450 ft. of gob entry in the Sayre mine using 208,200 lb. of rock dust or 3.23 lb. per linear foot of entry. Early in 1925 the Galloway company completed the dusting of its No. 11 and No. 15 mines but has not included any of its other mines in the program.

The self-propelling distributing machine used at the Sayre mine is shown in one of the illustrations. On this machine, which was designed and built at the company shop, a separate motor is provided for propelling and both motors are controlled by fully-enclosed automatic starters. It takes but one man to operate the machine.

The rock dust in 50-lb. bags is carried in a mine car attached to, and pushed ahead of, the duster. Without stopping the machine, the operator empties the 50-lb. bags into the hopper, and between times sits beside the hopper and directs the leather nozzle as the character and shape of the entry demands.

In September, 1924, rock-dusting was started in the mine of the New Castle Coal Co., at New Castle, Ala. At that time two miles of entry were dusted. This territory was given a second dusting in March, 1925, and a third application in October of the same year when the work was extended to the face, making a total of somewhat over five miles of dusted entry. Samples taken just prior to the October application showed the combustible to be still above the assumed safety limit of 60 per cent.

In this mine 4 lb. of rock dust per linear foot of gobbed entry was applied at the first dusting. In the second and third applications 2 lb. per linear foot was used.

The gasoline-driven machine used at New Castle is shown in another illustration. A mule is used to pull the machine and dust car. The dust is handled in 100-lb. bags and the machine hopper holds 500 lb. The 16-in. blower is driven by a 2½-hp. engine. Feeding of the dust into the blower discharge pipe is accomplished by a rotating cylinder 4 in. in diameter and 8 in. long. This cylinder contains four measuring pockets and its drive shaft is fitted with cone pulleys providing for three speeds.

The powdered dolomite used in Alabama mines is all fine enough to pass through a 40-mesh screen, and

A Gas Engine Drives It

This duster is used at New Castle. M. G. Launius, superintendent, is standing back of the machine. It is not self-propelling. A mule furnishes the tractive power for the machine and a dust car. The blower and feeder are driven by a 2½-hp. engine.

60 to 70 per cent is of 200-mesh. The price, f.o.b. the mill in bulk, is $3 per net ton. In 100-lb. bags the price is $4.75 per ton, with a rebate of $1.50 for the return of all of the bags in good condition. If put up in 50-lb. bags the price is $6.50 per ton with possible rebate of $3.

The cost of applying the dust varies widely. A fairly representative figure is that of a company which reports that its labor cost is $5.11 per ton of dust applied. The labor and material cost is $1.63 per linear foot of entry. This company uses a self-propelling machine which requires but one operator.

The future development of rock-dusting in Alabama will no doubt depend somewhat upon the action of leading companies such as the Tennessee Coal, Iron & Railroad Co., and the Woodward Iron Co. The Alabama Fuel & Iron Co., one of the large producers, recently decided to rock-dust all of its gassy mines and has bought a dusting machine and two carloads of dust with which to start.

Contrary to the usual order, rock-dusting in Alabama was not started by the larger companies but instead by the medium-tonnage producers. It is now spreading slowly but surely to include companies of all sizes.

COAL AGE INDEX

THE INDEXES *to COAL AGE are furnished free to all who ask for them. The index for the last half of 1925 is now ready for distribution. A copy can be had by addressing a postcard to the subscription department of COAL AGE.*

These Entries Are Dusted According to Alabama Practice

At the left is a view down the 14th straight in Sayre mine. Here roof and ribs are rock-dusted. The bottom is kept wet by daily sprinkling. Spillage of fine coal from end-gate cars is considerable. Frequent rock-dusting would be required if an effort were made to keep the combustible matter in the roadway dust down to the safety limit of 40 per cent. In the center is the rock-dusted main slope of the New Castle mine. Two miles of entry was dusted in September, 1924, when the practice was adopted. At the third dusting, in October, 1925, the work was carried to the face. About five miles of entry in the mine is now dusted. At the right is the second straight cross off the 14th left in Sayre mine. This entry was dusted for the third time about a month before the picture was taken. Rock-dusting with the light colored dust used in Alabama relieves a mine of much of its gloom.

Why Tuberculosis Rate Is Low in Missouri Mines

In the editorial on p. 150 of the Jan. 28 issue of *Coal Age*, the tuberculosis rates in the northern part of the state of Illinois are shown to be higher than in the state of Missouri though there is much rock brushing and bottom lifting in both of these low coal areas and the question is asked: "What gives the Missouri miner his low tuberculosis rate?" This question appears as a comparison with the northern Illinois condition. I believe the reasons to be as follows:

The Missouri coal mines are moist and there is a minimum of dust of either rock or coal in suspension.

The northern Illinois coal mines are dry to a much greater degree than the mines of Missouri, with the consequent increase in the quantity of rock and coal dust found suspended in the air of the mines.

You will probably remember that whereas Missouri has in the past been quite a coal-producing state, its record for explosions in the last twenty years has been low.

A. W. DICKINSON.

Rock Springs, Wyo.

Shooting More Important Than Shearing

Mr. Levin's article, in your Dec. 31 issue, on a new shearing machine again brings up the perennial question of center shearing as an aid in producing more lump coal.

At the 1924 summer meeting of the Rocky Mountain Coal Mining Institute I presented a paper on this subject (subsequently reproduced in *Coal Age)* in which was set forth the results of a number of tests made in Clear Creek Mines of the Utah Fuel Co., all of which indicated that shearing was not advantageous.

Up to that time my experience in cutting and shooting had covered only the usual blocky type coals; recently, however, a case where the coal was decidedly laminated came under my observation, and it seemed that shearing would be a great aid in securing more lump and in preventing over-shooting. No opportunity was afforded to try machine shearing, but some tests with the pick confirmed the view that shearing would result in considerable economies.

In the article referred to I pointed out certain inherent difficulties in shearing, among which was the relative instability of the cutter bar when putting in a vertical cut. The kerf in shearing is apt to overrun the expected width enough to upset all calculations as to the amount of slack to be produced. I was never able to reduce the percentage of slack by shearing. I was able to produce somewhat larger and better lump, but never to an extent that would make the process economical.

Mr. Levin also states that it is questionable if snubbing the face will yield results comparable with center shearing in increasing the percentage and grade of the lump. This is a surprising statement, though it probably will hold good in the rather rare cases of highly laminated coals. In the case of blocky coals, however, snubbing with proper depth of undercut and properly controlled shooting is by long odds the most promising method.

LONGER BARS NEEDED

In the matter of cutting practices, too, much dependence has been placed on the machinery builders and not enough on the technical staff of the mines. The determination of the proper length of cutter bar for a given mine is seldom given much attention, and often the changing of the length of the bar makes a surprising difference in the amount and grade of the lump. There is one certain length of bar for each seam or mine that will give maximum results. I am convinced that longer bars than are now customary will prove feasible and economical in most cases.

The crucial point in all programs for improved mining is blasting. In most districts the rule-of-thumb methods of practical miners prevail, in others overworked pit bosses and powder salesmen conspire to "improve the shooting," often with quite good results. The old theory of the independent miner furnishing his own supplies and being responsible for every detail of his "place" still hangs like a millstone around our necks, hampering progress at every turn. I know of one instance where the profit on the sale of powder to the miners through the company store prevented the adoption of a shooting system that promised large economies.

Wholly aside from its safety aspects, shooting looms large in any economic study of detailed mining expenses. That it, along with dozens of other serious matters, is concealed in a "contract mining rate" by no means minimizes its importance. In fact the big job just now is to segregate this contract mining rate into its detailed elements, study each one as we study hoisting or greasing pit cars, and apply the knowledge thus gained in reducing costs.

When we get down to brass tacks and apply scientific studies and methods to our blasting practices there will be less demand for additional "loose ends" to shoot to, and the extra machinery, power and labor necessary to produce them.

THOMAS A. STROUP.

Quincy, Ill.

Coal Truck Aids Oil Tank

We have just had a very unique experience with our unfriendly competitor, oil. Our Park Ridge yard had a hurry call from a man who used to be one of our customers, but this fall put in oil. Our ex-customer asked us to loan him a heavy tow-chain, as a big oil truck from Hackensack which was delivering oil fuel to his house was stuck about a mile from him. With a sincere desire to help him out, we sent the chain and our driver to see what could be done to assist, but the latter returned about half an hour later reporting that the oil truck was stuck so deep in the snow that he did not think it would get out that night.

It looks as though our customer will be in bad, and perhaps run the danger of freezing up the plumbing in his house.

This is just another one of the oil-burner hazards that people do not usually think about at the time of oil burner installations. Although this customer's oil burner is a very high-priced affair, and supposed to be one of the best that's made, it is no better to him than any other on the market at a particular crisis like the above, and he might rather and much more safely have stuck to good old coal, the safe and standard fuel.

Book Reviews

Distress Follows Ruhr and Lorraine Separation

With civilized peoples, progress, comfort and wealth depend on the mineral resources of the soil as much probably as on the intelligence of the population. The Ruhr and Lorraine districts with their respective wealth of coal and iron will accordingly have much to do with the good fortune of the German and French nations by which they are owned. Coal is relatively useless without iron. No modern population can progress without the latter, and if it be not available, the coal is of but little industrial value. Today, owing to the war, the line between Germany and France is roughly that of the line separately the coal of the Ruhr from the iron of the Lorraine district. Unless, then the two can be brought together the deposits are of little value to either nation. The bitterness engendered by the war, therefore, acts to the detriment of both regions, creating a difficult international situation. This is the theme of the fifth volume of the series of books being prepared by the Institute of Economics on the problems of international industrial reconstruction.

Guy Greer, the author, appears to be an unbiased witness of the embarrassment caused by the divorce of the two regions, and in this book of 328 pages measuring 5x7½ in. he speculates on the effects that may be expected to follow. The title of the book is "The Ruhr-Lorraine Industrial Problem." The publisher is the Macmillan Co., 60 Fifth Ave., New York City, and the price, $2.50.

The World's Rival Fuels and How They Are Handled

A mine of information is the book on "Fuels and Their Combustion," by Robert T. Haslam and Robert P. Russell, professor and assistant professor of chemical engineering, respectively, at the Massachusetts Institute of Technology. Every part of the subject of fuels is covered, from their formation in the geologic ages, their composition and distribution, to their uses, whether burned in the raw state or converted into powder form, gas or into one of the many other forms by the carbonization process.

One is surprised to note, however, that low-temperature distillation is so casually treated. The Piron-Caracristi process is briefly described, as also the Greene-Laucks and Economic Carbonization processes, but the McEwen-Runge, McIntyre and amalgam processes are conspicuously absent. Something is said about Carbo-coal also, though the equipment and methods are not described. American low-temperature distillation methods in fact are given a scant page and a half—and indeed, Europe is treated to about an equal space. It should be said, however, that the general principles of low-temperature carbonization are well described.

ALL THE FUELS FOUND AND MADE

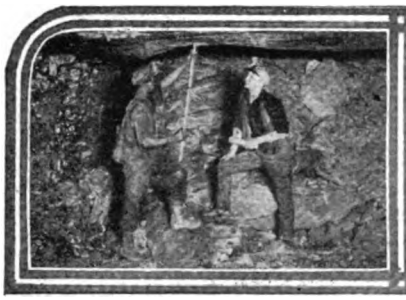
The book, which contains 809 pages, measuring 6x9 in., commences with a review of the fuel situation, then discusses the origin and composition of coal, the types of coal and their classification, spontaneous combustion and storage, coal resources and coal production, petroleum, other primary fuels, the chemistry of combustion reactions, combustion of elementary fuels, combustion calculations and the properties and combustion of gaseous fuels. So much for theory. This is followed by combustion of coal on grates, the operation of hand-fired furnaces, mechanical stokers and furnaces, powdered coal, the combustion of fuel oil, furnace efficiency and heat losses, producer gas, water gas and oil gas, and the carbonization of coal. At the end of the book are three lengthy appendices, one on the flow of liquids and gases, another on the flow of heat and a third on the rate of heating.

LOSSES IN FUEL USE

The book will be found a valuable addition to any engineer's library and especially to a coal man who is interested in the uses to which his coal is being put or may be put in the future. The book is published by the McGraw-Hill Book Co. and sells for $7.50.

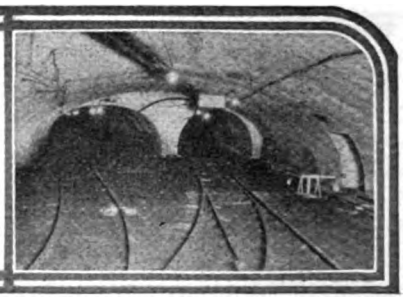
In discussing the fuel situation it shows a chart credited to George Otis Smith, exhibiting how with waste—in mining, in transit and in combustion—15,700 lb. of coal may be used up to produce 1,000 hp.-hr., whereas with up-to-date conditions in all three parts of the operation 1,320 lb. would serve the purpose, the combustion and plant losses in the one case requiring 10,000 lb. and in the other only 1,200. Fortunately for the industry, no small portion of these economies already has been effected at most large plants.

The reviewer is influenced overmuch by a personal interest in pyrite, and may be excused for taking exception to the author's declaration that "The pyrites is mainly formed by the intrusion of rock." The rock is not intruded, and Thiessen's view, long advocated editorially by *Coal Age*, that in almost all plants there is sulphur enough to account for the sulphur in the coal would seem warrant for believing that the pyrites in coal is no extraneous material. It should be said, however, that after this strange and inexplicable remark the author quotes Thiessen as testifying to the presence of sulphur in the proteins entering into the coal mass, which "on putrefaction yield hydrogen sulphide which would precipitate the heavy metal sulphides."



R. DAWSON HALL.

Progression in Chemical Analysis



Analytical methods are receiving revision for purposes of attaining greater accuracy in the case of bodies the ultimate analysis of which we are seeking and to obtain more uniform results in the case of materials regarding which we desire only a proximate analysis. Hence a revision and fourth edition of Wilfred W. Scott's book on "Standard Methods of Chemical Analysis" will be welcomed. To the first volume twenty-seven and to the second twenty-six specialists contribute, so the work is not a one-man book but a well-ordered symposium of specialists.

Volume 1 deals with the elements and Volume 2 with materials such as paints, fats, waxes, oils, alloys, cement, gas, asphalts, tars, pitches, carbon steel, explosives, water, rubber, soap, slag and so forth. Coal is given 18 pp. and methods for analysis of fuels, 29. The actual text in the two volumes which are of equal size occupies 1,805 pages each 6x9 in. The books are published by D. Van Nostrand Co., 8 Warren St., New York City, the price being $12 for the two volumes.

Underground Operation

How Track Grades Govern Locomotive Capacity

Resistance to haulage arising from grades, says James L. Libby in the *Employees' Magazine* of the Union Pacific Coal Co., is always 20 lb. per ton for each per cent of inclination, 1 per cent of 2,000 lb. being 20 lb. The track resistance for cars equipped with plain-bearing wheels is about 30 lb. per ton on level track, whereas those equipped with roller bearings have a resistance of about 20 lb. per ton. Most mine cars weigh approximately three times as much loaded as they do empty, and on this basis the most efficient grade is ¾ per cent in favor of the loads for trips with plain-bearing wheels and ⅓ per cent for those with roller-bearing wheels.

Angle of Car Repose

The angle of repose, or that grade on which cars are on the verge of movement by gravity and on which if moving they will not accelerate in speed, is 1.5 per cent for plain-bearing and 1 per cent for roller-bearing wheels. These grades are ideal for gravity switches when cars are well oiled, in proper repair and the tracks are kept clean, but if the cars are kicked in, a lighter grade is preferable. Starting friction is about 60 lb. per ton for plain-bearing and 35 lb. for roller-bearing wheels.

The rated drawbar pull of a locomotive depends upon the weight on the drivers. With cast-iron wheels this pull is ¼ of the weight, or 400 lb. per ton, whereas with steel-tired wheels it is ¼ the weight, or 500 lb.

On grades a locomotive cannot develop its rated drawbar pull because of the loss of effort or the power required to raise the machine itself up the grade, and thus 20 lb. per ton of locomotive weight must be subtracted, amounting to 5 per cent of the load for cast-iron wheels and 4 per cent for steel wheels.

Put in a simple way, using rolling friction at 30 lb. per ton for the load hauled and taking the drawbar pull at ¼ the weight, a locomotive will haul 13.3 times its own weight in tons on a level track, whereas on grades it will show the following results: Up a 1 per cent grade it will haul 7.6 times its own weight; up a 2 per cent grade 5.1 times its weight; up a 3 per cent grade 3.8 times its weight; up a 4 per cent grade 2.9 times its weight; up a 5 per cent grade it will haul 2.3 times its weight. Down a 1 per cent grade it will haul 42 times its weight; down a ½ per cent grade 20.5 times its weight, and down a ⅓ per cent grade it will haul 14.4 times its weight. A close approximation to the haulage capacity, in tons, of a motor working on a grade, as compared to the weight of the machine, may be found by the following rule, which is as nearly correct as the theoretical values, when condition of the track is taken into consideration.

Fifteen divided by the numerical per cent of adverse grade plus one, equals the number of times its own weight that a locomotive will haul up a given grade. Thus, for a one per cent grade we have: Load hauled = 15 ÷ (1 + 1) = 7½ times locomotive weight.

Up a 2 per cent grade we have 15 ÷ (2 + 1) = 5 times weight of locomotive.
Up a 3 per cent grade 15 ÷ (3 + 1) = 3¾ times weight of locomotive.
Up a 4 per cent grade 15 ÷ (4 + 1) = 3 times the weight of the locomotive.
Up a 5 per cent grade 15 ÷ (5 + 1) = 2½ times the weight of the locomotive.

Inasmuch as a locomotive will haul 13.3 times its weight on a level track, 50 per cent additional on a downgrade of ½ per cent and 200 per cent in excess of a level haul on a 1 per cent grade, the necessity for the proper grading of main haulageways is apparent.

Did Powhatan Blast Start In Mine or Tipple?

In the explosion which took place on Feb. 15 in the mine of the Powhatan Mining Co., Powhatan, Ohio, killing one man and burning twenty-two others, several seriously, coal dust played a major role. The explosion spent its greatest force in the shaft bottom and hoisting shaft, from which it extended to the tipple, ripping off much of the sheathing from this structure without damaging the equipment to any extent. This mine was rock dusted—to what extent has not been ascertained—and open lights were used. The coal is emptied from the mine cars by a rotary dump on the bottom and hoisted by skips.

Chief Inspector Jerome Watson, of the Ohio Department of Mines, in an interview with the *Wheeling Daily News*, as reported in the issue of Feb. 16 of that paper said:

"The findings seem to indicate that a short circuit in the tipple set off the blast which swept down the shaft. Everything in the shaft and entry indicate that the trend of the force was downward. Had the explosion come up unquestionably more damage would have been done to the tipple.

Open-Air Explosion

"The small damage to the tipple was the result of an open explosion. Had the dust been more closely confined there the force would have been as great as in the mine and a complete wreck would have been the result. This is another point in favor of the theory that the blast started there and went down, thus leaving the tipple before serious damage was done.

"When the blast reached the bottom of the shaft it was at its height and wrecked the weighroom and burned the men who were within the area it swept over. After passing down the entry a short distance the blast encountered rock dust and moisture. Both these elements tended to weaken the force and it spent itself after running a few hundred feet."

Some have wondered why, after examining the mine following the explosion, Mr. Watson chose to fix the location of the source of ignition in the tipple rather than in the shaft bottom, in the absence of unquestionable evidence backing his belief.

Digitized by Google

Several years ago the U. S. Bureau of Mines conducted a series of tests at its experimental mine at Bruceton, Pa., in an attempt to propagate an explosion of coal dust inby from a point 150 to 200 ft. from the mouth of the drift by means of a blownout shot. While the blownout shot in these tests in some cases ignited the coal dust outby of the point of ignition, in no instance did propagation extend inby. In view of this fact it is held by some that it is unreasonable to suppose that an explosion of dust in the open, where no propelling pressure might be built up, would extend down the shaft and propagate itself for several hundred feet along the shaft bottom.

Safety Kits Save Lives At Overton Disaster

In the explosion which took place in the Overton No. 2 mine of the Alabama Fuel & Iron Co., near Birmingham, Ala., Dec. 10, 1925, costing the lives of sixty-one men, no less than twenty men were saved from the toll of afterdamp by the use of self-rescuers, according to George A. Anderson, district inspector for the Associated Companies. On arriving at the mine, Mr. Anderson gathered up all the self-rescuers he could handle. On his way to the Fifth Level he met several men traveling to the surface who were equipped with self-rescuers. Wearing one of these masks himself, he explored Fifth Right entry in the upset airway and there found three men, to each of whom he gave a self-rescuer.

The Alabama Fuel & Iron Co. has a large supply of self-rescuers in the office for such an emergency. Furthermore, many of the miners were equipped with the mask by an optional plan whereby a man paid for the equipment in installments, one being deducted from each pay.

One of the victims found by the rescuers had the mouthpiece of his self-rescuer in his mouth, but had failed to attach the clip to his nose in time to save himself from carbon-monoxide poisoning. One man was found overcome with his head over his bucket, supposedly having been in the act of taking a drink before putting on his self-rescuer. One of the men saved by the rescue party said he had left his self-rescuer at home in a trunk. Several other men stated they had left their masks at home.

Fireboss Lowery of Overton No. 2, wearing a Gibbs apparatus went into the mine immediately after the explosion, and in the Fifth Right heading found six men who had not ventured out because of the presence of afterdamp outby the point where they were located. Two men had attempted escape and were killed, but the six men had decided to wait for help. Not having self-rescuers with him, Lowery went out and got six of them for the live men whom he had found. Protected with this equipment they made their way to the surface without assistance and in safety.

Fear Finds Creosoted Ties Lower Track Costs

T. G. Fear, general superintendent of the Inland Collieries Co., is enthusiastic over the results obtained from the use of creosoted mine ties in one section of Indianolo mine, Indianola, Pa. About three years ago he had occasion to retrack the main haul of this section and then decided to use creosoted ties. These are protected from the wearing effect of rail movement by pressed-steel tie plates. The ties purchased were 5x7 in. and 5½ ft. long, yellow pine impregnated with 6 lb. of creosote per cu.ft. by the pressure-vacuum process. A sawn cross-section of one of these ties selected at random, disclosed a thorough impregnation of the preservative to the heart of the wood.

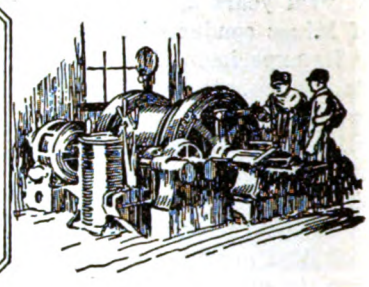
Mr. Fear's comments on this matter are worthy of careful consideration: The first cost of the treated ties is roughly 2½ times that of untreated ties of the same grade, but he estimates that they will last three times as long. The saving in this regard is slight; but when labor, uninterrupted operation and freedom from costly derailments with their accident hazards, are considered he is confident that a large saving is made. Much labor is involved whenever the ties have to be replaced. Furthermore, it is a difficult matter to restore the ballast and align the rails to their original state after new ties are inserted, particularly as the job is done under pressure on Sundays during holidays, at night and during off-shifts.

"Slab System" Suggestion Proves Valuable

Lew Roach, manager of the mines of the Elkhorn Piney Coal Mining Co. in eastern Kentucky and southern West Virginia, reports that the article on the "Slab System," by George E. Harkess, which appeared on page 822 of the Dec. 10 issue of *Coal Age*, supplied a suggestion which is proving of considerable value in Mine No. 1 at Weeksbury, Ky.

This mine is worked on the room-and-pillar system with rooms 24 ft. wide. The average height of the coal is approximately 43 in., and, generally speaking, the roof is fairly good, being sandstone in a large portion of the mine. The slabbing system of developing the 24-ft. rooms was first tried at Weeksbury about the middle of December and proved a success from the start. It has resulted in increased production per man, descreased car-gathering cost, increased percentage of lump and decreased explosives cost.

Besides the advantage of presenting loose ends for shooting down much of the coal, the system has the distinct advantage of making it possible to spot and load two cars at a time. This decreases the car-handling cost and cuts down delays. Mr. Roach reports that the loaders and mining-machine operators are enthusiastic over the system, and that it results in a gain of approximately 20 per cent in production per loader.



Self Rescuer in Service

The device, which saved lives in Overton, Ala., is a small canister containing a chemical which absorbs carbon monoxide. Attached to the canister are a mouthpiece and a nose clip. The total weight is less than 1 lb. At the right is shown a miner carrying the self rescuer, sealed in a tin can, on his belt. At the left, he has it in position for use.

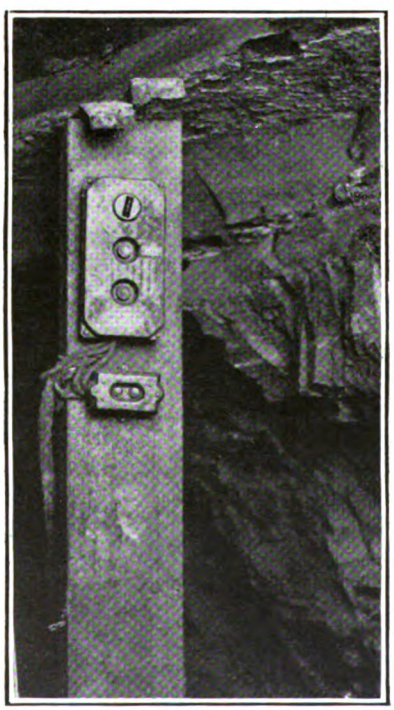
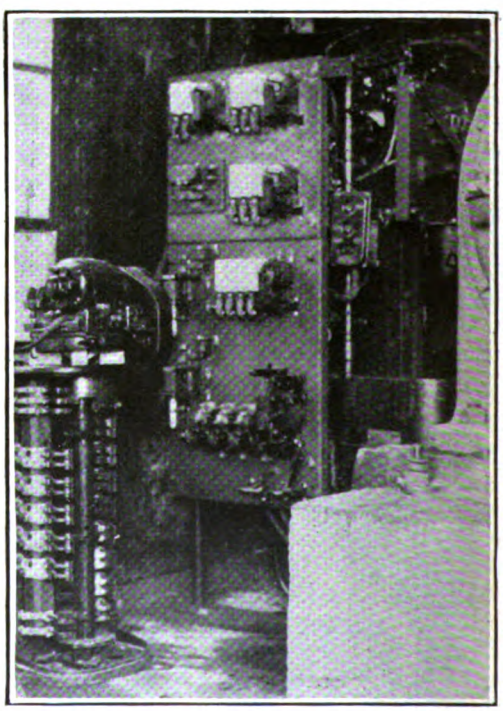
Practical Pointers For Electrical And Mechanical Men

Fan Speed Is Controlled From Inside of the Mine

When variable-speed motors are attached to mine fans the reason, usually, is either to effect a power saving by supplying less air at times when there are few or no men in the mine, or to provide for an excess of air during periods of rapid development. On a new fan at the Nuttallburg (W. Va.) mine of the Fordson Coal Co., a motor of the variable-speed type has been installed primarily to compensate for changes in the temperature of the outside air. This machine is located at the top of a recently-completed rock slope and is at an elevation approximately 350 ft. higher than the main portal of the mine, as is shown in the accompanying sketch. The main opening is a drift in the side of New River gorge, and the fan is located back from the stream on what might be termed the plateau or table-land of the region.



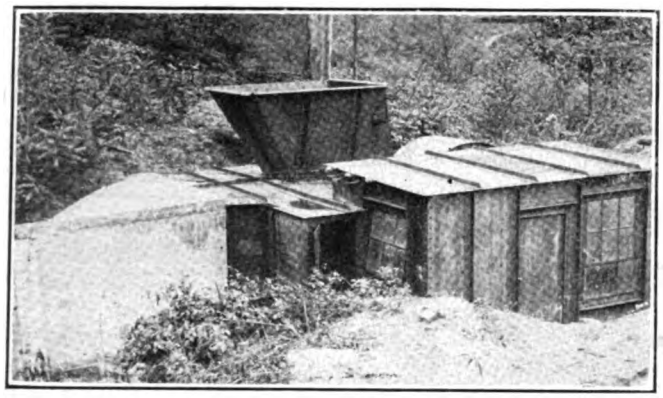
With the large difference in elevation between the two openings above noted temperature changes in the atmosphere must be counteracted with variations in fan speed if the quantity of air circulating through the mine is to be kept even approximately constant. On days when extreme temperatures prevail sufficient natural ventilation is obtained without the fan.



In order to eliminate the need for a man in constant attendance on the fan and to make it convenient for the mine foreman to start and stop the equipment or to alter its speed, a remotely-controlled automatic starter with motor-driven secondary controller was installed. A control cable is carried from the fan, down the slope, and to a push-button station located at a central point in the mine. This station has four push buttons and an indicating iight. The buttons and an indicating light, the latter are labelled "Start," "Stop," whenever the drum controller at the fan is between any two of the running points.

If the foreman finds that there is insufficient air circulating in the mine and therefore decides to run the fan "one notch" faster, he pushes the "fast" button and holds it until the lamp first lights up and then goes out whereupon he releases it immediately. The controller is then on the next-higher running notch.

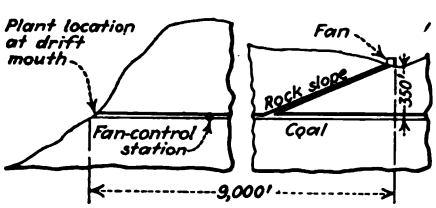
In case the foreman wants to de-



At Nuttallburg, the Fan Is Controlled from Within Mine to Keep a Constant Current Despite Variable Natural Ventilation Conditions

On the left is the muddy, steep, mountain road, a "good" part of two miles long, that leads from the tipple to the fan. This indicates why full-automatic control was used and provision made for changing the fan speed from inside the mine. In the center is the control station within the mine. From this point, the fan which is some 2,000 ft. distant and 350 ft. high in elevation, can be started, stopped or changed to any controller point. At the top of the upper box is a lens behind which is a lamp indicating the controller positions. On the right the edge of the 75-hp. slip-ring motor can be seen. To the left of the illustration is the automatic starter beside which can be seen the motor-driven drum controller which changes the fan speed.

Digitized by Google



Steel-Cased Fan

The small steel building adjoining the fan housing contains the 75-hp. motor and complete control equipment. A short silent-chain drive makes the arrangement compact. The motor house is locked and visited about once a month.

termine on which point the fan is operating, he holds the "Slow" button depressed until the lamp ceases to flicker on and off. This indicates that the controller has moved to the slowest point. Having counted the number of times that the lamp lighted up during this process he knows on what point the fan was operating. He can then push the "Fast" button and bring the speed back up the desired number of points.

Electrically there is nothing complicated about the arrangement. The 75-hp. 2,300-volt motor is of the wound-rotor type, and the automatic starter is a piece of standard equipment provided with an additional contactor for cutting out the secondary controller at starting. This provides for starting the motor with full secondary resistance in circuit, regardless of the point at which the drum controller is set. The fractional horsepower motor which drives the drum-controller cylinder is wound for 220-volts three-phase, this current being supplied by small transformers. One of these latter also supplies single-phase current for operating the contactors of the automatic starter and for the signal lamp at the push-button station.

Sketch Showing Fan Location

The coal bed outcrops in the somewhat steep bank of the river while the fan is installed almost two miles inland on the plateau. In extreme weather natural ventilation furnishes sufficient air to the mine workings but the fan must supply any dearth when the temperatures of outside air and mine are nearly equal.

The fan is a 5x3-ft. machine of the multi-bladed type fitted with a complete steel casing and motor-house. Silent-chain drive is used. This permits of an extremely compact installation; the motor, automatic starter, motor-driven drum controller, secondary resistance and control transformers all being housed in a 6x12-ft. building.

As the fan is in an out-of-the-way place and is inspected only about once a month, precautions have been taken to protect the bearings in case of heating. All fan and motor bearings are fitted with thermostats. The electrical control equipment, although out of the ordinary, is but a combination of various pieces of standard equipment.

"Desmoking" a Smoky Coal For Smithing Purposes

Any good smithing fuel should contain only small quantities of sulphur and volatile matter. Sulphur tends to harden the metal heated and make it brittle and a high-volatile content makes the fire dirty and gummy, interfering with such processes as welding, simultaneously smoking up the whole shop. Some coal companies have long purchased smithing coal from other regions, but several southern Illinois operators "devolatilize" the product of their own mines before using it in their shop forges and furnaces. In this form the fuel is practically a coke.

Another type of coking furnace is that shown in Fig. 1 of the accompanying illustrations, this particular furnace being used at the No. 8 mine of the Old Ben Coal Corp., at West Frankfort. This consists of four walls of red brick, lined with firebrick above the grate or what would be the grate of an ordinary furnace, but which in this case is really a floor. The top is partially closed by means of firebrick blocks supported by old rails extending between the side walls. The outside dimensions of this furnace are roughly 6x5 ft. and the height is approximately 6 ft. A twyer pipe supplied with suitable draft openings extends from rear to front.

Still another device intended for this purpose is shown in Fig. 2, this photo being taken at the Valier mine of the Valier Coal Co. The sides and rear end of this furnace are built up of old rails to a height of about 3 ft. The front is left open and the bottom slanted from either side to the twyer pipe in the center.

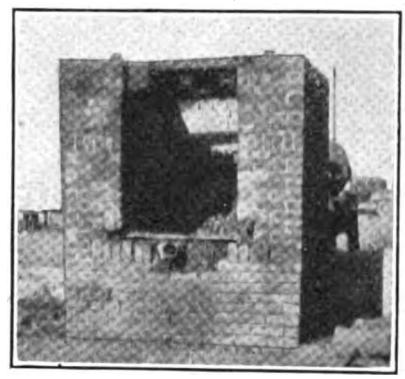


Fig. 1—Old Ben Coking Furnace

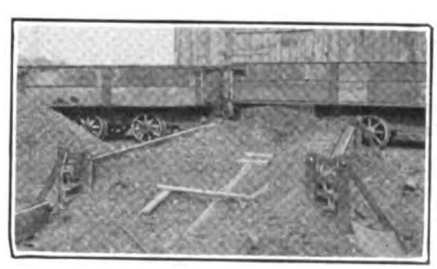
This furnace much resembles a blacksmith's forge with side and end walls. From 200 to 400 lb. of coal may be coked in it per charge, the length of time necessary depending almost entirely on the quantity of coal treated.

All these furnaces are operated in a similar manner. A fire of paper, shavings and kindlings is first built over the twyer above which small coal is piled. If the charge is a large one, its top is covered with fine coal or even dirt. Draft, which is supplied by a fan, as a rule located within the shop building, is turned on when the fire is first lighted. This blast is continued until the entire mass burns clear and red and practically without smoke. The draft is shut off and the contents of the furnace thoroughly quenched with water.

The result is a small sized coke which, although it may be somewhat discolored, forms an excellent smithing fuel that may be used in the shop forges and furnaces with good results.



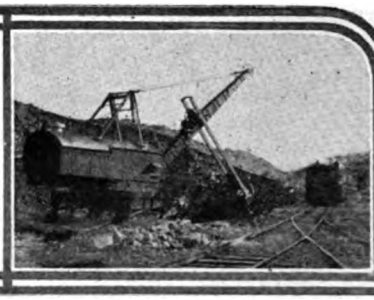


Fig. 2—Coking Furnace at Valier

Both sides and the rear end are made up of old rails. This furnace is of such size as to take several tons per charge, and the time necessary for coking may be several hours.

Seek Plan to Settle Labor Problems In Soft Coal Industry; Congress Welcomes Shift of Responsibility

By Paul Wooton
Washington Correspondent of *Coal Age*

The bituminous coal industry, not to be outdone by the railroads and the anthracite producers, is considering what machinery it can set up to handle labor questions. Many operators think action of this sort is the best guarantee against having some half-baked plan foisted upon the industry by Congress.

Plans to this end have not taken definite form and the difficulties are such that they probably will move slowly. It is believed that Congress would welcome some assurance from the soft-coal producers that they will undertake to work out some plan of arbitration. When efforts were being made to draw the federal government into the anthracite strike some of the House leaders promised to consider coal legislation after the strike, when the situation would not be surcharged with emotion and when an opportunity would exist to consider the problem deliberately.

The real truth is that these leaders now are looking for a way out of their commitment. This loophole would be furnished were they to be able to point to active efforts in the bituminous-coal industry looking toward arbitration machinery. On the other hand they feel that they will have to go through with the program if the strike remains the only recourse in case of dispute.

Some consideration has been given the President's suggestion that the recommendations of the Harding Coal Commission be followed, but some difficulty has been found "in putting these pious proposals into legislative form," as one of those interested put it.

Congress Wary of Coal

Moreover, Congress wants to adjourn. There is a campaign coming on and the members are anxious to be free to participate. The legislative program already is longer than they wish. There are enough worries and uncertainties without adding such a controverted matter as coal legislation, so that any development which would make it unnecessary would be greeted with three cheers on both sides of the Capitol.

As has happened in every previous instance when coal legislation has been initiated, investigation reveals a fundamental obstacle in the form of a constitutional question. The attitude of the courts in the Federal Trade Commission cases has thrown in doubt the whole question of compulsory returns of facts. If fact-finding were eliminated from the principal pending bills there would not be much left.

There is a disposition on the part of many members of Congress, and apparently on the part of the administration, to take at its face value the arbitration feature of the anthracite settlement. The belief of some observers that both sides will nominate agents, rather than arbitrators, is by no means universally held. In the paragraph of the settlement referring to arbitration it says "the Board shall be obligated within ninety days after appointment to arrive at a decision on all issues in controversy." The two arbitrators are obligated under the contract to arrive at a decision.

Conflict of Interpretations

The provision that these two "may enlarge the board to an odd number" has been the cause of some confusion. It does not say they shall add an odd member. If the two are obligated under the contract to agree, it seems plain, the permission to add a third member simply is a means to help them carry out the obligation of the contract, which is to agree. Apparently this clause is just as mandatory as that referring to "co-operation and efficiency." President Lewis, in speaking of that clause, declares that "it is a mandate just as strong as the English language can state it."

Regardless of the actual binding force of the arbitral feature of the agreement, Congress has been impressed sufficiently with the promise that it will work out to allay demand for the setting up of arbitration machinery by federal edict.

Advance View of Safety Film

An advance showing of the master film of the picture being prepared in co-operation with the Peabody Coal Co., Chicago, showing safety devices employed in coal mines, was made in Washington March 4 before members of the staff of the Bureau of Mines. The picture is in three reels and is one of the most pretentious thus far undertaken by the Bureau.

Lake Cargo Cases Reopened

The Lake Cargo Coal cases, in which a decision was handed down last July, have been reopened by the Interstate Commerce Commission. An order made public last week gives the parties to the case until March 22 to advise the Commission whether they desire to submit additional evidence. The cases were reopened upon the petitions of the original complainants, backed by the Pittsburgh Chamber of Commerce and the State of Pennsylvania.

At issue is the adjustment of rates from Ohio and western Pennsylvania to the lower lake ports as compared with rates from southern West Virginia and eastern Kentucky. The tentative opinion prepared by the examiners who heard the evidence recommended decreases in the rates from the two states first named. The opinion of the Commission, however, declined to disturb the existing adjustment and dismissed the complaints.

Urges State Fuel Commission In New York

Assemblyman Louis A. Cuvillier, Democrat, of New York, basing the necessity therefor upon action by the State Chamber of Commerce calling for a "fact finding" investigation of prices charged for fuel, introduced in the Assembly at Albany March 8 a bill creating a state fuel commission as a permanent agency of the state government and appropriating $25,000 to enable it to carry out its proposed work.

The commission would consist of three members to be appointed by the Governor and to serve without pay except for their necessary expenses. The commission would have power to make a general investigation of the fuel industry and to fix the prices to be charged by the wholesaler and retailer.

Many of the provisions of the bill are adapted from the State Fuel Commission law enacted under Governor Miller, except that the Cuvillier bill contains no provision allowing the state to go into the business of buying and selling coal, and that it would constitute a permanent commission and not be subject to dissolution on the proclamation of the Governor as was the Miller law.

The bill was referred to Committee on Ways and Means.

Stocks of Substitutes At New York City Delay Movement of Anthracite

New York consumers were urged to use more bituminous coal or coke in an appeal issued March 3 by the New York State Coal Commission following a conference among representatives of the railroads, coal dealers and public organizations held in New York City. The statement pointed out that there is a congestion on the railroads because of an oversupply of soft coal for which there is a very limited demand. The Department of Health was asked to refrain from strict enforcement of the smoke ordinance until after April 1, in order to encourage the use of bituminous coal.

After the congested condition of the terminals had been pointed out at a meeting of the Atlantic States Shippers' Advisory Board earlier in the day, the Coal Commission issued its statement calling on the public to use soft coal or coke until adequate supplies of anthracite can be obtained. In line with the petition of the Advisory Board the commission in its statement expressd the hope that "the authorities will cooperate in regard to the enforcement of the smoke ordinance."

Figures reported by the American Railway Association and read in the meeting of the Atlantic States Shippers' Advisory Board showed that on March 3 there were 8,498 cars of coal, totaling more than 450,000 tons, in the New York tidewater terminals, while an additional 3,945 cars, containing about 200,000 tons, were being held at points outside the tidewater terminals awaiting orders for movement and the relief of congestion already existing. Of this total of 12,443 cars, only 1,887 contained anthracite; the remainder being bituminous coal, together with something over 1,000 cars of coke.

Congestion Is Widespread

A. G. Warren, who represented E. J. Cleave, district manager of the American Railway Association, at the meeting, explained that cars being held outside of the terminals because of congested conditions extended as far west as Harrisburg and as far south as the Maryland division of the Pennsylvania R.R.

In its statement the advisory board declared that "the supply of anthracite will not be sufficient to satisfy the full demands of the New York district before May 15," and warned that "restricted deliveries of bituminous coal on hand and in transit will ultimately affect the supply of cars for the movement of anthracite in the district."

George J. Eltz, member of the New York State Coal Commission and of the Coal Merchants' Association, in summing up the situation, said there is an oversupply of soft coal and coke on hand which must be used in order to free the transit and terminal facilities for the handling of anthracite.

"Whether the public wants to continue the use of soft coal or no," he declared, "it must do so or do without coal. However, it may be assured that there will be no increase in the price of anthracite even though the demand is far greater than the supply."

The statement of the Coal Commission was as follows:

"Sufficient anthracite is not yet reaching the New York market to supply the demand. Owing to congestion at the railroad terminals and to the backing up of cars filled with substitutes, as reported by the American Railway Association, it will be several weeks before sufficient anthracite can be supplied.

"Under these considerations, this commission urges consumers to use low volatile mine-run soft coal or coke when anthracite cannot be obtained."

Dr. Louis I. Harris, Health Commissioner of New York City, said last Thursday that by March 10 he would have reports on the coal situation from the State Coal Commission, the dealers, the railroads and his own investigators, when it would be decided when the complete elimination of smoke would be required.

"This does not mean that I am enthusiastic about the present state of the atmosphere, but it is reasonably good," he said.

Hugh Shirkie

Who will succeed the late Col. D. B. Wentz as president of the American Mining Congress. Mr. Shirkie was elected by the directorate at a special meeting called in Chicago, March 8. He is a well-known operator, being president of the Shirkie Coal Co., Terre Haute, Ind.

Senate Defers Naming Hunt To Trade Commission

After nearly two hours' discussion of the reappointment of Charles W. Hunt, of Iowa, to be a member of the Federal Trade Commission, the Senate in executive session on March 5 deferred action until a later date.

The fight against reappointment was led by Senator King, Democrat, Utah, who charged that Hunt was a reactionary and was not enforcing the law. The appointee was defended by Chairman Cummins of the Senate Judiciary Committee. Another attempt probably will be made this week to get action on the nomination, with indications that it will be confirmed when it comes to a vote.

Chamber Backs Downing Bill; Hits Retail Prices

The Chamber of Commerce of the State of New York has indorsed the Downing bill to make the State Public Service Commission a coal fact-finding agency. This action was taken by the Chamber at its regular monthly meeting at New York City last Thursday, following the presentation of a report on coal prices made by the Chamber's committee on public service in the metropolitan district. The organization did not go on record, however, until after Major Elihu Church, local fuel administrator during the 1922 crisis, had attacked the report and asked that it be referred back to the committee for further consideration.

The report, based upon a survey of prices charged by the cellar trade and peddlers for coal in bag lots, exonerated the cellar dealers of charging exorbitant profits although these dealers were charging 54 to 106 per cent over the prices they claimed to be paying for the coal at the retail pockets. "Profiteering is and has been going on," asserted the report and the large retailers must bear some of the onus of oppressive prices. At the same time, the report admitted that the co-operation of some retailers had held down bag prices in certain sections of the city. In offering its recommendations for the future the committee said:

> Your committee does not recommend at this time the establishment of a governmental body with regulatory and judicial power over coal. In fact, this Chamber is strongly opposed to federal regulation in actions taken in March, 1921, and December, 1925. What it does recommend is the establishment in the State of New York, as soon as possible, of a fact-finding agency which shall have the power to subpoena witnesses under oath, and thus obtain exact information upon actual costs of coal, upon profits obtained and upon what profit is reasonable. This fact-finding agency should begin its investigations at an early date that it may be ready and fully advised for action in the next fuel emergency. Generally the mere prospect of publicity of the fact that a seller has been found to be profiteering is sufficient to stop such practice.

Retailers Criticize Report

J. Vipond Davies presented the report and moved its adoption. The report, he said, had been criticized by the retail interests. The Chamber was asked by the New York State Retail Coal Merchants' Association to give the retail trade a hearing before taking final action, but this request was ignored by the Chamber.

Major Church, in moving that the report be referred back to the committee, condemned the committee for its failure to consult with the retailers and for comparing, without identifying, prices on screened bituminous with contract figures on mine-run coal. He also wanted to know whether Frederick H. Ecker, president of the Chamber and member of Governor Smith's coal advisory commission, had ever sought information through that commission.

Condemning the fact-finding proposal as useless for emergency operation, Major Church remarked that there were small boys who liked to collect "birds' eggs and lead pencils without knowing just why. When these boys grow up, they want to collect facts."

Fayette-Greene Operators Canvass Coal Industry's Needs in Pennsylvania

Pennsylvania's fight for more favorable freight rates on coal and recognition by membership on federal agencies will continue unswervingly until its aim has been accomplished, U. S. Senator David A. Reed told 322 coal and coke operators representing 92 per cent of the bituminous tonnage of the western Pennsylvania field at the third annual banquet of the Fayette-Greene Coal Producers Association at the White Swan Hotel, Uniontown, Pa., March 6.

Operators, intelligently organized and directed, must get into the fight, said Charles O'Neill, secretary-treasurer of the Central Pennsylvania Coal Producers Association. William H. Donner, president of the Donner Steel Co., gave instances of alleged rate discrimination against Pennsylvania coal. Many of these rates, he said, had been arbitrarily made during the war while the railroads were under federal control.

Delbert H. Pape, assistant executive secretary of the National Coal Association, spoke on the importance of research and statistics to the bituminous coal industry.

State to "Fight for Rights"

Senator Reed, in outlining the campaign now being waged in behalf of Pennsylvania's coal industry, showed how the state has been ignored in representation on important governmental agencies. "We know why so many of our mines are shut down, so many of our blast furnaces cold, so many of our train crews idle," said he, "and we intend not only to demand our rights but to fight for them, and this means not only to demand that Pennsylvania have a fair share in these appointments but to fight all appointments from other states until Pennsylvania's just claims are recognized."

Mr. O'Neill presented interesting data on tonnage changes in coal. He referred in detail to rate cases now pending, including the all-rail rate case to New England states from West Virginia, and the lake cargo and tidewater cases. "The wage question is being solved by the operators of Pennslyvania," he declared. "Reductions in wage levels are gradually being made throughout the state and accepted by the miners, despite opposition to this sound policy by the United Mine Workers. There has been no disposition on the part of of the railroads, however, to meet the necessity of the situation by readjustment of their freight rates on coal. The rates from Pennsylvania in all directions are in every instance on a much higher level per ton mile than the rates from the southern fields that are competitive with Pennsylvania and are rapidly taking their markets."

"It is true of coal in only a slightly less degree than it is of oil," said Mr. Pape, "that the burning of raw coal under a boiler involves the waste of certain constituent elements of the coal that could be much more profitably utilized for other purposes. Chemical research into methods of carbonizing coal and into the utilization of the by-products obtained during the process is a field which has as yet hardly been scratched and whose possibilities are almost immeasurable.

"In support of this statement let me quote a paragraph from a paper entitled 'A Critical Analysis of the Future Demand for Gasoline and Lubricating Oils for Automotive Uses,' read before a meeting of the Society of Automotive Engineers by its president, H. L. Horning. The quotation is as follows:

"' . . . coal is the most promising of all our sources of raw material. By this I do not expect the well-known aromatics derived in the usual distillation to be the source of coal fuels, but on the contrary, I expect developments in chemistry within the next decade to show us how to convert coal directly into motor fuels as primary products and with valuable byproducts. There probably exist today suppressed, known, or awaiting development, facts which constitute the very basis for this great step. I am absolutely certain that organic chemistry could solve this in a little time. When these changes will come about depends on economic causes and not for want of scientific ability. Economic changes will always lag behind scientific achievement.'

"While the development of more economical methods of burning coal may in the first instance tend to contract rather than expand its market and benefit the industry only after the reduction in the cost of coal as fuel has enabled it to replace oil and electricity, the discovery of new byproducts or of new methods of utilizing the byproducts already known may bring with it an expansion in the demand for coal of very large proportions. I need only refer to the effect of the by no means impossible development of satisfactory fuel for internal combustion engines from the distillation of coal."

Officials indicated that definite action would be taken within a week to launch an aggressive program to obtain relief for the region from the conditions attacked.

W. Russell Carr, local attorney, was toastmaster. G. Carl Areford of Uniontown is president of the Fayette-Greene Coal Producers Association; W. W. Parshall, vice-president; T. M. Whyel, treasurer, and J. Fred Shean, secretary.

British Dole in 7 Years Costs £240,000,000

Great Britain's out of work "dole," which is credited in many quarters with saving the nation from industrial disaster and is bitterly assailed by others as a soporific influence, has cost the government nearly £240,000,000 since it was first instituted, in January, 1919.

Sir Arthur Steel-Maitland, British Minister of Labor, stated in the House of Commons March 3 that the payments in unemployment insurance by the government totaled approximately £239,830,000. He added that 855,000 persons were "on the dole" for the week ended Feb. 20.

Believe 28 Dead in Explosion In Eccles (W. Va.) Mine

Twenty-eight miners were entombed and are believed to have perished as the result of explosions early in the evening of March 8 in mines Nos. 5 and 6 of the Crab Orchard Improvement Co., near Eccles, W. Va. Thirty-seven men were rescued and one body was recovered after the disaster, but officials of the company, in checking up at 1 a.m. following the blasts, held out little hope for the twenty-eight men still in the mine.

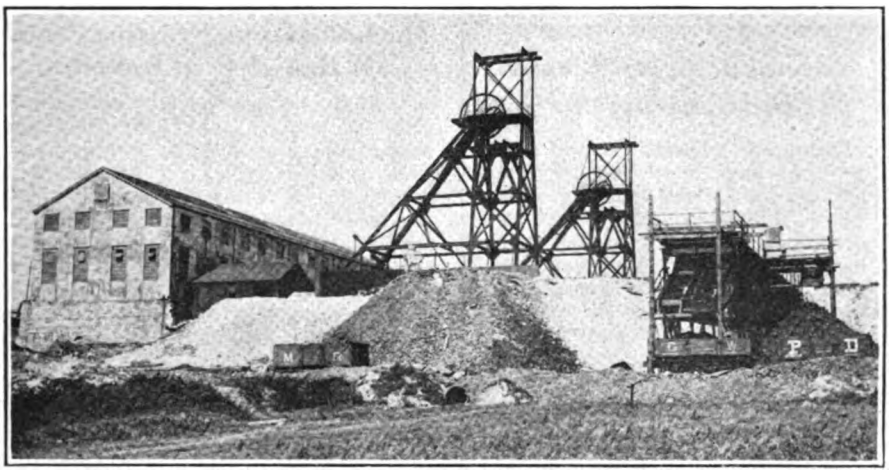
The first explosion, according to mine officials, occurred in No. 5, where twenty-nine men were working, and spread to No. 6, imprisoning thirty-seven others. Rescue crews went into No. 6 soon after the blast occurred, and brought out the thirty-seven survivors. Two of this crew are missing. They said this mine was little affected by the explosion. No. 5 mine was filled with poisonous gases and the rescue men could not go down the shaft. The body of the one man lost was found in a lateral connecting the mines.

Many of those rescued were burned and gassed. The shaft of No. 5 was wrecked by the blast, closing this entry to the rescuers, who were working through No. 6 in the effort to learn the fate of the entombed men. These men formed the night shift of No. 5.

The explosion occurred in the same mine that was wrecked by a gas explosion in April, 1914, with 186 fatalities. At that time it was an open light that ignited the coal gas and caused the disaster. No explanation of Monday's explosion has been received.

The Crab Orchard Improvement Co., which operates the mine in which the explosion occurred, is a subsidiary of the Stonega Coke & Coal Co. of Big Stone Gap, Va.

Mine No. 5 lies at the bottom of a 520-ft. shaft and is underneath Mine No. 6, which has a depth of 250 ft. A connecting shaft joins the two. No. 6 is located on the Sewell coal seam, while No. 5 is on the Beckley seam.



Open Coal Statistics Bureau In Huntington

The Bureau of Coal Statistics of the high-volatile fields of southern West Virginia, eastern Kentucky and Virginia was opened Feb. 25 in the First Huntington National Bank Building, Huntington, W. Va. F. C. Respess, formerly of Williamson, is secretary of the bureau, which will compile reports of past sales in the high-volatile fields.

The bureau is sponsored by several coal associations and directed by officers of these associations. Bureau officers are: William L. Cummins, of Red Jacket; D. H. Morton, president of the Kanawha Coal Operators' Association, of Charleston; S. W. Patterson, of Huntington; J. S. McKeever, of the Kanawha association; G. W. Bausewine, Jr., secretary of the Williamson association, and D. C. Kennedy, secretary of the Kanawha association.

At present reports are being received from the Kanawha and Williamson fields, but Logan, northeastern Kentucky and the Clinchfield valley will be covered later.

New Chislet Colliery at Westbere Court, Kent, England

This mine, four miles from Herne Bay, is one of five in Kent, England, and therefore not far distant from London. The British Government proposes to guarantee the principal and interest on a loan of $10,000,000 for the development of the Kentish fields, to be spent by Messrs. Pearson & Dorman Long, Ltd.

Ask Federal Aid for Coal Industry in Canada

Protection to the coal mining industry of Canada such as the United States Government grants American coal interests, is asked of the Dominion Government, in a resolution adopted March 3 at the opening session of the 28th annual general meeting of the Canadian Institute of Mining and Metallurgy. The meeting lasted three days at the Windsor Hotel, Montreal.

A request for government protection of Canadian coal interests against the dumping of American coals originally was put in the form of a resolution adopted at the western meeting of the association held at Winnipeg last November.

W. LeB. Ross, of Winnipeg, declared that the interests of not only the west but the east were involved in this matter, that coal being produced in the western provinces needed protection against the dumping of coal in their parts by United States interests, as well as in the Maritimes.

Ford Tipple at Stone, Ky., Destroyed by Fire

Fire of undetermined origin completely destroyed the coal tipple of the No. 5 operation of the Fordson Coal Co., located near Stone, Ky., at 10:30 p.m. March 5, causing damage estimated at $50,000. Until checked by a volunteer bucket brigade the flames threatened to spread into homes of miners.

The fire, which was confined to the tipple by the volunteer firemen, threw 225 miners temporarily out of employment. Officials of the coal company announced, however, that the workmen would be given employment in other operations of the company until the tipple of the No. 5 mine can be replaced. All equipment in the tipple was destroyed.

Plans have already been discussed by mine officials for the replacement of the tipple with a modern one of entire steel construction, and it is expected that work on the new structure will begin in the next few days.

Double Tracking Held Up By I. C. C. Ruling

With the rejection by the Interstate Commerce Commission of the application of the Van Sweringen interests of Cleveland to consolidate a number of railroads in the Middle West, particularly the Chesapeake & Ohio, the Hocking Valley, the Nickel Plate and Erie, officials of the Hocking Valley announce that completion of the work of double tracking the Hocking Valley from Columbus to Toledo has been held up until a favorable ruling is had from the Commission. A part of the double tracking project was completed last summer and it was planned to go ahead with the work at once, completing the line from Columbus into Waybridge, near Toledo. The project to build a line 63 miles in length from Gregg, Pike Coounty, Ohio, to Valley Crossing near Columbus, connecting the Norfolk & Western and the C. & O. and carrying coal traffic now routed over the N. & W. from Waverly into Columbus also has been abandoned.

Names Committee to Arrange N. C. A. Convention

Morton L. Gould, president of the National Coal Association, last week named the following committee to select the date and place and outline the program for the 1926 meeting of the National Coal Association: Telford Lewis (chairman), vice-president, Jasahill Coal Mining Co., Johnstown, Pa.; D. C. Kennedy, secy., Kanawha Coal Operators' Association., Charleston, W. Va.; Otis Mouser, president, Stonega Coke & Coal Co., Philadelphia, Pa.; C. F. Richardson, president, West Kentucky Coal Co., Sturgis, Ky.; Hugh Shirkie, president, Shirkie Coal Co., Terre Haute, Ind.; C. F. Spencer, president, Pittsburg & Midway Coal Mining Co., Pittsburg, Kan.; Ezra Van Horn, general manager, Clarkson Coal Mining Co., Cleveland, Ohio.

At a meeting at the Waldorf-Astoria, New York City, on March 23, the committee will consider invitations from commercial and civic bodies representing thirty-four cities.

Pittsburgh Coal Co. Has Deficit in 1925 Due to Curtailed Operations

High wages paid to coal miners and the suspension of operations at many mines because they were being operated at a loss are blamed for a deficit of $1,266,940 in the revenues of the Pittsburgh Coal Co. for 1925, according to W. G. Warden, chairman of the board of directors. This compares with a net loss of $454,083 in 1924.

The annual report shows gross receipts of $33,832,177 for 1925, against $44,025,345 in the preceding year. The company has earned nothing on either the preferred or common stocks for the last two years. The general balance sheet shows current assets of $16,332,718 and current liabilities of $2,781,529. Total assets were valued at $158,262,244.

In his report to stockholders Mr. Warden said:

"The extremely difficult conditions confronting the company in 1924 continued without abatement during 1925. Facing the certainty that the price of soft coal in its markets would continue to be fixed by the producers employing non-union labor, including those of the remote freight rate-favored districts of southern West Virginia and eastern Kentucky, and that in consequence it would not be possible to market the product of the company's mines except at prices below production costs under the existing wage scale continuing until April 1, 1927, your officers early in the year, with other producers in Pittsburgh, urged the officers of the United Mine Workers to meet in conference looking to a return to the wage scale of November, 1917. The request, however, was refused notwithstanding that twice during the year 1917 and again in 1920 they had been granted upward revisions of the wage scales then in effect.

"After careful study of every phase of the situation so developed, it was the unanimous judgment of your directors that the mines ought not longer be operated at a loss. Accordingly, the company's mines in the Pittsburgh district were closed down one after another and before the end of May all had been closed, operations of its Ohio mines having been discontinued early in the preceding year."

The mines were reopened in November, according to Mr. Warden, on a wage scale equal to that of November, 1917. The number of men employed has steadily if slowly increased, until at this date at all of the mines of the company there are about 3,000 men at work, producing approximately 12,000 tons a day, equal to 17 per cent of capacity.

C. & O. to Open Coal Bids

Word has been received in Charleston that the Chesapeake & Ohio R.R. will open bids March 15 on from 105,000 to 135,000 net tons of coal to supply its fuel needs during the next coal year. The bids will be submitted to the headquarters of the fuel department in Richmond, Va.

Heroism Awards Voted To West Virginia and Alabama Coal Miners

The Joseph A. Holmes Safety Association on March 5 voted awards for heroism to Lee Fetty and John McNeil, of Farmington, W. Va., and to R. D. Taylor, of Attala, Ala.

Mr. Fetty, who was machine boss in the No. 8 mine of the Jamison Coal & Coke Co., Farmington, W. Va., was on duty in the 20th right section of the No. 8 Mine on the night of Jan. 14, 1926, when an explosion occurred in the 7th right group of entries, which resulted in the loss of the lives of 19 persons. The explosion shut off the ventilation from the section of the mine in which Fetty was working and he stated that he felt a puff of air such as is produced by a fall of roof in the mine, following which he noticed that the air had ceased to circulate. He also found that the air compressor had stopped and there was no electric power at the air compressor.

Find Safety in Stable

After having gotten together all of the men he decided that the air compressor station was too small in which to barricade the men and conducted them to the 20th left entry, adjoining an underground stable, and directed the men to remain there under the seal of the doors and other barricades that they might construct until fresh air reached them. He then made an exploration toward the shaft and found that he was able to get down only to the 16th left entry, which was about 1000 ft. from the stable. At this point he encountered very strong afterdamp and retreated and reported to the men that it would not be possible for any men to get through the afterdamp. Three men disregarded his instruction, however, and attempted to go out through it, two of them losing their lives, the third being able to retreat to the barricade.

In Barricade Nineteen Hours

The general superintendent of the mine, W. C. Dobbie, stated that in his judgment, after talking with all of the men who were saved by barricading, Mr. Fetty was wholly responsible for gathering up the men and directing them to the 20th left, where they barricaded themselves. After having been in this barricade for 19 hours, Fetty went out into the main entry and discovered that fresh air was beginning to circulate. He then led all of the men in the barricade toward the shaft and on their way out they met the men who were engaged in conducting the air into the mine.

John McNeil, a compressor engineer at No. 8 mine, was on duty in the compressor station of the mine at the time of the explosion and assisted Mr. Fetty in the protection of their fellow workmen.

While R. D. Taylor saved no life he jeopardized his own life in an effort to protect one of his comrades on Dec. 19, 1925, at the bottom of the No. 2 slope, Attala Mine, Sloss-Sheffield Steel & Iron Co., in Alabama. A crew of miners had finished their day's work and preparations were being made to fire a round of 10 holes, charged with 40 per cent gelatin dynamite, each charge to be fired with a detonator by means of fuse. A pump was located 32 ft. above the bottom of the slope and preparatory to firing the charges the suction pipe was removed and carried into the pumproom by Alex Logan and Oscar Harris. Harris opened the electric switch in the pump room and called "All right," which R. D. Taylor, another workman, understood as a signal to light the fuse, which he proceeded to do. It appears that when Harris threw the oil switch he fell into the electric wires.

Logan stood on the slope near the entrance to the pumproom to display his light so Taylor would be able to see his way back to safety. Upon lighting all of the fuses he started up the slope and Logan, who was 40 ft. further up the slope, called out "There's a dead man in there." Taylor turned and could see the prostrate form of Harris. He immediately rushed to the bottom of the slope, hoping to be able to cut off the fuses. He succeeded in cutting off three or four, but as some of the shorter fuses had burned down to the collar of the hole he immediately retreated up the slope a distance of 50 ft., where he found refuge in a room. Immediately following the discharge of the several shots Taylor and Thomas returned to Harris and moved his body from contact with the wires and endeavored to resuscitate him, but without success.

New Directors Elected

Scott Turner, president of the association, presided. George S. Rice, General W. H. Bixby, Alan H. Willett, and J. J. Rutledge were elected directors for the ensuing year. James F. Callbreath was elected first vice-president and William Green second vice-president. T. T. Read resigned as secretary of the association, as he enters upon his new duties with the American Institute of Mining and Metallurgical Engineers March 15.

Economic Crises Blamed On Governments

Economic fluctuations and crises are not invariably the result of private initiative, but are oftentimes influenced, as regards the development of international trade, by harsh measures of government, according to a report drawn up by the mixed committee on economic crises for the League of Nations Council and made public at Geneva, Switzerland, March 5. Modification of the methods employed by the authorities since the war, in the opinion of the committee, an Associated Press dispatch says, would attenuate the gravity of world economic crises.

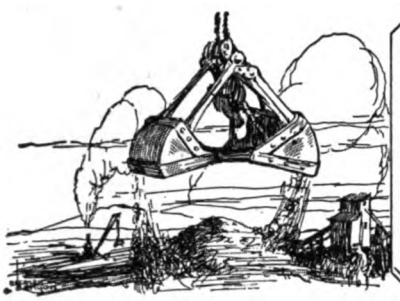
The committee places emphasis on the necessity of establishing complete, accurate indices for the measurement of fluctuations of economic activity and the compilation of statistics of industrial production and stocks as a guidance for further studies.

Mechanization Pressing Need Of British Coal Industry

Grouping of collieries by mergers, in order to bring about greater mechanization and higher efficiency in operation, is advocated by Sir Richard Redmayne, K.C.B., as one of the chief needs of the British coal industry. Sir Richard, who is a member of the Safety in Mines Research Board and formerly was Chief Inspector of Mines, offered this suggestion in the course of a lecture recently delivered at the University of Sheffield, England. It was the first of a series of six lectures by authorities on "Some Problems of the Mining Industry."

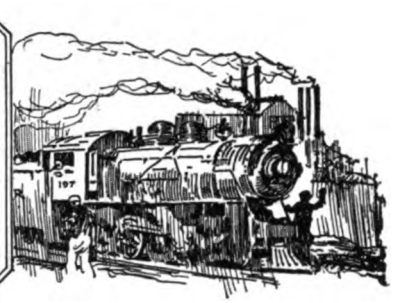
Sir Richard divided his talk into three parts: the economics of production, of distribution and of consumption. More extensive use of machinery was necessary he said, in order to increase output per man per shift. Only in this way, he thought, could Great Britain keep pace with Germany, her chief competitor, whose labor costs were lower. Cheaper production, he said, would help the industry not only in Great Britain but throughout the world, as it would encourage the more extensive use of coal.

If the coal producers would combine to form a selling association and retail their own coal, said he, quite a saving could be made to the consumer. A colliery in Northumberland started to retail its own coal and reduced the price of coal to the consumer about 7s. a ton. All of Germany's coal was being sold by a syndicate and very few dealers were being employed in the cities.



Sees Economy in Carbonization

In the matter of consumption of the coal he thought that the greatest saving could be effected through carbonization. All of the coal could not be made into metallurgical coke nor could all coals be made into low-temperature cokes for domestic use. By combining a low-temperature carbonization plant with an electric generating plant the greatest power could be gotten from the coal and the valuable byproducts of distillation recovered.



Tennessee Products Corp. Issues Bonds

The Tennessee Products Corporation announces a new issue of $1,500,000 first mortgage 6½ per cent ten-year sinking fund bonds, which is being marketed by Rogers Caldwell & Co.; Taylor, Ewart & Co. and the American National Co. The Tennessee Products Corporation recently was formed by the merger of the Chattanooga Coke & Gas Co., Inc.; Bon Air Coal & Iron Corp. and J. J. Gray, Jr., and owns or controls properties located at Chattanooga, Goodrich, Eastland, Clifty, Rockdale, Bon Air, Ravenscroft, Clarksville, Collinwood and Lyle, Tenn. The proceeds from the sale of these bonds and certain junior securities will be used for the acquisition of properties and for working capital, betterments and corporate purposes.

Production And the Market

Sharp Drop in Output and Ease in Price Decline Feature Bituminous Coal Market

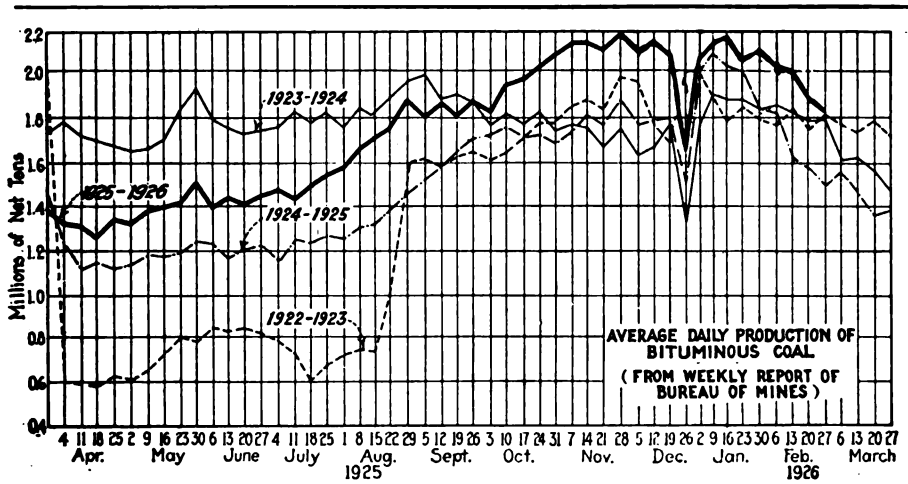
The coal trade of the country is still engaged in working out the problems created by the juxtaposition of the unexpected resumption in anthracite mining and the seasonal decline in soft-coal demand. The readjustments necessary are being effected with surprisingly few major upsets to business. Such changes as have taken place were, for the most part, anticipated and discounted.

Sharp reductions in the production of bituminous coal and a milder rate of decline in price levels mark the course of the market. Output the last week in February, according to the Bureau of Mines, dropped to 10,895,000 net tons. Preliminary figures point to further declines during the first week in March. Nevertheless, there is too much unsold coal on wheels to make the situation comfortable.

However, even that admittedly bad situation has been ameliorated somewhat by sharper weather in the West and by railroad purchases of tonnages rejected by retailers in the East. A check against adding to these accumulations is found in the increasing number of mine shutdowns.

Price Levels Descending

Spot prices on bituminous coal are again at the same levels as ruled a year ago. *Coal Age* Index for March 8 was 167 and the corresponding price was $2.02. Compared with the preceding week this was a loss of two points in both index figure and average price. Generally speaking, all tidewater prices receded. Inland, prices on sized coal weakened, but quotations on slack advanced. This latter increase was due more to decreased output than to any expansion in industrial demand.



Contract developments to date have been kept well under cover. At present the outlook in the East from the standpoint of prices is not promising and the freedom with which coal is moved in all parts of the country gives the buyer the initial advantage in price haggling. Much, of course, will depend upon the development of the lake trade. The revival of the lake rate fight will not assist an early clarification of the situation.

Anthracite Production Up

Anthracite production, which got off to a bad start, made a quick recovery the last week of February, when the output reached 1,611,000 net tons. This tonnage is being fed out over as wide an area as possible—particularly by the larger producers. Some of the smaller independents are racing for the markets which will pay the highest prices. The day of extravagant premiums, however, will be short and its decline already has set in.

The most interesting feature in the current anthracite situation is the apparent scarcity of the usually despised pea coal. New York complained of this two weeks ago; Philadelphia protested last week. There also is a better demand than usual from household consumers for No. 1 buckwheat. In the steam trade, however, the small sizes are facing hot competition from the bituminous coals and independent prices are slipping.

Production of beehive coke is rapidly declining. For the week ended Feb. 27 the decrease was over 26,000 tons. The ovens must now look to the metallurgical trade for an outlet to their production. There has been an increase in orders placed by the foundries, but spot buying of furnace coke has been negligible. Some operators are entering the gas market with raw coal.

Estimates of Production

(Net Tons)

	1925	1926
BITUMINOUS		
Feb. 13	9,758,000	12,011,000

Middle Western Screenings Up

Advances of 5 to 25c. per ton featured the market in screenings in the Middle West last week. The increase was due to curtailed output following the slump in demand for prepared sizes rather than an expansion in the requirements of industrial consumers. Illinois, Indiana and western Kentucky mine-run, on the other hand, have not benefited by the change.

Prices on prepared coals have been fairly well maintained. Southern Illinois 6-in. lump commands $2.75@$3, with strip-pit offerings 50c.@$1 under those figures. Central Illinois is $2.50 @$2.75. The widest range is in Indiana—$2.25@$3. A cold snap helped the market, but it is realized that these flurries can have no lasting effect.

More mines are closing down every day and some of the miners are deserting the fields. Further demoralization of union operations in Illinois and Indiana is feared as a result of the announcement that one of the largest producers in the first-named state has taken over the output of a number of mines in non-union western Kentucky.

Outlying Fields Also Hard Hit

The other Illinois producing districts are faring no better than the central and southern fields. Some mines in Duquoin and Jackson County are having a hard time to find a market for two days' output; only the most fortunate can average four days a week. Contract tonnage represents the bulk of the movement from the Mt. Olive section. Operators in the Standard district still seem bent upon seeing how much tonnage can be sold at a loss. There are unconfirmed rumors that several Belleville mines will go on a cooperative basis.

Eastern coals had hard sledding in the Chicago market last week. One eastern Kentucky operator cut his circular from $2.50 to $2.25 and competing producers soon followed his lead. Not to be outdone, some West Virginia shippers cut 4-in. high-volatile block to $2, although the general range is $2.25@$2.75. Smokeless factors have held lump, egg and nut at $3.50@$4, but mine-run is to be picked up at $1.75.

Up to the close of last week there had been no real movement of anthracite into Chicago. The fact that shipments were en route, however, induced retailers to let go of scanty stocks in their yards at $17 for egg, range and nut. Shippers of first quality coke are busy catching up on unfilled orders and prices are strong.

Kentucky Domestic Slump Grows

Demand for prepared coal from Kentucky mines still is slipping. Intermittent cold spells do not bolster up the market, as retailers are more interested in cleaning up yard stocks than in ordering more coal forward. A quarter has been clipped off the top prices on block coals. Eastern Kentucky block is $2.25@$2.75; lump, $2@ $2.25; egg, $1.75@$2; nut, $1.65@$2,

*Net tons, f.o.b. mines. †Advances over previous week shown in **heavy** type; declines in *italics*

Digitized by Google

Western Kentucky block is $1.75@$2; lump and egg, $1.50@$1.75.

Optimists envisage a dollar minimum on screenings in the near future. Current offerings show western Kentucky at 85c.@$1 and eastern Kentucky at 90c.@$1.10. Western Kentucky nut and mine-run are $1.25@$1.50, but the upward swing in screenings is expected to boost nut. Eastern Kentucky mine-run is $1.35@$1.50.

The contract outlook is still very uncertain. Many buyers think they will be safe in playing the spot market; some sellers have no desire to renew business on the same basis in effect in 1925-26. In the meantime, the volume of steam tonnage moving is the best feature of the market.

Weather Helps Northwest

King Winter came to the aid of the docks at the Head of the Lakes last week and lightened the fears of operators who were beginning to view their piles of domestic coal with misgivings. Under the stimulus of weather demand, shipments were increased to dock-consuming territory. Prices, particularly upon smokeless coals, recovered from a dragginess which had threatened reductions. Progressive improvement is reported in industrial demand and the docks again are edging Illinois and Indiana out of some business in the Twin Cities. Stocks on the docks are estimated at 3,500,000 tons.

The weather also toned up drooping domestic trade at St. Paul and Minneapolis. Some retailers have started to advertise all-rail anthracite for sale. Little response is made to pleas for renewals of steam contracts. Spot prices on industrial coals are heavy. Anthracite is coming into Milwaukee in increasing quantities and is readily absorbed by eager consumers. Retail prices are: Stove, $16.80; nut, $16.65; pea, $14.25; buckwheat, $11, curb or chute delivery.

Kansas operators are marking time, awaiting the official demise of the coal season. Mines are averaging two days a week. The slowing down of production has created a growing scarcity in screenings. Arkansas operations are at a low ebb. Steady curtailment is the rule in Colorado as domestic demand dwindles. This has cut down the number of "no bills" and strengthened the position of steam sizes. Prices are unchanged. Utah markets are at the mercy of the vagaries of the thermometer. Slack is firm at $1.50, although the immediate demand is not large.

Weather Flurry Relieves Cincinnati

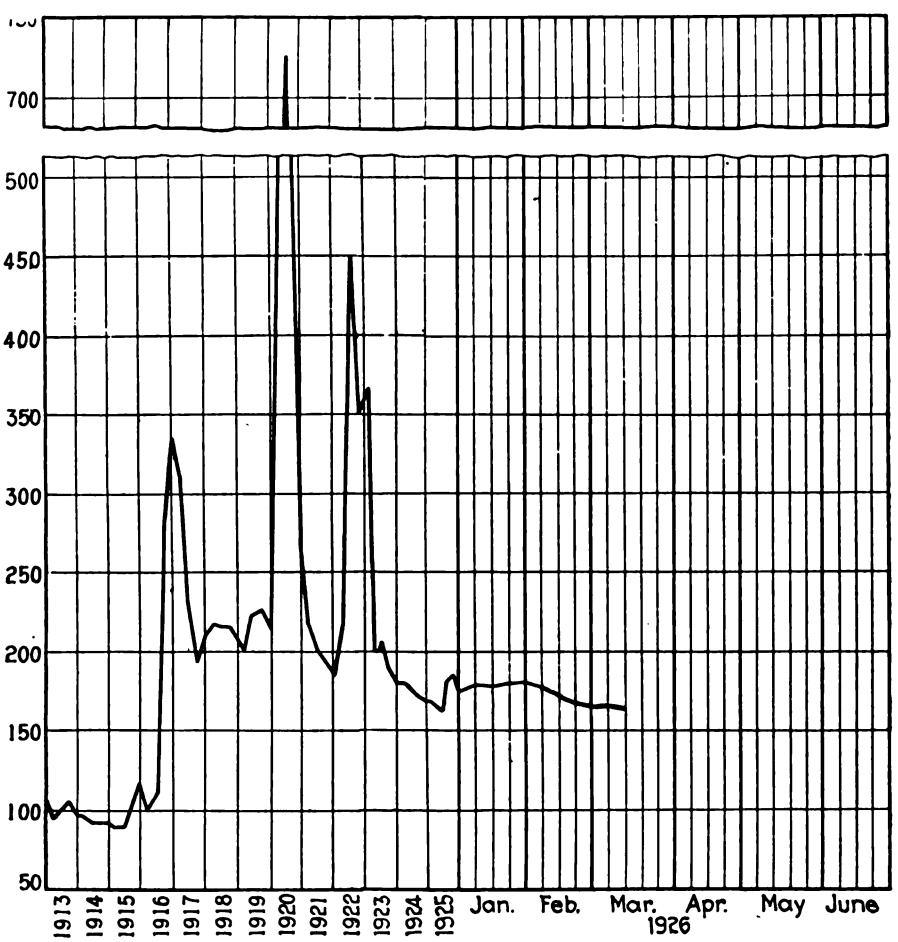
A cold-weather flurry brought relief to the Cincinnati trade last week. It enabled West Virginia producers to get rid of considerable tonnage on wheels at the mines, but resulted in no appreciation in price levels. As a matter of fact, operators still are feeling their way on the price question. For example, there is a spread of 50c. in smokeless circulars on the larger screened sizes and the spot-market range, $3.75@$4.25, is 25c. under circular quotations. Mine-run has weakened to $2@$2.25 and slack is up to $1.10@$1.50, with the bulk of the tonnage moving at $1.25.

High-volatile prices on prepared sizes have been fairly well maintained. Quotations on mine-run and slack are stronger. Reduced production, of course, is the real support of the market at the present time. Movement through the Cincinnati gateway, according to the latest weekly interchange report of the American Railway Association, decreased 583 loads and the number of empties on their way to the mines decreased 1,219.

The Cincinnati retail situation is unchanged. River business is finding its stride with the approach of spring. Approximately 11,000 tons a week are now coming down the Ohio.

Central Ohio Marks Time

Aside from a slight weather stimulation to domestic trade the past week, the central Ohio market is featureless. Even this stimulus did not result in many orders for shipment. Large industrial consumers are in a comfortable position as regards reserve stocks on hand. The curtailment in production and the closing down of mines incident to the decreased demand for sized coal, however, have pushed quotations on spot screenings to $1@$1.15. Southern Ohio output is now less than 20 per cent of capacity.



An increase of 15 to 20c. in the price of slack was the outstanding feature of the eastern Ohio market last week. Spot prices on other grades from the No. 8 field were unchanged. Distress coal, however, has diminished and fewer shippers are willing to take the risk of shipping coal on open billing.

During the week ended Feb. 27 the No. 8 field produced 212,000 net tons, or approximately 36 per cent of potential capacity, as compared with 248,000 tons the preceding week and 224,000 tons a year ago.

The effect of the resumption of anthracite mining on central Pennsylvania production is becoming more marked as the weeks go by. During the last week of February daily loadings of coal dropped 400 cars, as compared with a decrease of 200 cars the preceding week. Pool 1 coal is quoted at $2.80@$2.90; pool 71, $2.55@$2.65; pool 9, $2.35@$2.50; pool 10, $2.25@$2.30; pool 11, $2@$2.10; pool 18, $1.90@$2. Lump is $3.50; egg, $4; slack, $1.50.

Weakness Spreading in Pittsburgh

Weakness is spreading over the Pittsburgh district market. Domestic demand is down to the season-end dregs. Industrial and railroad consumption is heavy, but Pittsburgh district mines

Weighted average price	$2.02	$2.04	$2.06	$2.10	$2.02	$2.18

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

must fight non-union competition to retain an equitable share of this business. Production is dropping and probably does not exceed 20 per cent of capacity. This is reflected in stronger slack prices, which have advanced 20c. since the anthracite strike settlement.

The gloom characteristic of Buffalo trade opinion has, if anything, taken on a darker tinge. Quotations nominally are unchanged, but business is solicited so actively that it is impossible to present a true price picture. The industrial consumer who insists upon driving a hard bargain does not have to look far to find a seller who can be driven.

There is an unmistakable downward trend to bituminous prices in New England. Coal is piling up at most of the distributing points. Spot demand is moribund. Even those consumers who will use soft coal the coming season are waiting until the situation created by the anthracite strike has cleared up before making new commitments.

Downward Trend in New England

Prepared bituminous is offered freely around $3 mines. Slack has been a choice morsel for the bargain hunters. There is a weak demand for screened short-haul Pennsylvania bituminous, but this will die as soon as anthracite is moving in normal volume.

There are large accumulations of Pocahontas and New River coal at Hampton Roads which can be had at $4.40@$4.60, but there are few spot buyers. On cars at Boston and Providence quotations have sagged from $6.50 to $6 and $5.85.

The New York bituminous market is "shot to pieces." Spot demand has weakened and prices are on the downgrade. Reports of congestion at the local piers and en route brought more cancellations. Rejection of shipments in the terminals on the plea that the tonnage was of inferior quality added to the confusion. On Long Island alone it was announced that 575 cars of soft coal and 407 cars of coke had been rejected. The railroads are being appealed to to take over such coal.

Some foreign coal was received last week and additional cargoes are on the high seas. Consignees say that they will be able to move that tonnage without trouble. Screened bituminous coal from Pennsylvania and West Virginia has dropped out of the local picture.

Philadelphia Turns to Contracts

As at New York, the Philadelphia market for bituminous coal for domestic consumption seems to be on its last legs. There is more distress tonnage than shippers like to admit. Bargain-hunting steam coal buyers have absorbed considerable coal of that description. Producers are combing the market in an effort to persuade consumers to enter into contracts for the new year or to renew existing agreements. Although the major producers are holding out for a $2.65 base, there are others willing to take on tonnage at $2.20@$2.25.

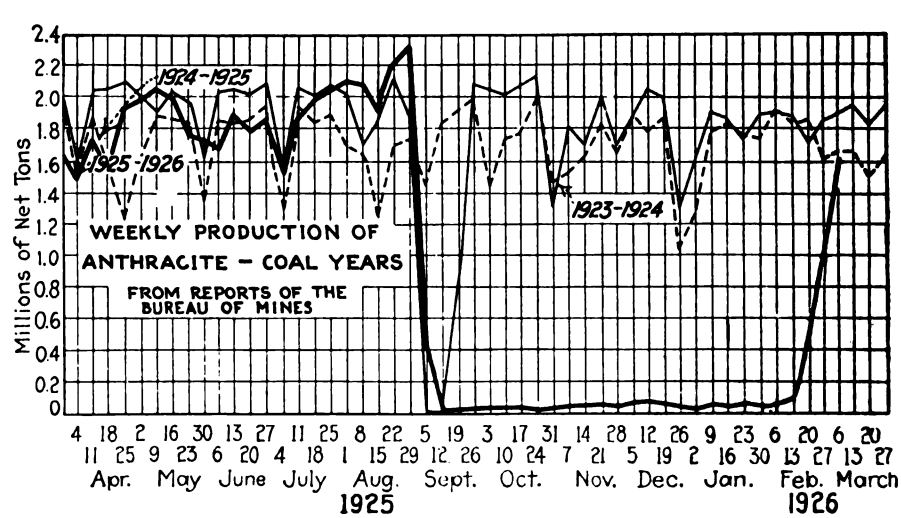
The collapse of the demand for screened coal has forced many mines to close down because they cannot pick up enough industrial business to justify continuing operations. This has strengthened the position of slack coal, which is due for a further increase with the re-entry of cement mills into the market.

Dullness controls the Baltimore bituminous market. Buying of prepared coal is a hand-to-mouth business. Industrial coal moves through normal channels and does not stir up the spot market. Bunker trade, for the most part, has shifted to the Virginia ports. Despite that fact, however, there is no particular snap to the market at Hampton Roads. During the past week an effort was made to clear out old stocks in anticipation of April 1 contracts. Dumpings for the week ended March 4 dropped to 414,270 gross tons.

No Change at Birmingham

The Birmingham industrial market shows no material change. Spot buying of the lower grades of coal is slow and restricted, but medium and high grade fuels find a fair market. Washed coal is in active demand by the coking ovens. Bunker trade, too, has been healthy. Domestic demand has settled down to a weather proposition.

The gradual absorption of the large stocks of substitutes by consumers and railroads has helped the movement of anthracite to the New York market. As the stocks of soft coal and coke diminished, orders for hard coal increased, but the operators are not pressed to make deliveries. Under these circumstances, some of the independents are finding it difficult to exact the premium prices they asked when mining was first resumed.



With plenty of soft coal on hand or under contract, some of the producing companies are confronted with accumulations of anthracite steam sizes. Company circulars are the top figures and some sales are made at less. Toward the end of last week barley was offered as low as $1.35.

Philadelphia Wants Anthracite

Philadelphia retailers are clamoring for anthracite. Independent shippers with premium coal are not deaf to these cries. The percentage of premium tonnage being absorbed is causing some distributors to change their ideas of retail prices. While there are many dealers who are holding egg and nut at $15.75 and stove at $16, others are asking $16.75 and $17 and in a few cases $17.50. Pea is $12 and $13. Retailers complain that they cannot get enough of this last size. Buckwheat also is in good demand.

In an effort to move some of the substitutes on hand, retailers have insisted that consumers take coke and anthracite in equal quantities. During the cold snap last week many were able to sell this idea to their customers. Retail coke prices are $4@$5 under the yard cost of that fuel.

Baltimore dealers are trying to distribute limited receipts of anthracite in a manner that will take care of the

greatest number of customers. Little independent tonnage is being purchased. Retail prices are on a pre-strike basis.

Buffalo seems to have enough anthracite to meet current pressing demands—too much in fact to suit some distributors loaded up with high-priced coke or bituminous coal. Across the border, Toronto dealers are working at high pressure to take care of anthracite demand and to sell, where possible, a mixture of hard coal and coke. The large domestic anthracite is retailing at $16; pea is $13. Coke has been cut to $15, a reduction of $2.

Connellsville Abandons Hope

Connellsville has definitely placed the hope that there would be a revival in retail demand for coke in the limbo of forgotten things. The region is now concentrating its coke attention upon metallurgical business. Standard furnace coke is $3.25@$3.50; foundry coke, $4.50@$5. Production has decreased sharply. Some mines are now seeking to sell the raw coal to the gas trade.

Blast furnaces have bought little spot or prompt coke. It is probable, too, that they will postpone negotiating second-quarter contracts until the eleventh hour. Foundries have been fair buyers to cover requirements upon which orders were withheld during the price orgy.

The Connellsville *Courier* reports coke output in the Connellsville and Lower Connellsville regions the week ended Feb. 27 at 103,100 tons from the furnace ovens and 102,900 tons from the merchant ovens. Compared with the preceding week, furnace oven output decreased 7,600 tons and the output from the merchant ovens dropped off 18,560 tons.

New York Coal Imports

Custom House reports show that imports through the Port of New York during the months of November, December and January last included 180,465 tons of anthracite, 37,431 tons of coke, 5,148 tons of bituminous coal and shale and 20 tons of slack and culm.

Imports by months were:

November—46,342 tons of anthracite, valued at $478,843, an average cost of $10.33, and 2 tons of bituminous coal and shale, valued at $19.

December—83,272 tons of anthracite, valued at $836,227, an average cost of $10.04 per ton; 5,146 tons of bituminous coal and shale, valued at $28,130, an average cost of $5.46; 20 tons of slack and culm, valued at $138, an average cost of $6.90, and 33,342 tons of coke, valued at $216,143, an average of $6.48 per ton.

January—50,851 tons of anthracite, valued at $447,080, an average cost of $8.77 per ton, and 4,089 tons of coke, valued at $37,922, an average of $9.27 per ton.

New England Fuel Committee May Be Permanent

The New England Governors' Fuel Committee, according to statement by Vice-Chairman Eugene C. Haultman, will function until June 1, at least, and it is probable that arrangements will be made whereby the committee will continue as a permanent body. The committee believes it has done good work for New England and should continue to function as a protection, if nothing more, to the people of that section against the possibility of future fuel troubles.

Coke Output Sets New Record In January

Output of byproduct coke in the United States during January, according to reports by operators to the U. S. Bureau of Mines totaled 3,804,000 net tons, an increase of 44,000 tons, or 11.7 per cent, compared with the preceding month. The coke plants operated at about 92 per cent of capacity.

Beehive coke production continued to increase during January, the total being estimated at 1,381,000 net tons, an increase of 74,000 tons, or 5.7 per cent, compared with December.

Monthly Output of Byproduct and Beehive Coke in the United States.*

(In Thousands of Net Tons)

	Byproduct Coke	Beehive Coke	Total
January, 1926	3,804	1,381	5,185
December, 1925	3,760	1,307	5,067
November, 1925	3,557	1,213	4,770
October, 1925	3,402	1,006	4,408
1925 monthly average	3,332	893	4,225
1924 monthly average	2,833	806	3,639
1923 monthly average	3,133	1,615	4,748

*Excludes screenings and breeze.

Coal consumed in both beehive and byproduct coke plants in January was 7,644,000 tons, 5,466,000 tons being consumed at byproduct plants, and 2,178,000 tons at beehive plants.

Estimated Monthly Consumption of Coal in Manufacture of Coke

(In Thousands of Net Tons)

	Consumed in Byproduct Ovens	Consumed in Beehive Ovens	Total Coal Consumed
January, 1926	5,466	2,178	7,644
December, 1925	5,403	2,062	7,465
November, 1925	5,111	1,913	7,024
October, 1925	4,888	1,587	6,475
1925 monthly average	4,787	1,371	6,158
1924 monthly average	4,060	1,272	5,332
1923 monthly average	4,523	2,507	7,030

Of the total output of byproduct coke during January, 3,153,000 tons, or 82.9 per cent, was made in plants associated with iron furnaces, and 651,000 tons, or 17.1 per cent, was made at merchant or other plants.

Foreign Market And Export News

Shipping Delays Upset Welsh Coal Movement; Tyne Spot Trade Slow

Though the general aspect of the coal trade in South Wales is promising, and there is enough business in hand to ensure a fair degree of activity for the next two months, the position for immediate shipment is less favorable on account of shipping irregularities, with the consequent arrears in deliveries. Where the tonnage is that should be ready in Welsh ports nobody seems to know.

A serious handicap has been the sharp rise in freights for South America and the Mediterranean, representing 6s. in the former case and around 2s. 6d. per ton in the latter. This rise has meant serious loss to many exporters who accepted cheap c.i.f. contracts some months ago.

As a rule, the collieries, are well booked to the end of April, and the output in Wales has risen from around 700,000 tons per week last September to over 1,000,000 tons. In addition to this there is the possibility of the Cambrian Collieries reopening. These mines were closed in August, 1924, when they employed around 3,500 men. Besides the 200,000 tons for the Paris, Lyons & Mediterreanean Ry., reported last week, orders have been booked for 25,000 tons for the Portuguese Rys. and 20,000 tons for the Spanish Andalusian Rys.

The market at Newcastle is irregular due largely to shipping delays, higher prices and higher freights. In consequence there is a fair quantity of coal on the market for ready sale at less than current prices. Most of the collieries are well booked into March.

Output by British collieries during the week ended Feb. 20, according to a special cable to *Coal Age*, totaled 5,420,000 gross tons, compared with 5,400,000 tons in the preceding week.

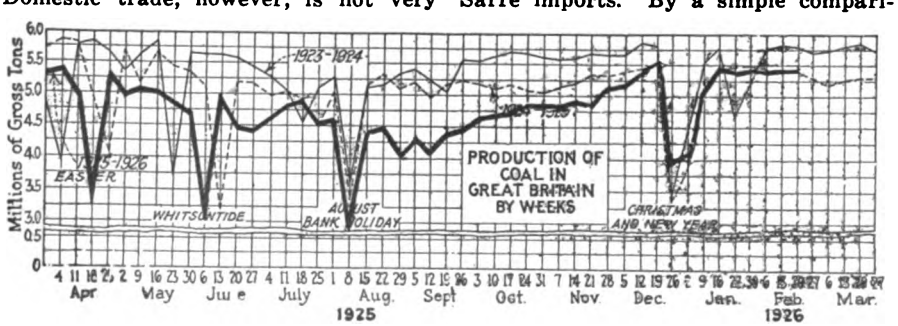
Industrial Demand Rules Belgium

Demand is undoubtedly better for Belgian industrial coals, although stocks are still available, reports Brussels under date of Feb. 18. French coal, however, which has increased about 15 fr., is less a factor than ever and the same is true of German free coal. Domestic trade, however, is not very large, because of milder weather, but there are no surplus stocks available.

It is declared that the coal fields producing lean and anthracitic sizes alone make money, all the others being in deficit.

The Coke Syndicate quotes 125 fr. nominally. Indemnity coke is 120 fr., but it is possible to get fuel at 115 fr. and even less.

French Domestic Demand Eases; General Outlook Good



Paris, France, Feb. 18.—The market for French coal remains satisfactory; there is more easiness, however, in domestic consumption, due to milder weather. Scarcity of flaming coal continues.

Russian anthracite is hard to move because it is not successful in the stoves used in flats (salamanders). Donetz cobbles, however, give satisfaction in central heating plants, but prices are considered too high in comparison to those of Welsh anthracite.

Receipts of Ruhr coke have been on the increase, but it is reported that with March deliveries of indemnity coke will be reduced in volume and prices increased over 10 fr. French metallurgical plants will have their allotment of coking smalls cut from 120,000 to 90,000 tons per month. These changes are attributed to a depletion of funds at the disposal of the Agent of Payments (Dawes plan).

In 1925 France imported 18,296,419 metric tons of coal, as compared with 25,106,584 tons in 1924. The 1924 figures, however, included 5,214,030 tons from the Sarre, now covered in French production. In 1925 France exported 4,606,443 tons of coal, as against 2,245,098 tons in 1924. Exports in 1924 did not include shipments from the Sarre. What part of 1925 exports came from the Sarre cannot be determined from the published figures, but it probably approximated 2,300,000 tons.

If we add to the output of 1925 (48,033,564 tons) the amount of the imports, and if we deduct the exports, we arrive at a total of 61,724,000 tons, which represents the tonnage put at the disposal of consumers in the past year. This does not include the stocks existing on Dec. 31, 1924, nor the Sarre imports. By a simple comparison we may say that in 1924 the consumption fixed in this way had come to 67,816,000 tons.

Polish-Italian Contract Signed

The Polish Ministry of Industry and Commerce has announced the conclusion of a contract with Italy by which Poland will export 500,000 metric tons of lump coal to that country annually, payment to be cash against delivery. It is not known whether all or only half of this amount will be used for the Italian railways. Poland, in return, is to give special concessions for the importation of Italian oranges upon which there have been special restrictions heretofore.

News Items From Field and Trade

ALABAMA

Preparations are being made by Moss & McCormack to sink two slopes at their operations near Carbon Hill, Walker County, where they are developing extensive mining operations. These slopes will be about 850 ft. deep and will tap the Jagger seam of coal. The company is now producing coal from the Corona seam through six drift openings. A large mining camp is nearing completion and tipple buildings, washery and preparation machinery of the most modern type have been erected and placed in operation. A mechanical loader has been installed in one of the openings and the company plans to add a number of additional machines of this kind, if they prove satisfactory. The mines are located on a spur which taps the main line of the Frisco railroad at Carbon Hill. Main offices of the company are in Birmingham.

INDIANA

The Knox Consolidated Coal Co., Indianapolis, is considering the rebuilding of the power house at its Bruceville mine, near Bicknell, and of the tipple at Indian Creek mine. The Bruceville power house was destroyed by fire Jan. 13, with a loss of $25,000, and the Indian Creek tipple was partly destroyed by fire Jan. 2, causing a loss of approximately $65,000.

The Prior Coal Co., Marion, has filed a final certificate of dissolution.

The LeNoir Coal Co., Bloomfield, has filed a final certificate of dissolution.

ILLINOIS

The Illinois Miners' Examining Board will hold sessions this month as follows: Duquoin, Miners' hall, March 12; Centralia, Miners' Hall, March 13; Staunton, Labor Temple, March 15; Springfield, State House, March 16; Danville, court house, March 17; Farmington, Moose Hall, March 18; Peoria, court house, March 19, and Lincoln, City Hall, March 20.

A loss of almost 50 per cent of the coal in Illinois results from present methods of coal mining, according to a report of the State Geological Survey, located at the University of Illinois. The survey covers eleven fields in twenty-seven counties, representing nearly the entire output of the state. In the mining of 69,785,000 tons of coal, the report states, 67,045,000 tons was lost. Pillars account for most of the loss, the average being 39 per cent, but investigation showed, the report says, that 32 per cent of the loss was avoidable.

Plans are being made for the opening of the old Tazewell County coal mine, at Pekin.

KANSAS

Incomplete reports from Kansas coal mines, James A. Sherwood, state mine inspector, announced March 1, showed a production of 4,705,820 tons. Six shaft mines and three shovel mines had not yet sent in complete reports to the inspector's office. The total production from all mines in 1924 was 4,491,069 tons. The nine mines yet to report on last year's business are expected to raise the total to the neighborhood of five million tons.

KENTUCKY

An involuntary petition in bankruptcy was filed last week in the U. S. District Court at Louisville against the Rockport Coal Co., operator of two Ohio County mines located at Rockport and Centertown. Assets of the company were estimated by the attorneys at $100,000 and liabilities were said to be $125,000 to $150,000. It was charged that in addition to the alleged fact of its insolvency the company made preferred payments to certain creditors. The company's coal mines, it is said, have never resumes operations on their original scale since the 1924 strike. The firm is incorporated in Kentucky with H. L. Tucker, Central City, as president and R. C. Reid, Rockport, as secretary.

The Harlan-Jellico Coal Co., Louisville, operating a mine in Harlan County, has changed its name to the Dougherty Coal Co. The company is owned by the Dougherty interests of Louisville.

A bill has been passed by the lower house of the Kentucky Legislature to create a central purchasing department, for state needs of every kind. Coal, instead of being purchased by several buyers, would all go through one buying office. It is an administration bill and is almost certain to become a law.

NEW YORK

Edward W. G. Borer, Philadelphia, was elected a director of the By-Products Coke Corp. at the annual meeting in Syracuse, Feb. 23, after a vote of stockholders increasing the number of directors from 14 to 15. C. D. Caldwell, president, announced that application will be made to list stock of the company on the New York Stock Exchange. Stockholders voted to reduce the number of preferred shares from 50,000, $100 par, to 20,000, $100 par, and increase the number of common shares from 100,000, $100 par value, to 200,000, no par. It will be distributed to present owners on a two to one basis. Principal offices of the company were transferred from Syracuse to New York City.

MASSACHUSETTS

Deliveries of bituminous coal by retail dealers in Massachusetts during January were reported as 369,621 tons, which is an increase of over 60,000 tons over deliveries in the preceding month. Coke deliveries increased from 46,665 tons in December to 66,781 tons in January. Deliveries of foreign and domestic anthracite and semi-anthracite totaled 83,710 tons in January, which makes the total amount of anthracite delivered this winter up to Feb. 1 3,802,000 tons, as compared with the total deliveries last year (April 1, 1924, to March 31, 1925) of 5,115,717 tons.

MONTANA

The Northern Pacific R.R. reports that a saving of $700,000 was effected in 1925 through the use of coal from the open pit mines in the Rosebut strip of Montana.

PENNSYLVANIA

Officials of the St. Clair colliery announce that operations will be resumed in the course of a few days. This mine was one of the few that suffered during the long anthracite strike through a walkout by maintenance men. The interior of the mine is now being put in readiness for work. The breaker has a normal production of 1,000 tons a day when going at full speed.

The Consumers Coal Co., Harmarville, has reopened its mine after being closed for six weeks on account of obstruction of navigation in the Allegheny River by ice. About 450 men have returned to work. The coal of this mine is shipped largely to Follansbee, W. Va., for conversion into coke.

Since the settlement of the anthracite strike the following coke ovens have been blown out in the Connellsville field: Washington Coal & Coke Co., Star Junction, 100; A. M. Byers Co., Orient plant, operated by Hillman Coal & Coke Co., 160; all ovens at the Republic plant of the Republic Iron & Steel Co.; all the ovens at the several

Digitized by Google

plants of the Corrado interests; part of the ovens at the Tower Hill plants of the Hillman Coal & Coke Co.; Snowdon Coke Co., 200; Union Connellsville Coal & Coke Co., closed down entirely; all ovens of the Footedale plant of the H. C. Frick Coke Co.

The washery of the Pittston Coal Co., near Pittston, was destroyed by fire Feb. 21. It had been idle during the anthracite strike, and workmen were preparing it for a resumption of operations when the fire occurred. The owners announce that the structure will be rebuilt.

A step toward segregation of the coal properties from other holdings of the Lehigh Coal & Navigation Co., was taken Feb. 23 at the annual stockholders' meeting, when a resolution was adopted providing for the appointment of a committee of three stockholders and three members of the board of managers to study the company's financial structure and report recommendations. The resolution asserted that the recent suspension of anthracite mining had resulted in bringing to public notice "so-called earning figures" of the large producers, and added: "Said figures as applied to the Lehigh Coal & Navigation Co. are misleading, as the actual earnings and the total net assets, apart from the coal lands and improvements, are far in excess of earnings and actual value of said coal lands and improvements." Samuel D. Warriner was re-elected president of the company.

The Pittsburgh Coal Co. reports production for the week ended February 27 by its eight mines in western Pennsylvania operating on the 1917 scale was 33,304 tons, a new high record. Banning No. 2 mine, which has been operating since last August, set up a new record with 7,732 tons.

The Hudson Coal Co.'s new breaker at Olyphant will supplant the Eddy Creek, Miles Slope and Olyphant breakers. The new coal-preparing plant will centralize the Mid-Valley output of the Hudson mines. It will be electrically equipped throughout and embody modern flotation processes for better preparation of the coal.

Anthony R. Panne, of Old Forge, president of the Old Forge Colliery local of the Pennsylvania Coal Co. and for years touted by the union as a radical, has been named a field worker and organizer of District 1, United Mine Workers. Rinaldo Cappellini, president of District 1, announced the appointment.

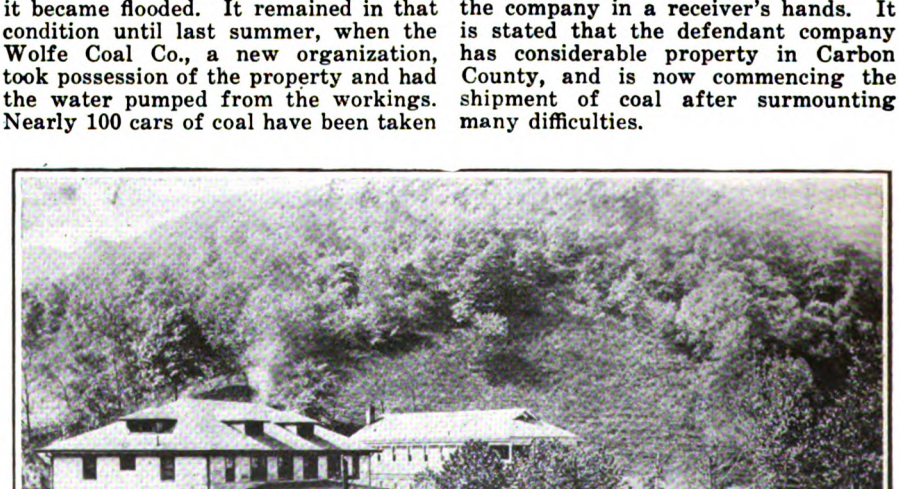
Much protest is heard throughout the anthracite region because of the delay on the part of Governor Gifford Pinchot in appointing seven anthracite mine inspectors to fill vacancies caused by death or resignation. Some of the vacancies have existed for months. Three bituminous mine inspectors also have to be appointed. In the list of ten vacancies one has existed for two years.

Coal interests in the Pittsburgh district have been successful in having the government revise its plans in connection with the Youghiogheny River basin. Another survey will be made with a view to development. A recent report by Major Daly, in charge of the U. S. Engineers in the Pittsburgh district, disapproved the project for development, which occasioned emphatic protests by the Pittsburgh Coal Co. and others, who declared there were millions of tons of coal in the river basin that will be needed in this district shortly, and the only economical means of getting it out will be via river.

For a consideration of $1,600,000, the Wheeling Coal Co. sold to the Redstone Coal & Coke Co. all its rights of way, titles, privileges, rents, liberties, property and 987 acres of virgin coal lands, situated in Luzerne township, Pa., according to a deed filed Feb. 25. The Wheeling Coal Co. is a Wheeling (W. Va.) concern, while the Redstone Coal & Coke Co. is a Pittsburgh corporation. The transaction was concluded by Isaac M. Scott, president of the Wheeling company, and E. T. Weir, president of the Redstone concern.

State foresters and foresters in the employ of the Philadelphia & Reading Coal & Iron Co. have decided to work together to accomplish the reforestration of the Pottsville region. A large number of trees will be planted this year, and with the watchmen keeping vigilant outlook on high towers which have been provided, it is believed fires can be promptly conquered. Over 350,000 trees already planted are in a flourishing condition.

Pine Forest mine, in the Pottsville region, which was idle for more than two years, has resumed operations. with seventy-five men at work. John Boyd has been placed in charge of the plant.

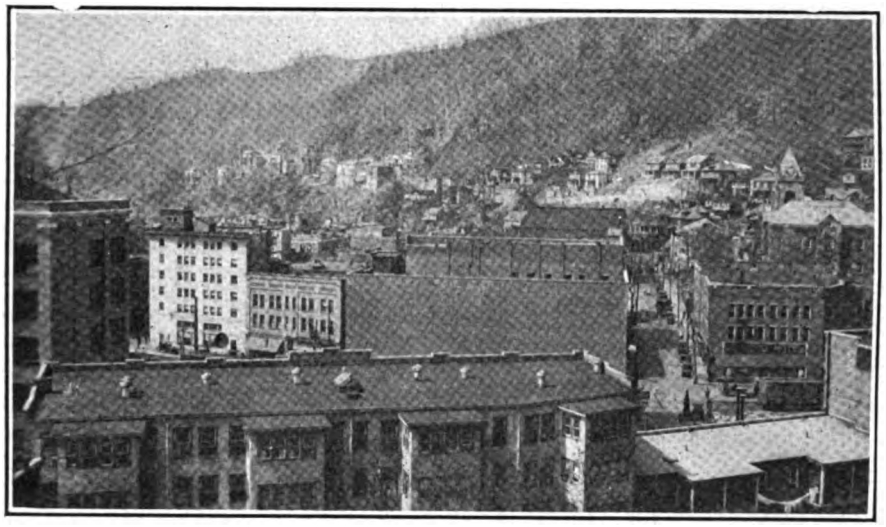


When operations were resumed in the anthracite field after the long strike coal was hoisted from the old Woodside mine, near Freeland, for the first time in 38 years. This mine was abandoned by Coxe Bros. & Co. back in 1888, when it became flooded. It remained in that condition until last summer, when the Wolfe Coal Co., a new organization, took possession of the property and had the water pumped from the workings. Nearly 100 cars of coal have been taken from the mine since the strike and officials say that the tonnage will be increased later. The coal is being prepared for market at a Lehigh Valley Coal Co. breaker at Drifton.

One new breaker was finished and another almost ready for operation when the anthracite miners recently resumed work after their long strike. The new all steel and electrically equipped plant of the Coleraine Colliery Co., near Hazleton, was tested two days after the strike ended and was accepted. It is intended to prepare about 400 tons of coal a day at this plant for the present, but later the tonnage will be doubled. The breaker cost $100,000. The new breaker of Madeira, Hill & Co., at Marion Heights, is almost ready for work. Three shifts are at work on the structure. Work on this plant was halted during the strike because of a dispute between the union and employers as to the loading of coal.

UTAH

The Salt Lake County Commissioners have asked for new coal bids after rejecting three. The lowest price offered on slack was $3.40. Because the city authorities were getting this coal at $3.20 it was decided to advertise for more bids. It was understood by the Commissioners that a number of bids had miscarried.



Those seeking to place the Great Western Coal Mines Co. in the hands of a receiver were severely scored last week by District Judge L. B. Wight, of Salt Lake City. Counsel for the petitioner is said to have sought the receivership without acquainting the coal company officials with the fact. It was declared that none of the creditors outside of this petitioner wanted to place the company in a receiver's hands. It is stated that the defendant company has considerable property in Carbon County, and is now commencing the shipment of coal after surmounting many difficulties.

Consolidation Coal Co. Provides Recreation Center at Van Lear, Ky.

The employees of the Millers Creek Division of the Consolidation Coal Co. have a new club house and a modern recreation building located within a few hundred feet of the company's office building and store at Van Lear, Ky. The club house (left) has strictly modern plumbing, five bathrooms, showers, and is heated by a steam controlled vacuum vapor system.

A Busy Mining Community in the Hills of West Virginia
That mining is on a profitable basis in this region is evidenced by this view of the mining town of Welch, W. Va. Substantial business buildings comprise the central part of town while the residential section, as may be seen in the background of the picture, extends well up the hillside.

VIRGINIA

Negotiations have been closed for the purchase of the Gunton Park properties of the Smokeless Coal Corp., of Pulaski, by the Gunton Park Anthracite Collieries Corp., a new company headed by former Senator L. Heisler Ball, of Delaware, the principal stockholders being Delawareans. The property, located seven miles west of Pulaski, comprises 1,200 acres. At a depth of 650 ft. a 7-ft. seam has been located in connection with three separate veins. Fifty cars of coal have been shipped to Northern markets during the preliminary developments. Proceeds from the sale of $600,000 7 per cent bonds will be expended in equipping and electrifying the mines and building a standard gage connection to the Norfolk & Western, one mile distant. It is contemplated having the mines equipped and producing coal by April 1.

WEST VIRGINIA

The capital stock of the Glogora Coal Co. has been increased from $500,000 to $1,000,000; that of the Blue Ridge Coal Corporation from $200,000 to $400,000; of the Export Coal Co. from $150,000 to $300,000; of the Hubball Guyan Coal Co. from $25,000 to $100,000.

The Grey Eagle Mining Co., organized under the laws of the State of Delaware, in which Thomas A. Shewey, of Grey Eagle, and others are interested, has been authorized to transact business in West Virginia.

The Crown Coal Co. has purchased from the Whyel Coal & Coke Co., Harry Whyel and the P. V. & K. Coal Co. 2,200 acres of coal land in the Arnettsville section. The deal involves a consideration of approximately $1,000,000, it is stated.

Charles E. Hawker and Cecil H. Humphrey, of Fairmont, have obtained a controlling interest in the Rosedale Coal Co. operating in the Monongalia field and Mr. Hawker has been elected president and Mr. Humphrey general manager. The new board of directors includes Edward G. Donley and A. J. Garlow, of Morgantown, and Charles F. Clement, of Philadelphia. The company was formerly owned by John L. Hatfield, W. S. John, Mrs. Asa Sterling and Isaac Van Voorhis. Under the reorganization the company will be closely affiliated with the Winslow Coal Co., of Pittsburgh, which conducts a large brokerage business in the soft coal area. An increase in capital stock has been authorized to build additional houses for miners and to erect a new tipple in order to increase production from 2,500 to 4,500 tons per day.

One of the largest intensified safety drives in southern West Virginia will be staged in the Logan field on March 21, when safety meetings will be held at Braeholm, Amherstdale and Lundale. Robert M. Lambie, chief of the state Department of Mines, will address the meetings.

Stockholders of the Crystal Block & Coke Co. have elected directors for the current year and the Crystal Block Mining Co., a subsidiary concern, has chosen practically the same directors. The only change in the directorate of the Crystal Block Coal Co. was in the election of L. A. Osborn in the place of Howard N. Eavenson. The board as elected includes Col. Edward O'Toole, Dr. R. V. Shanklin, J. M. Tulley, J. H. Barker, E. O'Toole, Jr., L. A. Osborn and L. E. Wood. On the board of the mining company are Colonel O'Toole, Dr. R. V. Shanklin, J. H. Barker, L. E. Wood and Howard N. Eavenson. The Crystal Block Mining Co. recently declared a 50 per cent cash dividend.

Although strenuously opposed by representatives of its stockholders, sale of the Lewis mine of the Hudson Coal Co. to the Wentz Corporation, of Philadelphia, for $340,000, was confirmed on Feb. 18 by Judge Birk S. Stathers of the Circuit Court of Harrison County. The mine, located on the Baltimore & Ohio R.R. near Wolf Summit, in Harrison County, was offered for sale on Feb. 6 and the Wentz Corporation was the only bidder. When the sale came up for confirmation on Feb. 15, stockholders of the Hudson company raised objections to the confirmation on the ground that the mine had been appraised at $1,000,000. Since last May the mine has been operated under the receivership of P. H. Knode, of Philadelphia, employing about 250 men.

Since installing new equipment, including shaker screens, loading booms, etc., costing $25,000 at the Vanbail mine, the Vanbail Coal Co. has been able to increase its capacity from 150 to 200 tons a day.

A safety meeting was held Saturday evening, Feb. 27, by employees of the Pocahontas Fuel Co. at Jenkinjones, McDowell County. The chief addresses were by Thomas Stockdale and William D. Lee, district state mining inspectors. A. V. Sprole, director of safety of the Pocahontas company, was in charge.

Members of the senior class in mining engineering in West Virginia University at Morgantown, were given a thorough and practical course in mine rescue and first aid training. R. M. Lambie, chief of the state department of mines, will be in charge. It is planned to give the training in a coal mine in the Scott's Run section. The students entered the mines with self-contained breathing apparatus, flame safety lamps, all-service gas masks. Burrell methane indicator, carbon monoxide and various approved equipment.

The Blue Ridge Coal Corporation of Charleston, is erecting a new tipple and equipment of shaker screens and loading booms at Brush Creek, Boone county. A three-track tipple is also being erected at No. 2 mine, and it is being equipped with shaker screens and loading booms. A year ago the company erected a new tipple and obtained shaker screens and loading booms at mine No. 3. The work of erecting the plants is in charge of J. J. Ross, the president of the company.

McComas, in the Matoaka district, has the largest mining extension school in the state, according to officials of West Virginia University. Fifty-seven men are enrolled in the McComas class. Coal company officials are urging the men to attend the school and they report that there is a marked improvement in efficiency along mining lines.

P. D. Costello, superintendent at the Jamison No. 8 mine of the Jamison Coal & Coke Co., states that a contract has been given for boring holes in front of the workings at No. 8 mine, in which vacuum pumps will be installed to draw the gas from coal to be mined. This safety measure was determined upon following the explosion in Jamison No. 7 mine last year. The company also is installing air-driven puncher machines in No. 8 mine to replace the electric driven cutting machines, as an additional safety measure. The installation will be completed within a few weeks, it is stated. Since the explosion in No. 8 mine, Jan. 14, almost the entire working has been dusted with limestone.

Personal

There is an opening on the editorial staff of *Coal Age*. Please address J. E. Spurr, *Coal Age*, 10th Ave. and 36th St., New York, giving such information as would be of interest.

J. W. Powell, formerly a consulting mining engineer of Welch and Charleston, W. Va., who is at present chief mining engineer of the Autonomous Industrial Colony Kusbas, Kemerovo, Siberia, arrived in Welch last week. Mr. Powell is on vacation for three months and expects to return to Siberia in May or June. While in the United States he will investigate coal-cleaning equipment, coal-cutting and conveying machinery, storage-battery locomotives, mine cars and haulage equipment and coal- and rock-drilling machines and other coal-mining equipment. Mr. Powell reports great progress in the development of coal mines in the Kuznets coal basin during the past two years.

John Laing, president of the Wyatt Coal Co., residing in Charleston, W. Va., sailed March 6 from New York City for a Mediterranean tour. Mr. Laing, who is accompanied by his family, will visit the Holy Land, Italy, France and the British Isles.

S. Pemberton Hutchinson, president of the Westmoreland Coal Co., Philadelphia, and former president of the National Coal Association, is a passenger on the "Lapland," which sailed from New York March 6 on a Mediterranean cruise.

Oswald Cooper, lately connected with the Chicago office of the West Virginia Coal & Coke Co., who was recently operated upon for appendicitis, has resigned and will be connected with mining operations with which his father, Dr. Cooper, of Beckley, W. Va., is connected.

The resignation of **A. H. Lichty** as vice-president in charge of industrial relations of the Colorado Fuel & Iron Co. has been announced, to take effect the end of March. According to present plans, it was said, the vacancy created by this resignation will not be filled, the work handled by Mr. Lichty being distributed among other officials, in accordance with a reorganization policy which is being put into effect. Mr. Lichty has been with the Colorado Fuel & Iron Co. for the last five years. No announcement has been made of his plans for the future.

A. M. Bingham has resigned as secretary-treasurer of the Temple Anthracite Coal Mining Co., Scranton, Pa. It is reported that in the near future Mr. Bingham probably will embark in business with Frank Hemelright, formerly president of the Temple company, who is now on a trip to Honolulu. Mr. Bingham's resignation was announced soon after the retirement of his chief. Mr. Bingham continues as a director in the coal company in which he has been prominently identified for more than 25 years. Mr. Bingham resides at Dunmore, Pa.

H. G. Ecker, general manager of W. H. Bowater, Inc., 25 Broadway, New York City, returned from England last week on the "Mauretania."

William P. Jennings

William P. Jennings, recently appointed president of the Temple Anthracite Mining Co., Scranton, Pa., has also been elected president of the Temple Coal Co., Mount Lookout Coal Co., Lackawanna Coal Co., Ltd., and the East Bear Ridge Collieries Co., as well as a director of these companies. He succeeds F. H. Hemelright, who has retired. Before joining the Temple companies Mr. Jennings was for 38 years in the service of the Pennsylvania Coal Co. and the Hillside Coal & Iron Co., where he rose from door boy to general superintendent.

P. M. Snyder has announced the appointment of **J. F. Cornwell** as purchasing agent for the subsidiary companies of the Massachusetts Gas Co. operating in the Winding Gulf and other smokeless fields of West Virginia. Mr. Cornwell has been with the New River company since 1924 as assistant purchasing agent.

Otis Mouser, who for thirty years has been connected with the Wentz coal interests, has been named to succeed the late Col. D. B. Wentz as president of the Virginia Coal & Iron Co. and of the Stonega Coke & Coal Co., as well as chairman of the board of directors of the Hazle Brook Coal Co. and the General Coal Co. **E. B. Leisenring** is the new president of the Hazle Brook Coal Co. **Col. Ralph H. Knode** has been chosen president of the General Coal Co.

Joseph P. Jennings, formerly superintendent of the Southern division of the Pennsylvania Coal Co. and the Hillside Coal & Iron Co., has been appointed general superintendent, in charge of all the colleries of the two companies. He succeeds his brother, William P. Jennings, who recently became president of the Temple Anthracite Mining Co. Other Pennsylvania-Hillside officials promoted are **Jesse Palmer**, mine inspector in the Northern division, who has been made superintendent of the Northern division, and **John M. Dobbie**, mine inspector in the Southern division, who has been named superintendent of the Southern division.

Traffic

New England Seeks Permanent Rail Rates from West Virginia

Petitions have been filed with the Interstate Commerce Commission by the New England Governors' Fuel Committee and the New England Traffic League asking that the present temporary rates on bituminous coal from southern West Virginia be made permanent. April 30 is the date set for the expiration of the emergency rates.

It is understood that New England's plea will be directed primarily toward the maintenance of rates on all sizes of low-volatile coal, while shippers of high-volatile coal in southern West Virginia seek permanent rates on that grade of coal to all Northeastern points, including New England.

The petitions will seek further hearings in I. C. C. Docket No. 15,006, commonly known as the anthracite substitute case.

Supporting petitions have been filed by the Boston Chamber of Commerce, Associated Industries of Massachusetts, Manufacturers' Association of Connecticut, Springfield (Mass.) Chamber of Commerce, New Haven Manufacturers' Association, Associated Industries of Maine, Connecticut State Manufacturers' Association, Associated Industries of Vermont, Providence (R. I.) Chamber of Commerce, New Hampshire State Chamber of Commerce and Portland (Maine) Chamber of Commerce.

The Kanawha Coal Operators' Association of Charleston, filed a petition with the Interstate Commerce Commission in Washington, D. C., on March 3, for a further hearing and for an order requiring the permanent continuance of through routes and just and reasonable rates to the six New England states, New York, New Jersey, Pennsylvania, Delaware and Maryland. The four points asked for in the petition are: First, a further hearing; that the commission by order require the respondent carriers to maintain the temporary or emergency rates; that they maintain permanently for the future through routes and joint rates on bituminous coal from the Kanawha-Coal River district and that the commission may enter orders for rates that are reasonable and just.

Stays Reconsignment Privilege On Anthracite at Detroit

In I. & S. 2619 the Interstate Commerce Commission has suspended from March 5 until July 13 several tariffs of the Grand Trunk and Wabash in connection with the reconsigning privileges on anthracite at Detroit, Milwaukee Junction, West Detroit and Port Huron, Mich. The suspended schedules propose to cancel free diversion and reconsignment privileges at those points and assess regular diversion and reconsignment charges in lieu thereof. Hearing is set for March 24 at 10 a.m., at the Detroit Board of Commerce Building, Detroit, Mich. The American Wholesale Coal Association is the principal complainant in this proceeding.

Digitized by Google

Coming Meetings

American Mining Congress. Southern industrial development conference, Hotel Peabody, Memphis, Tenn., March 15-17. Acting secretary, Henry M. Payne, Southern Division, American Mining Congress, Memphis, Tenn.

Heating and Ventilating Exposition at new Madison Square Garden, New York City, March 17-23. E. P. Frenz, Hotel McAlpin, New York City.

New England Coal Dealers' Association. Annual meeting, State Armory, Worcester, Mass., April 7 and 8. Secretary, E. I. Clark, 141 Milk St., Boston, Mass.

American Welding Society. Annual convention, 29 West 39th St., New York City, April 21-23. Secretary, M. M. Kelly, 29 West 39th St., New York City.

National Retail Coal Merchants' Association. Ninth annual convention, New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

Electric Power Club. Convention at The Homestead, Hot Springs, Va., May 24-27. Secretary, S. N. Clarkson, B. F. Keith Bldg., Cleveland, Ohio.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, in conjunction with the annual meeting of practical operating officials. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. The fourteenth congress will be held in Madrid, Spain, commencing May 24, 1926. From May 5 to 22 excursions of interest to the visiting delegates will be arranged. Information concerning the congress can be obtained from the secretary of the organizing committee, Enrique Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

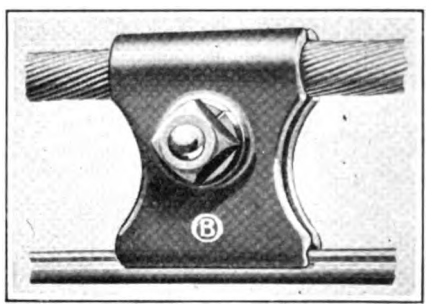
Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.



American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

New Equipment

Clamp Makes a Flexible Trolley Line

A new duplex wire clamp lately developed by the Ohio Brass Co. is employed in the construction of a flexible type overhead for mine trolley systems. The feeder cable is strung above the trolley wire and also acts as the messenger wire from which the contact wire is suspended.

The construction possesses the same advantages as the high-grade catenary systems used on electrified railroads, namely, the wire is level without sag and free from the rigidity of other types of construction which develop excessive and destructive wear at hanger supports.

Clamp Ties Feeder and Trolley

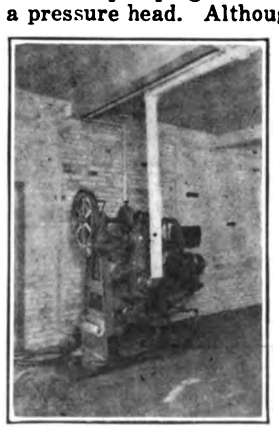
Trolley wire and feeder are held together by this clamp thus making a flexible trolley line with many feeder tap connections.

To make possible this type of overhead, at low cost and in practical form for mining conditions where low headroom is a factor, this new type of duplex trolley-feeder wire clamp has been developed. The feeder cable is suspended from a regular feeder sling or clamp attached to an insulated hanger. These duplex clips which grip the cable in the upper half and the trolley wire in the lower half are spaced at intervals on either side of the hangers. A bolt, nut and lock washer are used to tighten the grip after the clip is adjusted to position. This construction is said to be both permanent in character and economical in cost.

Gear-drive Gasoline Locomotives Announced in Four Sizes

A new line of gasoline gear-driven locomotives, ranging in size from eight to twenty tons, is announced by the Davenport Locomotive Works, Davenport, Iowa. In these, geared transmission replaces the roller-chain transmission and individual wheel drive of the present Davenport gasoline locomotives, although the manufacture of the original type will also be continued.

Many new features of design and construction have been incorporated, among which is a three-point suspension principle with cross equalizer to give improved tracking qualities. Semi-elliptic springs have been employed because of the wider distribution of stresses and better dampening of shock obtainable with this type. A fully inclosed, roomy, all-steel cab is provided for comfort and convenience in operation.



Open, accessible design has been used in these machines to facilitate quick adjustments and repair, and the construction is rugged and simple throughout. Various new mechanical features have been incorporated. The master clutch is a step jaw clutch which is always halfway in when the faces are engaged, thus eliminating the possibility of chipped corners on the clutch faces.

Both engine and transmission have individual force feed lubrication systems with pressure gauges in the cab. Alemite fittings are provided for the journals at the driving wheel.

Climax engines are used—six cylinders in the sixteen- and twenty-ton sizes and four cylinders in the eight- and twelve-ton—with four speeds forward and four reverse. Both speed and direction selection clutches slide on splined shafts for accurate, positive engagement and lock automatically in position. These advantages will be readily appreciated by practical coal mining men.

It Pumps Sludge Against Moderate Pressure Head

Careful preparation of coal by the wet process, that is coal washing, has brought its own problems in the way of sludge recovery and disposal. In the accompanying illustration is shown a diaphragm pump recently developed by the Dorr Co., of New York, and intended for use in pumping silt or sludge against a pressure head. Although this machine is a new development it has already demonstrated its utility in this type of service.

Diaphragm Pressure Pump

As ordinarily constructed a diaphragm pump is intended to operate against little or no head. Machines of the type here shown, however, are operating successfully against heads up to 35-lb. per square inch.

This pump, known as the Dorrco, has been installed in several operations and is working against pressures ranging

Digitized by Google

up to as much as 35-lb. per square inch. Because of the design and construction of the machine, however, no noticeable strain is placed upon the diaphragm and the machine handles the coal sludge without difficulty.

With Line Oiler Air Drills Never Lack for Oil

A constant supply of lubricating oil is necessary for the up-to-date hammer drill if it is to work with maximum efficiency and minimum upkeep cost. If it were not for the human equation, the oil reservoir of the hammer drill itself would be amply large enough to supply this need, but as it is always necessary to take the human factor into consideration, the extra weight that would necessarily be added to the hammer drill to secure the increased reservoir capacity would be detrimental. For this reason, the Sullivan Machinery Co., Chicago, Ill., has designed a line oiler, which is shown in the accompanying cut, to meet this need.

OILER INSERTED IN LINE

This oiler, which is known as the "J-C" line oiler, consists essentially of an egg-shaped casting, of a net weight of 7 lb. and strong enough to stand the abuse of underground work, simple in principle of operation, and with an oil reservoir of sufficient capacity so that it requires only two fillings per eight-hour shift. The common method of using the oiler is to attach it with ordinary hose connections to the end of the air hose and then to use a short length of hose (8 to 10 ft.) between the oiler and the drill to be lubricated. It is possible to use lubricating oils of varying viscosity by merely changing the feed nozzle of the oiler. Experience has proved that hammer drills equipped with this oiler give better performance with less upkeep.

An arrow on the oiler indicates the direction of the flow of air through it. Part of the air is deflected into the oil reservoir, forcing the lubricant out through the nozzle into the air line. A plugged hole is provided for filling the oiler.

It is well recognized that adequate lubrication is essential to the proper operation of most machines. Rock drills are carefully constructed pieces of mechanism and sensitive in operation. It is, threfore, highly important that they be efficiently oiled not only in order that they may work properly, but also to reduce wear and maintenance charges.

Crawler Loader Has Large Capacity

A new crawler loader, known as the "Grizzly," has been placed on the market by the Link-Belt Co. of Chicago. This machine contains many improvements, in design and detail of construction, and is said to handle crushed stone, gravel, sand, phosphate and like materials at the rate of 1½ cu.yd. per minute, or about 140 tons per average hour.

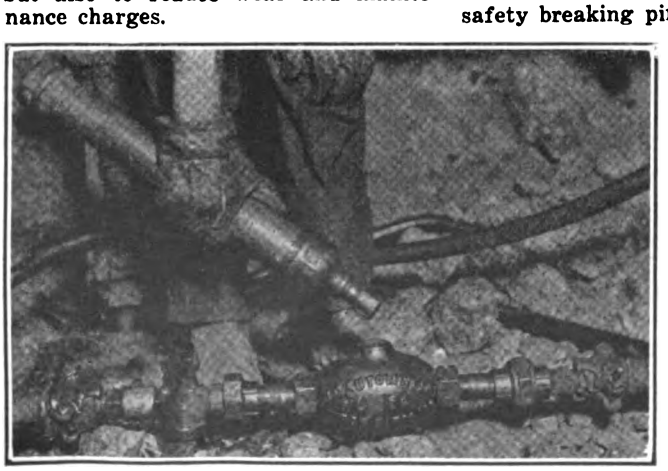
This loader is a one-man machine. Its propulsion, operation, and care can be handled entirely by one worker of average intelligence. Four units make up this machine, namely, the elevator, the chassis, the power plant, and the crawler. The unit system of construction is employed enabling the operator to inspect the machine easily, and to make any adjustment or repair without tearing the whole machine apart.

Special attention has been given to the lubrication of moving parts, all of which are provided with Alemite fittings or grease cups placed within reach of the operator. All bearings and moving parts are large enough to keep wear to a minimum, thus assuring long life to the complete unit.

It is claimed by the builder that any one can learn to operate this machine with but a few minutes' instructions. It can travel forward and reverse; and turn right or left when traveling in either direction. The starting, turning, and stopping are all controlled by two hand levers, which automatically apply brakes when stopping. The elevator is controlled by separate hand lever, which operates a steel clutch. This disengages automatically when machine is started in reverse.

The buckets used in the elevator are of special design, with reinforced edges to reduce wear. They are spaced closely enough, on double strands of malleable iron and steel chain, to insure a steady delivery of material to the delivery chute the principle involved being that close spacing of buckets permits a lower speed of the elevator, with consequent less wear of parts.

Head and foot sprockets are made of manganese steel, cast in two parts, and clamped on hexagonal steel shafts. This eliminate troublesome keys. The hexagonal shafts are journaled, and are run in babbitted bearings, oil-grooved, and provided with Alemite fittings. The driving wheel on the elevator head shaft is provided with a safety breaking pin. The chute at the head of the elevator, as ordinarily furnished, is of the swiveling type. It operates through an angle of 180 deg. and can be controlled from the operator's platform.



The feeder consists of manganese steel paddles, securely bolted to the hexagonal foot shaft, and so arranged as to produce a steady feed of material to the buckets. Feeder adjustment and collapsing mechanism are both controlled by a hand wheel within reach of the operator.

The chassis is made of heavy angles, plate and channels, securely riveted together, making a substantial support for elevator and machinery. A large steel casting is riveted to the chassis, forming the connection to the front crawler shaft. The rear of the chassis is supported on a large steel bracket casting, pinned to the rear axle.

The power plant is a simple, compact, gasoline unit of 30 hp. at 1,200 r.p.m., equipped with a governor; an electric motor may be substituted if desired. The truck transmission has 3 speeds, giving 33 ft. or 66 ft. per minute in the forward direction, and 29 ft. in the reverse.

All driving and control machinery for crawler and elevator is housed-in. All shafts are of turned and all gears of cut steel. Bearings are bronze-bushed. The housing is dust tight, and partly filled with oil, which assures sufficient lubrication to all parts.

All drives are made by means of roller chains, running on steel sprockets. All are protected by sheet steel guards. The crawler is of channel and plate construction, riveted together, making a rigid housing for sprockets and idlers. The sprockets are of the self-cleaning type, made of steel, bronze-bushed. The treads are made of special heat-treated steel, cast in one piece, 11 in. wide, 11⅞ in. pitch, and run on cast steel idlers, also bronze-bushed, with large chambers for lubrication. A special design of shoes and sprockets guarantees self-cleaning. The rollers are of large diameter, and keep the bearings up out of the dirt.

Keeps Drill Oiled

The line oiler shown here should be as close to the drill as possible. It can be used with all pneumatic tools

Association Activities

Open billing of coal was vigorously condemned at a meeting of the **Chicago Wholesale Coal Shippers' Association** held Feb. 26 at the Illinois Athletic Club in Chicago. T. C. Irwin, of the Abbott-Irwin Coal Co., introduced a resolution, which was unanimously adopted, protesting against the shipment of coal without orders. The practice was held to be one of the crying evils of the coal industry and the Chicago wholesalers desired to go on record as definitely opposed to it.

Obituary

William M. Strachan, widely known in Indiana mining circles, died Feb. 17, at Rochester, Minn., where he had gone for treatment following an illness. Mr. Strachan was superintendent of the Fort Harrison Mining Co., of Terre Haute, having under his supervision the Wabash, Talleydale and Bardyke mines.

RUNAWAY!

(An Actual Occurrence. Quoted from a Customer's Letter)

"....You will be interested to know that we had a runaway of fifty-five empties, due to the breaking of the hitching pin on the motor, which allowed the cars to get away and run for a half mile, when they collided with seventeen others on the empty track. All but eight cars were derailed, the track was torn up for a considerable distance, trolley poles were knocked down, but only one car damaged, and that not seriously. I think this is conclusive evidence of the sturdiness of the equipment. The cars are working fine....and the men like them. We have weighed loads as high as 4,100 lb., which is more than twice the capacity of the old cars. (Which had less than 2,000 lb.). Our mine organization is sold on this type of equipment."

The same strength and stamina that enabled these cars to withstand this terrific test enables them to stand up year after year, in the hardest service. Hockensmith cars are designed for each specific installation, and arranged to work with existing tipple and haulage equipment. They are solving other mines' transportation problems, and they can help in yours.

This low type, maximum capacity car is lowering haulage costs, by decreasing trips, and providing the maximum ratio of coal capacity to dead weight. It saves time in spotting, and reduces roof and bottom work. Ideal for use in low seams, and with mechanical loaders.

Carloads of Thermal Units

It is said that one reason for the decline in the tonnage of coal has been the fact that the miners have been disciplined and have produced better coal and that the operators have been cleaning the coal more carefully at tipples and sending a better product to market. If the tonnage declined, the heat units marketed did not.

All of which shows that coal preparation, not only better quality but better size is in the air. No one who wants a good market can continue to operate without some kind of preparation. Next week Thomas Fraser, of West Virginia University, will give some facts and advice on the problem of sizing and hand cleaning, an important matter now machine loading and scraping put all the coal seam on the mine car without discrimination and perhaps some of the roof and floor also.

Take Another Look

Some of the heavily pitching seams have been opened by headings driven in the coal. That was best perhaps in the days when the market was unestablished and rockwork unduly expensive, but is it the way to do the work today? In Washington State a mine saved a big lift, an exceedingly lengthy haul, an unequal hoisting load, much trouble with snow and a number of inconveniences by putting a rock slope up to the surface. There are lots of concerns which have saved money by such rockwork, notably Sublet and Kenilworth.

Introducing AW-12

Something new and better, in rail bonding

Four distinguishing features make this new bond a distinct improvement. Each feature affords a substantial advantage to the user.

FIRST—The terminal hook clamps the bond to the rail base. A tap of a hammer sends it home. This holds the bond firmly in place while welding.

SECOND—The terminal itself forms a sort of a cup in which the molten welding metal is retained. The opening in the wall of the terminal permits starting the weld outside and working it inside. This insures development of welding heat on the rail base preparatory to the complete fusion of wire strands, rail base and the terminal.

THIRD—Every wire strand extends through the terminal and becomes an integral part of the actual weld. Insures perfect conductivity.

FOURTH—A soft copper sleeve protects the strands where they enter the terminal. Bending and vibration will not break them off.

Use O-B Copper Alloy Welding Rod, especially prepared for rail bonding. It contains the necessary elements, including fluxing material, for proper fusion of the metals to be welded.

Read over these points again! They mean better bonding, fewer breaks and less up-keep cost as soon as you get this new type bond in service.

Ask for O-B Type AW-12 Rail Bonds.

Dangerous Legislative Principles

THE SENATE COMMITTEE on interstate commerce has submitted a favorable report upon a bill to enlarge the membership of the Interstate Commerce Commission and to reorganize it upon a basis of mandatory regional representation. In pursuance of this latter aim, the bill (S. 2808) splits the country into seven territorial groups. One to three members of the Commission—the number varying with the size of the group and its commercial importance—would be appointed from each group. The total membership of the Commission would be increased from eleven to thirteen.

Proponents of the measure seek to justify such a regional reorganization on the ground that "the very structure of our government is based upon local self-government and local representation in the general government." They say that we should "bring together in the Commission as near as may be a personal knowledge of the transportation conditions and problems that exist in the different sections of the country." This from a committee that only recently refused to indorse a Presidential nomination to the Commission because the appointee had been a railroad director ought to provoke tears from those who hold consistency the most virtuous of vices.

Were inconsistency the only defect it might well be overlooked. But objection strikes deeper than that. The Congressional idea of local interests has been effectively exemplified in the log-rolling rivers and harbors appropriations bills in days gone by and in unanimous-consent action upon measures to flatter local pride with federal buildings far beyond community needs. The injection of anything akin to that idea in railroad regulation would be a national calamity.

The fear that a regional reorganization would open the way to a consideration of disputes from the standpoint of sectional desires instead of the national good is not as fanciful as it might seem. Since western Pennsylvania and Ohio were denied the relief they sought in the decision on cargo lake rates handed down last year, the energetic junior Senator from Pennsylvania has been outspoken in his criticism of the Commission and in his demand that a son of the Keystone State should sit on the rate regulating board. Had there been a Pennsylvanian on the Commission, is the implication, the decision would have been different. Of course, this ignores the fact that a Kentuckian opposed dismissing the complaints, but it illustrates what some Congressmen, at least, expect from regional representation.

No industry is more dependent upon transportation than the coal industry. To no industry are rate relationships between competing groups of mines more vital. Whether the Commission was right or wrong in the *Lake Cargo Coal cases* is beside this issue. What the industry needs, what the railroads need, what the country needs is a tribunal which will decide questions in the light of what it believes is just to all concerned. To break down the Commission into groups acting as watch-dogs over the private or sectional interests of individuals or communities would invite public distrust.

The Interstate Commerce Commission has won and held public confidence because the public felt that the Commissioners had divested themselves of all personal, partisan or sectional interests. Indeed, where there has been any suggestion that private opinion or past associations might color impartial judgment, individual Commissioners have refrained from participating in the decision. To insist upon such a reorganization as now proposed would be a backward step.

Danger, But No Signal

ACCUMULATING evidence that mechanical sparks and sparks resulting from static electricity may ignite mine gas further emphasizes the plain truth that the only sure way to prevent an explosion is to keep an explosive mixture from accumulating. The leaving open of a mine door and the resulting accumulation of gas has been, apparently, the underlying cause of a number of explosions.

The use of mine doors without an alarm or signal to indicate when they have been left open may be compared to operating a single-track railroad without block signals. Changing the single-track to a double-track road is the surest way of preventing head-on collisions, but when traffic does not permit of this expenditure, the installation of a signal system goes a long way toward eliminating the danger.

The same with the mine door. The safest way is to supplant the door by building an overcast, but this is not always possible or practicable. Then why not equip every door with a signal which has an indicator at some point where there is a man on constant duty. Not an unreliable open-circuit signal, but an "honest-to-goodness" closed-circuit signal such as used on railway or fire-alarm systems.

There are many variations and possibilities as to the arrangement. Cost is about the only limiting factor, and this can be held to a figure which is relatively insignificant compared to the risk eliminated. The time is sure to come when chance of a dangerous suspension of ventilation because of such a simple cause as a door being left open unnoticed will be practically eliminated.

Competition and Modern Merchandising

THE COAL MERCHANT or retail distributor is confronted with the same or similar problems encountered by other merchants. His commodity is an exceedingly useful one under certain circumstances and is in demand at certain times. Nobody buys it, however, except as a necessity. It falls into the class of commodities characterized by a large seasonal and usually a smaller continuing demand. Demand is difficult

Digitized by Google

to gage beforehand. Supplies are necessary and the amount of these supplies is related to demand, proximity of supply and reliability of transportation. Coal merchants like other merchants seek to avoid overextension in stocks on hand. Unlike other merchants they do not plan a selling campaign nor do they seek to sign up their customers in advance of requirements except in those instances where the coal merchant has studied modern methods of selling. Nevertheless, many of the more active coal distributors advertise sparingly and but relatively few follow up this initial concession to competition.

The ancient business policy of placing the goods upon the shelf, in this case the coal in the bin, hanging a firm name above the door and nailing a board carrying the word "office" above a desk in a corner, or a little room at the side, and installing a telephone, rules in the coal trade far more than it should. In contrast with this the live merchant has not only his delivery facilities well organized but he has analyzed the possibilities of the business and has classified all of his probable clients within economic distance of his supply depot. His classification dissects the business into large users or industries and steam power plants, apartment houses and office buildings, and buyers of relatively small quantities. His card index supplies all of the necessary information about each prospective customer. The total annual requirement which represents his theoretical market is estimated and his next objective is to obtain as large a proportion of this market as possible consistent with good collections. Necessarily he will seek to avoid "bad accounts" and "slow payers." The activities of his competitors will be studied and where one or more are quite successful in their business, the reasons for this success will be investigated as far as practicable. Out of this survey of possibilities an annual selling campaign can be intelligently planned and an adequate control of selling expense established.

Modern business is aggressive and seeks the buyer in the most direct way. Either the coal dealer undertakes to be his own salesman or he employs one or more salesmen who not only have "selling" experience but who also know something about coal, combustion and the ordinary difficulties which are experienced in using solid fuel for specific purposes. Back of all salesmanship is a certain amount of service for, unless the salesman has something to offer besides his commodity, he will have nothing to distinguish his solicitation from that of every other salesman. Any service which he can give to the buyer, as in the selection of the best grade of coal for the specific conditions, or in pointing out better ways of stoking that will result in greater efficiency, will, as a rule, be appreciated and remembered. Good-will is greatly developed through resourceful salesmen.

Another element in selling is the co-ordination of sales with a delivery campaign. Low-cost distribution is obtained when the trucks and wagons are continuously employed. With careful planning it is possible to accomplish this over a considerable period. The salesmen are therefore acquainted with the plan for low-cost delivery and schedule the delivery of their orders in accordance with this plan.

In many communities especially the smaller ones, the aggregate coal business is not sufficient to saturate the labor employed and the trucking facilities available. It is for this reason that the coal dealer frequently branches out into the building materials line and thus reduces overhead and operating costs during a period when the coal business is slack.

Existence of individual coal dealers is not alone determined by competition but largely by intelligent analyses of local situations and an aggressive policy having as its fundamental purpose the accumulation of good will and satisfactory service back of the firm's name.

Coal Land a Poor Investment

AT SEVEN PER CENT compound interest, money doubles itself about every ten years. When that investment is on land and taxes have to be paid, ranging in Pennsylvania bituminous regions from 15c. per acre in Center County to $46.59 per acre in Fayette County, as the Coal & Coke Committee of the American Institute of Mining & Metallurgical Engineers has shown, that doubling occurs much more speedily. The tax itself may be equivalent to 3 per cent. In consequence it does not profit any company to load itself with large reserves. All it needs is enough land to complete the life of its present operations.

Let some one else carry the load. If there were not so many volunteering to do it, the price of coal lands would decline, but whether it will or will not, it is better to purchase coal lands when one desires to work them and not to carry them year after year. Many of the larger corporations are "land poor" and will never get out of their more distant idle lands the money they are pouring into them. Unfortunately, to many operators land is like the bear of the story: they are as afraid to let go as to hold on to it.

An operator a few years ago was ready to join a combine then in process of formation. This new corporation *in posse* had no large land reserves, and the operator mentioned regarding it as essential that his virgin land should be accepted and at his own high figure. But the suggested combine hesitated to take the land at his price and consequently refused to take the mines also. As a result the combine failed to materialize. In a short while the operator with the magnificent land reserves went to the wall. He had loaded himself down too heavily with his virgin territory.

It is better to sell coal land at a slight loss than to carry it indefinitely as a continual burden on the company's exchequer.

Fire Extinguishers in Mines

THE FACTS thus far known regarding the Horning mine disaster suggest the necessity for adequate fire-fighting equipment in coal mines. In its earliest stages the mine fire, which later caused the explosion, was of no consequence so far as the intensity of the flame was concerned. Even so the jackets and coats which were utilized in attempts by the attendants to beat out the fire were no match for the flame and merely served to chase it from one spot to another, on and under the cutting machine which caused the fire. To all appearances this fire could have been easily extinguished by a hand extinguisher.

An extinguisher may not be needed often; but when it is—it is needed badly. Some day mine laws may be enacted compelling the installation of a small fire extinguisher on cutting machines and locomotives and larger portable units at strategic points.

Lake Cargo Rate Case Raises Big Economic Issues Between Competing Fields

Interstate Commerce Commission Opens Way to Renewal of Battle of Northern and Southern Districts for Tonnage Mastery

By Sydney A. Hale
Special Contributor, *Coal Age*

Car Dumper at Ashtabula Harbor

A FORTNIGHT AGO word came from Washington that the Interstate Commerce Commission had reopened the question of rates on lake cargo coal. In a few lines it was stated that the Commission had taken favorable action upon the petitions of western Pennsylvania producers and their allies for a reconsideration of its decision of last July in *Lake Cargo Coal Rates, 1925*, 101 I.C.C. 513.

Behind this simple announcement, however, lies a bitter struggle between Pennsylvania, Ohio and northern West Virginia, on the one hand, and southern West Virginia and eastern Kentucky, on the other, for the lion's share of a business which has averaged 23,750,000 net tons per annum for the past fifteen years and which at times has approached the 30,000,000-ton mark. The tonnage is large enough to appeal to any producing district. Moving during the months of the year when production generally is caught in the valley of the seasonal rhythm, the lake trade is doubly attractive.

Thirty years ago this business, then totaling 4,071,157 tons, was the exclusive possession of the northern district—i.e., Pennsylvania, Ohio and the Fairmont field of West Virginia. In 1923, when the total lake cargo shipments aggregated 29,839,918 tons, these same districts controlled only 62.61 per cent of the tonnage. The records for 1924 and 1925 "show so great a further loss of lake cargo business by these complaining districts," said counsel for the Pittsburgh group in his appeal to the Commission, "as to justify the assertion that they are now practically out of this market."

BUSINESS SHOWS TREMENDOUS GROWTH

The tremendous growth in the total volume of cargo coal shipped up the lakes to the Northwest since 1896 has pushed up actual tonnages from all fields, but some tonnage records are slipping fast. Western Pennsylvania and southern Ohio are the hardest hit. The Hocking district actually shipped less coal to the lakes in 1923 than it did in 1901. The Pittsburgh district, which furnished 65.54 per cent of the lake cargo tonnage in 1896, furnished only 26.74 per cent in 1923, and, as before suggested, figures for 1924 and 1925 would show up still more unfavorably. The share of the No. 8 Ohio and Cambridge fields, on the other hand, from 5.15 per cent to 15.66 per cent in 1923.

Protesting producers from the northern districts insist that their failure to maintain their grip upon the lake business to the exclusion of the southern fields is due primarily to the rate adjustments governing the transportation of coal from the Appalachian region to

Table I—Origin of Coal Cargo Shipments to Great Lakes: 1901-1923

1923	1,582,102	361,567	796	723	6.51

* For 1903 to 1906 inclusive the figures represent tonnages shipped from southern West Virginia; during that period (see Table I) shipments from the Kanawha and Kenova-Thacker and the New River-Pocahontas districts were not reported separately. From 1907 to 1923 the figures in this column cover shipments from Virginia and Tennessee.

† The figures in this column are the percentage of the total lake cargo shipments shown in Table I which the aggregate shipments covered in Table II represents.

the lower lake ports for transshipment. They insist that the rates they are charged are *per se* unreasonable and that the relationship between those rates and the charges in effect from the southern regions unduly prefer the latter and unjustly discriminate against them.

These questions are not new. They have been before the Interstate Commerce Commission in one form or another since 1912. Their importance, however, has grown because the encroachment of the southern fields upon consuming territory served by the northern districts has been increasing year by year. Southern West Virginia is pushing east and west; eastern Kentucky is winning new markets west and south. These districts stand as a barrier to southern expansion of the northern fields. They contest with Ohio and Pennsylvania for tonnage in the Northwest.

In the Middle West, Ohio and Pennsylvania must battle with Illinois and Indiana as well as with southern West Virginia and eastern Kentucky. Illinois is thoroughly alive to this latter competition. Coal-producing interests of that state intervened in *Lake Cargo Coal Rates, 1925*, with the generous proposal that there be no reduction in the rates from the Pittsburgh and Ohio fields, but that the differentials over those rates from the southern districts be widened.

Labor Intensifies Conditions

In recent years, the competitive situation between the northern and eastern districts of the Appalachian region has been further intensified by changes in the labor status of these districts. Ohio and western Pennsylvania are predominatingly union; southern West Virginia is predominatingly non-union; eastern Kentucky, too, has been free from dictatorship by the United Mine Workers of America. This is a phase of the situation which has been little stressed—particularly by the politicians who have injected themselves into the proceedings since the Interstate Commerce Commission dismissed the complaints of the northern districts last summer.

The mines that have lake cargo coal rates are divided into fifty-three originating districts, taking twenty-one different rates, ranging from $1.34 to $2.88 per ton. Many of these districts, however, "participate slightly, if at all, in this traffic. During the five-year period 1910-1914 only eighteen districts, and during 1923, only twenty-eight districts, shipped lake cargo coal. In 1923 sixteen districts shipped approximately 95 per cent of the total." These districts were the Middle, No. 8, Cambridge, Hocking and Pomeroy districts in Ohio; the Freeport, Pittsburgh and Connellsville districts in Pennsylvania; the Fairmont, Kanawha, Tug River, New River and Pocahontas districts in West Virginia and the Big Sandy, Hazard and Harlan districts in Kentucky. The controlling base rates are $1.63 from the No. 8 and Cambridge fields, $1.66 from Pittsburgh, $1.81 from Fairmont, $1.91 from the southern West Virginia and eastern Kentucky high-volatile districts and $2.06 from Pocahontas and New River. The history of these rates is summarized in Table III.

Tried to Cut Southern Rates

The first clash of the conflicting interests came to a head before the Commission in 1912. Late in 1910 and during the first quarter of the following year the Chesapeake & Ohio, Baltimore & Ohio, Kanawha & Michigan and Norfolk & Western railroads, stirred to action by complaints of the Pittsburgh and Ohio No. 8 fields that existing rates unduly preferred West Virginia, filed tariffs advancing those rates. The Baltimore & Ohio proposed to increase its Fairmont rate from 96.75c. to $1; the other lines proposed to advance Kanawha and Kenova-Thacker from 97c. to $1.0625 and Pocahontas-New River from $1.12 to $1.2175.

The Commission suspended the tariffs on protests of affected shippers. Upon hearing, the Norfolk & Western assumed the burden of justifying the increase. The Commission, in *Advances in Coal Rates by C. & O. Ry. Co.*, 22, I.C.C. 604, held that the Norfolk & Western was entitled to the increase from the Thacker and Pocahontas districts, but that the other three roads and their connections had not made out a case. In order to preserve established relationships, the Norfolk & Western canceled the tariffs naming the higher rates and restored its old charges.

Simultaneously the Commission announced its deci-

sion in the first formal complaint specifically attacking the rates from the Pittsburgh district to the lakes: *John W. Boileau vs. P. & L. R.R. Co.*, 22 I.C.C. 640. The order in this case directed the defendant carrier to reduce its rate on cargo coal to Ashtabula Harbor from 88 to 78c. per ton. The finding was based largely upon a study of the costs of transportation—one of the pioneering excursions of the Commission into that field of railroad economics. In commenting upon the complainant's contention that the rates attacked were unreasonable as compared with those in effect from West Virginia, the Commission declared that the evidence indicated that the rate complained of—which had fluctuated between 70c. and $1 from 1887 and 1900—had been raised step by step for the purpose of permitting competing coal fields to participate.

A petition for a modification of the order was filed. This petition asked for a further reduction in the Pittsburgh rate and the establishment of a differential in favor of Pittsburgh against competing West Virginia districts. The Commission declined to modify its original order, holding that such modification would mean the fixing of minimum rates on West Virginia

TABLE III—Base Rates on Lake Cargo Coal Traffic

(Rates in Cents per Net Ton)

	From				
In effect	No. 8—Cambridge, Ohio	Pittsburgh District	Fairmont District	Southern High-Volatile	West Virginia Low-Volatile
1906	80	83	91‡	92	...

B	*123*	*126*	*160*	*191*	*206*
Current Rates	163	166	181	191	206

* The first set of rates (Group A) was proposed by the examiners for the Interstate Commerce Commission and submitted in their tentative opinion in *Lake Cargo Coal Rates, 1925*. The second set (Group B) was suggested by the Pennsylvania and Ohio complainants in that case. The decision of the Commission, however, refused to change the existing rate structure.

† Also applicable to the Harlan, Hazard and McRoberts districts in eastern Kentucky. Since that date these districts have been on the same rate basis as southern West Virginia.

‡ South Jellico (Tennessee) group added.

§ Pocohontas-New River basis made applicable to Stonega.

traffic: *Boileau vs. P. & L. E. R.R. Co.*, 124 I.C.C. 129. Under the interstate commerce law then in effect the Commission's rate-fixing power was limited to establishing maximum rates.

In summing up its conclusions, however, the Commission made a statement with respect to the reasonableness of the Pittsburgh rate which has risen to plague it in later proceedings. The Commission said:

From the point of view of the specific cost of doing this particular business, the rate is still too high; but, as we have said before, cost is only one of the elements entering into a rate. When we consider the coal rates from all the fields which will be affected by this change in the Pittsburgh rate, the disturbance in established differentials, the possible deflection of the currents of coal trade, and its effect upon operators elsewhere, the effect upon the carriers directly involved and the indirect effect upon other carriers, and all the other valid considerations, we are forced to the conclusion that a rate lower than this would not be just and reasonable under the conditions disclosed by this record.

Four years later the Pittsburgh producers again attacked the lake cargo rates. The Commission, in an investigation instituted on its own motion, *Lake Cargo Coal Rates*, 46 I.C.C. 159, declined to pass upon the intrinsic reasonableness of the rates because of the abnormal conditions brought about by the entrance of

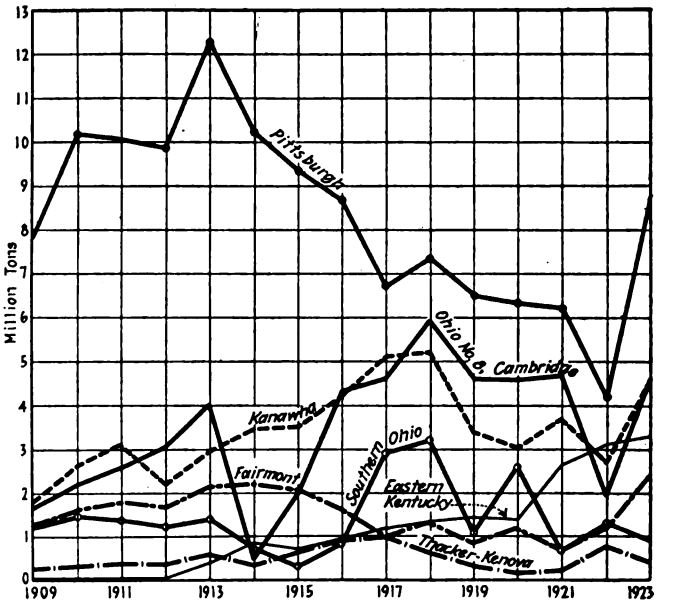

Fig. 2—High-Volatile Lake Cargo Shipments

This chart, a companion to Fig. 1, is a study in the trend of high-volatile coal shipments.

the United States into the World War. The Commission did, however, prescribe certain district relationships, which became effective on Aug. 13, 1917, four months after an increase of 15c. per ton had been made on all cargo rates.

In *Lake Cargo Coal Rates, 1925*, the old issues again were raised. Operators in Pittsburgh, Panhandle, Cambridge and Ohio No. 8 districts alleged that their rates were unjust and unreasonable and discriminated against them. Southern Ohio intervened to support that position, with the reservation that the rates from the southern Ohio fields should be continued on a parity with No. 8 and Cambridge rates. Fairmont charged that northern West Virginia rates were unduly high when compared with those in effect from the Pittsburgh and Ohio districts.

DRASTIC REVISION DISALLOWED

The examiners who heard the evidence recommended a revision changing every rate in effect on lake cargo coal. The proposed readjustment, summarized in Table IV, was sharply attacked by all parties to the record and was disregarded by the Commission. A similar fate awaited the elaborate costs studies upon which the Pennsylvania-Ohio complaints based their plea for

TABLE IV—A Rate Readjustment That Failed

Rates (in Cents per Ton) Suggested by Interstate Commerce Commission Examiners and Rates Now in Effect

District	Present Rate	Proposed Rate	District	Present Rate	Proposed Rate

a 40c. reduction. Admitting that progress had been made in cost accounting since the *Boileau case*, the Commission observed that "it by no means follows that our duty under the law to prescribe just and reasonable rates has been reduced or assimilated to a mathematical process."

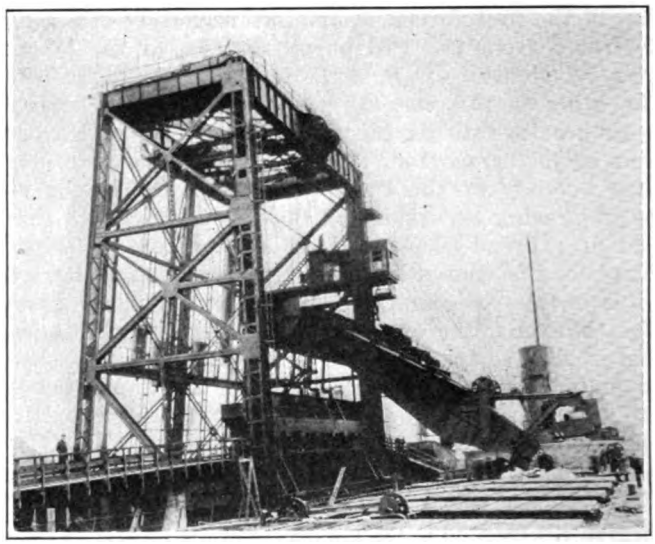
The Commission found nothing offensive in the fact that the Ohio No. 8 district paid 9.87 mills per ton-mile for an average haul of 165 miles to the lake ports and the Pocahontas field paid only 4.85 mills per ton-mile for an average haul of 424 miles or that the other southern districts, as shown in Table V, also paid less per ton-mile than the northern fields. It dismissed the complaints.

Conditions the past lake season did not make the dismissal more acceptable to the Pittsburgh district. The suggestion that the Pittsburgh producers appeal to the Commission to reconsider its action met with a favorable response. Governor Pinchot appealed to the Pittsburgh Chamber of Commerce to ask for a reopening of the proceedings and promised state support in a fight against non-union competition in lake and seaboard markets. Subsequently the State of Pennsylvania filed a petition with the Commission.

The United Mine Workers, too, appears in the role of an unofficial ally. In some quarters its interest in the situation is credited with having stirred Governor Pinchot to action. The union, weaker in power than it has been for many years, is developing a new sensitiveness to actions which may prejudice the successful operation of union mines. In its present chastened frame of mind it is willing to do almost anything to assist union fields—except to consider a revision of the Jacksonville wage agreement. So the leaders of that labor organization are outspoken in their condemnation of what they say are rate decisions fostering the non-union fields.

Opponents of the northern districts are not behind their adversaries in pressing the fight. West Virginia, not satisfied with the rejection of the complainants' pleas in the case, professes to believe that coal producers within its borders, and not Pennsylvania and Ohio, are the real victims of the existing adjustment.

In a narrow, technical sense, in moving for a reconsideration of *Lake Cargo Coal Rates, 1925*, the petitioners are asking the Interstate Commerce Commission again to pass upon two transportation questions:



(1) Are rates of $1.63 and $1.66 per ton for average hauls of 165 and 172 miles excessive;

(2) Do differentials ranging from 18 to 43c. per ton for additional hauls ranging from 96 to 304 miles represent a fair spread or are they so low that they deprive the northern districts of their natural advantage of greater proximity to the lake ports;

In a broad sense, however, the issue involves the whole question of the part transportation adjustments should play in the allocation of markets. That is no simple problem. It is not simple because rate-making itself is a complex undertaking, involving the evaluation of many elements. It is not simple because it involves the examination of many factors to determine which are and which are not determined by the rate adjustment.

TABLE V—How Rates and Distances Compare

District	Average Distance to Lake Ports, Miles	Rate	Ton-Mile Earnings, Mills
Ohio No. 8	165.2	$1.63	9.87
Cambridge	172.2	1.63	9.47
Pittsburgh	177.1	1.66	9.37
Fairmont	261.2	1.81	6.93
Kanawha	362.8	1.91	5.27
Big Sandy	384.4	1.91	4.97
Hasard	419.2	1.91	4.56
Harlan	446.9	1.91	4.28
McRoberts	469.5	1.91	4.07
Pocahontas	424.8	2.06	4.85

Lake Cargo Coal Movement Is a High-Speed Business

Because the shipping season is limited by nature, the transportation end of the trade must be a highly co-ordinated business. Movement from mines to docks must be expedited, delays at the loading ports minimized. This calls for a high degree of managerial skill and efficient, high-speed machinery.

QUESTION A COMPLICATED ONE

There is, for example, the question of how much weight should be given to the cost of production. With a few exceptions mines in Ohio and Pennsylvania are paying day labor $7.50 for eight hours' work. In the southern fields the rate is probably $4 to $5—in some cases possibly less. Tonnage rates, too, are considerably higher in the northern districts, where the Jacksonville agreement, continuing the peak 1920 scale, is still in effect. Total labor production costs, it is estimated, are 25 to 65 per cent greater in the union areas than in the competing southern high-volatile districts.

To what extent are these changes responsible for the fact that the Pittsburgh district contributed only 14.5 per cent of the lake cargo total in 1924 and less than 9 per cent in 1925? Is the swing from union to non-union operation the explanation of the growth of Kanawha's share of this business, which increased from 11.58 per cent in 1909 to 25 per cent in 1924 and 29.75 per cent in 1925? What weight should be given to the fact that the average mine price on southern West Virginia high-volatile coals last year was $1.68, as compared with $1.97 for the No. 8 field and $2 in the Pittsburgh district? Is any special significance to be attached to the fact that the Pittsburgh mine average was 32c. higher than the West Virginia average quoted and the freight rate to the lakes 25c. per ton less?

Technically, such questions are outside the scope of the Commission's inquiry. Actually, however, they intrude into the case because of the way the issues have been framed. One side contends it is being deprived of its natural share of a desirable business because of a prejudicial rate adjustment. The other side answers that its opponents are trying to set up rate barriers to impede the free movement of tonnage and to narrow the territory from which consumers can draw their fuel supplies.

Fans with Blades that Curve Backward Best Meet Varying Mine Pressures*

High Speeds Make Big Fans Unnecessary—Manometric Efficiency No Longer Gage of Good Fan Construction — Fan Should Meet Pressure Variations with Minimum Change in Air Delivered and Power Required

By Louis W. Huber
Instructor Co-operative Mining Department,
Carnegie Institute of Technology,
Pittsburgh, Pa.

Louis W. Huber

THOUGH centrifugal fans were first developed to ventilate mines and though the mines were the first places to be ventilated, mining men display much lack of knowledge on mine ventilation in general and on fan performances and characteristics in particular, even though it is true that mines are much better ventilated than they were twenty to thirty years ago.

The average mine operator is woefully dependent on the engineers in the service of mine-fan manufacturers when he is in the market for a fan, and this fact works to the disadvantage of both operator and manufacturer. The former may be imposed upon by an unscrupulous sales engineer and induced to buy a fan which is not suited to the mine. When it is operating it may be wasteful of power and may be even an accessory to a serious mine disaster. More often, however, it is the fan manufacturer who suffers. If the operator asks him to build a fan that will deliver a certain quantity of air against a certain specified pressure and requiring a specified horsepower when operating under these conditions, the manufacturer may build a fan that will comply with these specifications to the letter, only to find when the fan is installed that it is delivering a greater quantity of air against a lesser pressure or a lesser quantity of air against a greater pressure and is requiring more horsepower than specified in the first case and delivering less air than that specified in the second.

WITH forward-curved blades a 10-per cent rise in water-gage causes the fan that was delivering 100 per cent at maximum efficiency to deliver only 16 per cent of that quantity at that efficiency and the horsepower for maximum efficiency that was 50 is reduced to 19—not at all a satisfactory condition, for a 10-per cent increase in pressure is quite likely to occur. Also a 10-per cent drop in pressure gives an increase of 26 per cent in volume, but this demands of the fan motor a 28-per cent overload. This injures the motor unless it is of excessive capacity for the work that it should normally perform.

In either case the operator usually upbraids the manufacturer for not meeting specifications and refuses to pay for the fan. The trouble in either case outlined above is that the pressure necessary to force the specified quantity of air through the mine has been estimated incorrectly by the operator or his engineers. When a fan is designed and built to deliver a certain quantity of air against a certain specified resistance it will operate at its maximum efficiency only when it is working under the conditions for which it was designed. With these conditions changed the efficiency of the fan will be changed.

A basic consideration that cannot be overemphasized is that a definite pressure is necessary to force a given quantity of air through a mine. For example, if it takes a pressure of 1½ in. of water gage to force or draw 100,000 min.-ft. through a mine it makes no difference what means we use to cause the air to be coursed through the mine. We know from the mathematics of ventilation that the pressure necessary to cause ventilation varies directly as the square of the volume, when conditions causing resistance remain unchanged. This means that if a 2-in. water-gage pressure is required to force 100,000 min.-ft. through a mine, 8 in. will be required to force 200,000 min.-ft. and only ½ in. will be required to force 50,000 min.-ft. through. This simple and unfailing law is surprisingly often not understood. It is not at all rare for a mine-fan manufacturer to get an inquiry such as this: "We now have a fan at our mine that is delivering 50,000 min-ft. at 1 in. and we want more air; will you please quote us on a fan to deliver 100,000 min.-ft. at 1 in.?" Obviously it is impossible to build a fan that will do this, for, unless the ventilating system is changed so that the resistance is decreased, 4-in. pressure will be required to force 100,000 min.-ft. through the mine no matter what type or make of fan is used.

It is interesting to trace the development of the centrifugal mine fan and see how some of the old, obsolete and incorrect ideas and efficiencies still persist. Years ago when mines were first ventilated by means of centrifugal fans, the latter were direct-connected to

*Article presented to the American Institute of Mining & Metallurgical Engineers, at the annual meeting, February, 1926, and entitled "Operating Characteristics of Centrifugal Fans and Use of Fan-Performance Curve."

Digitized by Google

steam engines. The speed or revolutions per minute of the fan depended on the steam-engine speed and was limited to the maximum speed of the steam engine. The pressure generated by a centrifugal fan depends on the peripheral velocity or tip speed—that is, the velocity or speed of the tips of the centrifugal-fan blades.

At first the mines to be ventilated were small. So also were the volumes and pressures required. As the mines became larger, the quantity of air and the pressures required became larger and so did the fans. As the fan speed was limited to the maximum speed of the steam engine, when a greater tip speed was required in order to generate higher pressures, the only alternative was to increase the diameter of the fan, so that higher tip speed could be attained, although the revolutions per minute of the fan remained the same. This condition resulted in the building of huge fans and of spreading the doctrine that it took a big fan to deliver a large quantity of air. Fans of 25-, 30- and 40-ft. diameter were common, and the records show that they were built as large as 60 ft. in diameter. Both the huge obsolete fans and the opinion that it takes a large fan to deliver a large quantity of air still remain with us to a certain extent today.

GET SPEED WITHOUT INCREASING DIAMETER

Now let us consider the development of another industry, that of electric-power generation, during the period just cited. In the early stages of electric-power generation, electrical engineers met with the same problem as mine-ventilation engineers; they had to drive their generators with the same slow-speed reciprocating steam engine. As the power output of an electric generator depends on the rate of cutting magnetic lines of force, when greater quantities of power and higher voltages were required it became necessary to increase the tip speed of the armature. This was accomplished at first by increasing the diameter of the armature and hence resulted in the building of large generators, the speed in revolutions per minute of which was low, but whose armature-tip or peripheral speed, and hence the rate of cutting magnetic lines of force, was high. We seldom find this type of generator in use in electric-power generation today, however; it has given way to the small, high-speed, and efficient generator. With the advent of the high-speed and efficient steam turbine, electrical engineers designed and made use of high-speed generators, and the result was smaller, more efficient, and less expensive units.

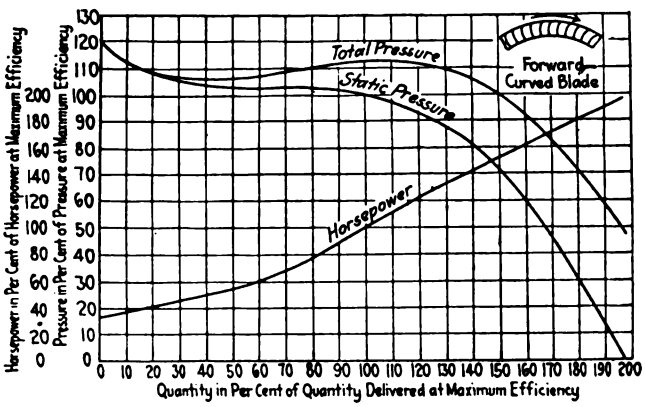

Fig. 1—Characteristic for Forward-Curved Blades

Take a given per cent of pressure and increase it or decrease it 10 per cent and note the position on the static-pressure curve which will result. Tracing downward note the horsepower at maximum efficiency for that point on the curve and tracing further downward note also the quantity of air delivered at that maximum efficiency. The result is startling. The fan is evidently not "stable" at constant speed.

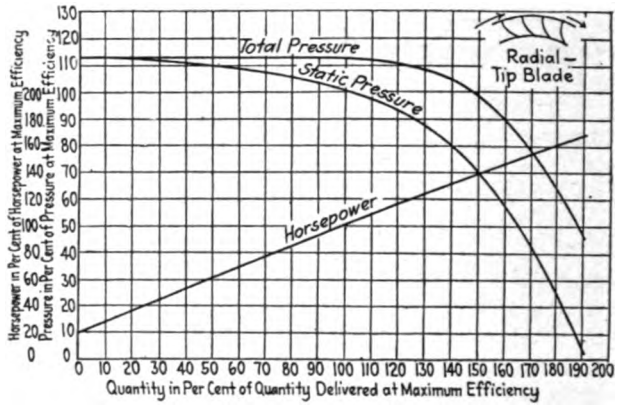

Fig. 2—Characteristic for Radial-Tip Blade

Here the static-pressure curve is flattened out where it has a drop for the forward-curved blade, and all the conditions are improved but not much as can be seen by making a trial. An increase in pressure of 10 per cent causes a 54-per cent decrease in volume and 44-per cent decrease in horsepower.

We frequently see extremely large slow-speed fans in use at our mines today; in fact it is rare to see smooth-running, high-speed, efficient ventilating units at mines, although they have been used for years for forced draft on mechanical stokers, for public-building ventilation, and on exhaust systems in factories.

Another relic of the old days that has been handed down to us along with the old-type fans is manometric efficiency. This no longer means anything to us, yet we see it in practically all mine fan tests, and it is frequently used in sales arguments. One manufacturer said to me not long ago that manometric efficiency as it is calculated is meaningless but that he still calculated and emphasized it because mining engineers demanded it.

MANOMETRIC RATIO FUTILE

Let us investigate manometric efficiency and see of what importance it really is. The definition of manometric efficiency is the ratio of actual pressure developed by the fan to the theoretical pressure or, as we express it in mine ventilation terms, actual water gage to theoretical water gage. In determining the manometric efficiency the actual water-gage pressure developed by the fan is measured, and the theoretical water gage is calculated from the tip or peripheral speed. The formula for calculating the theoretical water-gage pressure is:

$$w.g. = \frac{v^2 \times 0.078}{g \times 5.2}$$

The method by which the formula is obtained should be explained. In this formula water gage is expressed in inches of water. Let v = velocity of the periphery of the fan wheel in feet per second. This will be equal to

$$\pi \times \text{diameter in feet} \times \text{r.p.m.} \div 60$$

0.078 = weight of air in pounds per cubit foot under average conditions of temperature and pressure and g = the acceleration of gravity in feet per second per second. The above formula was developed for calculating the theoretical pressure developed by a straight-blade or paddle-wheel type fan and is only correct when used in connection with this type of fan. Let w = weight of air in pounds per cubic foot; q = quantity of air in cubic feet; v = velocity of periphery of fan wheel in feet per second; $q \times w = W$ = weight in pounds.

Digitized by Google

$$W \div g = \text{mass} = M$$

Therefore, $qw \div g = M$ = mass of air moved by the fan.

Mv = momentum = $qw \times v \div g$; $qw \times v \div g$ = momentum of air in motion; it is also equal to the force producing or destroying this momentum; $qw = v \div g$ = a definite force and this force acts through v ft. per sec. Force multiplied by distance equals work. Therefore $qw \times v^2 \div g$ = work done in foot-pounds. Work is also equal to $p \times q$ or pressure in pounds per square foot multiplied by quantity in cubic feet. Therefore, $p \times q$ = work in foot-pounds; p, pressure in pounds per square foot, is also equal to $H \times w$ or height of air column in feet multiplied by weight of air in pounds per cubic foot. As $p \times q$ = work in foot-pounds and $p = H \times w$, $H \times w \times q$ = work in foot-pounds. Therefore $H \times w \times q = qw \times v^2 \div g$ and by transposing we get

$$H = \frac{q \times w \times v^2}{w \times q \times g} = \frac{v^2}{g}$$

As 1 in. of water in the gage equals 5.2 lb. per square foot the water gage equals $H \times w \div 5.2$, and if we assume the weight of air to be 0.078 lb. per cubic foot the expression becomes

$$w.g. = H \times 0.078 \div 5.2$$

We know from the preceeding that $H = v^2 \div g$ and by substituting the value $v^2 \div g$ for H the expression becomes

$$w.g. = \frac{v^2 \times 0.078}{5.2g}$$

This formula expresses the theoretical water gage that a straight-blade or paddle-wheel type fan which has no slippage around the tips of its blades will develop. By no slippage of air around the tips of the fan blades we mean that the velocity of the air leaving the fan blade is equal to the velocity of the blade tip. Obviously it would be impossible for air to leave the tip of a straight blade with greater velocity than that of the blade tip and the maximum possible velocity of air leaving a straight blade fan is equal to its peripheral velocity. It is evident then that formerly, when straight-blade fans were the only fans in existence and high peripheral velocity or tip speed was difficult and expensive to produce, it was highly desirable to have the air leaving the tips of the blades with a velocity as close to the peripheral velocity of the wheel as possible so that as high a pressure as possible was obtained by a given tip speed. This meant approaching 100 per cent manometric efficiency. Under these conditions all fan manufacturers strove to obtain it and it was under the circumstances a legitimate sales argument.

At the present time, however, by means of our high-speed electric motors and steam turbines we can easily get, with a comparatively small fan wheel, much more tip speed than is required to generate pressures sufficient for mine ventilation. Moreover, as our higher-speed motors and turbines are more efficient and inexpensive than those of lower speed, it is now desirable to have a fan of low manometric efficiency so as to make use of the high-speed machines on direct-connected ventilating units.

In the past few years, fan design, especially that applying to large constant-volume fans, has improved wonderfully after a long period of stagnation. Fans are now being built according to mathematical theory rather than by hit-or-miss methods. The increased activity in scientific fan design is due, in large degree, to the advent of the airplane. With the development of this new device the attention of our prominent physicists and mathematicians was attracted to the theory of air flow, and the study of aerodynamics was as thoroughly investigated and developed as thermodynamics and hydrodynamics. Much of the theory and mathematics of these two sciences have been incorporated into the theory and mathematics of air flow or aerodynamics, so that blade shapes and air passages in our modern scientifically designed fans are as carefully worked out as impeller shapes and passages in our steam turbines and centrifugal pumps.

Centrifugal fans can be classified according to the curvature of their blades. We will consider the following four general types: (1) The forward-curved blade fan—that is the fan with blades curved forward in the direction of rotation, (2) the radial-tip blade fan, (3) the partial backward-curved blade and the straight-blade or paddle-wheel type fan, and (4) the full backward-curved blade fan. In order to study the effectiveness and performance of these different types of fans it is advantageous to study their characteristic operating curves. These are illustrated in Figs. 1, 2, 3, and 4.

In order to construct a characteristic operating curve it is necessary to get data on the performance of a fan when it is operating at constant speed but against different resistances. To get these data the fan is set

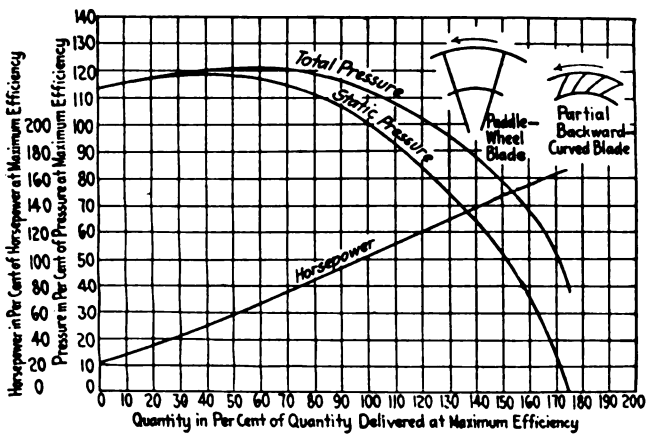

Fig. 3—Characteristic for Straight Paddle-Wheel Type or Partial Backward-Curve Blade

The steeply pitching static-pressure curve shows that a 10-per cent increase or decrease of pressure has less effect on volume at maximum efficiency than in either of the two previous instances. So the fan is "stable" in this regard. With a 10-per cent increase in pressure the decrease in volume would be 17 per cent and the decrease in horsepower 14 per cent.

up and is driven by means of an electric motor on which power readings can be easily taken. It is connected so that it discharges into a straight air duct.

At a point sufficiently distant from the fan so that a smooth flow of air is procured in the discharge air duct provisions are made to read static and velocity pressures. Average velocity pressure, static pressure and horsepower input are the three readings it is necessary to take for each resistance against which the fan operates. The fan is caused to run against different resistances by placing restrictions, usually in the form of orifice plates, in the end of the discharge duct.

The resistances vary from infinite resistance, when the duct is blocked tight so that no air can flow, to practically no resistance, the air flowing unhindered from the fan through the duct and into the outside

Digitized by Google

atmosphere. The horsepower output and static pressure are observed for each resistance against which the fan operates and the average velocity pressure, from which the velocity and subsequently the volume of air delivered is calculated, is observed for all resistances except infinite resistance which allows no air to flow. These readings are taken simultaneously for each resistance against which the fan operates and the speed of the fan is kept constant.

Let us consider the action or performance of each of the aforementioned types of fans under conditions that occur in mine ventilation. A desirable requirement for mine fans is that they deliver a constant volume, not easily altered by changing conditions in the ventilating system.

DROP IN PRESSURE UNBALANCES FAN

Let us assume that each of these fans is operating at a mine at constant speed and at its maximum efficiency and something occurs down in the mine that decreases the resistance and causes the pressure against which the fan is operating to decrease 10 per cent. Short-circuiting of the air through opened doors, or through broken stoppings and overcasts could easily cause this. The driving of new splits or increasing of the size of entries would also cause a decrease in resistance.

With the forward-curved blade fan, Fig. 1, a 10-per cent drop in pressure would cause a 26-per cent increase in volume and a 28-per cent increase in horsepower. With the radial-tip blade fan, Fig. 2, this drop in pressure would cause a 26-per cent increase in volume and a 20-per cent increase in horsepower. With either the

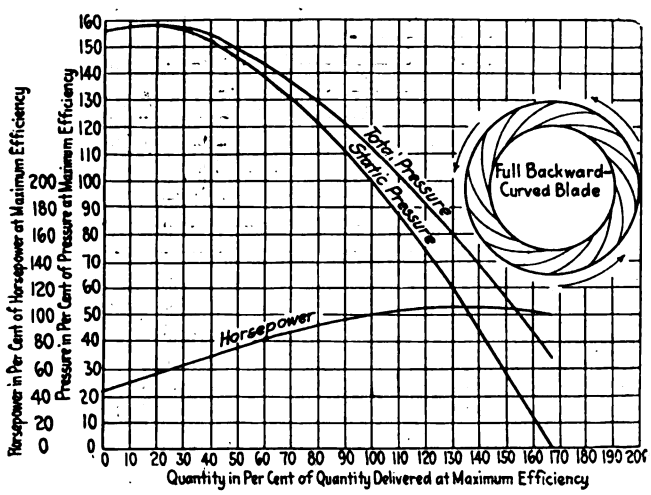

Fig. 4—Characteristic for a Full Backward-Curved Fan Blade

Here the pitch of the static-pressure curve is steeper than ever, and the horsepower characteristic is drooping. The maximum "stability" in consequence is afforded.. A 10-per cent increase in pressure decreases the volume only 9 per cent and the horsepower still less—only 3 per cent.

paddle-wheel type or partial backward-curved blade fan, Fig. 3, the increase in volume would be 13 per cent and the increase in horsepower 13 per cent. With the full backward-curved blade fan, Fig. 4, a 10-per cent drop in pressure would cause but an 8-per cent increase in volume and a 2-per cent increase in horsepower.

Now let us determine how a 10-per cent increase in pressure would affect the performance of each of these types of fans. We will assume again that each of these fans is operated at the point of maximum efficiency and at constant speed. An increase in resistance and, correspondingly, an increase in pressure, is caused in coal mines by falls and other obstructions in the aircourses, by installing smaller regulators, by extending the workings without providing new splits, etc. With the forward-curved blade fan, Fig. 1, a 10-per cent increase in pressure causes an 84-per cent decrease in volume and a 62-per cent decrease in horsepower. With the radial-tip blade fan, Fig. 2, this increase in pressure would cause a 54-per cent decrease in volume and a 44-per cent decrease in horsepower. With either the paddle-wheel or partial backward-curved blade fan, Fig. 3, the decrease in volume because of 10-per cent increase in pressure would be 17 per cent and the decrease in horsepower 14 per cent. With the full backward-curved blade fan the decrease in volume would be 9 per cent and the decrease in horsepower 3 per cent.

These considerations show us that the forward-curved blade fan is delicate and easily upset; that slight changes in operating conditions when it is running at its point of maximum efficiency will cause a large change in volume and horsepower and cause the fan to be operating very inefficiently. A fan of this type is not stable and should not be used for mine ventilation unless precautions are taken and determinations regularly made to prevent the resistance of the mine from changing. It is essential when a fan of this type is selected for mine ventilation that the resistance of the mine be accurately estimated in advance.

BACKWARD-CURVED BLADE FAN IS STABLE

The other types of fans are more stable as we proceed down the list in the order discussed above. The full backward-curved blade fan is by far the most stable and approaches a constant-volume fan. It will operate efficiently throughout a long range on its characteristic operating curve, a desirable quality with conditions in the mine constantly changing. Moreover at the present, with our incomplete knowledge of mine resistance, it is guesswork to estimate the resistance a mine will offer to a certain volume of air within at least 10 per cent of the actual resistance, unless we already have a fan operating at the mine. Certainly, under these conditions, a sensitive fan which will not work efficiently under conditions different from the peak for which it is selected is not the best fan for the job.

Table I—Effect of Ten-Per Cent Increase or Decrease in Pressure on Centrifugal Fans

	Resistance or Pressure Decrease 10 per cent Increase in Vol. Delivered by Fan, Per Cent	Resistance or Pressure Decrease 10 per cent Increase in Hp. Required by Fan, Per Cent	Resistance or Pressure Increase 10 Per Cent Decrease in Vol. Delivered by Fan, Per Cent	Resistance or Pressure Increase 10 Per Cent Decrease in Hp. Required by Fan, Per Cent
Forward-curved blade, Fig. 1.....	26	28	84	62
Radial-tipped blade, Fig. 2.....	26	20	54	44
Paddle-wheel or partially backward-curved blade, Fig. 3.....	13	13	17	14
Full backward-curved blade, Fig. 4	8	2	9	3

Next to the volume of air delivered by a fan the mine operator is interested in the horsepower the fan will require. On observing Figs. 1, 2 and 3 it is seen that the horsepower curves for each of these fans rises very steeply with increase in volume and decrease in pressure. If the forward-curved blade fan, Fig. 1, is run wide open, that is, against no resistance, it will require 196 per cent of the horsepower required at its point of maximum efficiency; the radial-tip blade fan, Fig. 2, 168 per cent, and the partial backward-curved blade or paddle-wheel type fan, Fig. 3, 165 per

Digitized by Google

cent. A drop in pressure or decrease in resistance and increase in volume occur coincidentally.

It is evident that as such changes take place more horsepower is consumed and the driving motor, engine, or turbine must be of ample size and capacity to take care of this overload. This means that in installing the ventilating unit with any of these three types of

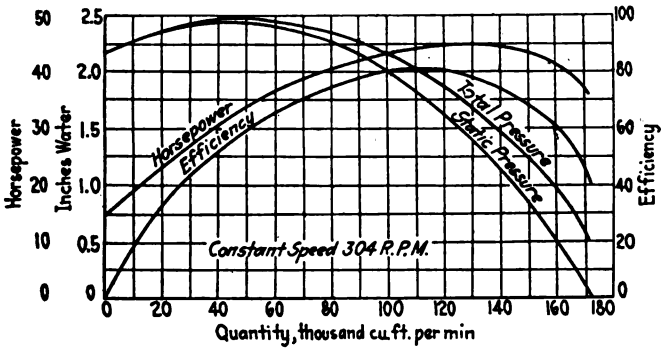

Fig. 5—Performance Curve Full Backward-Curved Blade Centrifugal Fan

This fan is designed to deliver 100,000 min.ft. against a static-pressure resistance of 2 in. of water gage when operating at 304 r.p.m. Note the drooping curves of the total and static pressures and of horsepower and efficiency giving the fan stability with a wide range of pressure. Such a curve should be supplied with every fan.

fans it is necessary to provide a driving motor that has excess capacity. It is common when installing such units to provide a motor that can deliver about 35 per cent more energy than is normally needed and, of course, this means a more expensive unit.

It will be observed on Fig. 4 that the full backward-curved blade fan has a drooping horsepower characteristic. The horsepower curve is self-limiting, and the horsepower required cannot exceed a certain maximum no matter how the resistance is changed. When this fan is run wide open against no resistance it requires no more horsepower than it does when operating at its point of maximum efficiency and under no conditions will it require more than 106 per cent of the horsepower required at this point. This means that if the fan required 100 hp. when operating at its point of maximum efficiency a 100-hp. motor that would stand a 6-per cent overload would be big and safe enough for the unit under any circumstances.

When coal mines generated their open power, the energy consumed in the different mining operations was not given much consideration. With the more general electrification of mines and the use of purchased power, mine operators began to give this important contribution to the cost of mining the attention it warranted. Even now the large power consumption of mine ventilation is not appreciated as it should be. A recent survey of the energy consumed in Illinois coal mines, made by the University of Illinois Mining Engineering Experiment Station, showed that ventilation as a consumer of power was as important as haulage and mining. This study, which included 50 representative mines in Illinois, showed the power consumption to be distributed as follows:

	Per Cent		Per Cent
Hoisting	17.2	Mining	22.1
Ventilation	22.2	Haulage	23.0
Pumping	5.0	Miscellaneous	10.5

When it is considered that ventilation requires as much power as haulage or mining and more than hoisting, it is readily apparent that it is important to have the ventilating unit operating as efficiently as possible. The mechanical efficiency of the fan is of equal importance with its operating characteristics and it may be more important. Fortunately, the mechanical efficiency of a full backward-curved blade fan is high. In fact, the efficiency of a well-designed full backward-curved blade fan is from 15 to 20 per cent higher than either of the first three types considered. Although this type of fan was first designed for forced-draft duty, it meets all the requirements of a good fan for mine ventilation as well as if it were originally designed for this purpose.

Much of the argument on whether a fan meets specifications and guarantees when it is bought would be avoided if fans were sold with a performance curve. The guarantee of a fan manufacturer usually states that the fan will deliver a certain quantity of air against a certain pressure when operating at a definite speed and that it will not require more than a specified horsepower. If the resistance of the mine is overestimated most fans will deliver more air against less pressure and will require more horsepower and, if the resistance is underestimated, they will deliver leess air against greater pressure and will require less horsepower. In either of these latter two cases it is an open question whether the fan is fulfilling the guarantee.

A performance curve as illustrated in Fig. 5 when compiled for a constant fan speed should indicate what quantity will be delivered, what horsepower will be required, and with what efficiency the fan will run when it is operating against different pressures or resistances.

The fan for which the performance curve shown in Fig. 5 is drawn is a full backward-curve blade fan designed to deliver 100,000 min.-ft. against 2-in. static-

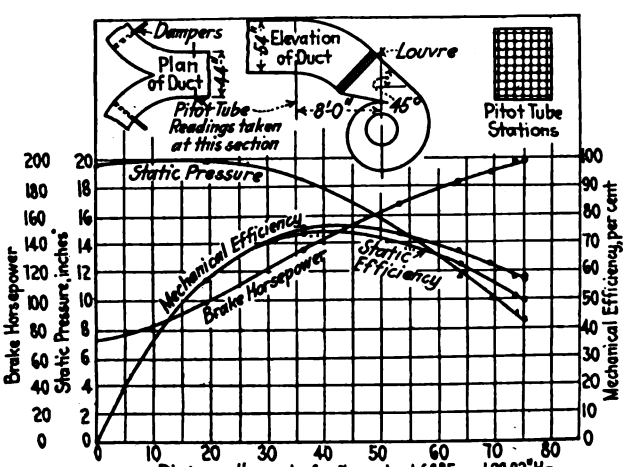

Fig. 6—Characteristic Operating Curve for Partial Backward-Curved Blade Fan

This fan was designed to deliver 42,500 min.-ft. against a static-pressure of 17.5 in. of water when operating at 1,200 r.p.m. The test was made after the fan was installed.

pressure resistance when operating at 304 r.p.m. and would be guaranteed by the manufacturer to require not more than 43 hp. when operating under these conditions. This work would give the fan a total mechanical efficiency of 80 per cent.

If the resistance of the mine were more than that estimated, say 2.28 in. of water gage for 80,000 min.-ft., or less than estimated, say 1.62 in. of water gage for 120,000 min.-ft., we could easily determine how the fan should perform against these changed conditions

Digitized by Google

by consulting the performance curve. According to the graph the fan should require but 40.5 hp. when operating against the higher resistance, 80,000 min.-ft. at 2.28 in. water gage, and 45 hp. when operating against the lesser pressure, 120,000 min.-ft. at 1.62 in. water gage.

In the first instance its total mechanical efficiency should be 74 per cent and in the second case 80 per cent. If the purchaser of a fan were given a performance curve with each fan as it is bought there would be no room for argument later as to whether the fan were meeting its guarantee. It is a simple matter for fan manufacturers to construct such a curve, and the responsible companies are glad to do it, for, as stated before, reputable manufacturers suffer more because of the lack of knowledge of the mine operator and his engineers than the operator does.

After the fan is installed and accepted by the mine operator it is advantageous for him to have and keep a performance curve. By frequent fan tests and reference to the performance curve it can be ascertained at just what point on the curve the fan is operating and whether the efficiency can be improved by decreasing or increasing the resistance. This use of the performance curve to check up on operation is more important on fans of the first three types discussed than on the full backward-curved blade fan, for the horsepower and efficiency curves of the latter are broad and flat. This characteristic indicates that there will be relatively slight change in horsepower and efficiency through a wide range in quantity of air delivered and pressure developed.

There is little doubt but that the backward-curved blade fan will be the predominating type among newly installed fans in the future, and it is likely that many progressive mining companies will see fit to replace the old inefficient fans now in use, because ventilation and the power required for it are demanding more and more attention.

Better Fans Would Pay Dividends

As most mine-ventilating units are in operation 24 hr. per day and 365 days per year the cost of power used for ventilation at 2c. per kw.-hr. is $130.80 per hp. per year. A saving of but 5 hp. would effect a saving of $654 per year. If the fan to accomplish this saving were bought for $5,000, the money saved on power would pay 6 per cent in yearly interest on the original investment and provide a sinking fund to pay for the fan in less than 10 years. Fig. 6 shows an operating curve of a backward-curved blade centrifugal fan.

With the more general use of graphic charts for analyzing operating costs there is no doubt but that the enormous quantities of power required for mine ventilation will attract the attention of mine operators to the ventilating units and demonstrate conclusively not only the desirability of having a highly efficient ventilating unit at the mine but also that mine operators can afford to replace the old-fashioned inefficient fans that are so frequently found at otherwise modern and efficient coal mines with those of newer and more satisfactory design.

A CARBON MONOXIDE recorder developed at the U. S. Bureau of Mines, Pittsburgh experiment station, and which is so sensitive that it detects as little as 1 or 2 parts of carbon monoxide in 1,000,000 parts of air, has been installed at the Liberty Tunnels in Pittsburgh.

Coal Men Discuss Loading With "Mechanicals"

At Rock Springs One Scraper Loaded 288 Tons in 12 Hr.—Four Cuts per 8-Hr. Day Made and Loaded Out in Entry

BY R. DAWSON HALL
Engineering Editor

That mechanicalization of loading is "unquestionably reducing the cost of production" of coal and that mechanical loading will be the ultimate stabilizer of the coal industry was the declaration of Eugene McAuliffe, president of the Union Pacific Coal Co. at a meeting of the American Society of Mechanical Engineers in the Auditorium of the Engineering Societies Building in New York City to discuss "Material Handling in Coal Mines," Thursday, Mar. 11. The Materials Handling Division of the society had obtained the co-operation of the National Coal Association and a large number of coal men attended, some coming from great distances.

Mr. McAuliffe presided and in his opening address invited the co-operation of their hosts, the "Mechanicals," and of the American Society of Electrical Engineers in the development of coal-mining practice. Mr. McAuliffe added that "he had visioned methods whereby development work could be carried on during the period of low market demand, the same force being put on face and room production when the demand was brisk, thereby establishing a more regular work year."

Mechanize Is to Americanize

Nixon W. Elmer, a material-handling engineer of Quincy, Mass., said that the miner had cars only 75 per cent of the time and that not by any means necessarily at the time when he needed them. He believed that a group bonus would eventually be paid to the gang working the loader or feeding the conveyor. To him it seemed that by mechanicalization loading was made not only a lighter but a more cheerful job, the men mingling together and not being localized in separate gloomy chambers. As he put it: "To mechanize is to Americanize." In his belief one device should be installed at a time and not a combination of many. The conveyor should come first, he urged. It pays for itself rapidly and does not raise a cleaning problem. The loader, he thought, should be introduced later.

In discussing the paper, Mr. McAuliffe declared that the coal industry would welcome an injection of outside constructive advice that would assist in the solution of its loading and other problems. Edwin H. Johnson read an address on "Mechanical Loading in Coal Mines" and remarked that machine loading added to the impurities in the large coal but had no effect on the quality of fine coal, because the miner had never endeavored to clean the smaller impurities from his product. Machine mining has reduced tonnage where the number of cars hoisted in the shaft was close to capacity. The machine-loaded cars having a light load caused the hoist to work under less favorable conditions. To remedy this sideboards had to be used to increase car capacity.

W. K. Kavanaugh, president, Southern Coal, Coke & Mining Co. of St. Louis, stated that two men with a machine had loaded 125 tons in one day in one of his mines and that into cars of only 1½-ton capacity. He was shooting from the solid, and he believed that with

Digitized by Google

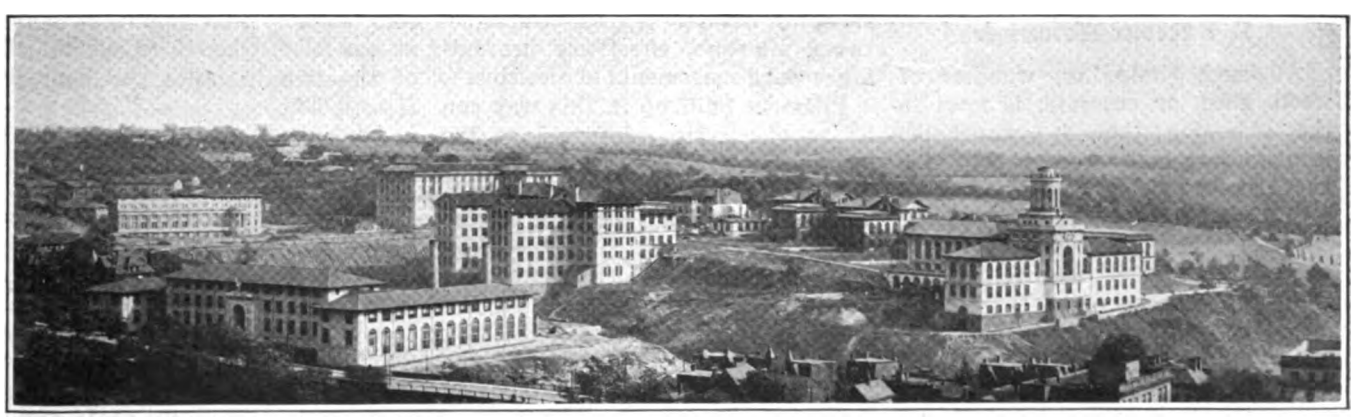
a careful and judicious placing of shots the percentage of fines was not much increased. With loading machines the impurities in the coal made it necessary to put more men alongside the picking belts. The fines were loaded into cars and shipped to a washer. C. E. Bockus, president, Clinchfield Coal Corporation welcomed mechanical methods to coal mines, but said that the efficiency of mining operation was not a proper subject of criticism so long as coal that had to be hauled two miles in small cars underground was delivered in the railroad car at the price of $1.50 per ton.

Col. Edward O'Toole, general superintendent, U. S. Coal & Coke Co., Gary, W. Va., gave a brief review of the difficulties with roof action. The load that comes on the pillars with a meager 100 ft. of cover where the coal is 50 per cent extracted is 16 tons per square foot. This is the load prescribed as the limit for a brick foundation. To obtain a break in the roof the span has to be three times as great as the depth of the main resisting stratum.

Span Three Times Thickness of Rock

Thus if the main stay for the roof was a body of 200 ft. of solid sandstone, the span that would cause a break would have to exceed 600 ft. Mr. O'Toole described his machine, which last month had an average output per man-hour of 2.47 tons. Under the methods prevailing where loading machines are not used the output for the same month was 1.88 tons. Thus 0.59 tons more per man-hour was produced by machine than by the old methods. The men working with the machine were paid $1 an hour and the man in charge of the machine received $1.25.

H. F. McCullough, of H. C. Frick Coke Co., admitted that the room-and-pillar was, as Mr. Elmer had said, an institution to which mining men were attached, but it was no more to be respected as an institution than the horse-drawn vehicle of thirty years ago. He believed in a wide face and in rapid extraction as a means of outstripping roof failure.

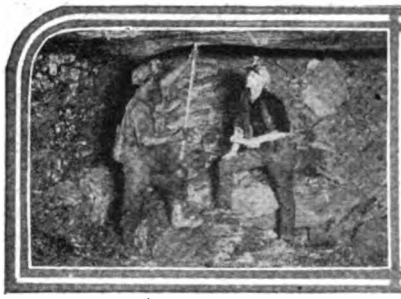


S. W. Blakeskee, division superintendent, Pennsylvania Coal & Coke Corporation, said that a dry, hard floor was desirable and a good roof. However, with too good a roof the conditions were unfavorable as the roof would not break and the crush became insupportable. S. W. Farnham described the scraper shovel of the Union Pacific Coal Co. at Rock Springs. He said his firm had increased the horsepower of the actuating motors of its scrapers from 10 hp. to 40 or 50 hp. and has enlarged its scrapers accordingly. The Rock Springs machine was a three-drum hoist with two drums for the straight face and another drum to direct the scraper at right angles to the face where that was desired. The machine had loaded 475 tons in a single 8-hr. shift into 3½-ton cars.

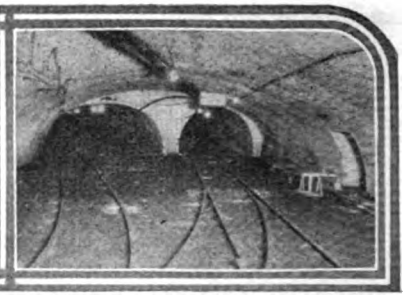
Mr. McAuliffe described the conditions at the Hanna mine in Wyoming where the coal is undercut, shot down to a height of 8 ft. and loaded by small loading machines. Though the model of shovel used had long been discarded by the manufacturer the results obtained are excellent. The upper coal is then shot down to a height of 36 ft. and loaded by ordinary surface shovels of the "steam-shovel" type using electric operation. The small shovels used for the 8-ft. cut have loaded an average of 147 tons a day. The tonnage has dropped heavily recently because the machines are being used for driving heading which is narrow work. There are twelve machines of the last-named type, and there are eleven out of twelve in service every day, because the repairs are well and expeditiously performed. The loading-machine men are paid $11.50 per day.

Mr. McAuliffe said that it was 90 per cent of the struggle to get the staff "sold" on the loading machine. Once the company's staff is interested in the operation of the machines the task is as good as performed. Mr. McAuliffe said that on an investment of $71,000 a saving was made last year of $54,800, all this in excess of depreciation, maintenance and 6 per cent for interest.

Rock Springs Coal Scrapers



The scraper face in the Rock Springs mine is 200 ft. wide. The coal unfortunately is 12 ft. thick. That makes the problem more difficult than if it were 6 or 8 ft. as is the general run of coal at Rock Springs. Five rows of props each with cross cap pieces 2 ft. long and of the dimensions of a railroad tie are used back of the face to maintain the drawslate. In a 12-day run the average production was 288 tons per scraper, the cost being 42c. a ton for the coal delivered to a car at the parting. Seven more scrapers, each having two drums instead of three, have been ordered. Six shaking conveyors are to be installed. In a 10-ft. entry, 7 ft. high, four cuts were made and loaded out in eight hours by three men, or about 67 tons of coal. Mr. McAuliffe advocated a wage of about $6 a day, graduated to the character of work done, with a bonus on all the coal mined. When the machine was being moved or repaired the men would be drawing a small wage and when the machine was actually loading coal they would be getting that wage plus a bonus.



A Good Many Ideas of Benefit to the Coal Industry Originate Here

The Pittsburgh station of the Bureau of Mines is located in the building occupying the left foreground in this picture. Here much experimental work of a laboratory nature goes on continually that the technical problems involved in coal may be more easily solved. The buildings of Carnegie Institute of Technology, an important engineering college, are behind the Bureau's station.

Underground Operation

Concrete Pilasters Sustain Both Sides and Roof

The combination of a friable coal and an uncertain roof is encountered fairly frequently in American coal mines. In rooms such conditions do not cause as much trouble as they do on main headings where the roof must be held up on permanent supports. The materials for this purpose commonly considered permanent are steel, masonry and concrete.

Although structural steel is frequently used for supporting the roofs of headings and haulageways, the legs of the three-piece sets normally employed for this purpose are seldom designed to withstand side pressure from the ribs which frequently develops with a friable coal or even with a solid non-weathering coal if the roof strata are full of slips, cracks, and clefts, and if the roof caves attain any great height above the coal.

Precast concrete timbers have been used to a somewhat limited extent to support the roof and sides of such passages. With reinforcement properly placed, the legs of concrete sets may be made amply strong to resist pressure from the sides. Such timbers are slightly more expensive to place than are steel sets, because of their greater weight, but when once in position they may be more durable than steel because they are immune to both oxidation and water.

To Prevent Movement

All such timbering, whether of wood, steel, or concrete, is open to the objection that it cannot be brought into direct contact with the surfaces to be supported. This is not of cardinal importance in the case of the roof, as experience has shown that it is advantageous slightly to cushion subsidence of the overlying strata upon wooden wedges or by other means. Control of the sides or ribs, however, is somewhat different, for here movement should be entirely prevented if possible.

No material will accomplish this result as well or as effectively as concrete cast in contact with the ribs. Thus a concrete archway with the aggregates rammed tightly between the forms and the roof and sides will probably sustain as great a top and side pressure as it is possible to resist. In extremely "runny ground, the outline or cross-section of such a passage might advantageously be made circular or elliptical, as these shapes better resist pressure from all sides.

Arches Even Unnecessary

It is comparatively rare, however, that such extreme measures need be taken in the mines of this country. In most instances even the arch need not be resorted to. In many cases, however, the roof strata contain slips or clefts extending in planes corresponding to the angle of compression shear, or at roughly 45 deg. to the horizontal or horizon. Here concrete pilasters, cast in place and supporting steel roof beams, afford ample support while at the same time they effectively prevent side movement of the rock strata.

Building a three-side form for these pilasters—that is, letting the rib itself form the fourth side—brings the concrete into perfect contact with the rib, and makes the pilaster from a structural standpoint practically a part of it. Slabs of rock separated from the main body of the roof by microscopic clefts, slips, or fissures act as beams between pilasters, effectively preventing inward movements of the ribs.

Pilasters built up in this way can be as effectively reinforced as the legs of three-piece sets that are precast on the surface. If the ribs against which they are cast are so friable or shelly as to require lagging, this can be placed before the concrete is poured. Such lagging should naturally be of a permanent nature. Old pipe or old rails can often here be used to advantage. In extreme cases corrugated galvanized iron might well be placed behind these "stringers."

Momentum Grades Decrease Tractive Effort

If levels are taken in the mine, and if these levels are then plotted and the tracks graded in accordance with the findings, the locomotives can haul larger trips. The track, when surfaced, should have preferably an average grade of ½ to 1 per cent in favor of the loads, according to J. L. Libby, writing in the *Employees' Magazine* of the Union Pacific Coal Co. But short slight changes in grade do not particularly interfere with the haulage, as the motor gets a run on the lighter pitches and will carry over the steeper portions, which are known as momentum grades.

Exceed Ruling Grades

Momentum grades are those which, although steeper than the ruling grades, can invariably be approached at a velocity sufficient to carry the trip over the summit with the aid afforded by the energy stored up in trip when approaching the grade. If it is assumed that the trip is moving without track resistance its energy will lift it up a certain vertical height, and if the motor is developing sufficient energy at the foot of the grade to overcome tractive resistance it will overcome the track resistance on the grade, provided it does not reach too low a velocity, hence the trip will climb the momentum height. That height, h, in feet, at sea level, when v equals velocity of the trip in miles per hour, is: $H = 0.035v^2$.

H then equals 0.1 ft. for 2 m.p.h.; 0.9 ft. for 5 m.p.h.; 1.3 ft. for 6 m.p.h.; 5.1 ft. for 12 m.p.h.; 9.0 ft. for 16 m.p.h.; 11.4 ft. for 18 m.p.h., and 14.0 ft. for 20 m.p.h.

For example, suppose that a locomotive is so loaded that its entire drawbar pull is necessary to overcome the resistance of the trip on a 1 per cent grade, but that through favorable grades it reaches the foot of a 2 per cent grade, 800 ft. long, traveling at a velocity of 16 m.p.h., will it carry over?

Eight hundred feet of 2 per cent

Digitized by Google

grade entails a vertical height of 16 ft. Assuming, as already said, that the locomotive's full loaded capacity is equal to surmounting a 1 per cent grade without retardation and, consequently, that the capacity for 800 ft. is 8 ft.; the difference is 8 ft.; which must be overcome by momentum. The momentum height for a speed of 16 m.p.h. is 9 ft., as stated. This, minus 8 ft. necessary for the grade equals 1 ft. of reserve, or a momentum head, which corresponds to 5 m.p.h. If the locomotive were moving at a low speed at the bottom of the grade, it would become necessary to split the trip in order to pull it over.

Where Too Much Mechanism Decreased Efficiency

Over a year ago we installed a shearing machine, used it several months and, thought it was all right mechanically. We then discontinued its use. Our trouble was that we were trying to do too many things at the same time. As we were loading coal mechanically on the day and night shifts we were required to keep in operation at one and the same time our loading machines, undercutters, locomotives, drilling trucks and the shearing machine. These pieces of equipment all trying to move over track in the same area, interfered with each other and caused much confusion.

Of course, right-of-way had to be given to the loading machines. Equally important was a clear track for the movement of cars to and from the loaders. As a result the undercutters were required to move and operate as best they could without interfering with the major operations of loading. And then, with still less freedom of action, came the drills and shearing machine.

SHEARS FIFTEEN ROOMS

The shearing machine could easily shear fifteen places per shift when not held up. It actually averaged about six places because it had to wait most of the time for a right-of-way to move from one place to another. Because this machine was idle most of the day the expense of keeping the men who manned it was prohibitive. Naturally, the ideal way would be to do all the cutting, drilling and shearing at night; but such a procedure would cut down production by permitting loader operation during only one shift.

One other objection was found to the shearing machine under our conditions: It produced lumps that were too big. We wanted lump coal and we got it, but the lumps were too big to pass between the top of the loader and the roof. When a big lump hung against the roof the usual result was a damaged conveyor. The shearing machine would work all right in a seam which is thick enough, but ours is not.

DAVID INGLE,
President Ayrshire Coal Co.
Oakland City, Ind.

Sliding Door Keeps Out Surface Fires

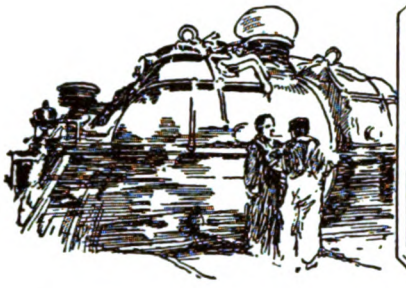
Unwilling to overlook a single opportunity to make its mines safer, the Union Pacific Coal Co. is equipping them all with sliding doors such as the one illustrated in the accompanying photograph. The door is mounted in the slope portal of No. 7 mine at Winton, Wyo., in such a way that it can easily be closed, by anyone who notices that smoke or flame from any nearby fire on top is blowing into the mine. The air intakes

It May Save Lives Some Day

This door, recently built at the portal of the Union Pacific Coal Co.'s No. 7 mine at Winton, Wyo.,—an air intake—is to be closed in case smoke or flame from any fire near the slope mouth threatens to blow into the mine.

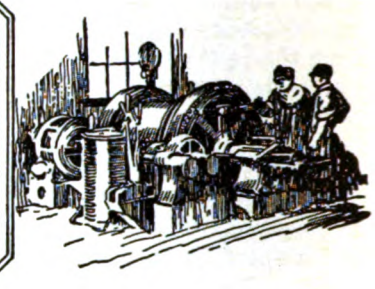
of Wyoming mines readily can draw in smoke and dust from considerable distances because of the heavy winds that so often blow in that country.

There is one chance in a thousand, possibly, that a conflagration of top buildings, or even a bonfire might send enough smoke into a mine to cause great excitement and possible injury to men underground. Two men were killed in a Colorado metal mine during an incident such as this. To reduce the likelihood of any such trouble at Union Pacific mines the sliding doors, made of wood and covered with sheet metal, are now being installed. Each one is counterweighted for ease of operation and is fitted with handles on the inside so that men can make their exit without difficulty even though the door might be closed.



Trucks for Fighting Fires Aid in Erecting Seals

About five years ago a fire broke out in No. 1 Shaft Mine of the Ford Collieries Co., at Curtisville, Pa., the fighting of which was greatly facilitated by two fire trucks, one a part of the equipment of the colliery and one brought from an adjoining mine. The fire had been burning for some time when it was discovered, so that the apparatus could not be utilized for entirely extinguishing the flame. But the two machines, operating alternately, one being discharged while the other was being filled, subdued the flames sufficiently to enable the workers to erect seals.



Each of the three shaft mines of the Ford Collieries Co. is equipped with a fire truck on which is mounted a closed tank of 80 gal. capacity and a reel of 500 to 800 ft. of 1¼-in. hose. These trucks are provided with unflanged wheels and are each mounted on a mine car truck, so that they can be pulled to any tracked portion of the mine by a locomotive. In the tank water is stored, and above it are receptacles for holding an acid and soda, which ingredients when mixed together with water in the tank form an aqueous solution of carbon dioxide of 80 to 100 lb. pressure per square inch. This pressure is preserved within the chamber until all of the solution has been forced from the closed chamber and through the hose. Every four months the chemicals are discharged to test the apparatus.

The fire truck is kept near the shaft bottom in a concrete-lined stall turned from a track which is always kept clear of standing rolling stock. The stall is padlocked, but the key is kept in a case with a glass front that, in the event of a telephone call for the fire equipment, can readily be broken. The apparatus is hauled to the nearest point to the fire to which mine track extends, from which point the hose is unreeled and carried to the fire, or the fire truck itself is unloaded from the mine truck and wheeled over untracked entry to any point desired.

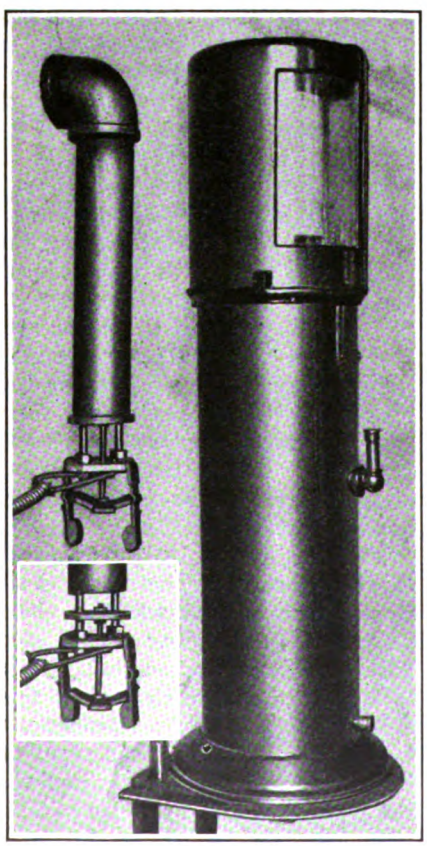
Practical Pointers For Electrical And Mechanical Men



Electric Siren Blows If Fan Slows Down

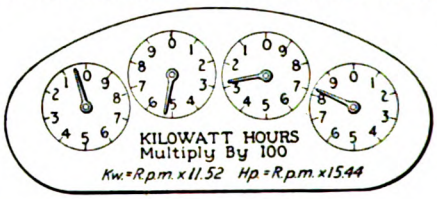
By properly equipping steam-driven fans with protective and alarm devices it is practical to operate them without regular attendants provided there is always someone available who can get to the fan within a few minutes. At the Virginia mine of the Gulf States Steel Co., near Bessemer, Ala., the fan is located several hundred feet from the power plant engine room yet this engine is tended by the shift engineer of the plant.

The engine, which is belt connected to the fan, is equipped with an automatic stop. This is so arranged that the throttle valve is closed by overspeed or can be shut from push buttons located at the fan and in the power plant. If for any reason the fan should slow down appreciably, the decrease in vacuum causes electric sirens in the power plant and at the tipple to be sounded.

In the accompanying illustration, the siren contact-making device can be seen at the left of the recording gage. The copper leaf contact brush is attached to a disk made of ¼-in. asbestos board. Normally this disk is held up against the open end of the 2-in. pipe by virtue of the vacuum created by the fan. In this position the circuit is open. Weights in the form of washers, added to or taken off of the contact brush, determine the amount of reduction in fan speed required to cause the contact to drop and blow the siren.

Contact Device Beside Water Gage

The insert in the lower left-hand corner shows the disk and contact after dropping and while blowing the siren. Normally the vacuum created by the fan holds the disk up against the open end of the 2-in. pipe.



Load Found by Timing Disk of Watthour Meter

Equipping substations with watthour meters has become standard practice, and many companies now have such meters installed on all important circuits and principal motors. It is often important to know the load in kilowatts or horsepower taken by a substation or by a large alternating-current motor driving a fan, pump, conveyor or the like. Many electricians do not realize that if the motor is equipped with a watthour meter this instrument can be used to indicate with fair accuracy the average kilowatts or horsepower input during a half minute, a minute or longer interval.

To use a wattmeter in this way it is necessary to know the meter constant and to count the revolutions of the meter disk during a period such as one minute. This constant which is the number of watthours per revolution of the disk is usually marked on the face of the meter. Having counted these revolutions per minute with a certain load, and knowing the meter constant, it is then a matter of simple multiplication to calculate the kilowatts or horsepower.

The electrical engineer of a company operating mines in southern West Virginia and eastern Kentucky marked in pencil on the register of all stationary watthour meters a simple formula for use in determining the load. The accompanying sketch shows the register of one of these meters.

The nameplate of the meter carries the following data; type D-6, 3-wire, 3-phase, 80-amp., 2,200 volts, 60 cycles, current transformer ratio

Formulas Marked on Register

The figure by which the revolutions per minute of the disk must be multiplied to give the kilowatts or horsepower, is determined from the meter constant which is usually found marked on the disk.

16 to 1, potential transformer ratio 20 to 1. On the upper disk (seen by removing the cover) is the marking, "K-192." For this particular meter the simplified formula can be found by substituting 192 for "K" in the following relation:

Kilowatts = r.p.m. of disk × K × minutes per hour ÷ 1000

then, Kw. = r.p.m. × 192 × 60 ÷ 1000

or, Kw. = r.p.m. × 11.52.

From this it follows that,

Hp. = r.p.m. × 11.52 ÷ 0.746 = r.p.m. × 15.44.

With these simple formulas it is hardly necessary to use a pencil in calculating the load after the revolutions of the meter disk have been counted for a minute. With a constant load, greater accuracy can be obtained by taking a longer time interval and dividing by the number of minutes. With a fluctuating load the method gives the average during the period of time that the revolutions are counted.

Instances are known where an elec-

Digitized by Google

trician was in the habit of going to the work and expense of connecting a portable indicating meter in the circuits of motors already equipped with stationary watthour meters. He did not realize the possibility of determining the load by timing the disk of the stationary meter.

Water Jet Protects Motors From Creek Floods

While employed by a coal company in the Birmingham district I was in charge of the power plant equipment. This was a steam plant with high-pressure turbines of the condensing type. The pumps that furnished condensing water were located on a creek about a quarter of a mile from the plant, and were controlled from the plant switchboard. They operated without attendance other than inspection by a plant mechanic once or twice a day. The pumps being of the centrifugal type were located just above the normal level of the creek so that they would not have a high lift.

Forestalling Flooding

When the creek was swollen during wet weather the water would rise on the discharge pipe from the building and flood the pump room, if the valve on this pipe had not been previously closed. When this valve was closed there was the additional danger of the pumproom being flooded by leaking or blown out packing. To prevent the possibility of this happening the mechanic had to go to the pumproom several times each day or night that the valve was closed. One rainy night the valve was not closed either through negligence on the mechanic's part or by his thinking that the rain would not be sufficient to raise the creek to flood stage. Of course, anyone familiar with the operation of centrifugal pumps realizes that there is a leakage at the packing glands all the time.

Creek Rose at Night

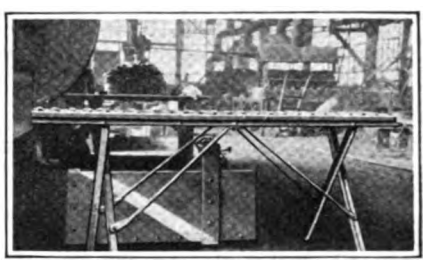
This leakage cools the glands and also prevents the pump from taking air. The creek rose up into the pump room, causing quite a lot of damage and killing the power for about half an hour. The actual damage of the pump motors and cables amounted to several hundred dollars, besides a costly production delay. The chief and myself decided that this must not happen again, so he suggested getting an ordinary water jet and connecting it to the discharge side of the pumps. As all the pumps did not run all the time the intake pipe of the jet was connected to the discharge of the two largest machines.

Removes Gland Leakage

This jet when tested was found to more than carry away the gland leakage. This would eliminate the necessity of the mechanic losing sleep at night on account of the pumphouse as the discharge valve was to remain closed in the winter or rainy season and the jet to be kept on continually. The small amount of water necessary to operate this device would never be missed. Each of the large pumps had a capacity of over 2,000 gallons per minute and the jet only required a ¾-in. pipe for an intake. The jet, installation and all, did not cost over $25.

Electric Power Costs in Southern Fields

Extensive data on mine power costs, principally in southern West Virginia, and Eastern Kentucky, are tabulated on a sheet made up by the West Virginia Engineering Co., of Charleston, W. Va., listing (without name of company) power and tonnage figures for 95 of their representative clients, during the year of 1924.



A summary of several of the columns of this sheet is shown in the accompanying table. The kilowatt-hour and cost figures include all power used inside and outside the mines. At practically all of the mines listed, the employees live in company houses and therefore power for house lighting is included.

It is interesting to note that there is an increase in kilowatt-hours per ton for operations producing above 10,000 to 20,000 tons per month. The cost per kilowatt-hour shows a regular decrease for larger tonnage, as is to be expected due to the sliding-scale rate schedules. The power cost per ton decreases but slightly as the production increases beyond 10,000 tons.

Comparing the cost per ton of purchased power against that of power generated by private steam plants, generally speaking, the operating cost alone of a steam plant is greater than the total cost of purchased power.

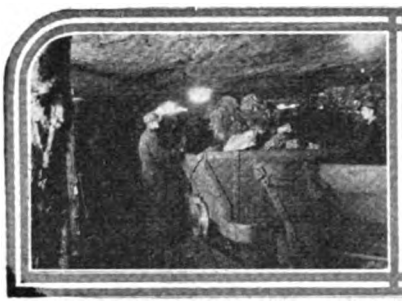
"Old Woman" Aids Work of Punch and Shear

In the machine or blacksmith shop, the "old woman" is a device that may take almost as many forms as the "old man." In the accompanying illustration may be seen a contrivance

"Old Woman" Beside Punch Press

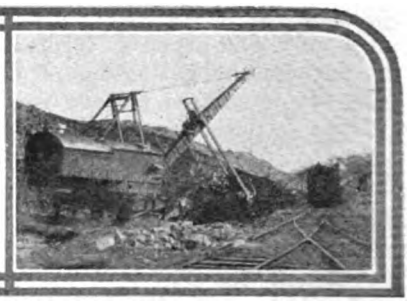
Car belts or other work for the press may be supported on this old woman. The rollers on its top render it easy to slide the work along as punching or shearing progresses.

of this kind intended to serve a punch and shear in a large mine shop. It is peculiar as old women go, in that its top is provided with a whole series of rollers so that the work it supports may be readily slid along upon it.



Little need be said in explanation of the illustration. The supporting frame is built up of small angles and straps and the top made such a height as to bring it to the level of the die plate of the punch or the lower or stationary jaw of the shear. The rollers extending across the top of this device make it easy to move the work along as successive holes are punched or piece after piece is sheared from the end. Its utility in punching such parts as car belts can readily be appreciated.

Summary of Power Data of Almost 100 Mines



Number of Mining Operations	Range of Monthly Tonnage	Kw.-Hr. per Ton	Cost per Kw.-Hr. c.	Power Cost Per Ton c.	Percentage of Electrification
Purchased Power					
14	0–5000	5.13	2.81 (a)	14.42 (a)	94.5
23	5,000 to 10,000	5.36	2.34 (a)	12.56 (a)	95.3
24	10,000 to 20,000	3.62	2.22 (a)	7.93 (a)	93.7
12	20,000 to 30,000	4.04	2.04 (a)	7.82 (a)	94.3
7	Over 30,000	4.19	1.86 (a)	7.81 (a)	98.6
Private steam plants					
13	9,000 to 60,000			8.69 (b)	92.4

(a) Power bills only; (b) Operating costs only, does not include fixed charges.
Why the steam plants are put in one group only instead of being divided into four classes as are the purchased power plants is not explained. Nor are any details available as regards the equipment in the private steam plants included.

News Of the Industry

Consumers Had 45,000,000 Tons Of Soft Coal Feb. 1; Would Last 28 Days if Evenly Distributed

Stocks of bituminous coal in the hands of consumers on Feb. 1, 1926, were approximately 45,000,000 net tons, according to the U. S. Bureau of Mines. This was slightly higher than at a corresponding date a year ago while Nov. 1, 1925, stocks totaled 48,000,000 net tons. Between Nov. 1 and Jan. 1 something less than 1,000,000 tons was added to total reserves, but between Jan. 1 and Feb. 1, 1926, approximately 4,000,000 tons was removed from storage. The trends of production and consumption since Feb. 1 indicate that storage piles have been further reduced.

At the rate of consumption prevailing during January, when the industries of the country were active and when bituminous coal was being substituted for anthracite, the stocks of bituminous coal on Feb. 1 were sufficient for 28 days. If no substitution for anthracite had been necessary the supply would have been enough for 31 days. This may be compared with a supply of 37 days on March 1, 1925; with 46 days on Jan. 1, 1924, and 24 days on Feb. 1, 1923. But all of these averages, however useful for comparison, fail to take into consideration the fact that the supply is never equally distributed. Some consumers may have plentiful supplies; others none.

Big Stocks at Head of Lakes

Besides the supply of coal in consumers' hands on Feb. 1, there were 5,176,000 tons of bituminous coal piled on the docks of Lakes Superior and Michigan, approximately 185,000 tons held in storage at the mines or intermediate points by producers, and 760,000 tons loaded in cars unbilled at the mines.

Anthracite and Substitutes.—By Feb. 1 the stoppage of anthracite production had caused retail dealers' stocks of anthracite to drop to the lowest level on record, with the possible exception of September, 1923. Retail stocks of bituminous coal on Feb. 1, 1926, when measured in tons, were large, though the volume was less than on Jan. 1, 1924, and some earlier dates. Surplus stocks of coke at merchant byroduct coke plants had dropped to 87,000 tons as compared with 832,000 tons on Sept. 1, when the anthracite suspension began.

The estimates of the total quantity of soft coal in the hands of commercial consumers are based on practically complete reports from byproduct coke plants and steel plants, railroads and utilities, together with reports from a selected list of other consumers—more than 5,000 in all. The estimate of 45,000,000 tons, which is believed to be accurate within 5,000,000 tons, does not include the quantity of coal in householders' bins, for which no reasonably accurate figures are obtainable, nor the tonnage of steamship fuel. The tonnage on hand on the Lake docks also is omitted from the estimate as above given, being classed as bituminous coal in transit.

As shown in the accompanying illustration the total stock of coal on Feb. 1 was higher than on March 1 of last year, the nearest date of 1924 which may be used for comparison. It is almost the same as the level on Jan. 1, 1921, but lower than the figures in the fall and at the end of 1921, and very much less than in the period October-December, 1923, when consumers were laying in large stocks in the event that there would be another strike.

The reports from consumers, together with some supplemental information, indicate that the average rate of consumption, plus exports, during November, December and January was around 12,300,000 tons of bituminous coal per week. This unusually high rate, while indicative of the business activity of the coal-using industries, also reveals that bituminous coal was being extensively used as a substitute for anthracite.

Comparison of the days' supply of the principal classes of consumers on Feb. 1, 1926, with those on varying dates during 1919-1925, given in Table I, shows that the reserves of each group are regularly lower than they were in March a year ago. Special interest attaches to the reserves held by retailers. At the rate their customers were demanding soft coal in January, retailers' stocks on Feb. 1 would only last 17 days. At the normal rate for January, however, when soft coal is not being used to replace anthracite, the same volume of retail stocks would have lasted 28 days. In comparing the figures for the dates given, it should be remembered that they are only averages, and as such do not reveal pronounced fluctuations between the individual plants in every group or the variations between different localities.

Reserves by States Vary Widely

Reserves of soft coal on Feb. 1 in terms of days' supply differed widely, as usual, from state to state. The best indicators for this purpose are the returns from the general industrial concerns, other than byproduct coke and steel plants. They are the largest single group of coal users, both as to number and tonnage consumed, and being widely distributed throughout the country their stores of coal are a sensitive barometer of conditions in the coal market. New England on Feb. 1 was carrying considerable stocks of coal, four of the six states showing more than 70 days' supply, the average for the entire region being 65 days. The stocks in the northern peninsula of Michigan also are maintained at a high figure, the highest in terms of days' supply for any section of the country. In New York State stocks averaged 59 days, almost the same as that for Massachusetts. Lower Michigan was carrying 53 days' supply; Colorado 46 days. The remaining states show reserves varying from 4 to 43 days' supply, except Oklahoma, which shows especially heavy reserves.

Public utilities, as is customary, carried larger reserves than any of the other groups of consumers. The coal-

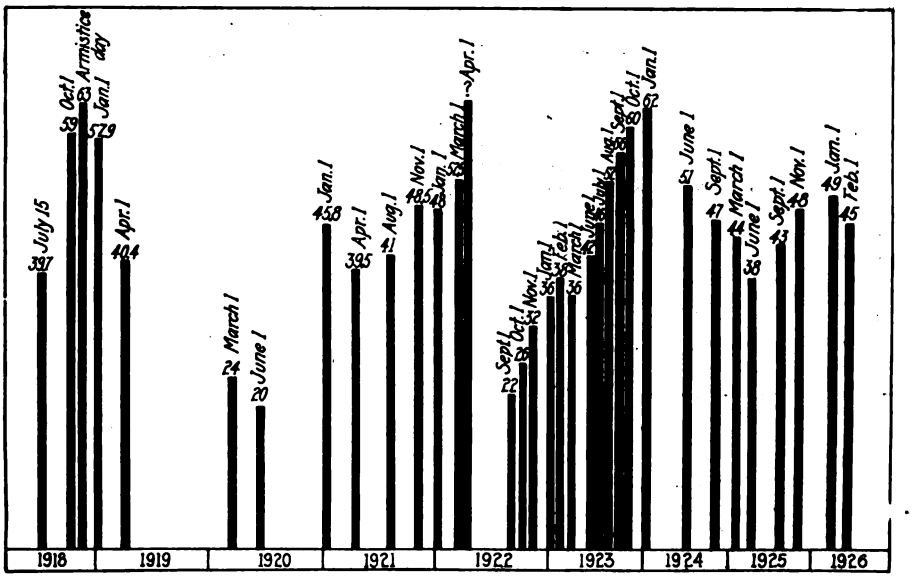

Table I—Days' Supply of Bituminous Coal in Hands of Various Classes of Consumers in the United States, Jan. 1, 1919, to Feb. 1, 1926 (a)

(Figures represent number of days that supply would last at rate of consumption at time of stock taking.)

	Jan. 1, 1919	Mar. 1, 1920	Jan. 1, 1921	Jan. 1, 1922	Mar. 1, 1922	Feb. 1, 1923	Jan. 1, 1924	Mar. 1, 1925	Sept. 1, 1925	Nov. 1, 1925	Jan. 1, 1926b	Feb. 1, 1926b
Byproduct coke plants...	32	15	29	42	39	20	35	25	22	26	26	23
Steel plants.....	42	9	42	48	48	26	43	30	30	32	28	26
Other industrials.....	65	27	64	51	56	36	55	40	38	44	39	37

Electric utilities.....	49	21	44	51	54	35	51	51	43	46	48	47
Coal dealers (bitum.)....	39	13	30	33	23	15	34	33	27	30	20c	17c
Railroads.....	32	11	23	35	42	18	44	35	28	30	27	25
Total bituminous.....	42	18	39	41	43	24	46	37	32	35	30d	28d

(a) These figures are based on incomplete data. (b) Calculated at average rate of consumption in January, 1926. (c) At delivery rates normally prevailing in January, the tonnage of bituminous coal on hand on Jan. 1 and Feb. 1 would be sufficient for about 33 and 28 days respectively. (d) Using the normal January rate of delivery of bituminous coal by retail dealers, the total stocks on Jan. 1 would be sufficient for 34 days, and those on Feb. 1 for 31 days.

Digitized by Google

Total Commercial Stocks of Bituminous Coal, Oct. 1, 1916-Feb. 1, 1926

Figures represent million net tons and include coal in the hands of railroads, industrial consumers, public utilities and retail dealers. Coal for steam ship fuel, on lake docks, in transit and in the bins of householders is not included. Reports are to the effect that since Feb. 1 stocks have been further reduced.

gas plants on Feb. 1 had a supply sufficient to run them, on the average, for 67 days; the electric central stations had a 47-day supply.

Byproduct coke and steel plants had a smaller tonnage in reserve on Feb. 1 than on Nov. 1, 1925, the decrease being greater for the steel plants. Complete returns from these groups follow:

Stocks at Byproduct Coke Plants

	Days' Supply			
	Mar. 1, 1925	Nov. 1, 1925	Jan. 1, 1926	Feb. 1, 1926
Low volatile	23	28	28	24
High volatile	26	26	26	23
Average	25	26	26	23

Stocks at Steel Plants

	Day's Supply			
	Mar. 1, 1925	Nov. 1, 1925	Jan. 1, 1926	Feb. 1, 1926
Steam coal	36	31	37	36
Gas coal	26	33	23	21
Average	30	32	28	26

The total quantity of railroad fuel on hand Feb. 1, according to information received from the American Railway Association, was 10,235,000 tons, or approximately a 25 days' supply.

All coal brought to the surface and made ready for market, but not yet delivered to a retail dealer or a consumer may be considered "in transit." The largest element in this mobile reserve is the coal in railroad cars, which, though it has never been accurately measured, is known to run into millions of tons.

A few producers of soft coal follow the practice of storing coal at the mines. The quantity stored at present is small. From a list of 43 companies that have at some time in the past stored in quantity at the mines or at some intermediate point, the bureau has received reports of only 185,000 tons so held on Feb. 1, or 36,000 tons less than on Nov. 1, 1925, the date of the last stock report. In March, 1923, these companies had 808,000 tons.

The total quantity of unbilled coal in cars at the mines was 760,000 tons on Feb. 1, as against 452,000 tons on Jan. 1, 504,000 tons on Nov. 1, 1925, and 600,000 tons on March 1 a year ago.

Reports from all of the companies show stocks of 6,551,000 tons on the docks of Lakes Superior and Michigan on Jan. 1, and 5,176,000 on Feb. 1, compared with 3,840,000 tons on March 1, 1925; 7,806,000 tons on Jan. 1, 1924; 3,129,000 tons on Jan. 1, 1923, and 7,151,000 tons on Jan. 1, 1922.

On Feb. 1, the date covered by this report, the anthracite suspension was still in effect, and the stocks of anthracite had fallen to a low level. It was not possible to obtain reports from all retail dealers, but a selected group who have been reporting regularly for seven years are covered by table II.

Table II—Coal in Yards of a Selected List of Retail Coal Dealers

(In Net Tons)

Date	Anthracite (a)	Bituminous (a)	Total
1919			
Jan. 1	910,988	1,411,231	2,322,219
1920			
March 1	718,510	615,632	1,334,142
1921			
Jan. 1	658,112	1,158,358	1,816,470
1922			
Jan. 1	1,208,935	1,303,074	1,512,009
March 1	1,052,464	1,062,995	2,115,459
1923			
Feb. 1	326,527	970,477	1,297,004
1924			
Jan. 1	949,441	1,421,999	2,371,440
1925			
March 1	1,109,418	1,012,260	2,121,678
Sept. 1	1,395,289	1,213,370	2,608,659
Nov. 1	745,445	1,300,150	2,045,595
1926			
Jan. 1	306,607	1,418,402	1,725,009
Feb. 1	183,757	1,221,133	1,404,890

(a) The number of dealers reporting their stocks of anthracite on each date was 535, although many of these had no anthracite at all on Feb. 1, 1926. The number of dealers reporting their stocks of bituminous coal on each date was 739.

A group of 21 byproduct coke plants supplying gas for city use reported only 87,000 net tons of unsold coke on hand Feb. 1, the lowest figure of record since October, 1923. The stocks on other recent dates have been: March 1, 1922, 987,000 tons; Jan. 1, 1923, 212,000 tons; Jan. 1, 1924, 772,000 tons; March 1, 1925, 606,000 tons; Jan. 1, 1926, 246,000 tons.

Wheeler Bill Proposes Seizure of Coal Mines By U. S. in Emergency

Senator B. K. Wheeler, of Montana, on March 11 introduced a bill to authorize the creation in a national emergency of a Federal Anthracite Corporation to take over coal properties and to operate them. The directors of this corporation are to be appointed by the President, representing in a measure the consumers and workers, but primarily the public as the owner and beneficiary of the properties.

"The detailed provisions of this bill are of little importance compared with its primary purpose," said Senator Wheeler. "I present it not as a finished product nor as a detailed program which should be enacted as written but as a challenge to industrial statesmen. A law of this character would provide the means for ending an intolerable situation; a means for substituting public order for private disorder in an essential industry; a means for substituting a reasonable average cost of production for the highest cost of production as the basis of price to the consumer; a means for substituting the payment of just wages as a matter of right and as the product of genuine collective bargaining for wages determined as the spoils of victory by the winner of an industrial war.

"In offering this bill, I invite intelligent constructive criticism to aid in developing a workable program to protect the public interest, which should be enacted into law before an emergency arises in order that the public may be prepared.

"No more than a fair price should be paid the present owners of the mines, which is to be based on the prudent cost of their investment."

Offers Bill to Regulate Coal And Prevent Strikes

A bill to regulate the coal industry and prevent strikes was introduced in the House March 13 by Representative Morris Jacobstein, Democrat, of New York. In event of a strike which could not be settled by any other means, it would empower the President to take over the mines.

The bill would establish a Bureau of Coal Industry as a federal agency, which would report on conditions of production, distribution and storage of coal, including costs, prices, profits, marketing, wages and working conditions. In cases of dispute between miners and operators the President would be empowered to "induce them to submit the controversy by voluntary agreement to the decision of arbitrators."

"If this failed, the President would appoint an Emergency Coal Board to investigate the situation and report within thirty days whether there was likelihood of a settlement and whether the public was being deprived of an adequate supply of coal. Only after the failure of all means of arbitration would the President seize the mines.

L. I. Dealers Embargoed for Refusing Soft Coal

Seven Long Island coal dealers were embargoed by the Long Island R.R. on March 15 because they refused to accept consignments of bituminous coal and coke delivered to their order after the anthracite strike was settled. More than 800 cars of soft coal and coke, it was said on March 15, were tied up on metropolitan zone tracks because the dealers to whom they were consigned would not unload them. It was said that at one time in the last fortnight there were more than 1,200 cars loaded with coal at sidings. Demurrage charges on these cars are said to total $35,000.

The dealers who refused to handle the soft coal and coke consigned to them, it is said, admitted having ordered the substitutes, but said that they were not up to specifications and gave other reasons for refusing the shipments. So long as the dealers mentioned in the embargo order refuse to receive the coal consigned to them they will be unable to receive hard coal, it was reported.

In a formal order filed with the Interstate Commerce Commission on March 1 by the Long Island R.R. the following dealers were embargoed: Rubel Coal & Ice Co., Putnam Coal & Ice Co., Commonwealth Fuel Co., Glendale Coal Co., and the Metropolitan Coal Co. On March 2 the embargo was extended to cover shipments to the Bushwick Coal Co., People's Coal Co., Shanley Coal & Ice Co. and the Home Co. The embargo was later lifted in so far as it applied to the Commonwealth and Shanley companies.

The embargo was held to be necessary by the Long Island Railroad because trackage was needed to bring hard coal into the city, and this work would be hampered so long as the tracks were clogged with the cars of soft coal.

N. Y. Retailers to Discuss Anthracite Situation

The anthracite situation, especially as concerns steam sizes, will be the chief topic of discussion at the eighth annual sectional meeting, New York group, of the New York State Coal Merchants' Association, which will be held Thursday, March 25, at the Hotel Pennsylvania, New York City. The meeting will open with a luncheon at 1 p.m., at which Richard J. Wulff, president of the Commonwealth Fuel Co., Brooklyn, will preside.

The business session will begin at 2 p.m. and the speakers and subjects so far arranged will be:

"Is Coke a Permanent Substitute?" by Walter R. Morris, Seaboard By-Products Coke Co.; "The Future of Bituminous Coal in Anthracite Territory," Charles A. Owen, president, Imperial Coal Corp.; "Merchandising Steam Sizes of Anthracite," Charles A. Connell, assistant manager, Anthracite Coal Service; "Our National Organization," Samuel B. Crowell, president, National Retail Coal Merchants' Association; "Can Domestic Sizes of Anthracite Regain Their Markets?" Arthur C. Wadley, president, Shanferoke Coal & Supply Corp.; "The Retailers' Viewpoint," Hiram B. Blauvelt, vice-president, Comfort Coal & Lumber Co., Hackensack, N. J. Dr. Louis I. Harris, Health Commissioner of New York City, also will be a speaker at the afternoon session.

The banquet will take place at 6.30 p.m., the speakers to be announced later. Charles B. Staats, of Albany, president of the New York State Coal Merchants' Association, will preside, and Thomas F. Farrell, vice-president, Burns Brothers, will be the toastmaster.

Fewer Oil Burners in Panama Canal in 1925

Fewer oil-burning vessels passed through the Panama Canal during the last year than coal burners and motor ships, according to a report submitted to the War Department at Washington last week. Although there were 119 fewer transits of commercial vessels in 1925 than in 1924, 85 more coal-burning and 94 more motor passenger and cargo ships passed through the waterway in 1925 than in the preceding year. There were, however, 300 fewer oil-burning ships using the canal. The total transits in 1925 were 4,774, as compared with 4,893 in 1924.

Smoke Ordinance Revived in New York

Dr. Louis Harris, Health Commissioner of New York City, announced on March 11 that after March 17 the city ordinance against the consumption of soft coal will be strictly enforced, particularly where a heavy smoke nuisance is created.

Dr. Harris stated that he thought the time had arrived when consumers would be able to obtain an adequate supply of anthracite, but he wanted those who have soft coal to have a chance to get rid of it by using it in combination with coke or some hard coal, so that it would not vitiate the atmosphere.

Dealers would be advised to warn buyers of these instructions.

In the case of a breach of the ordinance being committed health inspectors would issue a warning to the offender so as to give him a chance to stop the offense before any summary action is called for.

Schuylkill Exchange Dissolves

The Schuylkill Coal Exchange has gone out of business. Its chief object was the maintenance of order on mine property in the lower anthracite field in Pennsylvania belonging to the Philadelphia & Reading Coal & Iron Co., which will take care of this work itself hereafter. Robert J. Montgomery, vice-president and general sales agent of the P. & R. C. & I. Co., was president of the exchange and Joseph B. Givin, of the Charles D. Norton Coal Co., was secretary-treasurer.

19 Mines Sealed by Court To End Stream Pollution

A decree on March 11 by Judge Donald McPherson, presiding justice of the Fifty-first Pennsylvania Judicial Circuit (Fayette County), directs nineteen coal companies operating in the Indian Creek valley to seal up their mines so as permanently to prevent the pollution of Indian Creek by escaping mine water. The sealing is to be done in thirty days.

The order is by way of enforcement of a judgment of the Supreme Court rendered some time ago in favor of the Mountain Water Supply Co., Dunbar Water Supply Co., the Pennsylvania Railroad Co. and the Westmoreland Water Co., which six years ago began legal steps to maintain the purity of Indian Creek and restrain the operations of coal companies in the Indian Creek water shed.

At the hearing it developed that the Sagamore Coal Co., Melcroft Coal Co., Indian Creek Coal & Coke Co. and the Romney Coal Mining Co. are constructing a drainage tunnel through the coal seam to convey all mine water from their workings to a point below the dam of the Mountain Water Supply Co. By consent of the Pennsylvania Railroad Co., which is making a determined fight to keep its water supply pure for use in its locomotive boilers, and the associated water companies which serve the greater part of Westmoreland County consumers, these four coal companies were granted an extension of the rule until June 16, 1926.

Alabama Holds No-Accident Crusade at Mines

To wage a relentless fight against carelessness and to join intensively and without relaxing for one year beginning March 1, and from year to year thereafter, in a crusade to prevent injury to persons and property is the purpose of the Alabama Mining Institute, operating through its mine casualty committee. At a meeting formulating this campaign were present Erskine Ramsay (chairman), Milton H. Fies, W. E. Leake, A. Sicard, Eugene C. Morgan, James B. Donaldson and Priestly Toulmin. The committee has circulated a 67-point questionnaire asking for information as to safety provisions at the various mines. The committee urges membership in the Joseph A. Holmes Safety Association.

C. W. Hunt Confirmed for Trade Board

The U. S. Senate on March 10 confirmed the appointment of Charles W. Hunt, of Iowa, for another term as a member of the Federal Trade Commission by a vote of 48 to 20, after a debate lasting two hours.

The fight on Hunt revolved about the policy of the Trade Commission as it has been restricted by Commissioners Humphrey, Van Fleet and Hunt against the opposition of the Democratic members, Commissioners Thompson and Nugent. Hunt, former secretary of the Iowa Farm Bureau, was scored in speeches by Senators Walsh, King, Norris and others. Senator Cummins led in his defense.

Government Ownership and Private Management of British Coal Mines Urged in Royal Commission Report

A compromise of the demands of the operators and miners fairly accurately sums up the recommendations in the long-awaited report of Sir Herbert L. Samuel's Coal Commission for the reorganization of the British coal industry. The report, which probes deeply into every phase of the coal crisis, was issued March 10. It is signed by the Chairman, Sir Herbert L. Samuel; Sir William Beveridge, Gen. Sir Herbert Lawrence and Kenneth Lee, who were named six months ago to work out a plan to put the industry on a sound basis and eliminate the disputes between the miners and operators that threatened industrial disaster.

State ownership of the mines, but continuance of their development by private enterprise under government supervision, is recommended, the commission declaring against nationalization as recommended by the Miners' Federation.

The report is equally emphatic in declaring that the coal subsidy—in force since last August, when Premier Baldwin, by granting it, postponed the final solution of the coal problem until next May—should stop immediately and should never be repeated. In so deciding the drafters of the report line up firmly against all those who are advocating further purely temporary remedies, and in support of those wishing to see the coal crisis brought to a head once and for all by drastic means.

Opposes Lower Wages

The depression in the industry, says the report, cannot be attributed to political unrest or restriction of output by the miners or inefficiency of management, but it disagrees with the view of the mine owners that the only practicable remedy is to reduce wages, lengthen the hours of work and decrease railway rates by lowering wages of railway men.

It says that the way to prosperity lies in three chief lines of advance, namely, greater application of science to the mining of coal, larger units for production and distribution and fuller partnership between employees and employers.

The six outstanding points in the commission's report are as follows:

(1) The error formerly made of allowing ownership of coal to fall into private hands should be retrieved and the mineral should be acquired by the state by purchase or by declaration of state ownership.

(2) Amalgamation of many present small units of production is desirable and practical. Legislation should provide for compulsory transfer of interests under existing leases in such cases.

(3) Closer connection of mining and allied industries should be promoted.

(4) Existing provision for research should be largely extended by the industry with support of the state.

(5) Comparative agencies, particularly for selling, should be formed. A governmental system for the analysis and sampling of coal should be established. Coal authorities should be empowered to engage in the retail sale of coal.

(6) The existing wage agreement of the system is sound, but amendments are needed in the method for ascertaining profits. The seven and a half-hour working day under ground should stand. Profit-sharing schemes should be introduced and holidays with pay given later.

Would Withdraw Subsidy

"We express no opinion as to whether the grant of a subsidy last July was unavoidable, but we think its continuance is indefensible," the commission reports. "The subsidy should cease at the end of its authorized term and should never be repeated."

The nationalization scheme advocated by the Miners' Federation was rejected by the commission because it contains "grave economic dangers" and because it is neither "workable nor offers a clear social gain."

In the opinion of the commission nationalization would involve the state in the business of exporting coal. The state would become a coal merchant, which would lead to international complications, the report holds. The report also estimates that nationalization would cost £350,000,000.

The commissioners warn the public that their scheme cannot be applied immediately and is not a panacea for all the troubles of the industry. "It will take months to inaugurate it," the report states, "and years to put it into full operation."

Although there is no direct recommendation that uneconomic pits should be abandoned, it is implied in the body of the report that such pits should, in the natural course, be closed.

While advising the preservation of the present wage agreement system, the report recommends the miners accepting in the immediate future a smaller minimum percentage over the standard rates of pay. The report says:

"Disaster is impending over the industry and the immediate reduction in working costs that can be affected in this way alone is essential to save it. The minimum percentage is not a minimum wage in the usual sense of the term. The wages to the lowest paid men will be safeguarded by continuance of the system of subsidence and allowance."

The commissioners found that, if the government subsidy were excluded, 73 per cent of the coal mined in Great Britain the last quarter of last year was taken out at a loss.

One of the most interesting passages of the Coal Commission's report reads:

"Heat, power and light requirements of the country should be under the constant and comprehensive survey of a body formed for this purpose. We propose for consideration the establishment of a national fuel power committee, with advisory powers, to be composed of representatives nominated by the government from among official and other bodies concerned."

So far over £15,000,000 has been paid in subsidy, the table herewith showing the claims paid up to the end of February.

Keystone View Co.

Sir Herbert L. Samuel

Chairman of Royal Commission which has just presented its report on the British coal industry after six months' study.

British Coal Subsidy Payments, August to February

	Aug. to Nov., 1925	Dec., 1925	Jan., 1926	Total
Scotland	£1,464,895	£519,554	£427,162	£2,411,611

Better Track Facilities to Lakes for N. Y. Central

The New York Central Lines announce a program of laying additional passing tracks between Columbus, Ohio, and the Toledo docks in order to aid in the movement of lake coal and heavy traffic in general. The passing tracks, which will cost upward of $1,000,000, will be placed along the entire T. & O. C. track between the two cities named. A large part of the work will be done north of Kenton.

Was Horning Explosion Caused by Switch Of Cutting Machine Igniting Gas?

The substance of the verdict returned by the jury at the Coroner's inquest of the disaster of Feb. 3 in the Horning mine of the Pittsburgh Terminal Coal Corporation, at Horning, Pa., was that the twenty victims met death "through an explosion the cause of which was undetermined." This verdict however, failed to record certain facts established by the testimony, the recital of which did not leave the causes entirely shrouded in doubt. This, in short, is what the witnesses set forth: At the time of the explosion the victims were engaged in putting the finishing touches to two seals, inby of which was a fire which had originated from the ignition by a cutting machine of a feeder of gas in a clay vein. The inquest was held in Pittsburgh on March 11 by W. J. McGregor, Coroner of Allegheny County.

The fire which caused the explosion was started about 10:30 a.m. at the face of Butt 16 in Sec. 4. Prior to the fire on Feb. 3, Joseph Mott, fireboss, made two inspections of the places on his run, which included Butt 16. He read his report for that day covering these inspections. No gas was detected at the face of this entry nor at the face of the companion entry. He did detect, however, slight traces of gas being emitted from a clay vein at the face of 9-Face South, one of three entries from which Butts 15 and 16 are turned. Mr. Mott said that he had noticed a portion of a clay vein in the lower left-hand corner of the face of Butt 16. This place had remained idle for about six weeks prior to Feb. 3 while a crosscut was being put through to Butt 15 at a point a short distance behind the faces of these entries.

Test Failed to Reveal Gas

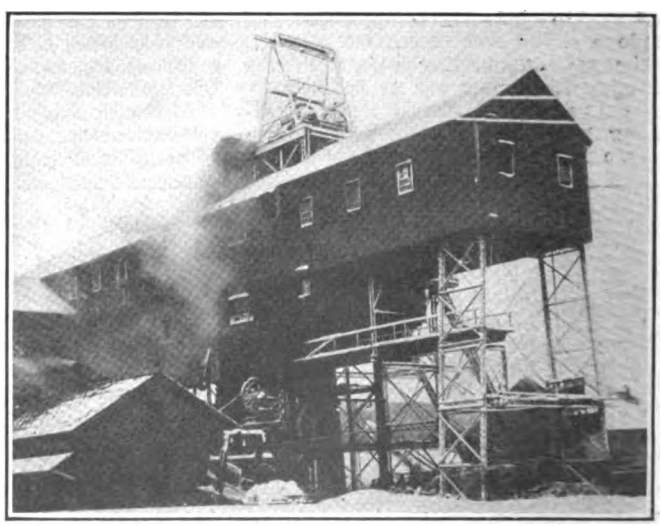
Frank Demshar and Rudolph Valentine, loaders, had been engaged as buddies in advancing these entries. Mr. Demshar testified that he entered Butt 16 at 7 a.m. on Feb. 3, intending to resume the advance of this place, the required crosscut having been completed. He remained idle until about 10 a.m., when the cutters arrived accompanied by George Denard, assistant foreman. Mr. Denard tested for gas, and finding none, instructed the machine men to proceed with the cutting.

On being questioned by Inspector John I. Pratt, technical adviser for Coroner McGregor, Mr. Demshar said that a test hole was not drilled into the clay vein prior to the cutting operation. No gas emission was noticed until the cut had been completed to a point about 8 in. from the right-hand rib. Gas being discovered at this stage, Mr. Denard told the cutters to stop the machine and ordered Mr. Demshar to get a piece of canvas. This was wrapped about the starting box (open type) of the cutting machine, after which an attempt was made to back out the machine. A burst of flame followed, which was not of sufficient intensity to burn any of the men present.

Mr. Demshar, who at one time was a cutter, was positive that ignition originated in the starting box. He stated that he advised Mr. Denard not to attempt to move the machine in the presence of gas, but was told that the machine had to be removed. As attempts to beat out the flame entirely failed, Mr. Denard set off in the open one shot of permissible explosive 10 min. after the fire started and another 10 min. after the first. No reason for his act was revealed at the inquest. It must be inferred that he expected the concussive force of these blasts to extinguish the flame. Mr. Valentine, the second loader, substantiated the evidence given by his companion.

Two types of cutting machines (shortwall and breast) were in use in this mine, according to Herman Ludwig, machine boss. The motors on the shortwalls were inclosed, but those on the breast machines were open. On some of the shortwall machines were starters which, he aptly remarked, "were closed and safe when properly adjusted." The machine used for cutting the face of Butt 16 on Feb. 3 was a shortwall equipped with an open starting box.

Joseph Trevorrow, who for 23 months ending Jan. 30 had been superintendent of the Horning mine and then had been transferred to another of the company's mines, explained that the workings of Butts 15 and 16 were ventilated by a split of 16,000 cu.ft. per minute. This air followed an inby course in Butt 16 and returned in Butt 15. The face of Butt 16 had been advanced to a point about 3,000 ft. from an airshaft and 9,000 ft. from the hoisting shaft. All workmen were equipped with electric cap lamps and the officials with flame safety lamps, some locked with keys and others magnetically.



At the time of his last inspection of the Horning mine as safety engineer, during the second week in January, G. W. Owing found conditions good. Haulways had been cleared of all débris in preparation for rock dusting, which had already been started. On no split did he find less than 12,000 cu.ft. of air at the last crosscut. Prior to the explosion rock dust had been applied as far as the end of the trolley wire in the main haulway of Sec. 4 and had been extended 100 ft. into Butt 15. Inasmuch as the dusting machine is propelled by a trolley locomotive, rock dust could not be applied by this means beyond the limits of the trolley wires.

John I. Pratt, state mine inspector of the seventeenth bituminous district, inspected the Horning mine on Jan. 12, 13 and 14. At that time the fan was developing 236,000 cu.ft. of air per minute against a 35-in. water gage. He found at that time some gas in two places in Sec. 4; otherwise the mine was in good condition.

Efforts to Extinguish Fire

Details as to the attempts made prior to the explosion to put out the fire and afterward to seal it were given by George S. Osler, vice-president and general manager of the coal company. When he arrived at the seat of the fire, about 12:20 p.m., he found that a 3-ply canvas stopping had been erected in Butt 16 intake at a point between a chute and the last crosscut. In his presence a line brattice was tacked to posts and carried up close to the cutting machine by men who held these posts while others attempted to move the truck of the cutting machine and put out the fire. A water box had been hauled to the scene. Pieces of canvas were wetted with water and used in an effort to extinguish the fire, which, obviously, was of small proportions. It broke out, however, with renewed vigor when fanned by the air which was conducted to it by the brattice. During this time tests for gas were made continually but none was detected. It was decided then to seal off the fire.

A 2-ply stopping was erected at a point about 100 ft. from the face. Behind this was erected a single-course dry brick stopping with a pilaster in the middle. The canvas stopping was completed at about 2 p.m. Outby of the dry brick wall was erected a double-course brick-and-mortar stopping which had been completed before the explosion took place, at about 4 p.m. Likewise on the return side, or Butt 15, a 3-ply canvas stopping was erected followed by a brick-and-mortar stopping which must have been nearly completed when the explosion occurred. Each of

Horning Mine Tipple

Twenty men who perished in the disaster of Feb. 3 met death, according to the jury at the Coroner's inquest, "through an explosion the cause of which was undetermined."

Digitized by Google

A Portion of the Town of Horning, Pa.

High winds and a heavy snowstorm, as shown in the picture, hampered the rescuers in reaching the scene of the explosion in No. 4 mine of the Pittsburgh Terminal Coal Corp. on Feb. 3. Twenty men were killed by the blast.

these airtight walls was provided with a pipe and valve.

The construction work was delayed by the fact that cars of supplies could not be hauled by locomotive to the location and therefore were pushed by men. Mr. Osler left the fire zone shortly before the explosion and was not aware that an explosion had taken place until told by men on the outside.

Coroner McGregor asked why so small an area was inclosed by the seals. He wondered whether a larger zone would have allowed for expansion and contraction to a greater extent and delayed the time when an explosive mixture might have been developed. Mr. Osler remarked that all present were of one opinion with regard to the most feasible location for the seals. He thought the explosion was due to a radical change of conditions after the walls were erected. He is certain that rock dust stopped the explosion from going any farther than it did.

Matches in Victims' Clothes

John B. Black, superintendent of the Allegheny County morgue, said that in a search he found matches in the clothes of a number of the victims. On two men he found cigarettes and on one tobacco and a pipe. Edward B. Laughlin, funeral director, testified that he found twenty matches in the clothes of one victim. He bore out the statement by Mr. Black to the effect that quite a few of the men had matches in their clothes.

State Mine Inspector Alexander McCanch testified as to the findings of a state investigation commission of which he was a member. The commission believes that the most likely source of ignition of the fire which afterward initiated the explosion was the starting box of the cutting machine. Coal dust must have propagated the explosion beyond the limits of the gas explosion which originated at the face of Butt 16, and the commission believes that gas may have accumulated at the face of 9-Face entry and assisted in the propagation. The commission is further of the opinion that a large open area near the seat of the explosion allowed it to expand and spend its force quickly without carrying any great distance, and that rock dust was a big factor in checking the flame.

William Young, captain of a rescue team of the Pittsburgh Coal Co., Beadling, Pa., testified that no great violence was displayed near the seat of the explosion. The bricks of the seals lay in such positions on the bottom as to lead one to decide that the walls were merely toppled over. Few of the bricks traveled any great distance and some of those near the bottom remained in the position in which they were set by the bricklayers.

Following are the commission's recommendations to Joseph Walsh, Secretary of Mines of Pennsylvania, following its investigation, which, incidentally, were not presented at the inquest:

"Because of the large number of mine officials lost in this disaster there will always be some doubt about the conditions and circumstances surrounding this explosion. The occurrence of this explosion announces in no unmistakable terms the great need of excluding from the working face, as far as consistent with mine practice, from dry and dusty mines that generate gas either regularly or intermittently all sources that give rise to ignition; that, to make rock dusting so effective as to confine flammation within narrow limits, all avenues of escape from the face of the workings must be liberally and systematically rock-dusted and that this treatment be extended and maintained close to the face concurrent with the advance of workings.

"It is equally important from the viewpoint of safety that all electrical equipment and material used in the mining of coal, which through defect or misuse may furnish a source for the ignition of gas or coal dust, be placed in the hands of competent and authorized persons and carefully supervised by the mine management."

California Mine Ships Coal

The first shipment of coal from Shasta County mines was made March 1, when five tons was dispatched from the mines on Oak Run to the Pacific Gas & Electric Co., San Francisco, to be given a working test in gas works. There is a possibility that the company eventually will substitute coal for oil as fuel in its various gas plants.

Kansas Union Men Restless; Would Close Strippings

Arrest of several of the officials of District 14, United Mine Workers, and Alexander Howat, deposed president of the district, has halted "marches" by union miners in the Pittburg (Kan.) district. The "marching," all of which was done in motor cars, was a gesture of the unionists to stop work at a number of steam-shovel mines in an effort to force the operators to sign a contract with the union under the Jacksonville agreement.

Charges of unlawful assembly were filed against seven district officials of the union and five miners. All were released under $1,000 bond each. Three miners also were charged with asault and battery.

Union district officials arrested included Matt L. Walters, president; Harry W. Burr, secretary-treasurer; Dan O'Donnell, vice-president; Charles Skidmore, William Brady and Ed McCluckie, district board members, and James Fitzgibbon, joint board member.

District President Walters declared that the union would seek to remove the cause of the controversey over wages at the non-union shovel mines by having the Kansas Legislature enact a law against removing coal from shallow veins. He declared that shovel mining is an economic waste of land.

Coronado Case Rival Results In Second Mistrial

The Pennsylvania Mining Co.'s $600,000 damage suit against the United Mine Workers resulted in a second mistrial at Fort Smith, Ark., March 13, when a jury reported itself unable to agree upon a verdict after more than fourteen hours of deliberation.

The coal company's suit was the outgrowth of the Jamestown labor troubles several years ago, and was similar in many respects to the famous Coronado case, which was tried in federal court for the third time last December. All three of the juries which heard the Coronado case failed to agree upon a verdict.

The Pennsylvania case was tried originally in 1920, the jury failing to reach a verdict.

Jail Awaits Bittner

The West Virginia Supreme Court of Appeals has dismissed the writ of error granted last June to Van A. Bittner, international representative of the United Mine Workers in northern West Virginia. The decision upholds the Monongalia County Circuit Court in sentencing Bittner to six months in jail and fining him $500 on a contempt charge for violating an injunction of Judge I. Grant Lazelle forbidding interference with non-union workers at mines on Scotts Run last spring. The court ruled that contempt charges would be reviewed by the court only to ascertain whether the lower court acted within its jurisdiction, holding that a circuit court may punish summarily, without trial by jury, a person who has disobeyed or resisted a lawful decree of that court.

May Defer Action on Oddie Bill Awaiting Results of Coal Industry's Efforts to Solve Own Problems

By Paul Wooton
Washington Correspondent of *Coal Age*

Impressed with the progress which the coal industry is making in providing for the settlement of its own quarrels and in the matter of voluntary fact-finding, Senator Oddie, of Nevada, chairman of the Mines and Mining Committee of the Senate, apparently is willing to withhold consideration of his bill until the results of these activities can be determined. He greatly prefers that the industry do these things for itself and, despite the advanced state of his plans, is inclined to await the result of current developments. Senator Oddie expresses his views on the subject as follows:

"When the President sent his first message to Congress, urging action on the report of the Harding Coal Commission, I felt, as chairman of the Committee on Mines and Mining, to which the report of the Coal Commission had been referred, that it was incumbent upon me to take action. This led me to draft the legislation which I introduced in January, 1925, just following the receipt of the Coal Commission's report.

"In the preparation of that measure I consulted with the representatives of all the departments interested and made a thorough study of the recommendations of the war-time fuel administration and of all other bodies which had studied the subject. I took especial pains to explain the bill to representatives of the industry.

"When Congress met last December the anthracite strike was in progress. The President again in his message urged legislation along the lines of the Coal Commission's report, but as the anthracite controversy dragged on it became increasingly clear that any legislation during the pendency of the strike would make less likely the settlement of the quarrel by the participants themselves—an end to which the President was committed.

Calls Settlement Constructive

"Now that the strike is over the constructive nature of the settlement has put a new aspect on the situation. It appears that this settlement has provided a means for arbitration and that peace and production are likely to continue in the anthracite region for five years. The agreement gives promise of accomplishing many of the ends contemplated by my bill. I find that the prospects of the settlement are so promising as to have impressed the administration to the point where it is not disposed to press for legislation at this time, but is inclined rather to await results under the new contract.

"In view of the existing situation there are reasons which may influence me not to push my bill at this time. If the settlement yields the happy results hoped for, legislation may not be needed. It is very much better that industry should set up its own machinery for settling disputes rather than have the method handed down from above by the federal government.

"On the other hand, if we find at the opening of the next session of Congress that we have a coal problem still with us, I then will press my bill, because I am convinced it is the one conservative and constructive proposition which has come from Congress after all these years of agitation."

In addition to the consideration being given plans for setting up machinery to handle labor disputes, the bituminous-coal industry is making rapid progress in its statistical activities. Apparently the coal operators are bent on doing their own fact-finding. The need now is for a clearing house where statistics of national interest can be assembled. The National Coal Association promises such a summary just as soon as the statistical work of the local associations has reached the point where it will cover enough tonnage to be thoroughly representative. Many local associations are planning to gather statistics dealing with other phases of mining.

Many Arrests as Troops Leave Southeru Indiana

Arrest of William Stinson, board member of District 11, United Mine Workers, at Boonville, March 13 brought the total number of arrests in the recent rioting in the southern Indiana mine fields to 55. About 25 more arrests are expected, according to Sheriff Spradley, of Warrick County, where the attacks on non-union miners occurred. All those arrested were said to be either members of the United Mine Workers or sympathizers of the organization.

The arrests followed a grand jury investigation, in which 96 indictments charging assault and battery, rioting and assault with intent to kill were returned.

Those arrested will be arraigned March 22. Bonds in most of the cases were fixed at $1,000.

The last of the National Guardsmen dispatched to Evansville Feb. 16 in connection with distrubances in the southern Indiana mine fields were withdrawn by order of Adjutant General William Kershner, March 12.

The troops, numbering approximately 50 officers and men, were quartered in the National Guard armory at Evansville throughout their stay, no disturbances occurring to warrant their dispatch to mine properties in the district. Two airplanes made daily reconnaissance flights over the district during their stay. This marked the first time that a National Guard aerial unit has been called into service during a labor disturbance.

Mine operators of the district entered a protest with Governor Jackson two weeks ago when withdrawal of the troops was first rumored.

Two-Year Pact Accepted by Nova Scotia Miners

A settlement between the British Empire Steel Corporation and the miners of District 26, United Mine Workers (Nova Scotia), was arrived at on March 11 at Sydney, N. S., when a referendum to accept a two-year wage agreement with the corporation was voted on and carried by a majority of 201. The agreement is based on the report of the Duncan Royal Commission. The number of ballots cast was 4,853, indicating that about half the Besco employed miners voted. Included in the agreement is the union check-off, but a provision whereby miners and their families were to be guranteed medical treatment for a small sum payable each week was not included.

Ohio Companies to Expand Byproduct Coke Plants

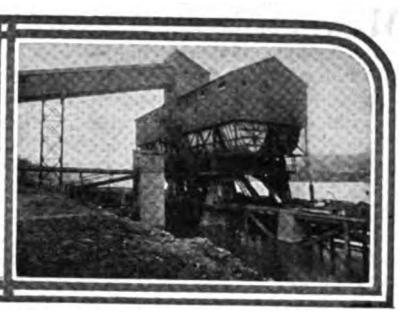
The Central Steel Co., Massillon, Ohio, has placed an order for a by-product coke plant, including all essential byproduct and benzol equipment as well as coal- and coke-handling machinery. The plant will consist of 49 Koppers-Becker combination ovens with a carbonizing capacity of approximately 1,350 tons of coal daily. On a basis of 70 per cent yield that would mean the consumption of 492,750 tons of coal and an output of 344,925 tons of coke annually.

The Republic Iron & Steel Co., Youngstown, Ohio, will add a battery of 43 Koppers-Becker combination ovens to its plant in Youngstown. The new unit is rated as capable of carbonizing about 1,100 tons of coal daily, or 401,500 tons per year, and when completed will give the company a total of 247 ovens with an annual coal-carbonizing capacity of 1,939,800 tons and an output of 1,257,860 tons of metallurgical coke.

Lawton Gets 60 Days in Jail And $200 Fine

Tyler G. Lawton, president of District No. 11, United Mine Workers (Indiana), who was found guilty several weeks ago of contempt of court by Judge Edgar S. Durre, of Vanderburgh County Superior Court, Evansville, was fined $200 and sentenced to sixty days in jail last week. His conviction and sentence grew out of his alleged interference with the operation of the Green Mound Coal Co. mine, near Washington, Ind., a property that was being operated on a co-operative basis following a receivership that had placed it under jurisdiction of the Vanderburgh County Court.

Mine union officials have declared that the conviction and sentence will be appealed to the State Supreme Court.



To Test Anthracite Culm Piles

The Bureau of Mines and the State of Pennsylvania have undertaken to cooperate in sampling of anthracite culm piles. The work is in charge of D. C. Ashmead. The amount of recoverable coal will be determined. Tests will be made of its quality and of the grade of all marketable sizes.

News Items From Field and Trade

ALABAMA

The Alabama Fuel Association is the latest association affiliated with the National Coal Association to inaugurate past sales reports. The system began operation on March 1.

ILLINOIS

The Paradise Mine at Duquoin, owned and operated for many years by the Paradise Coal Co., Duquoin, closed down March 12. It is the first time in several years that this mine has closed except for repairs or some similar cause. Officials stated that the mine would be closed indefinitely as the company could not operate the mine profitably under the Jacksonville agreement. Four hundred and fifty men are affected. The company owns large tracts of coal lands in the vicinity of the Paradise Mine and had planned to sink a new mine. These plans will be shelved temporarily.

Five company houses owned by the Black Star Coal Co. at Logan, near Benton, in Franklin County, were destroyed by fire recently. The fire truck from Benton made a run and prevented additional destruction.

Blue Bird Mine, belonging to the Harrisburg Coal Co., northwest of Carriers Mills, after being idle for more than a year, has resumed work. The mine employs about 150 men.

The Chicago & Eastern Illinois R.R. has placed an order for 500 coal cars with the Mt. Vernon Car Manufacturing Co.

Ten of the twelve mines owned by the Old Ben Coal Corp. in Williamson and Franklin counties have suspended operations. The latest of the company's mines to close down was the No. 20 mine, located in the Valier section, which suspended work March 13. High percentage of screenings found in the output and inability to compete with mines in the non-union Kentucky fields were given as the cause of No. 20's close. The mine normally employs 450 men. More than 8,000 men are employed by the Old Ben company when all twelve mines are running at capacity.

Possibility of the reopening of a number of mines in the Marion district is seen by coal operators there in the announcement that the Missouri Pacific R.R. will operate the Marion & Eastern R.R., serving that field.

The Lovington Coal Co., Decatur, has elected officers as follows: Oscar J. Danzelson, president; Dennis Houlihan, vice-president, and William R. Kirkpatrick, secretary-treasurer. The directors elected are Daniel Hall, W. L. Huff, R. E. Bowers, A. B. Chapman, D. A. Beggs and the above named officers. This company purchased the interests of the old bankrupt Lovington Coal Co., which include a mine at Lovington.

Divernon mine No. 6, Divernon, operated by the Madison Coal Co., will be electrically operated in the future, having been connected with the Central Illinois Public Service Co. at Kincaid.

INDIANA

The American Cannel Coal Co., Cannelton, has reduced its capital stock from $30,000 to $25,000.

KANSAS

Jackson-Walker mine No. 16, near Dunkirk, operated under lease by John Fulton for the last three months, was closed down March 5. The mine employed 150 men.

Tentative arrangements have been completed for holding the Kansas first-aid and mine-rescue meet on the athletic field of the Kansas State Teachers' College, at Pittsburgh, on May 22. Miners' and operators' organizations and the Pittsburg Chamber of Commerce will co-operate toward financing the meet. It is proposed to have the miners in Barton County, Missouri, immediately east of the Kansas line and included in District 14 of the United Mine Workers, participate in the meet. The question of whether this can be done will be passed on by W. D. Ryan of Kansas City, mine safety representative of the U. S. Bureau of Mines for the Southwest.

KENTUCKY

The Old Straight Creek Coal Corporation, composed of Charleston (W. Va.) coal tradesmen, has acquired the Hamby mine of the Straight Creek Fuel Co., near Pineville, Bell County, and will start to operate the plant soon. The mine produces 500 tons of coal daily.

PENNSYLVANIA

The tri-district executive board of the United Mine Workers, representing the anthracite union districts, 1, 7 and 9, has taken initial steps in a campaign to interest manufacturing and industrial plants in the anthracite region in burning anthracite exclusively. All of the local unions in the three districts will be asked to aid in the campaign.

A. K. Morris, vice-president and general manager of the Pennsylvania Coal Co., announced on last Friday that the collieries of his company on that day reached the peak of production since the termination of the strike. A total of 35,071 tons of hard coal was shipped in ten hours on Friday. The greatest daily tonnage ever shipped to market by the Pennsylvania was reached on Aug. 29 of last year, when 47,000 tons was shipped.

Hearings on the appeals of the large anthracite corporations for a reduction in county taxable valuations were continued last week in the Northumberland County courts. The operators are opposing a total assessment of approximately $34,000,000 for the three years beginning Jan. 1, 1925. They claim this an overestimate of $10,000,000. Three years ago the assessment was fixed at $24,000,000, or a 40 per cent increase. In a similar case in Schuylkill County the Supreme Court decided that the comparative sale value is the proper way to value coal lands for taxation purposes. This decision may result in the coal companies gaining their point in Northumberland County.

The Lehigh & Wilkes-Barre Coal Co. since the end of the suspension has had to obtain 200 laborers through New York and Philadelphia employment agencies because of inability to obtain local residents to work in this capacity at their mines. Officials of the company state that hundreds of mine workers who left this section when the suspension became effective have not returned. About sixty men a week are being brought into Wilkes-Barre and adjoining towns. The company finds boarding houses for the new employees and endeavors to place the men with others of the same nationality.

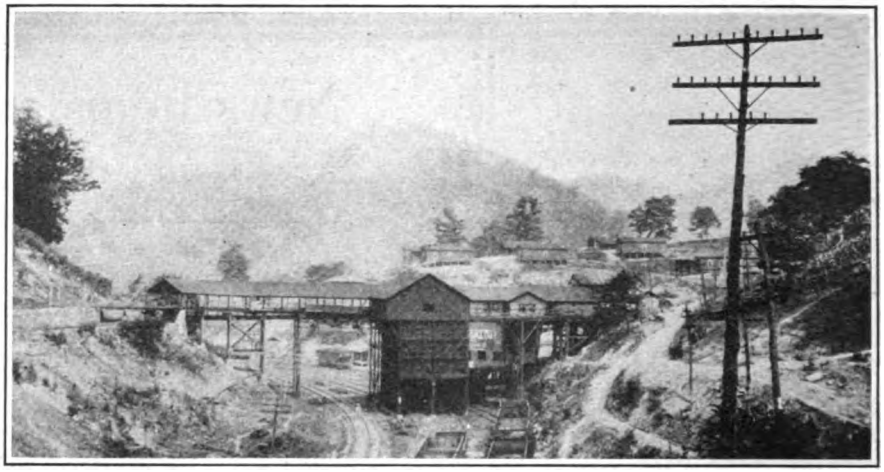
The history of anthracite is to be depicted in the historical exhibit by the State of Pennsylvania at Philadelphia during the Sesquicentennial. Arrangements have been made to take scenes associated with the early development of the great industries of the state and show them in addition to the present-day operations.

The land and plants of the Buck Ridge Colliery in Coal Township, Northumberland Country, will be sold at public auction at the court house, Sunbury, on March 22, according to an announcement by the receivers for the Puritan Coal Mining Co., Inc. One of the conditions of the sale is an upset price of $275,000 in cash to cover all claims and taxes. The plant has been operated for some time by the receivers, E. H. Suender and Benjamin K. Focht.

Digitized by Google

W. H. Blight, of Elmira, N. Y., who has been in the coal business for 45 years, recently purchased the Pine Run Coal Co., near New Bethlehem, Clarion County, from the Bader Coal Co., of New York and Boston. His new acquisition adjoins the Eagle Mine, of which Mr. Blight is the principal owner. The two plants will have a daily capacity of 25 carloads, mined from the Freeport and Lower Kittanning seams, which will be shipped via the Shawmut and Pennsylvania railroads.

The Pittsburgh Terminal Coal Corp. and subsidiaries for the year ended Dec. 31, 1925, report net income of $314,790 after depreciation, depletion, interest, federal taxes, etc., equivalent after preferred dividends, to 69c. a share earned on $12,000,000 outstanding common stock.



A series of lectures on the subject of "Combustion" has been instituted in Philadelphia under the auspices of the Anthracite Operators' Conference. The course, which is intended for the sales forces of the various anthracite operating companies, began March 10, and will continue for five consecutive Wednesday evenings. The first three lectures are to be given in the William Penn High School and the remaining two in the Central High School. It is understood that similar courses will be given in New York, Albany, Syracuse, Boston, Providence and Washington.

The Orient Coal & Coke Co., a subsidiary of A. M. Byers & Co., has inaugurated a co-operative group life insurance program providing $422,000 protection for its employees in Pittsburgh and Orient. With the adoption of this plan, the total coverage on workers either directly or indirectly employed by A. M. Byers & Co. has been increased to nearly $3,000,000.

The Hudson Coal Co. is reported to have plans in mind whereby all coal mined between Forest City and Archbald will be prepared for market at one new big breaker. It is said the company plans to build the new breaker close to the present Coalbrook plant and that after the new structure has been erected the present breakers at Vandling, the Powderly and Coalbrook at Carbondale, and the Archbald at Archbald, will be abandoned. When the new breaker is in operation the old structures, it is understood, will not be razed but instead will be turned into washeries, thus making use of some big culm dumps owned by the company. Official announcement of the company's plan to centralize the preparation of anthracite probably will be made before segregation of the coal and railroad interests of the company, which is expected soon.

Five hundred men formerly in the employ of the Buffalo & Susquehanna Coal & Coke Co. at its Sagamore Mine recently passed a resolution reaffirming their determination not to return to work until the company restores the Jacksonville wage agreement.

Bituminous coal transported by the Reading Co. during January, 1926, totaled 2,303,939 gross tons, compared with 1,596,158 tons in the corresponding month of last year.

Mine No. 9 of the Daniel Boone Coal Corporation

This operation, located at Lennut, Perry County, Ky., on the main line of the L. & E. division of the Louisville & Nashville R.R., is controlled by the Columbus Mining Co. The mine, which is one of the oldest and largest in the Hazard field, is equipped with shaker screens, picking tables and loading booms. The coal is taken from the Fire Clay Seam on both sides of the valley.

Fire early Thursday morning, March 4, destroyed the offices of the Rich Hill Coal Co., in Hastings, Cambria County. The United Mine Workers' hall, on the same block also was destroyed, as well as a number of stores and several dwellings. The total loss exceeds $200,000.

William J. Patton, vice-president of District No. 5, United Mine Workers, has been elected president of the Pittsburgh Central Labor Union of the American Federation of Labor. Mr. Patton was a former secretary and treasurer of District No. 5 of the United Mine Workers and served for a number of years as a member of the legislative committee at Harrisburg.

UTAH

The Interstate Commerce Commission on March 11 authorized the Utah Railway Co. to acquire control of the National Coal Railway Co. by purchase of its capital stock and by lease.

A tract of coal land in Carbon County, township 22.S., range 3 E., is to be offered for public lease in the near future on application of the Boston Acme Mines Development Co. and W. R. Hutchinson of Salt Lake City. A coal prospecting permit has been denied on the ground that it is a known coal section. A number of small coal leases have been granted to residents of Emery County for wagon haul, but the authorities have refused to allow individuals to tie up large coal deposits in this way.

The Salt Lake County Commissioners have rescinded their action regarding the refusal to accept a bid for coal because it carried 20c. a ton more than the city authorities were paying. The result is that the Kinney Coal Co. will receive $3.40 a ton for a supply of slack. The commissioners decided that they were not likely to get a lower bid, and also took into consideration that the contract under which the city was receiving its coal would expire soon.

The Denver & Rio Grande Western R.R. has been authorized by the Public Utilities Commission to construct and operate a new line in Carbon County. It will commence at a junction with its existing line near Spring Canyon, well known coal camp, and will extend in a general easterly direction for about 6.28 miles, connecting with tracks to be constructed by the Independent Coal & Coke Co. to serve its Aberdeen mine and to reach existing tracks to the Kenilworth mine of the Independent. Permission also was given the company to abandon 3.75 miles of road from Kenilworth Junction to the Kenilworth mines.

The Columbia Steel Corp., which was organized two or three years ago, more than doubled its earnings during 1925, according to the annual report. Net earnings on sales amounted to $1,895,-225. L. F. Rains, president of the Carbon Coal Co. and widely known in Utah coal-mining circles, was responsible for the organization of the company.

VIRGINIA

City coal contracts for the Danville municipal plants have been awarded, the Logan County (W. Va.) Coal Co. receiving the contract for 10,000 tons of steam coal at $1.75 per ton. The contract for 14,000 tons of gas coal was awarded to the Eastern Coal Co., also at $1.75. The price in both instances is the same as last year.

Whitney & Kemmerer have acquired two mines at Brier Ridge, in the St. Charles district, which are to be operated from this time on in connection with their other operations in the vicinity at Dorchester.

The Clinchfield Coal Corp. reports for the year ended Dec. 31, 1925, net income of $445,520 after charges, federal taxes, depreciation and depletion, equivalent after preferred dividends to $2.50 a share earned on outstanding 145,476 shares of common stock. This compares with $561,243, or $3.28 a share, earned in 1924.

The Virginia Iron, Coal & Coke Co. for the year ended Dec. 31, 1925, shows net profit of $193,297 after interest, federal taxes, etc., equivalent after dividends on 5 per cent preferred stock, to 68c. a share earned on $10,000,000

Digitized by Google

common stock. This compares with a net loss of $53,503 in 1924.

WASHINGTON

Operation of the 50-oven coking plant of the California-Alaska Corporation near Snoqualmie, 30 miles east of Seattle, is expected to begin in April. The California-Alaska Corporation acquired about 2,000 acres of coal lands about a mile south of the town of Snoqualmie last summer and has been pushing work forward to the point of commercial production of coke.

WEST VIRGINIA

T. B. Chafflin, of Montgomery, has acquired a valuable long-term lease on Cabin Creek in the Kanawha coal field, according to reports.

During February the mines of the Pocahontas Fuel Co. loaded 382,420 cars of coal in Mingo County; plants of the United States Coal & Coke Co. produced 289,365 tons, and the Fordson Coal Co. (Henry Ford interests), 107,750 tons.

G. H. Caperton, president of the New River Coal Co., Charleston, says that the smokeless coal operators at the recent meeting in Washington, D. C., decided to continue the New England service bureau in Boston, Mass. Effort is being made to educate consumers to burn West Virginia coal.

Production in the Tug River field broke all records during the week ending Feb. 13 with 166,638 tons and since that time, despite the settlement of the anthracite strike, output has been above 160,000 tons a week. In 1925 production was 6,064,732 tons as compared with 4,939,706 in 1924.

Branch offices have been established in Webster Springs by the Guardian Coal Co., of Philadelphia, Pa., with Hoover & Hoover, attorneys for the company, in charge. Establishment of this branch is the first step in the development of 7,500 acres of coal lands lying on Lick Run and Holly River.

Fire destroyed a large frame store building of the Kelly's Creek Colliery Co. at Ward, near Charleston, on March 3, causing a loss of between $75,000 and $80,000. The origin of the fire has not been determined.

Loading 2,559 tons of coal March 5, the Dakota mine of the Bethlehem Mines Corporation set a production record which exceeds any other day's loading in the history of the mine.

A fire broke out in mine No. 5 of the Crab Orchard Improvement Co. at Eccles, W. Va., on March 10, and was not extinguished entirely until March 14, according to reports. The mine fire followed the explosion. State mine inspectors and U. S. Bureau of Mines representatives fought the fire direct with extinguishers and fire hose. Robert M. Lambie, chief of the state Department of Mines, was a patient in the Beckley hospital three days, suffering from exhaustion and inhaling fumes of carbon monoxide following the explosion. Mining men say that Chief Lambie in his zeal to reach the portion of the mine where he figured that there would be sufficient oxygen in the mine air to support life, had overworked himself, having spent practically 26 hours straight in the mine. Mr. Lambie's drive to reach the men resulted in the rescue of 10 men.

The Elkhorn-Hazard Coal Co., Bluefield, has dissolved its corporate existence, according to papers filed at the office of the Secretary of State in Charleston. C. B. Bell was appointed trustee to dispose of the holdings.

The Lynwin Coal Co., Charleston, has been purchased by the Smokeless Fuel Co., Charleston.

The Pond Coal Co., Charleston, has disposed of its holdings and has filed notice of dissolution at the office of the Secretary of State.

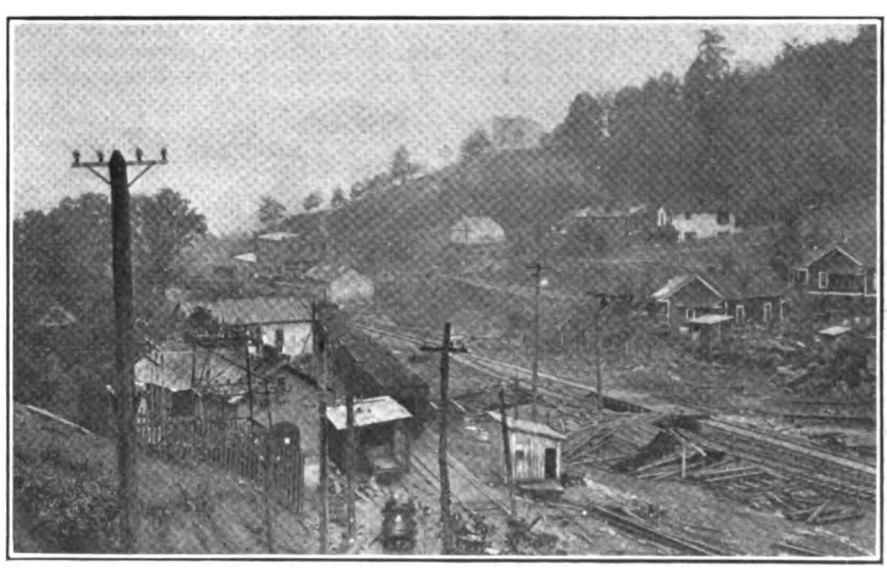
The Pocahontas Fuel Co., in McDowell County, produced 444,650 net tons of coal in January. The mines are located along the Norfolk & Western Ry. The plants of the United States Coal & Coke Co. in the same month loaded 297,650 net tons. These mines are located in the same field.

The Blue Creek Coal & Land Co., of Charleston, has sold the timber rights on a large tract of land in Elk district, Kanawha County, along Spangler fork of the Blue Creek to L. C. Steinbeck, of Charleston.

Preparations are being made to rebuild the tipple at the Hardesty mine, near Shinnston, destroyed by fire last week. Although the mine is working on a non-union basis, no union activity is regarded as being responsible for the fire. The tipple at this mine, however, was blown up about two years ago, during trouble near the mine.

The Daisy Coal Co., of Huntington, has surrendered its charter at the office of the Secretary of State.

WYOMING



The Kemmerer Coal Co.'s plant near Frontier is reported as shut down and the Central Coal & Coke Co., of Kansas City, is closing its Tipperary Mine, at Rock Springs. The latter company will work its remaining mines in that vicinity as near capacity as possible and may work some double shifts. The Cambria Coal Co. has closed its mines at New Castle. This action left New Castle without electricity, as the town's power was furnished by the Cambria company. This deficiency was soon solved by the formation of a local power company.

Considerable interest is evinced in the southern Wyoming field in a report that the Browning-Eccles interests will soon consolidate their various holdings in the Rock Springs district under one company. According to a recent statement the properties to be merged include the Lion Coal Co., at Lionkol; the Wyoming Coal Co., at Blairtown, and the Rock-Springs-Superior and Premier companies, operating at Superior.

Wyoming mines produced 6,557,576 tons of bituminous coal during 1925, according to the annual report of the state mining inspector, Hugh McLeod, issued on March 2. This was a reduction of output from 1924 of 156,977 tons. Sixty mines operated in 12 counties, with a total of 6,364 men employed. In 1924 7,210 men were employed at the mines.

CANADA

According to a statement made March 12 at Ottawa by Charles Stewart, Minister of Mines, negotiations for hauling coal from Alberta to eastern Canada at the rate of $9 a ton have been abandoned. He stated that the Governments of Ontario and Alberta were both opposed to the $9 rate, and favored the rate of $7. Whether any coal will be hauled at the low rate will be decided by the Canadian National Railways.

In the Fading Light of Evening at Balkan, Ky.

Looking toward the commissary from the man and supply incline of the Southern Mining Co. This mine, in the Tejay seam, is producing 1,400 to 1,500 tons per day. The coal averages 53 in. in thickness. Balkan is situated in Bell County, close to the Harlan County line. F. E. Gilbert, general superintendent of the three operations of the Southern Mining Co., lives in the white house in the left center of the picture.

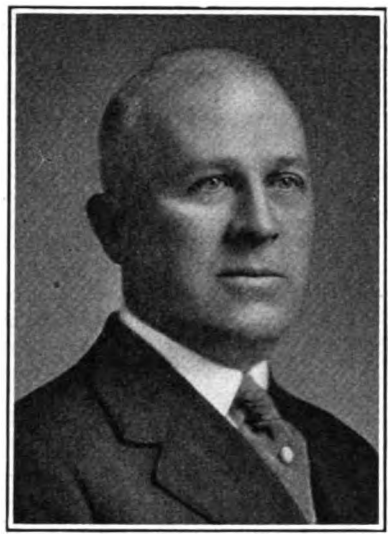
Personal

General J. B. Sanborn has resigned as president of the J. B. Sanborn Co., of Chicago, publishers of the Coal Dealers' Blue Book since 1886, and announces his retirement from active business. In 1898 he accompanied his regiment to Cuba, holding the rank of major. For several years he was head of the First Regiment of the Illinois National Guard and served with distinction in France during the World War as a brigade commander. He is succeeded by William S. Hamblen, who will continue the policies of the old management.

John L. Lewis, president of the United Mine Workers, is slightly ill at his home, Indianapolis, Ind., from an attack of influenza. Although the miners' president has been incapacitated for several days, he now is convalescing, Ellis Searles, editor of the *Mine Workers' Journal*, told the Associated Press.

Samuel D. Winsor, Jr., has been elected a member of the board of directors of the Westmoreland Coal Co., to fill the vacancy caused by the death of Col. Daniel B. Wentz.



W. M. Wilshire, now receiver of the Carnegie Coal Co., Pittsburgh, Pa., has been elected president and director of the West Virginia Coal & Coke Co. He succeeds C. E. Hutchinson as president and fills a vacancy on the board. Mr. Hutchinson continues as a director. The company operates mines at Omar and other sections in the Logan field as well as in the Elkins section of northern West Virginia.

Governor Gifford Pinchot, of Pennsylvania, has announced himself a candidate for Senator. He will be opposed by Senator George Wharton Pepper and probably Representative Vare.

George Gore, formerly with the North American Coal Corporation and well known in the Cleveland trade, has become associated with the Fuel Distributors, Inc., Cleveland representatives of the Coal River Collieries.

Herbert Greener and **Richard Pease**, of the Hugh-Wood Co. of Newcastle-on-Tyne, England, one of the largest British coal producing concerns, arrived in Welch, W. Va., during the latter part of last week, accompanied by Thomas S. Downing, Jr., of Philadelphia. As the guests of Col. Edward O'Toole, general manager of the United States Coal & Coke Co., they inspected Gary mine No. 6 and other plants in the Welch section. The British mining men, it is reported, are making a careful study of mining machinery, operating and safety in American coal mines.

Lewis Stockett, general superintendent at Calgary of the coal mines branch, Department of Natural Resources, Canadian Pacific Railway, has been elected president of the Canadian Institute of Mining and Metallurgy for the coming year. Mr. Stockett, who was born in the United States, has resided in Canada since 1905. He has been a member of the Canadian Institute for the past 21 years, and has belonged to the American Institute since 1881.

W. W. Inglis

William W. Inglis, president of the Glen Alden Coal Co., is on a southern cruise, having decided to take a rest soon after the mines resumed work following the long strike. Efforts have been made to adjust certain disputes in District 7 but so far no general meeting of the conciliation board has been held. It is said that none will be called until Mr. Inglis returns to his office.

Scott Turner, on leaving Canada to go to Washington to begin his duties as Director of the U. S. Bureau of Mines, tendered his resignation as chairman of the Toronto branch of the Canadian Institute of Mining and Metallurgy. The chapter declined to accept the resignation, so Mr. Turner has consented to serve out his term.

Dr. W. T. Thom chief of the fuel section of the U. S. Geological Survey, recently delivered the first of a series of eight lectures on coal, petroleum and oil shale to the students in geology at Princeton University, the lectures constituting a part of their regular term work.

The Fork Ridge Coal and Coke Co. Inc., Fork Ridge, Tenn., announces the appointment of **William H. Smith, Jr.**, as Southern sales manager, with offices in the Candler Bldg., Atlanta, Ga.

C. A. Cabell, president of the Carbon Fuel Co., who spent the winter in Florida, returned to Charleston early this week.

Obituary

War-Time Fuel Administrator Of New England Dies

James Jackson Storrow, of Boston, senior member of the banking house of Lee, Higginson & Co., who was Federal Fuel Administrator for New England during the war, died March 13 at the Hotel Plaza, New York City, where he had been staying for several weeks. He was 62 years old.

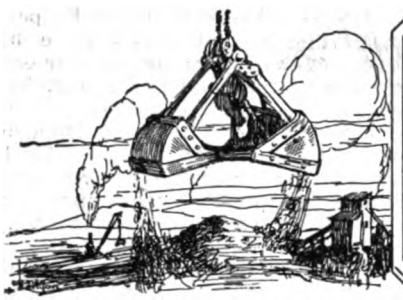
Mr. Storrow was graduated from Harvard in 1885 and from the Harvard law school three years later. For eleven years he practiced law as a member of Fish, Richardson & Storrow, which handled the legal business for Lee, Higginson & Co. The bankers finally persuaded Mr. Storrow in 1900 to leave the bar and join them as a partner. He had many other important business affiliations.

Mr. Storrow was Good Government candidate for Mayor of Boston in 1909, but was defeated. Subsequently he was elected to the Boston City Council and served four years, being president of it for the final year.

In the World War period he was Chairman of the Massachusetts Committee on Public Safety, pioneer organization of the kind in this country. When immediate action was necessary to relieve the acute coal shortage in New England in the war stringency, he pledged his personal credit for shipments of coal and subsequently shipped and distributed at his personal risk more than a million tons of coal, a gross business exceeding $10,000,000.

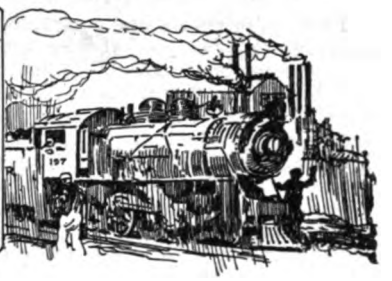
John B. Devers, 52, one of the wealthiest coal operators and land owners in western Kentucky, died in a Madisonville (Ky.) hospital March 9 of injuries sustained a week earlier when an automobile in which he and three others were riding was wrecked on a steep hill near Providence, Ky. The accident claimed the life of Ernest Jones, 40, of Providence, also. Mr. Devers leaves a wife and daughter.

George S. McSweeney, former president of the Montreal Amateur Athletic Association, and well known in Montreal business circles, choked to death while eating at the Mount Royal Hotel, Montreal, at 9.40 p.m. March 4. George Spencer McSweeney was born in Halifax in 1886, his father being the late Wm. B. McSweeney. He was educated at the St. Francis Xavier University and the Antigonish University. He began his business career with the Glace Bay *Gazette* and later was news editor of the Sydney *Post*. He then joined the staff of the Dominion Steel Co. at Sydney. Later he was transferred to the Dominion Coal Co. In 1916 he organized the Century Coal Co., Ltd., in Montreal. Mr. McSweeney was a member of the Board of Trade and a life governor of the Montreal General Hospital.



Traffic

Authorized to Intervene In Lake Rate Case



The Interstate Commerce Commission has authorized intervention in the lake cargo coal-rate case by the Public Service Commission of Pennsylvania, the Attorney General of Ohio, the Tri-State Coal Shipping Association, the Board of Commerce of Butler, Pa., and the Butler-Mercer Coal Operators' Association. The Commerce Commission recently announced a reopening of the case, giving the parties concerned until March 22 to advise whether they desire to submit additional evidence.

J. E. Gorman, president of the Chicago, Rock Island & Pacific Ry., announces the promotion on March 1 of Arthur Mackenzie from assistant freight traffic manager to freight traffic manager with headquarters at Chicago, Ill.

Production And the Market

Liquidation in Bituminous Output and Prices Nearing End; Technical Position Better

The liquidation in bituminous coal production and prices made necessary by the settlement of the anthracite strike is nearing completion. Notwithstanding the large number of individual price declines reported from various distributing centers last week, the technical position of the market has improved. For one thing, there is less distress tonnage to create fictitious price bases. For another, there is less coal at the mines and en route.

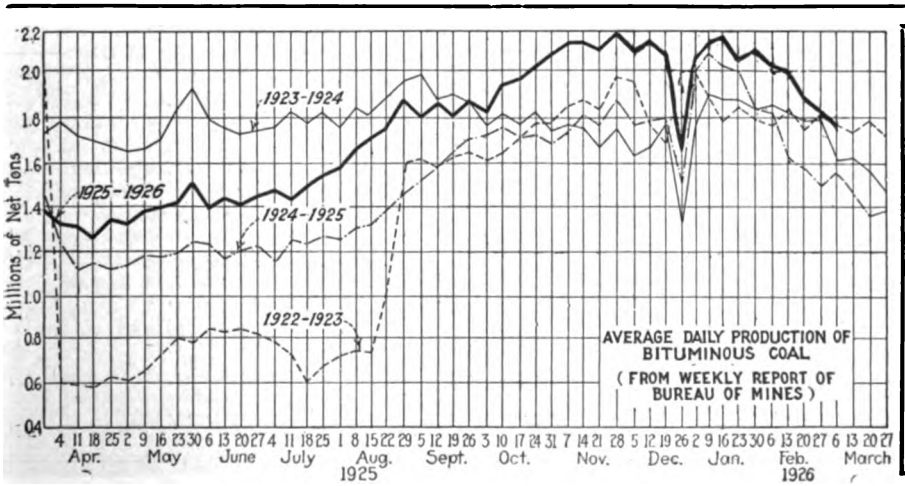
During the first week in March, according to the estimates of the Bureau of Mines, output totaled 10,500,000 net tons, as compared with 10,890,000 tons in the preceding week and 12,167,000 tons in the first week in February. Current output, however, is still 1,000,000 tons ahead of the figures for the first week in March, 1925. Even allowing full weight to improved industrial conditions, it would seem that there is still some shrinkage to be effected before production is strictly in line with consumption.

Coal Age Index of spot bituminous prices for March 15 was 168 and the corresponding price was $2.03. This was an increase of one point and 1c. over the figures for the preceding week. This increase was made possible by a stronger tone to screenings in nearly all producing fields and in all-rail central Pennsylvania coals in New England. Pool prices at New York and Baltimore were weaker.

Prepared Coals Suffer in Price Decline

With few exceptions, the prices on prepared coals were shaded in all markets. Naturally, seaboard quotations were the worst sufferers. Inland prices on eastern and southern high-volatiles, however, did not escape. Quotations in the Southwest and the Far West also sagged. The most conspicuous exception to the general trend was in southern Illinois, where the efforts to stabilize prices were abetted by the weather.

To the weather, too, must be given credit for pushing up anthracite output to 1,787,000 net tons the first week in March, as compared with 1,655,000 tons a year ago. The bulk of the buying, of course, is for current consumption. The average householder in the anthracite-consuming territory bought sparingly of other fuels during the suspension, so that his immediate requirements are not inconsiderable in the aggregate.



Chestnut and Pea Lead

In so far as there are pronounced indications of choice in the present buying, chestnut has the call over the lordly stove. The lowly pea size also is experiencing a period of public favor not ordinarily its lot. Demand, however, is not such that independent shippers have been able to move tonnage at the peak prices obtainable the first week production was resumed.

Spot movement of the steam sizes is back to pre-strike levels. That means that producers have little difficulty in selling rice and barley and that No. 1 buckwheat is more or less of a drug on the market.

Spot prices on metallurgical coke in the Connellsville region are close to the levels of a year ago. Furnace coke is possibly 25c. weaker and foundry 25c. stronger. Production, however, has not yet been brought within the limits of estimated demand. Output for the first week in March was only 51,290 tons under the record production four weeks earlier.

There still is yard-crushed coke waiting in vain for buyers. Ovens are laboring to make adjustments with their late eastern retail customers and to move rejected tonnage. The Alabama market, too, is easier, but no excess production is reported.

Estimates of Production

(Net Tons)

Winter Plays Heroic Role

King Winter in his roughest mood came to the rescue of the domestic business in the Middle West last week, but his blizzard visitations caused no flurries in the steam-coal market. The increased production of large coal, however, was not great enough to create an undigested surplus of steam sizes. As a matter of fact, spot prices on screenings in southern Illinois were stronger. Producers and sales agents are canvassing the contract situation, but buyers display little interest in early renewals.

Although running time in southern Illinois exceeded expectations, operators viewed it as "a flash in the pan" and are going ahead with plans for further suspensions. In general this was true also of the central, Mt. Olive, Jackson County and Duquoin fields. In all of them there was a better inquiry for domestic coal and a fair movement of industrial and railroad tonnage, with prices unchanged. Fourth Vein Indiana lump and mine-run, on the other hand, were weaker. The Standard district in Illinois was probably the greatest laggard.

Under the weather pressure, producers of high-grade Illinois coals had little difficulty in maintaining circular figures on prepared coal. No such good fortune attended eastern shippers of high-volatile coal to the Middle West. As low as $2 was quoted on West Virginia 4-in. splint block and eastern Kentucky in the Chicago market, but the best-known coals commanded $2.25 @$2.75. Smokeless lump and egg, too, were heavy and some prices were cut to $2.75. Anthracite is beginning to dribble in at standard prices. The better grades of coke are in good demand.

St. Louis, like Chicago, saw a brisker domestic demand because of weather conditions last week. The bulk of the buying in the Missouri city was in medium grade coals. Anthracite and West Virginia smokeless were backward, but coke held its own.

Western Kentucky Optimistic

Louisville trade observers are optimistic over the outlook for western Kentucky during the coming coal year. The basis for this optimism is the fact that the Peabody Coal Co. has taken over exclusive distribution in the Middle West and the Northwest of the output of four well-known operating companies with a combined daily capacity of 10,700 tons. This is believed to presage still more active competition between non-union western Kentucky and union Illinois and Indiana.

Current demand, however, is reflecting the normal seasonal slump. Large coal is weak, but nut and screenings have benefited from curtailed production. Mine-run is sluggish and some sales have been made around $1, although the general range is $1.25@ $1.50. Screenings are 75c.@$1.10; nut, $1.40@$1.65; lump and egg, $1.50@ $1.75, and 6-in. block, $1.75@$2.

Output is falling rapidly in the eastern part of the state. Many mines are

down in the Harlan field. Traffic in the Elkhorn and Hazard districts has dropped off to such an extent that it is reported that the Louisville & Nashville is laying off train crews. No improvement is expected until the lake movement gets under way. Prices, except on slack, are easy. Little block is bringing over $2.50 and some has sold at $2. Lump is $2@$2.25; egg and nut, $1.75@$2; mine-run, $1.35@$1.75, and slack, 90c.@$1.10.

Dock Trade Satisfactory

Despite weather ups and downs in demand, the volume of coal moving off the docks at the Head of the Lakes is substantial. February loadings were 19,219 cars, as compared with 23,990 cars in January and 17,666 cars in February, 1925. Stocks on hand March 1 were estimated at 3,450,000 tons and dock operators expect no troublesome carry-overs of any grade. The anthracite outlook for 1926-27 is encouraging.

The brighest spot in the present situation is the increasing demand for industrial coal. Most of the buying, however, is on a hand-to-mouth basis. Some of the docks are still scurrying around for screenings to take care of contract deliveries. Prices on all grades of coal are unchanged and there seems to be no inclination to shade quotations.

Hand-to-mouth buying characterizes the market at the Twin Cities. Accelerated demand due to weather conditions soon dies out. The all-rail trade from Illinois and Indiana is irregular and uncertain. With the movement of anthracite in heavier volume to Milwaukee territory, there has been a noticeable decline in consumer buying of coke and semi-bituminous coals. Retail prices, however, are unchanged.

Business Fades Out in Southwest

In the Southwest current business is confined to the odds and ends of the waning coal year. Production in Arkansas and Oklahoma is tapering off; few Kansas operations are doing better than two days a week. Accumulations of "no bills," approximating 300 cars, of which 250 are lump and egg, have caused Kansas prices to break 25@50c. Screenings, on the other hand, are firm at $2.35@$2.50.

Unbalanced demand has demoralized the Colorado market and cut into production. The dearth of domestic business is emphasized in April price lists, which go into effect next Monday. Under the new schedules Walsenburg and Canon City lump is $4.25; washed nut, $4; washed chestnut,$3; Trinidad coal, all sizes, $2.75; Crested Butte lump, $4.25; nut, $4; Crested Butte anthracite, $2.75@$6.75 for Elk Mountain and $4.50@$7.75 for Horace. The new bituminous prices are $1@$1.75 under March circulars.

The Salt Lake City market is in the doldrums. There is no active demand for any grade of Utah coal. Working time has been cut to one and two days a week. This has created a scarcity of slack.

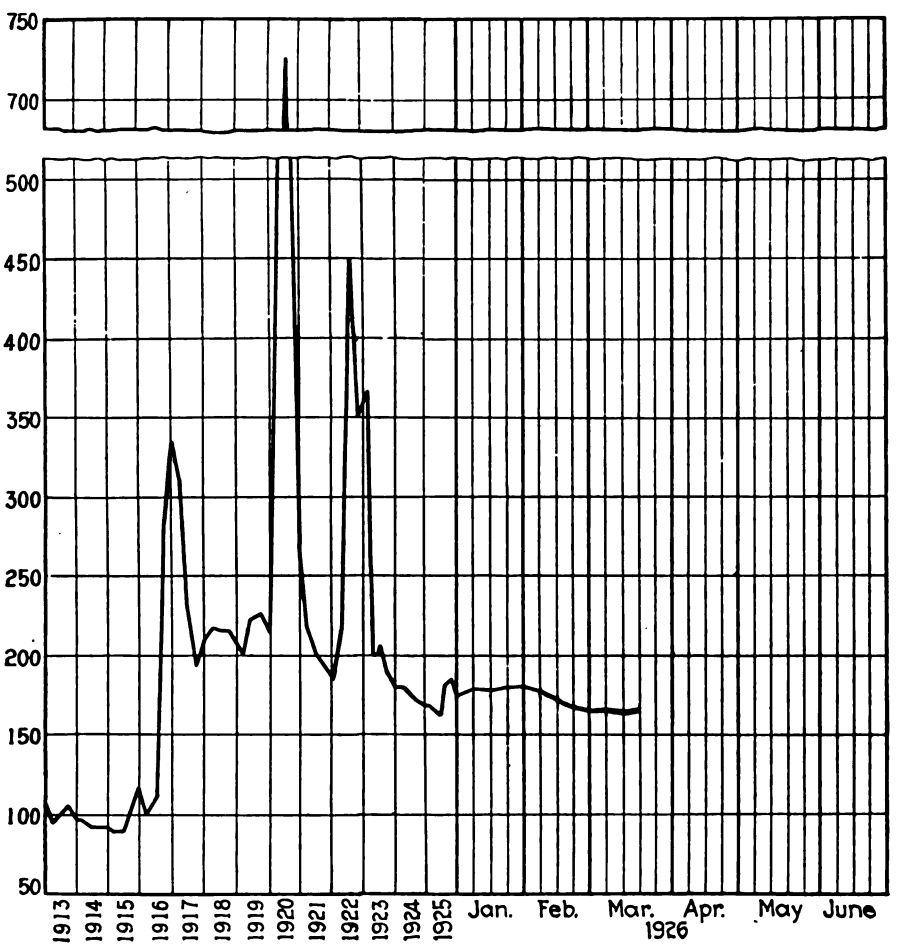
The lake trade holds the center of interest in the Cincinnati market. Two orders for 100,000 tons have been shuttled back and forth without decision. One larger order has been placed on a mine-run basis of $1.50 and this has had a disturbing effect upon the situation. The opening of Chesapeake & Ohio Ry. bids within a few days is another straw in the wind many will study.

Low-volatile shippers are going through a period of readjustment. New River nut prices are down to $2.50@$2.75; egg, $3.50@$3.75, and lump, $3.25. Mine-run is up to $1.25@$1.50. Standard Pocahontas prices are pegged about 25c. higher than the New River quotations.

High-Volatile Market Unsettled

The high-volatile market has been restive and unsettled, but the curtailment policy in production is showing its effect. For the first time since Christmas, loads moving through the Cincinnati gateway dropped to 10,483 cars, a decrease of 1,291 cars when compared with the preceding week. The number of empties going to the mines also is less. This reduction in output has stiffened screenings quotations 15 @25c. per ton and has taken most of the low-priced mine-run out of the market. Egg drags and only weather spurts prevent a bad slump in lump and block.

Repeat orders have kept the retail market brisk, with little sign of any revision of prices before April 1. River operations have been impeded somewhat by heavy snows, but there has been little diminution in the volume of tonnage.



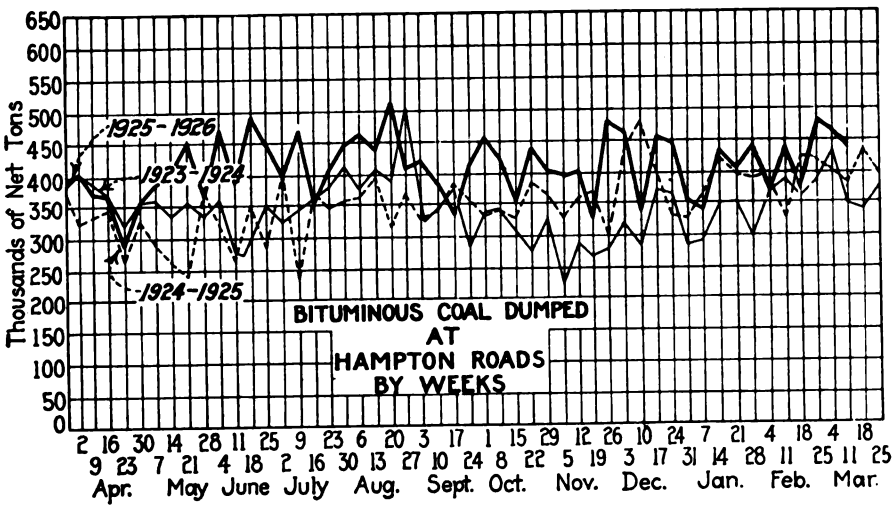
Central Ohio Looks to Future

Central Ohio coal men find speculation as to the future more interesting than consideration of the season-end dregs of trade. The outlook for domestic business is regarded as particularly favorable, although Kentucky and West Virginia will have first call on orders. A brief cold snap helped the Columbus retail dealers last week, but yard stocks were more than ample to take care of requirements. The steam trade is unchanged. Few contracts have been renewed.

Production in southern Ohio is still under 20 per cent of capacity. Until the lake trade opens up it is not likely that this percentage will be increased.

More Pittsburgh Mines Close

An increase in the number of mines closed down tells the story of the week in the Pittsburgh district. The largest operator in the field is producing about 14 per cent of its 1923 weekly average. Some individual mines are doing bet-



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	Mar. 15	Mar. 8	Mar. 1	Feb. 22	Mar. 16	Mar. 17
Index	168	167	169	170	165	179
Weighted average price	$2.03	$2.02	$2.04	$2.06	$1.99	$2.16

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average of the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

ter, but it is questionable whether they can maintain last summer's levels.

Minimum prices on mine-run and lump are unchanged, but maximum spot quotations have dropped a dime. Slack, on the other hand, has jumped another 20c., making a net advance of 40c. over the prices current when eastern demand for prepared coal created a surplus of fine stuff.

"No bills" are piling up in the central Pennsylvania district. The latest estimates place the total of unbilled loads at 1,800. Loadings the first week of March were 4,774 cars less than in the first week of the preceding month. Prices, too, are easier. Pool 1 is $2.60 @$2.75; pool 71, $2.45@$2.55; pool 9, $2.20@$2.30; pool 10, $2@$2.10; pool 11, $1.80@$1.85; pool 18, $1.75. Lump is $3.50; egg and nut, $4, and slack, $1.40.

Gloom is so thick in the Buffalo bituminous market that optimists do not look for a "real" demand for fuel before fall. Nominal quotations are unchanged, but steam slack has sold as low as $1.15. Colder weather has helped local retail trade, particularly in the sale of coke. The maximum curb price on that fuel is $12. Toronto dealers are busy taking orders for anthracite. Retail prices on Pocahontas have dropped $2 and on coke, $3. One factor plans to bring in two cargoes of Welsh and two of Scotch anthracite this spring.

Back to Pre-Strike Levels

The New England steam coal market is drifting down to the low levels of a year ago. Mines have not yet cut operating time sharply enough to bring production in line with demand. Surplus tonnage still crowds, while buying interest is at a low point. The larger consumers are well fortified with stocks and there is no call for bituminous coal as a domestic fuel.

Navy Standard coal at the southern loading piers is freely offered by all shippers at quotations which, for the time being, have established $4.35 per gross ton, f.o.b. vessels at Hampton Roads, as the minimum. For inland delivery, the same coals can be had at $6 or less on cars at Providence and Boston, with further declines in prospect.

All-rail trade shows no signs of betterment. Most of the central Pennsylvania districts are back to a part-time basis. There are relatively few cars of prepared sizes seeping in and even they are rapidly diminishing. Mine-run prices are firmer.

Distress Tonnage Disappearing

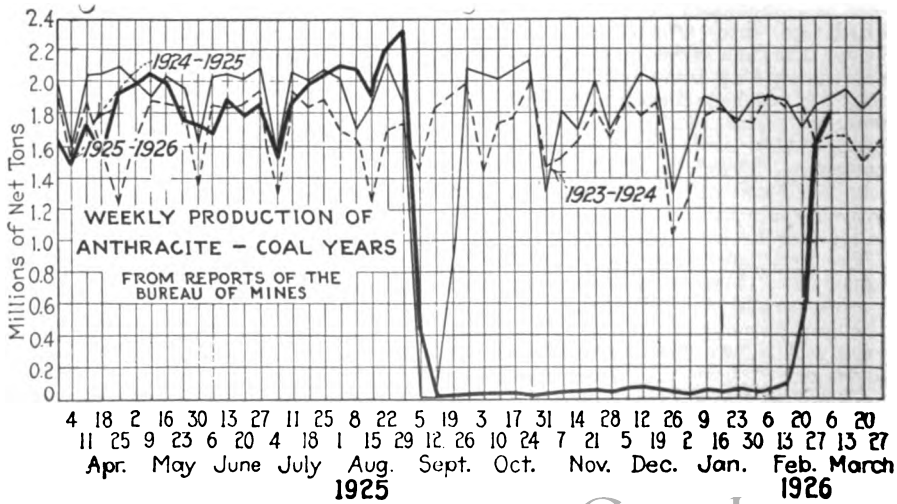
The New York bituminous trade is gradually working itself out of the mess left by the sudden termination of the anthracite strike. There is less distress tonnage to be moved, but there still is considerable foreign coal to be absorbed. During the first four days of last week 38,766 tons of anthracite, 6,000 tons of steam coal and nearly 10,000 tons of foreign coke were discharged and there are more cargoes en route.

Under such circumstances, the market for fresh-mined coal is stagnant. Contracting is slow. On new business, prices range from $1.90 to $2.75, depending upon quality and the producer's necessities. In the spot market almost any price may be heard. Some distress screened bituminous has been offered at $1.25 mines and some at the piers has been held at $4.25. Beehive coke is quoted at $5 or less, f.o.b. ovens.

The Philadelphia trade is in a Micawberesque mood. Industrial consumers, liberally stocked with coal, are unmoved by solicitation and limit their buying to bargain lots of distress tonnage. Such purchases influence regular contract customers to hold off renewals in the hope that sellers will make a downward revision in price offers. Spot movement, except in screenings, is very quiet. Coke ovens are trying their best to stay in the domestic market, but there is little interest shown in quotations of $5@$5.50 to the retail dealer.

Prices Decline at Baltimore

Keen competition for the comparatively small amount of tonnage to be sold in the Baltimore spot market has resulted in quotations 15@20c. less than prices ruling at the beginning of the month. Contracting, too, is backward as it is always difficult to convince a purchasing agent that it is good policy to commit himself to a fixed price when quotations are on the downgrade. Export trade shows some signs of renewed activity. February exports totaled 30,172 tons, against 19,866 tons the preceding month.



Hampton Roads is marking time. Until the contract situation has cleared, there will be little but routine business moving. Buyers are playing a waiting game to depress prices. Low-volatile coal is standing this pressure better than high-volatile. Some of the latter sold as low as $3.90 last week. Dumpings for the week ended March 11 dropped to 397,322 gross tons, as compared with 414,270 tons the preceding week.

Conditions in the Birmingham market last week were a repetition of those controlling the preceding fortnight. High and medium grades still move well, but the poorer grades are sluggish. On the whole, however, industrial demand is active. The domestic trade is soft. The coke market, too, is easier, but no surplus production is reported. Nut and egg coke are quoted at $5.25@$5.50; spot foundry and gas coke is $6.50.

Anthracite Movement Increasing

Anthracite receipts at New York are increasing daily, but shipments have not yet reached such a volume that the retailer can take care of all the orders on his books. Independent producers no longer are able to find buyers willing to pay extravagant premiums and little coal is moving at more than $1 over the maximum company circular. Most of the buying is for current delivery. Chestnut is the favored size. Pea is unusually active.

Conditions in the anthracite steam

Feb. 28, 1925	285,015	138,425	.....	.....

trade are rapidly approaching normal. No. 1 buckwheat, which has been a drug on the market since mining was resumed, is in no stronger position. Rice and barley, on the other hand, are in good demand and offerings are readily absorbed. Philadelphia steam consumers are displaying considerable interest in the question of contracts for next year.

Continued cold weather has made it impossible for retail distributors in Quakertown to catch up with orders and complaints are heard that the big companies have not kept up the rate of shipments with which they started. Independent producers are able to get around $12 for the larger sizes. As in New York, chestnut leads in demand, with pea a close second. Egg is the easiest of the major sizes. Retailers still are trying to clean up coke stocks on hand.

Baltimore Hard-Coal Trade Active

Retail dealers at Baltimore have been fairly active taking care of emergency demands for hard-coal. For the most part, purchases are confined to the big company shippers. Deliveries to householders are in one- and two-ton lots. Receipts have been increasing.

There is no particular clamor for anthracite at Buffalo. Producers asking $1.50@$2 over company circulars have hard sledding. It is predicted that lake trade will be slow in opening. Contrary to the reports from Duluth and Superior, Buffalo factors say that there has been little inquiry from the Head of the Lakes. But the basis for the forecast of a late lake opening is that there are many bare spots in all-rail territory which will have to be filled up before any large tonnage can be diverted to the boats.

Coke Situation Still Unsettled

The process of readjustment is the Connellsville region has not been completed. There is still considerable coke, which was produced with an eye to the domestic trade, which is without a market. Representatives of the shippers are trying to settle accounts with eastern buyers and to move rejected shipments.

The metallurgical market is steady but dull. Furnace coke seems to have hit a range of $3.25@$3.50 and foundry, $4.50@$5. Independent furnaces are delaying the negotiation of second-quarter contracts as long as possible to compel the ovens to make more favorable terms. Some may buy on a month-to-month basis.

Furnace-oven output in the week ended March 6 was 102,700 tons, according to the Connellsville *Courier*. Compared with the preceding week this was a loss of only 400 tons. Merchant-oven production dropped to 96,850 tons —a decrease of 6,050 tons. Even this total, bearing February figures in mind, seems excessive.

New York Seeks Coal Bids

Bids will be opened on March 23 by the Department of Purchase of the City of New York for 502,436 tons of coal and 600 tons of coke for use by the various city departments. It is expected that more than 25 firms will submit bids.

The tonnages asked for are: Broken, 800 tons; egg, 17,877 tons; stove, 11,910 tons; chestnut, 1,483 tons; pea, 7.546 tons; buckwheat No. 1, 244,153 tons; rice, 27,632 tons, barley, 50,100 tons; mine-run bituminous coal, 79,732 tons; George's Creek Cumberland coal, 203 tons; mixed coal, consisting of one-third soft coal and two-thirds No. 2 buckwheat, 61,600 tons, and coke, stove size, 600 tons.

Utilities More Efficient in Use of Coal in 1925

The total annual output of electricity by public-utility power plants in this country in 1925 was 65,801,000,000 kw.-hr., an increase of 11.5 per cent over the output for 1924. Of this quantity, about 34 per cent was produced by the use of water power, a slight increase over the percentage for 1924. It would have required the consumption of 23,000,000 tons of coal to generate this 34 per cent.

The amount of coal consumed in producing electricity in 1925 was only 7 per cent greater than in 1924. The amount of oil was 38 per cent less and the amount of gas was 4 per cent less than in 1924. Although the oil consumed totaled more than 10,000,000 barrels and the gas nearly 50,000,000,000 cu.ft., coal represented nearly 90 per cent of all the fuel used by electric-power plants. The coal plus the coal equivalent of the oil, gas and wood used in the generation of electricity by public-utility plants in 1925 amounted to about 45,000,000 tons, or an average of nearly 3,000 lb. a second, or 100 carloads an hour throughout the year.

Efficiency in the use of fuel continued to increase in 1925, as there was a decrease of about 0.1 lb. in the average consumption of coal per kilowatt-hour compared with the rate of 1924. This apparently small gain amounts to more than 2,000,000 tons of coal for the year.

Warns Against Hasty Buying

The Boston Chamber of Commerce issued a statement on March 11 warning the public against hastily placing large orders for independent anthracite, which it asserts is being offered at an increase over circular prices. John F. O'Connell, chairman of the Chamber's fuel committee, recommended the continued use of substitutes, declaring that the public can keep prices down by waiting a few weeks before stocking up with anthracite.

Foreign Market And Export News

Shipping Troubles Still Hamper Welsh Trading; Tyne Buying Backward

The Welsh steam coal trade has been in rather an unsettled state owing to the prolonged gales of unusual severity. Where buyers have been found for prompt shipment a few sales have taken place at reduced prices, though colliery owners are well booked up for some time to come. The lack of shipping is causing great inconvenience to some operators and stoppages are frequent.

Ships also are scarce owing to the heavy exports of coal to North and South America. In many cases these ships are being held for homeward cargoes, which are not always forthcoming. This condition of things is expected to last another week or ten days, though the advanced freight rates to South America and the Mediterranean ports no doubt will attract tonnage to South Wales.

Work at the pits, of course, is irregular, and prices for spot shipment are discounted 6d. or more per ton. Owing to these conditions there is not so much talk of restarting closed mines, and nothing has so far come of the suggestion of reopening the Cambrian pits.

The Newcastle market is dull and rather weak and is suffering from the same trouble as South Wales. Foreign buyers are holding back on this account. German and Silesian coals are ousting many British varieties in the European market. Most of the collieries are fairly well employed, though prices seem to be taking a downward tendency.

Output by British collieries during the week ended Feb. 27, according to a special cable to *Coal Age*, totaled 5,370,000 gross tons, compared with 5,420,000 tons in the preceding week.

Little Change in French Demand

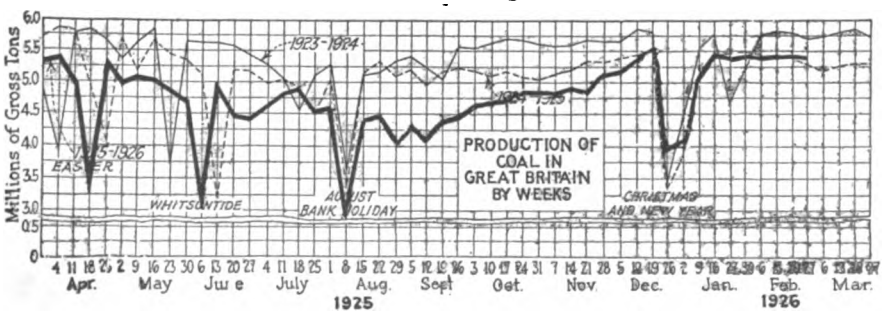
Paris, France, Feb. 25.—There has been little change in the French market the past week. The tone is firm although the demand for domestic coals is not so great. Even flaming coals, which were very scarce, are coming in more plentifully, consequently the buying of British coals D.C.B. and Hastings will be reduced.

Canal transport is still very slow, owing to their obstruction by barges in some places between the Belgian frontier and the Nord and Pas-de-Calais on the one hand, and Paris, on the other.

During the first 13 days of February, France received 186,900 tons of coal, 122,600 tons of coke and 14,700 tons of lignite briquets, from the Ruhr. During the first twenty-three days of this month the O.R.C.A. received 208,600 tons of coke from the Ruhr.

The price of the indemnity coke for March has been definitely fixed at 163 fr. on truck Cierck, plus 5.1 fr. customs duties, plus 1.15 fr. for the O.R.C.A.'s expenses, or a total of 169.25 fr.

During January, France imported 1,432,409 metric tons of coal and exported—principally to Belgium, Germany and Switzerland—300,605 tons. Of the imports, 803,701 tons came from Great Britain, 164,375 tons from Belgium and Luxemburg, 4,609 tons from the United States and 384,960 tons from Germany. Coke imports for the month were 459,578 tons; exports, 55,652: patent fuel imports, 125,997 tons; exports, 18,338 tons.



Belgian Demand Enters Decline

The seasonal falling of in demand for domestic grades of coal in the Belgian market has been intensified by a decline in the orders placed from industrial fuel, reports Brussels under date of Feb. 25. The latter decline is attributed to dissipation of fears of a general British coal strike. Screened sorts, however, are still very scarce in the Borinage and coking smalls are steady.

In general the market in coke is fairly firm. There also has been some improvement in the demand for patent fuel.

During January, Belgium produced 1,976,320 metric tons of coal, as compared with an output of 1,936,670 tons in December. Stocks on hand declined from 1,558,020 tons on Dec. 31, 1925, to 1,398,120 tons on Jan. 31, 1926. Coke production for the month was 321,220 tons—25,120 tons less than in December. Patent fuel output for January, 203,630 tons, showed an increase of 25,540 tons over the December figures.

A decree recently published by the Spanish Government restricts the use of British coal on railroads and state subsidized industries to 10 to 30 per cent. In many instances the use of foreign fuel is banned.

Buys More British Anthracite

Canada's imports of Welsh and Scotch anthracite coal from the United Kingdom increased from 275,277 net tons, valued at $2,472,737, in 1924 to 560,684 tons, valued at $5,138,342, in 1925. Figures for the latter year include, as nearly as it can be ascertained, the tonnage imported through Portland, Me., and transshipped to Canada after the close of navigation on the St. Lawrence.

Quebec received the largest shipments, totaling 487,049 tons, the remainder being assigned to New Brunswick, Ontario, Nova Scotia, Prince Edward Island and British Columbia. Retail prices increased steadily during the year, starting at $16.50 per ton in May and reaching $23 per ton in December.

American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

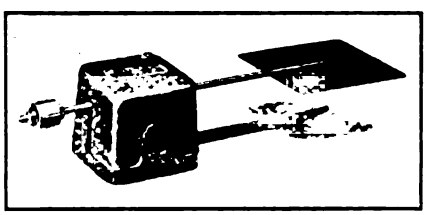
New Equipment

Soldering Iron Heats Quickly

A new soldering iron of light construction and designed to heat up quickly has been recently placed on the market by the General Electric Co., of Schenectady, N. Y. This iron is made in standard sizes ranging from ½ to 1¼ in. tip.

Power consumption ranges from 70 watts for the smaller iron for light and intermittent use, to 350 watts for the larger size on heavy duty. The irons for heavy duty are provided with radiating stands for the purpose of maintaining the iron at the correct operating temperature when temporarily not in use. The rapid rate of initial heating is brought about by unusually good heat conduction between the heating element and the copper tip. Heat from the tip is prevented from reaching the handle by means of a special mechanical construction between the two parts, this being in the form of a spiral made from a steel rod. This also provides a rigid connection between the handle and tip.

Instead of mica, usually used for an electrical insulator in the heating unit of soldering irons of this type, the heating unit has an insulating powder so highly compressed that it becomes a good heat conductor and will withstand temperatures of more than 2,000 deg. F. The iron is provided with a standard lead and connection plug. Its construction is simple, and all parts are easily replaceable.

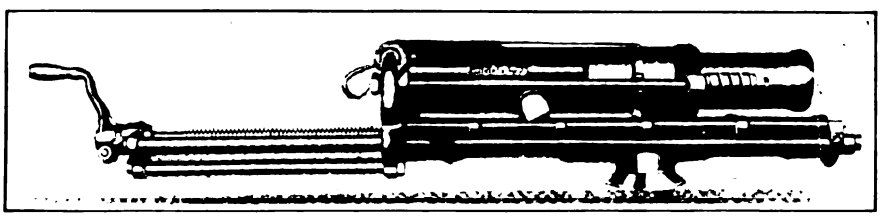


Waugh Drifting Drill for Hard Mine Usage

Two new rock drills have recently been developed and placed on the market by the Denver Rock Drill Mfg. Co. of Denver, Colo. These are models 7 and 17. In the model 7 the manufacturer claims a pneumatic hammer drill of simple symmetrical construction and high efficiency. The design is conservative yet many original features of proven value have been incorporated. The drill steel is rotated by means of a ratchet, pawl and rifle bar. The valve is of the tubular type operating axially in the machine. It is completely housed within the cylinder and is fully protected against rough usage.

Drop forgings and high-grade alloy steel subjected to scientific heat treatment have been used throughout in the construction of this machine. Provision is made for easy replacement of parts, ordinarily subjected to the heaviest wear. The ratchet ring and pawls are reversible, thus doubling their life. Lubrication is effected by an automatic air-line oiler, which obviates use of inefficient oil chambers, packings, plugs and other parts in the machine proper and contributes to higher drilling efficiency and long dependable service. Model 17 is similar in design to the No. 7, but is heavier and more powerful.

Will Act as Watchdog Over Ventilating Current



Although designed primarily for installation on air-cooled electrical apparatus such as transformers, regulators and similar equipment the air-flow relay shown in the accompanying illustration and recently placed on the market by the Albert & J. M. Anderson Mfg. Co., of Boston, Mass. may also be installed to show the existence or non-existance of an air current in the ventilation passages of a mine. This device is placed directly in the path of the air and consequently is operated by the air flow itself. As a result it performs a service which cannot be rendered by devices that indicate only the pressure of the air supplied.

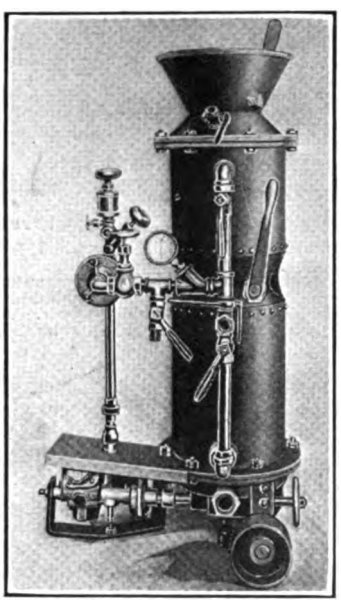
Watching the Ventilating Current

The relay here shown is designed for installation in an upwardly moving current. It would be an extremely easy matter to make the vane vertical and thus adapt this instrument to a horizontal air flow. A fall in current velocity would thus be readily detected.

In the construction of this relay a counterweighted aluminum vane is pivoted on steel points and may be so adjusted that the minimum flow will allow the vane to drop, thus tilting a mercury-tube switch also suspended on the same pivot. This tube is so

Drill for Tripod Mounting with Automatic Air-Line Oiler

This drill is fitted for mounting on the ordinary tripod or bar. It is claimed by the maker to be extremely simple and rugged in construction, and highly efficient in operation. Oil chambers are made unnecessary because the air is lubricated by the automatic air-line lubricator.



Digitized by Google

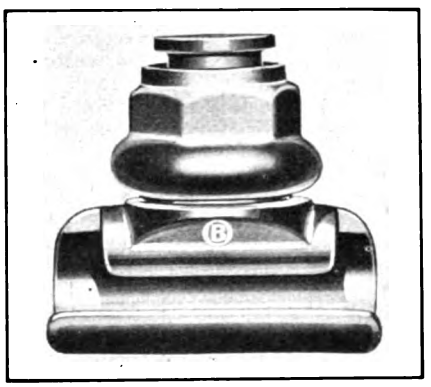
mounted that when the air current is reduced to what is considered the danger point, the vane drops, the switch tilts and opens the signal circuit. A fixed pointer attached to the base of the relay extends below the vane. This assists the observer in quickly noting the angle of the vane when seen from a distance.

Standard relays of this type are of the single-pole variety designed to control non-inductive currents of ½ amp. at 250 volts or one ampere at 125 volts direct or alternating current. A hole is tapped in the side of the case for connection of a ½-in. conduit, permits ready insertion of the lead wires. This device will doubtless be found useful in mines where it will indicate both visually and audibly any decided changes that may take place in the velocity of air flow.

Baby Cement Projector for Repair Work

A small size "Cement-Gun," known as the Type N-00, which can be operated with a one-drill compressor, has recently been developed and placed on the market by the Cement-Gun Co., Inc., of Allentown, Pa. This machine is particularly adapted to the repair and restoration of honeycombed concrete and other small patchwork as well as for small construction. It is easily

For Light Guniting of Furnace Lining and Mines.



This new cement-gun weighs only 200 lb. and can be operated on 60 cu.ft. of free air per minute. Because of its ready portability it is particularly adapted to small jobs and repair work

portable, weighing only 200 lb., and requires only 60 cu.ft., actual measurement, of free air per minute for proper and efficient operation. It is thus available for use with small portable compressors such as are standard equipment in many mines. Its operation is identical with that of larger machines of the same make, and it offers all the advantages of the larger cement projectors with the exception of capacity.

This machine is well adapted to the repair and the maintenance of furnace linings. It may also be used for general repairs around mines, industrial and other plants where the supply of compressed air is limited.

An Easily Installed Feeder Clamp

A new member of the bulldog family was recently announced by the Ohio Brass Co. It is a cable clamp, which consists of a simple cable sling with clamping jaws similar to those applied to the standard bulldog clamp. The cable sling may be used first when

Clamp Holds Feed Wire

This device can be used as a support to hold the wire when being installed and later to keep it from sliding or pulling off its support.

stringing a feeder line and later as a support by turning the nut which squeezes the sling and jaw together, thus providing not only a rest for the cable, but an effective grip as well. This grip eliminates longitudinal motion and prevents tension from being carried through the cable to its end supports.

This cable clamp is tapped for attachment to the standard insulated hanger. Flecto Iron, a new malleable iron developed by the company is used throughout its construction.

Swiveled Air-Motor Hoist Pulls in Any Direction

A new size DU "Utility" air-motor hoist has been recently developed and placed on the market by the Ingersoll-Rand Co. of 11 Broadway, New York City. This size of hoist has been especially designed for use with portable compressors and is suitable for a wide variety of work. It is a general-utility machine, particularly adapted to portable use. It consist of a light compact hoist of the winch type provided with mountings by which it may be attached to the rear end of a 5½x5 or a 5x5-in. portable compressor, to the side of larger machines or to compressors mounted on motor trucks. It is always ready for use and adds but little to the overall dimensions and weight of the compressor that drives it. It is thus extremely useful for temporary service where a greater pull than its capacity is not needed.

This machine is sturdily built and is claimed to be reliable and economical in operation. It is capable of exerting a rope pull of 1,000 lb. and of coiling 350 ft. of ⅝-in. cable. A swivel bolt through the base permits the machine to be swung around into any desired position. It is provided with a clutch so that the cable may be easily paid out by hand or by a down-grade load without revolving the motor and consuming air. A hand brake is provided on the drum to check unwinding and to stop motion in any desired position. The throttle control is sturdy yet extremely sensitive so that any desired speed up to 65 ft. per minute may be attained, this, of course, under full load of 1,000 lb. and with an air pressure of 80 lb. per square inch.

Some of the principal dimensions and details of this machine are as follows: Rope speed, at 80-lb. air pressure, 61 ft. per minute; width, 15 in.; length, 25⅜ in.; height, 19½ in.; net weight, 250 lb.

This machine is said to be highly economical in air consumption. Even when lifting a 1,000-lb. weight it can be operated by a 5½x5-in. portable compressor. A winch head can, of course, be furnished in place of the rope drum normally supplied.

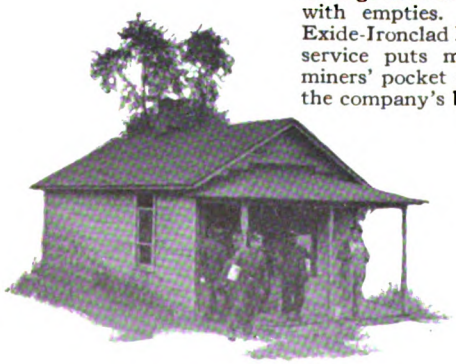
More tons go over the tipple or breaker each shift when a mine has a smooth-running haulage system. And one essential of a good haulage system is to have Exide-Ironclad Batteries in the haulage motors.

More tons over the tipple

Steep grades won't stop a motor, even with a heavy trip, when that motor is powered by an Exide-Ironclad. This battery always carries power in reserve.



An Exide-Ironclad is remarkably efficient on charge, for it takes current in quickly, easily, and stores up an unusually high percentage of it.

These miners are collecting their pay. How much money they made depends in part on how well the haulage motors kept them supplied with empties. The speed of an Exide-Ironclad Battery in gathering service puts more money in the miners' pocket and more profits on the company's books.

Back to the charging barn after a hard day's work — but the motor has plenty of pep and speed still left, for its battery is an Exide-Ironclad This battery stays on the job month after month with no time out for repairs, for it is built rugged.

A Big British Hoist

When coal is 3,000 ft. below the surface and 300 tons must be raised per hour, it is interesting to note just how the load is handled. Next week will be described the way in which the Harworth Colliery, in Nottinghamshire, England, tries to meet this problem. Many of our engineers have gone over to Europe recently to find out how mines are operated there. In consequence *Coal Age* is publishing interesting stories now and again on this subject. We shall be glad to hear comments regarding this plant and any other here or abroad.

For Better, Not For Worse

Carter Goodrich has written a book entitled "The Miner's Freedom." Probably Nixon W. Elmer has never read it, but he effectually refutes it in his article for next week's issue. Work in groups, low lifting of coal or the handling of a machine is better than loading cars by hand—working as is the rule in ones or twos, double shoveling, raising coal to shoulder height and pitching it several feet. The miners like mechanical loading. It makes the day less long and more cheerful. To the mine worker labor-easing loading machinery is to be the great gift of this second quarter of the twentieth century. Mr. Elmer has other interesting viewpoints on the loading proposition. Don't miss his article.

Feeder and trolley from a single hanger

Two operations in one!

A chance to cut the bill of materials and the electrician's work almost in halves. One bolt in the roof instead of two. One hanger instead of two. One clamp to carry instead of two. One nut to tighten instead of two.

Doesn't this proposition appeal as a means of accomplishing worth-while economy?

O-B Combination Feeder-Trolley Clamps are made of Flecto-Iron, the special heat-treated malleable which eliminates all chance of brittleness after hot-dip galvanizing.

Eliminating Brittle Castings

Mine Electricians use thousands of galvanized malleable fittings for electrical overhead work. However, few appreciate that the hot-dip galvanizing process takes the life out of one in five ordinary malleable castings—makes them brittle.

O-B Flecto Iron was developed to eliminate this possible brittleness. Flecto iron castings are never brittle. Hot-dip galvanizing does not decrease its ductility. This has been definitely proved by the past two years during which time all O-B galvanized malleable fittings have been made of Flecto Iron.

Evils of Substitution in Marketing Coal

TO DISTINGUISH one kind of coal from another, or "good" coal from "bad" coal, requires something more than casual inspection, and chemical analysis may be necessary. However, when a given coal is used its qualities are quickly learned, and its freedom from objectionable characteristics is soon apparent. To the ordinary consumer one coal looks like another and trade names are quite essential as a convenience in ordering and as an aid to marketing. Thus the coal trade is like marketing in other lines where trade marks are essential for the protection of an established business. Intensive selling by advertising in the coal industry requires, therefore, to be focused about a trade name, and where a coal of excellent quality has established a good market, this trade name becomes an asset and greatly assists in reducing general marketing expense.

But competition is keen and various expedients are invoked to overcome the popularity of a given coal. Some of these are above criticism, but others are decidedly unfair. Substitution of one coal for another is, unfortunately, a marketing practice that frequently characterizes a given locality. The coal dealer buys, at lower cost, a coal almost as good as an established coal and boldly sells it under the same name as the better coal, or else, if his conscience troubles him, he claims that it is just as good, which may or may not be the case. This practice is dishonest. More than this, it destroys the confidence of the consumer and he is not to be blamed if he harbors the opinion that coal dealers are generally unreliable. Wholesalers of the best type fight substitution as do coal retailers who have established their business on the basis of honest dealing with their customers.

No business can prosper that retains the disease of substitution. A producer who substitutes poor coal for the coal of better quality which he has been regularly supplying, is no better than the retailer who sells one coal under the name of another of an entirely different character. The producer should maintain his coal grades and the coal trade generally should eradicate retailers' substitution. Consumers' confidence is essential in every business, and where it exists sales resistance disappears and marketing costs are reduced to a minimum. Coal dealers' associations can render no better service to their members, than by ousting substitution through square dealing.

Underground Superintendence Needed

A SHORT time ago a chief state mine inspector was heard to remark that mine superintendents who search tirelessly for causes of and protection against typical accidents, which recur with more or less frequency at their plants, are not in the majority. Perhaps this is due to the fact that the average superintendent does not spend as much time underground as he should. Someone is required to co-ordinate the individual efforts of sub-bosses toward safety. Someone is needed to note where supervision fails. Every company should expect its superintendents to assume that responsibility, even where a safety engineer is employed.

Why is it that so many superintendents neglect the underground operations? Some are seen filling in at odd jobs at the tipple or some other point. They are to be commended for their energy but in the same breath criticized for their misconception of duty. They would do better to spend in the mine all of the time not devoted to performing their managerial duties on the outside.

Others are known to remain on the outside during the greater part of the time simply because they are not familiar with the "ins" and "outs" of mining, for which reason they let the mine foreman shoulder all responsibility for underground supervision. In such cases the companies that employ them—on the merit of business ability alone — are responsible. Two-headed authority at a mine plant does not lead to co-ordination of operations.

The superintendent should superintend. If he is to accomplish the purpose for which his company has employed him he must allocate his time to duties in proportion to their importance. Certainly underground operations are at least half of the works.

The Architect and Solid Fuels

IN PACIFIC COAST cities and towns recent residence construction is being too greatly influenced by the fuel situation, which situation is for the moment dominated by oil fuels and gas. The exigencies of cheap residence building have resulted in the elimination of chimney construction in many instances, or where chimneys are constructed, they are not infrequently of flimsy design or of use only for fireplaces. The better architects, recognizing that even in especially favored localities heating furnaces are highly desirable, provide a chimney for this purpose. In not a few instances the chimney is badly located, necessitating long connecting pipes which require frequent cleaning; chimney flues are often too small, resulting in insufficient draft and cleaning expense. Where coal is burned as a fuel under these conditions considerable inconvenience and annoyance results and salesmen for oil-burning equipment and for gas heating appliances take full advantage of the situation to the detriment of the coal business. A properly placed chimney of ample flue dimensions with a good coal-burning heating furnace is easily one of the safest and most satisfactory heating units for residence purposes. If care is taken in the design of the installation, coal can be almost as conveniently burned as oil or gas and it is invariably cheaper both in first cost and in operation. Gas fuel is probably the most convenient but it costs a great deal more for operation. Fuel oil requires special equipment and there are also

Digitized by Google

elements of danger of several kinds in its use by inexperienced persons. Use of coal fuel requires a knowledge of a few simple rules in stoking and once these are learned the heating furnace gives very little trouble and requires only occasional attention. Necessarily care must be taken to select a suitable coal, preferably one that cokes and does not clinker. Very soft coals are not satisfactory.

Although oil fuel at present dominates upon the Pacific Coast, even a state like California uses much solid fuel and many householders prefer this to any other. Needless to say, a good coal burning heater is independent of interruptions of power or of gas supply. It avoids the noise of oil burners as well as oil leakage with its attendant fire risk. Conditions are rapidly changing in the petroleum industry and fuel oil prices may be expected to increase to a level that will again restore the advantage to coal. It is therefore the duty of architects in general to include in their residence and apartment plans adequate chimneys for burning solid fuel. Without this precaution the change from oil to coal may require reconstruction at considerable cost. No modern apartment or dwelling can be considered to be satisfactorily planned which does not provide for the contingency of changing fuels.

Larger Copper

SMALL locomotives and 500-volt power were reasons for No. 2/0 trolley wire being adopted for the early installations in coal mines. A change of sentiment favoring 250 volts and the use of larger locomotives brought the No. 4/0 wire to its present position as the size most commonly used.

Now we have indications that wire larger than 4/0 is to come into use. One large producer in Pennsylvania is installing No. 6/0 trolley on the main haulways. The section of the wire is of such shape that it can be hung by the standard 4/0 clamps. It has a 59 per cent greater area than the No. 4/0 wire.

The trend toward larger mine cars and heavier locomotives makes it appear reasonable that there are numerous places where heavier trolley wire should be used. Paralleling the trolley with a feeder cable gives the same effect but is a more expensive method. Difficulties of handling solid copper in sizes above 4/0 will no doubt be the limiting factor in future developments toward the larger wire.

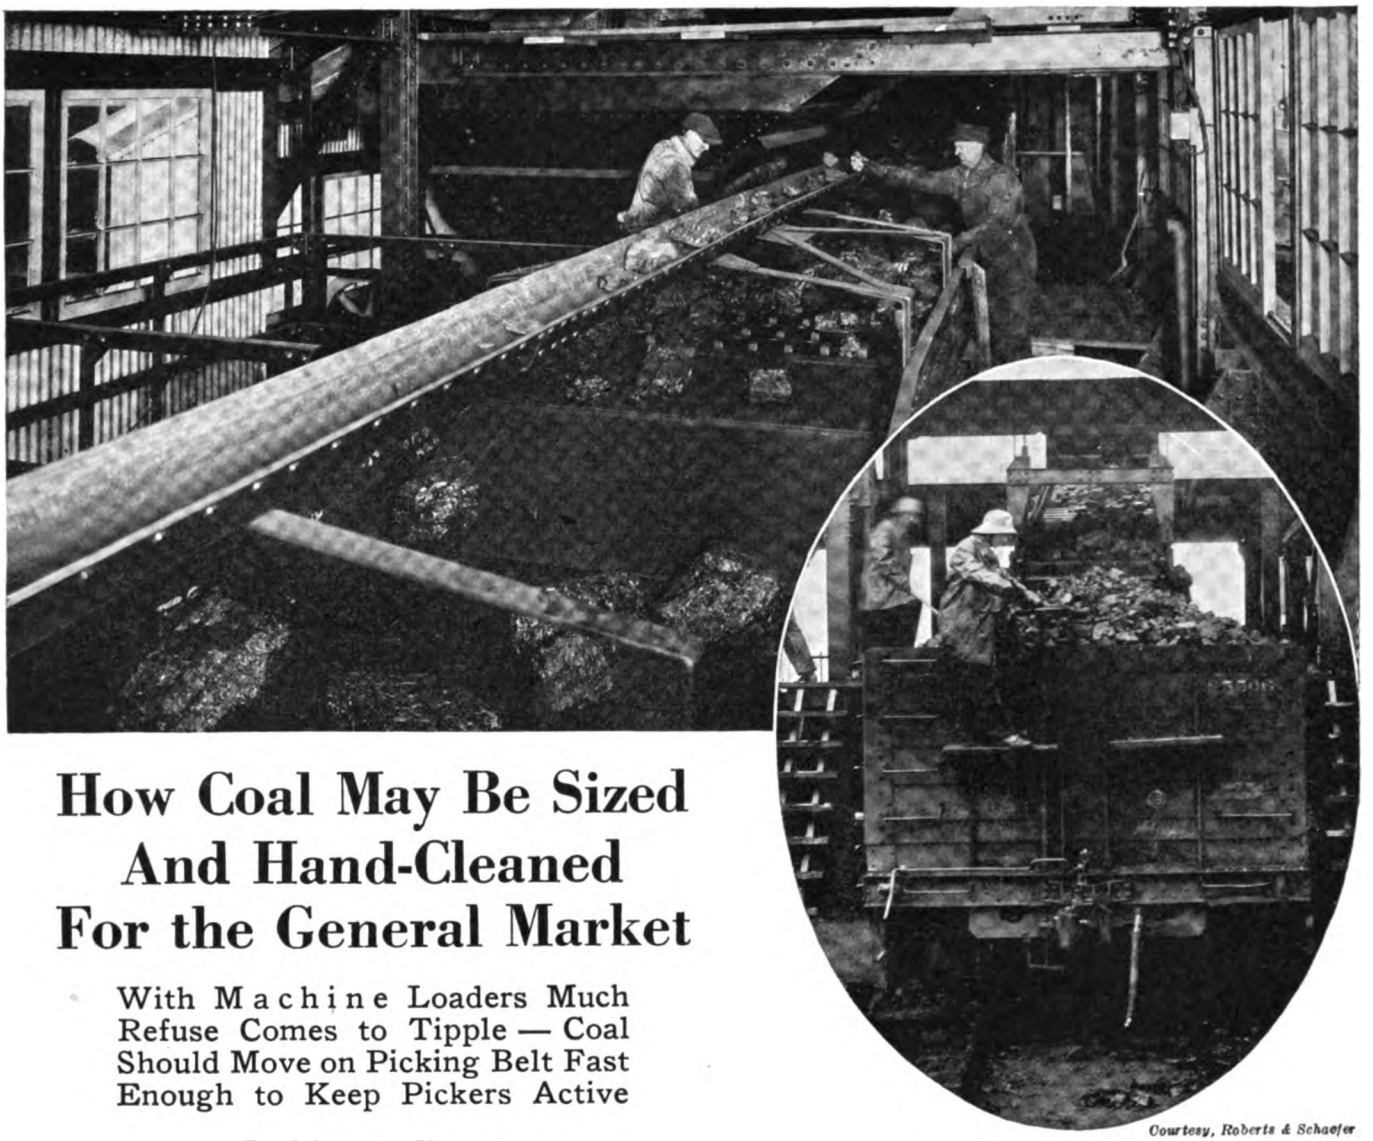
Laying the Ground for Accord

PLEASING RELATIONS with the public need cultivation. We all know the individual who means well but is always arousing the animosity of people because he does not give due consideration to his manner of approach. His heart is right, but his actions so belie his purposes that explanations and excuses are continually necessary. And after all, one may as well confess it, he has faults of heart as well as faults of manner, and if he would give some consideration to these also, he would make a better sort of citizen—outwardly and inwardly better.

The coal industry needs a window dressing, and it needs certain internal reforms also. It needs to inquire just what these are and not to wait as it has been in the habit of doing till the public is in an irritable mood. Explanations at such a time do not explain, apologies even do not mollify.

Anyone who has seen two persons trying—honestly trying—to compose an ancient quarrel will recall how a trifling word or action has almost invariably ended in creating a condition more vexed and harassing than existed before, a disagreement that was slumbering and dying being suddenly revived and bursting into flame once again, making pacification more hopeless than ever.

To take a suggestion from pathology: A food that will cheer and sustain a healthy person will be poison to his system when he is sick and ailing. The disease will turn the best of viands into an intestinal irritant. Important, therefore, is it that the body be kept in health, so that it may be able to assimilate the food it needs. Important also is it that the public may have a mind so unsoured that it can judge without prejudice and be prepared to accept the operators' statements at their right value.



But to attain that end must be a long record of honorable dealing with no lapses. E. E. White, formerly of the E. E. White Coal Co., recently denounced the action of those producers who raise prices to an exorbitant level and send impure coal to market and so injure the business of other operators. This has no reference to the history of the recently concluded anthracite strike or to the action of the bituminous coal companies consequent thereon. There was not, as far as the coal producer was concerned, any profiteering, and it has not been the practice in the past of the larger companies, in times of big demand, to force prices to the top level. Repeatedly they have met together, to save the public from high prices which competition has induced.

Oil Must Be Combatted

THE abnormal development of petroleum, especially in the California oil fields, has unsettled established business in coal, particularly in the marine bunker trade on the Pacific Coast, which is now greatly restricted. In Pacific Coast ports fuel oil has displaced coal and has reduced the marine market to nominal proportions. Recently plans were advanced to convert the coastwise vessels of the Canadian government merchant marine from coal to oil burners. This would have been consummated, but for the protests of the British Columbia coal interests. Success attended their efforts and it is understood that the contracts for the change in equipment are going to be or have been cancelled.

This incident brings into prominence the need of the coal industry to protect its markets from encroachment. Declining production in the petroleum industry foreshadows increased prices and a diminishing surplus. The increase in cracking practice indicates a more profitable use for petroleum than for fuel purposes. Thus, although present prices favor fuel oil, it does not necessarily follow that this condition will be maintained for a long period, and it may be quite temporary. It is, therefore, unwise for marine or other established solid-fuel users to be too greatly influenced by low price levels that characterize flush production from new oil districts. Nevertheless, the situation is such that coal men generally should study the situation and take steps to maintain their existing markets by either raising the quality of their coal or by suitable price adjustment to meet liquid fuels.

How Coal May Be Sized And Hand-Cleaned For the General Market

With Machine Loaders Much Refuse Comes to Tipple — Coal Should Move on Picking Belt Fast Enough to Keep Pickers Active

By Thomas Fraser
Assistant Professor of Mining, University of West Virginia, Morgantown, W. Va.

CONDITIONS governing preparation of commercial coal differ materially from those which determine the treatment to be given to metallurgical fuel, defining as commercial coal the product that is to be sold on the open market as domestic or general industrial fuel. The introduction of mechanical or concentrated hand-loading systems for handling coal at the face will, in many cases, result in delivery of dirtier coal to the tipple than was previously received and hence will necessitate more careful attention in the preparation plant. If these new mining methods are widely adopted, the use of special cleaning devices will become mandatory at many commercial mines where heretofore it has been optional. Therefore, a study of preparation equipment and processes especially adapted to the preparation of coal for general market is timely.

The objects in commercial-coal preparation are (1) to size the coal to suit the requirements of the different users and (2) to free the coal of excessive extraneous impurities. The sizes to be made depend upon the destination of the coal under treatment; the domestic consumer demands well-sized coal free from slack; the railroads use mine-run coal for the greater part, but demand a clean fuel and often prescribe a limiting percentage of slack; the steam plant may use mine-run, unassorted screenings or sized coal, depending upon the type of equipment. Profitable operation of a mine with all these markets available depends, in a large measure, upon production of a maximum proportion of those grades that command the highest prices, which are normally the larger sizes suitable for domestic use. To obtain the desired result, preparation of the best grade of coal must be the major consideration from the beginning of the coal-producing process, for the operations at the face and even the general layout of the mine—direction and width of working places, rate of advance, method of roof support and general transportation system—greatly influence the size of coal ultimately produced. Therefore, with regard to sizing as well as cleaning, preparation of the coal should begin at the working face. This, however, is not an appropriate answer to every argument for the installation of preparation equipment, though it is often so interpreted. Though preparation *should* begin at the face, it usually has to be completed on the surface if a high-grade product is to be shipped.

To produce the maximum proportion of lump coal, that object must be the determining factor in selecting methods of cutting, drilling, shooting and loading the

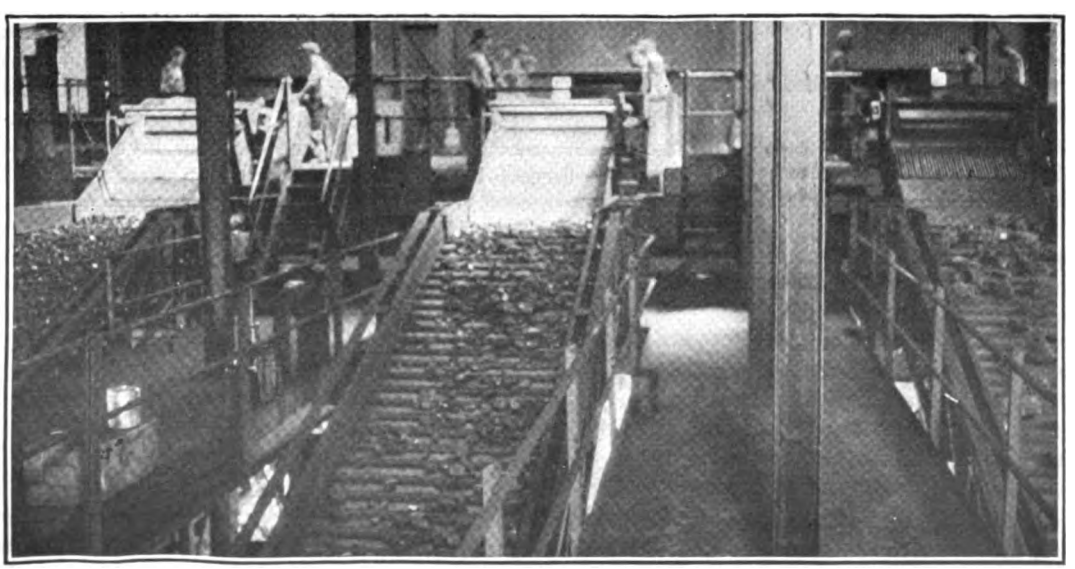
coal. For a commercial mine, one of the first requisites of a loading device should be ability to load lump coal broken down without any more violent shooting than is necessary for the best results in hand loading and, in any proposed changes in mining method, the effect on the size of coal delivered to the surface is one of the important features to be investigated.

THREE GENERAL TYPES OF TIPPLES

In regard to the kind of preparation plant required, mines may be divided into three general classes, (1) mines serving, primarily, run-of-mine coal consumers, (2) mines shipping lump coal and screenings, (3) mines supplying miscellaneous domestic, steam, and railroad markets with sized coal. The large consumers of mine-run coal are the railroads and some kinds of steam power plants. Under unusually favorable working conditions that permit the coal to be mined free of impurities, a producer of mine-run coal requires only a simple surface plant equipped with means merely for dumping the coal and loading it into the railroad cars or barges without excessive breakage. If the conditions are such that clean coal cannot be produced at the face, a surface preparation plant should be provided to clean the coal and, as coal in the run-of-mine condition cannot be sorted effectively, screening is necessary as a preliminary step, if much dirt is to be removed. In such a plant the coal is separated by bar or shaker screens into products of a sufficiently limited range of sizes to facilitate cleaning by hand. These products are hand-picked on separate picking tables or belts and reassembled and loaded for shipment as picked mine-run coal.

Mines producing only two sizes of coal, that is, lump and screenings for the general domestic and industrial market predominate in many sections in the Appalachian region; especially where the coal is strongly caking. Coal of this kind fuses into a coke mass when fired; hence, sizing is not so essential and the advantages of a closely sized fuel are not so marked as with a coal that is free-burning. At operations of this class, bar screens are commonly used, with either 1¼-in. or ¾-in. spaces producing 1¼-in. lump or ¾-in. lump for domestic and hand-fired industrial furnaces and the corresponding sizes of slack for stoker use or for coking. Methods of cleaning depend upon the quantity and kind of impurities present, and whether they are found mainly in the lump coal or in the slack. If the coal is mined in a comparatively clean condition, the lump coal is given a superficial inspection by the car trimmers, and the slack is shipped as mined. If more thorough preparation is necessitated by the condition of the coal or the demands of the market, the lump coal should be hand-picked on belts or tables before loading; the slack can be cleaned only by a washery or other mechanical treatment plant.

Cleaning by hand is greatly facilitated if the coarse coal is screened into several sizes for separate treatment. This is done at most commercial mines that produce both domestic and steam coal of the free-burning type and at many mines working coking coals. This sizing is usually done with shaker screens, but bar screens may also be used for this purpose. Shaker screens have the advantages of (1) handling the coal more gently, (2) using less headroom in the preparation plant, (3) sizing the coal more completely and (4) distributing and discharging the separate sizes more conveniently for subsequent treatment and loading. When lump coal, egg, nut, and screenings are made, the three larger sizes are well prepared for hand cleaning on picking belts. If the screenings are to receive further preparation, mechanical means are necessary as hand-picking the very small size is prohibitively costly.



NUT IF DIRTY NEEDS MECHANICAL CLEANING

The economic limit of hand-picking depends upon (1) the cost of labor (2) the quantity of dirt in the coal and (3) the completeness of cleaning desired. The economy of preparing the nut sizes by hand is open to question and, if more than one- or two-per cent ash reduction is necessary, either 1 x 2 in. or 2 x 3-in. coal can probably be cleaned more cheaply, and certainly more effectively, by a simple mechanical cleaning plant than by hand.

No definite information is available on the effectiveness of hand-picking in terms of percentage ash reduction, or on the cost of hand-picking on the basis of dirt removed. O'Toole[1], in a paper presented at a meeting of the American Iron and Steel Institute, showed that the cost of thorough cleaning of Pocahontas coal is very high when preparation of small coal by this method is attempted. However, his figures are for practically complete removal of dirt and bone coal which is not necessary at the usual commercial preparation plant.

Normally, with well-disciplined leaders, the larger

[1]O'Toole, Edward, Dry Cleaning of Coal by Means of Tables, American Iron and Steel Institute, May 27, 1921.

Plant with Three Picking Tables

Speed of picking has to be regulated to suit the quantity of refuse to be removed. Making it slower than is necessary has a despiriting effect on the employees who are likely to be more observant when they have more occasions to exercise their vigilance.

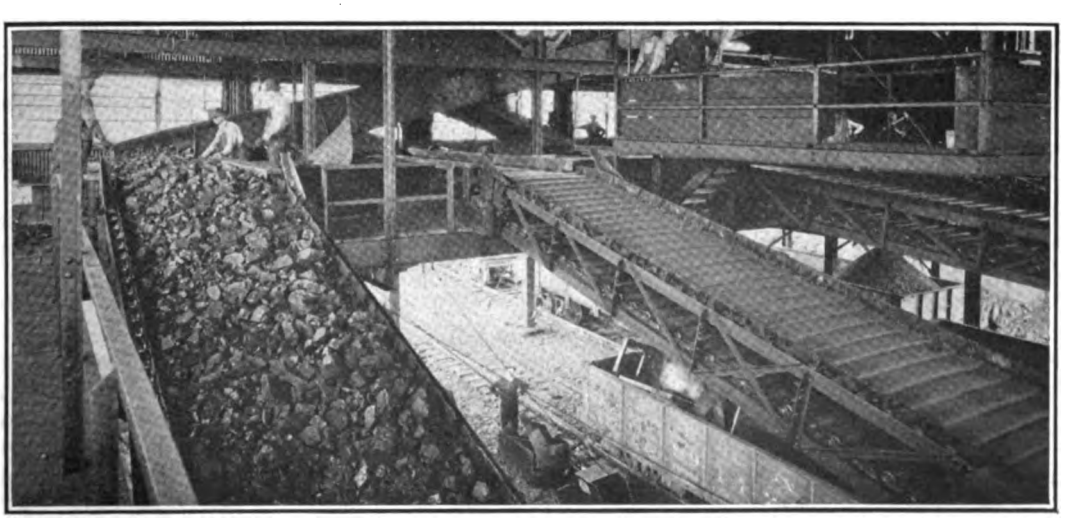
Digitized by Google

sizes of coal come to the tipple in such a condition that the removal of a small quantity of conspicuous free dirt is sufficient to insure shipment of attractive domestic grades of coal. Though no specific data are available on the cost of picking dirt from the various sizes of coal, the operation is not a complicated one, and the conditions in any given case should not be difficult to evaluate. It is basicly a materials-handling problem—to identify and remove, piece by piece, the extraneous material in coal. Given the most favorable conditions for identification of dirt particles, the cost depends upon the capacity of a man for handling material, which will vary mainly with the size of pieces being handled. The proper and logical unit for expressing this capacity is net tons of dirt handled rather than gross tons of coal passed under the picker's observation. Therefore, the determining factors so far as coal characteristics are concerned are, (1) ease of identification of dirt, (2) size of coal, (3) quantity of dirt to be removed. The conditions that lead to the maximum proficiency of the worker are conditions that facilitate distinction of dirt from coal and that enable material to be removed from the coal stream and disposed of with the minimum effort or fewest movements. Conditions that facilitate identification of refuse are (1) good illumination without glare, (2) uniform size of pieces, (3) thin uniform layer of coal, (4) slow and steady movement of coal, (5) proper position of workmen at the picking table.

Conditions insuring maximum rate of handling material by the workman are (1) convenient arrangement of picking table, refuse conveyor or chute and workman, (2) uniform size of pieces, (3) thin uniform layer of material, (4) uniform and sufficiently rapid travel of belt to keep picker busy. As regards travel of belt, conditions for thorough cleaning and for maximum rate of material handling are, in a measure, conflicting. The best rate of travel for picking belts may vary somewhat with ease of distinction of dirt from coal, but it may be generally assumed that the highest rate that will permit ready identification and removal of pieces of dirt will result in maximum proficiency of the worker. For example, a given tonnage of coal passed before a picker on a belt traveling at the rate of 100 ft. per minute will probably be picked more effectively than the same tonnage in a layer twice as deep passed before him at the rate of 50 ft. per minute. In addition to handling the same tonnage in a thinner and better exposed bed, the faster moving belt necessitates a more wide-awake condition and quicker movements on the part of the worker, thus tending to increase his capacity.

Picking-table products are seldom sampled as a means of controlling or evaluating hand-picking operations. Hence typical data on results of hand picking are not available. Because the coal and dirt are often not broken apart in the large sizes of coal commonly treated by this method, the refuse, as discarded, usually carries coal with it, and the average ash content of the rejected material is not as high as that of washery refuse. Picking-table refuse from lump and egg coal will usually run from 25 to 40 per cent in ash. A rough estimate of the reduction in ash obtained by picking may be made by weighing the total pickings obtained from the day's production of coal of any given size and calculating the ash reduction by the formula commonly used for figuring washery yields.

Picking Tables at Gay Mine, Near Logan, W. Va.



In this mine a large binder is removed by cutting the face two or three times. The coal is loaded by machine and when it arrives at the tipple receives careful inspection.

$$\frac{\text{Raw-coal ash} - \text{washed-coal ash}}{\text{Refuse ash} - \text{washed-coal ash}} = \text{Proportion of refuse (shrinkage).}$$

For example, if 1,000 tons of lump coal of 9 per cent ash content are loaded, the improvement that may be expected by picking out 30 tons (3 per cent) of refuse containing 40 per cent of ash is as follows:

$$\frac{9 - \text{cleaned-coal ash}}{40 - \text{cleaned-coal ash}} = 0.03.$$

From which, the ash content of the cleaned coal is calculated as 8 per cent.

Cleaning Strip Coal

Coal from open pits is nearly always machine-loaded, and it was early found that it needed cleaning to make it acceptable to the market. This plant of the United Electric Coal Co. at Cuba, Fulton County, Illinois, has picking tables and loading booms in a well-planned tipple.

Balancing the Helps and Hindrances to Success in Loading Coal by Machine

For Best Results in Machine Mining, Equipment Suited to New Agency Should Be Introduced in Every Phase of Mine Operation But These Improvements Can Be Made One by One

By Edward H. Johnson
Mining Engineer, The Coloder Co., Columbus, Ohio

Edward H. Johnson

IN MOST of the coal mines of the country the addition of new machinery is a compromise. The management realizes that the new equipment cannot operate at 100 per cent efficiency, partly because of the natural conditions, but largely because of other equipment now in service that is sub-standard. A fan may be throttled by clogged aircourses, a pump by a corroded discharge line, mine locomotives by poorly ballasted mine track, mining machines by low voltage, haulage by inadequate hoisting equipment. To an even greater extent mechanical loaders must make concessions to physical restrictions and unbalanced mine machinery.

The loading-machine salesman who rates his machine at a certain tonnage is either mentioning conservative figures or is taking much for granted. Overzealous estimates and unjustified claims have greatly delayed the ultimate success of loading machines. Rare indeed are the loaders that develop a 40 per cent time efficiency, and even these may suffer further losses incident to low voltage or improper face preparation of the coal. No machines used underground today are so dependent upon the proper co-ordination of other mine equipment and upon the mental attitude of the management and the employees. I know of one installation where the loaders have failed due to the deliberate intention of the management to discredit their operation. But as the electric hoist is superior to the windlass, as electric haulage is better than hand tramming, so is machine loading better than hand loading and bound to supersede it.

Every mine manager is familiar with the problem of getting the highest possible yield with the machinery and labor available, efficient and otherwise. What he might do with other means is likely to be only of academic interest except as individual changes in equipment and personnel may be found possible. The introduction of one or more mechanical loaders may constitute one of these changes. After such a change has been made, the mine manager still has other equipment that was installed for a hand-loading operation. The haulage and face preparation faults at once appear. The question of cleaning the coal intrudes itself.

However, if this manager is resourceful and tenacious, and if the judgment of the purchasing official was good, an equilibrium is soon reached in the mining operation, and the cost of production is lowered. New opportunities will present themselves to straighten out the kinks, and as difficulties are solved cost will be further reduced.

Certain installations of loading machinery may have been successful because of unusual physical advantages in the mine, but success is more likely to be the result of a thorough study of all the problems involved. Let me list a few of these questions that have to be answered by the prospective user of machine loaders.

1. Is the loader adapted to the coal bed in which it is to work? 2. Can I supply the loader with empty cars that will enable it to load a satisfactory tonnage? 3. Are my power supply and my wiring and bonding practice adequate? 4. Can I provide sufficient auxiliary cleaning underground or at the tipple, with an added cost that I can safely absorb? 5. Can I make such changes in my system of mining as may be necessary? 6. What will be the effect upon my labor relations? 7. Can I prepare the coal so that the machines can load it readily and with a minimum degradation?

MACHINE MUST BE ADAPTED TO COAL BED

An unfavorable answer to any of these questions will make successful mechanical loading difficult until corrections can be made. Many of the mines subject to competition that cannot give favorable answers to these questions are due to be eliminated. This is an admitted fact by mine operators. I wish briefly to comment on each of the questions that I have listed.

The choice of the proper loader should not depend upon the skill of the salesman. It is a problem for engineering analysis. In general the best answer will be found through recourse to consulting engineers or firms, who should have the data at their disposal.

Even where conveyors or scrapers are used the haulage system may interpose a stumbling block because of delays in the changing of cars or because the mine cars are of small capacity. The question mentioned "satisfactory tonnage," not "maximum tonnage." This is a rather important distinction. A maximum output may result in higher unit costs of haulage or maintenance than 80 per cent of that maximum. The law of diminishing returns will be found to apply to machine loading. Though the operator may not be able

Article entitled "The Engineer's Viewpoint of Mechanical Loading" read before the "Materials Handling Division of the American Institute of Mechanical Engineers," New York City, Mar. 11. Mr. Johnson was the joint author with F. E. Cash of the bulletin on "Mechanical Loading in Coal Mines" published by The Carnegie Institute of Technology and the U. S. Bureau of Mines.

Digitized by Google

to increase the capacity of mine cars, such a change, where possible, is of definite advantage in any sort of mechanical loading.

There is inevitably a loss in efficiency of the haulage because machines do not load mine cars as heavily as do hand loaders, except in the rare instances where the loaders are paid by the car. This has resulted in an actual loss in tonnage where the hoist has been operating at its maximum capacity. Sometimes sideboards which add to mine-car height will overcome this difficulty. A machine-loading operation will require just as many mine cars as one operated by hand loading provided the cars are of the same average capacity. That is, it is generally agreed that more mine cars of the same size are needed with a mechanical loading operation.

There is no mystery about wiring practice, track bonding and devices to maintain and protect the voltage. The best methods are also the safest and their introduction will be fully justified.

Coal cleaning is an important problem, as wet or dry launders or hand picking have to accompany most of the loader installations. One comforting fact has been established. The increase in the refuse in machine-loaded coal is in the larger sizes. The small pieces of refuse that escape the eye of the men on the picking tables have also been missed in the past by the hand loader at the face. Refuse carried out with the coal represents a slight loss in haulage efficiency and creates a further waste-disposal problem on the surface.

Changes in the system of mining are often considered to be a part of the machine-loading problem. The use of certain of the loading devices on the market depends upon minor or major changes in mining methods. The mining handbook of the American Mining Congress warns us that room and pillar mining is institutional and that radical changes are of doubtful value. Major changes in existing practice have in several cases discredited the cause of machine loading because instances have occurred where the new mining system has failed.

Any mining system that contemplates a change in the method of controlling or guiding the roof action is an experiment in itself. Its success or failure will depend upon the engineering judgment that led to its adoption, almost independent of the loading devices that are used. This statement must be qualified by the admission that the rate of advance or retreat of the working face will naturally be governed by the degree of success of the machinery used.

ROOF-CONTROL METHODS NEED TRIAL

Although I am an enthusiastic advocate of long-face experiments and roof-control devices, I see these as problems to be solved individually in every mine. Changes in panel dimensions, room centers, track layouts, crew organization, and so on, may be considered as part of the machine-loading problem.

The attitude of labor is more of an individual problem for the local management than an issue to be considered in this article. The labor question is a problem in sociology rather than in engineering.

Face preparation of coal for the machine loader is a matter in which mine operators require as much education as the shotfirers. When the mine operator can be brought to see that the opening of cracks in the face of the coal, wide enough to allow the miner to insert his pick point, is *not* the proper way to obtain lump coal, it will be easy to teach the shotfirers. There are too many mines in the country where the hand loader at a machine-cut face makes as many fines with his pick as the mining machine makes in undercutting. A new installation in Wyoming reports an increase in lump coal production with machine loading.

The mine with the best record of continuous operation in Illinois during 1925 is located in that part of the state that lies nearest to the coal fields of Kentucky, the low wages of which have kept many Illinois mines idle for the past two years. This mine is one of the few if not the only mine in that state that loads all its coal mechanically. The spread that exists between machine-loading costs and hand-loading costs, at least in high-wage districts, is a large fraction of the total cost, in some cases exceeding 50c. per ton.

The mine manager to whom this story comes, invariably says: "That is all very well, but my conditions are different." He is entirely correct. He sees the nature of his coal bed, the requirements of his market, and his equipment of men and machinery which are like none other in the land. It is possible that he is too close to his own problem to get a proper perspective of it unless he is a man of wide experience. Every mine is an individual problem, not to be solved by application of any general formulas. The mine superintendent should be consulted in making the choice of loaders, but he should not bear the whole responsibility for their success or failure.

NEED FOR MACHINES OF MANY TYPES

There is a constantly increasing variety of loaders from which to choose. Several of these machines are built to suit special conditions or to serve a particular purpose. Among these are machines that mine and load the coal, machines that load and convey the coal, and machines that work in conjunction with conveyors. Another class includes conveyors that are loaded by hand, which, although they are not loaders in fact, are generally considered in that connection. Some machines are portable and load either into mine cars or conveyors. No machine has been built to suit all conditions, so there is need for machines of several types. I believe that the industry has ceased to seek for something that will revolutionize it. We shall undoubtedly make better progress by a steady improvement of the means at hand than by waiting for the final perfected machine.

A degree of co-operation between manufacturer and operator is necessary to the success of machine loading and advantageous to both parties. By trying out ideas in machine design in the mines of friendly operators, the manufacturer has been able to discover and remedy the inherent weaknesses that are sure to develop. Thereafter it is the manufacturer's duty to maintain a standard of quality and workmanship that will permit operation with a minimum of delay and maintenance expense under the conditions for which the machine was designed. The manufacturer and his representatives should refrain from extravagant claims for his equipment. Statements should be based upon conservative estimates of competent engineers rather than enthusiastic sales propaganda. Failure to observe these principles places the operator in a defensive position.

The user of machines also has some obligations to fulfill. He should not blame the machines for failures that rightly come from defects in his own organization. Machines cannot load satisfactory tonnages if they are not properly supplied with empty cars, work-

Digitized by Google

ing places or rated voltage. Face conveyors of nearly all types will have a brief life of service if the coal is shot down onto them. Unless they are kept at some distance from the face the cost for replacement parts is sure to be high. This may be satisfactory to the operator, but in broadcasting his experiences particulars of operation should be given. Prospective users are accustomed to ask for trial installations and to demand that the machines make good without any help. Machines never become really successful until after they are paid for, and the operator has become convinced that he must make them succeed or suffer a loss. He will then know he cannot shift his burden on the manufacturer.

Mining codes and company regulations, when well enforced, operate to reduce the hazards of mining. Beyond this, many questions have to be settled by some one using his best judgment. The human element, particularly when adequate supervision is not the rule —and this applies to most hand-loading operations— is able to defeat the safety efforts of state departments and mine operators. To whatever extent it becomes possible to increase the man-day tonnage of underground labor, the fatal accidents per million tons mined will be proportionately decreased. The added hazard which may be expected through closer grouping of men in concentrated workings should be neutralized by the direct supervision thus afforded.

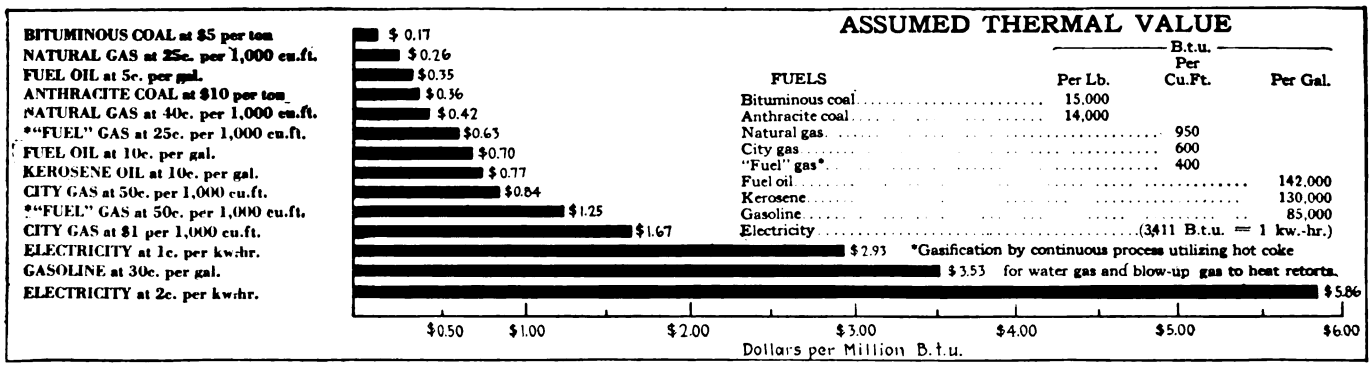
SPECIALIZATION SHOULD INCREASE SAFETY

Another factor of safety is expected to result from mechanization of mine operations. Nearly every man employed underground will be a specialist in some line, educated to his job. As such he can be expected to take better care of himself.

It is the duty of engineers to insist that safe equipment be specified, and it is the obligation of mine managers to provide for its operation in a safe manner. The United States Bureau of Mines defines in its certificate of permissibility not only the limitations of design but also the conditions of operation. Gears and chains should be guarded, electric motors should be enclosed, stray currents should be traced and eliminated, ventilation must be positive, supervision must be adequate and intelligent.

The operation of a coal mine is much like playing a game of chess; rather, a simultaneous series of games. In one game, the manager is matched with the requirements of his market, in another with his labor situation, in yet another with the physical conditions of his property. In each game he is dealing with an infinite number of possibilities with a limited number of variables. Of necessity he must win each game. Mechanical loading may be a handicap in one game, but a decided advantage in another one. To accept a handicap in an easier game may be wise if that handicap is turned to an advantage in the more difficult game.

The general use of mechanical loaders will yield some results of general advantage to the industry. Large companies can dominate the field, because the coal pirate will no longer be able to raid the market. The destructive competition of low-wage fields in the natural markets of the higher-wage districts will be somewhat neutralized, as the direct labor cost will represent a smaller fraction of the total cost of production.



BENEFIT TO THOSE WHO ARRIVE FIRST

As there are now mechanical loaders that will operate successfully even under unfavorable conditions, the mine operators who first see the light and follow the pioneers will derive the greatest benefit in decreased costs of production and larger profits. The motto of the average man is this: "Be not the first by which the new are tried, nor yet the last to lay the old aside." Such operators will load their coal by mechanical means only when the competition of their neighbors drives them to it. The pioneering has been done. Who shall decide when we have advanced beyond the experimental stage!

The cause of mechanical loading might seem, from the foregoing discussion, to be beset with many difficulties. The importance of the pros and cons is not always to be judged by their number. The big advantage—cost reduction—is sufficiently large to be almost certain, if the engineering judgment is not at fault. There are many other savings and advantages, known as intangibles, which are not always reflected in the direct costs, but which result eventually in additions to net revenue. These may be merely mentioned. Their importance will be readily apparent.

Mechanical loading means concentration of mine workings; delivery of tonnage from one-quarter to one-half of the present developed area; rapid development and recovery in new properties, resulting in quicker, therefore greater, returns from the original investment; saving in timber through the more rapid evacuation from the territory being operated; saving in steel rails, mine ties, trolley wire and bonds for the same reason; possibility for better supervision and greater safety for men and machinery.

Coal Is Cheapest for Heat Treatment of Metals

This chart, compiled by the W. S. Rockwell Co. of New York, is intended to show that, upon a basis of cost per million B.t.u., coal is the most economical of all sources of heat for the treatment of metals. The chart covers the comparative cost at assumed unit prices and assumed B.t.u. per unit of consumption of fuel. Furnace design and many other factors enter into the heat treatment of metals but the fuel cost, taken alone, is represented here. It is heartening to see what a lead bituminous coal has over all rivals.

Wet Haulage Slope Kept Free of Ice by Split Of Air Passing Up It

Abandoned Old Slope in Coal for a Steeper Slope in Rock That Saved Trackage to Tipple—Use Former Slope as Intake—New Road Reduces Height Coal Has to Be Hoisted

By Thomas Murphy
Master Mechanic Northwestern Improvement Co.,
Roslyn, Wash.

BY MAKING a new slope in the roof rock, the Northwestern Improvement Co. shortened its haulage underground nearly half a mile and cut down its surface haul almost three-quarters of a mile. This gave a more permanent slope and one that had a grade more nearly in accord with that of its extension within the coal bed. Moreover, it saved hoisting the coal as high as was formerly the case, the top of the new slope being 120 ft. lower than the top of the old one. But the new slope was wet and icy in the winter season, so 2½ per cent of the air delivered to the mine was allowed, in the winter months, to pass back out of the mine up the slope. This kept the roadway in good working order. The old fan was kept in place and could be run by steam-driven power equipment provided the hydro-electric power-driven fan should be closed down for lack of current.

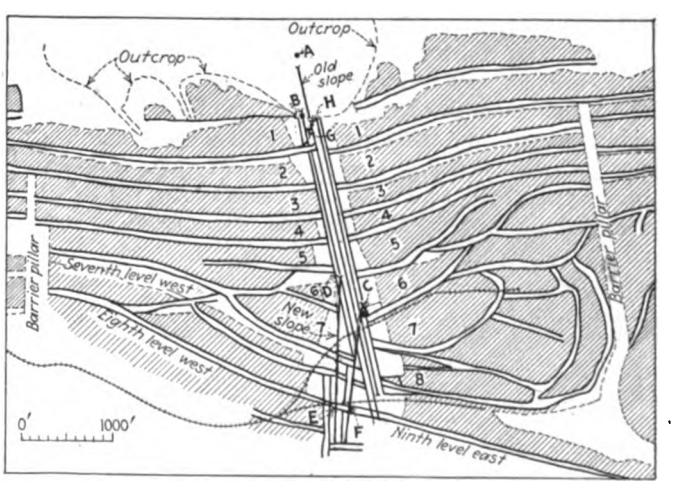
The Northwestern Improvement Co. at present operates three mines in the Roslyn-Cle Elum field of Washington, all of which are equipped with modern hoists, fans, and screening plants, and within the last year have been thoroughly rock-dusted.

This company's No. 5 mine was opened in 1904. The original opening was a slope starting in the bed, where the coal outcropped in a shallow gulch on the mountain side, and heading straight south down the pitch which is approximately 20 deg. at this point.

The main slope has an average width of 12 ft. and there is an airway and a manway on either side of the slope. Levels were turned off the slope east and west on about 500-ft. centers and driven 1 deg. to the raise. Rooms 20 ft. wide on 50-ft. centers were driven straight up the pitch. The old slope was driven down 4,000 ft. where the Eighth West and Ninth East Levels were turned.

COAL BEYOND SLOPE PITCHES 36 DEG.

It was then found that the pitch of the bed increased to 36 deg. Diamond-drill borings disclosed the fact that this pitch continued for 2,000 ft. further south into a syncline. As all the coal had been worked out above the Seventh Level and as the 4,000-ft. haul up the old slope together with a 3,600-ft. locomotive haul from the top of the slope to the tipple was too expensive to operate, it was decided to drive a new slope on a 30-deg. 30-min. pitch through the rock to the surface from a point on the Eighth West Level 500 ft. west of the old slope.



The slope was driven 7x14 ft. for a double track and is 1,500 ft. long. An 800-hp. double-drum single-reduction geared hoist connected to a 2,300-volt slip-ring motor was installed to provide transportation.

The accompanying rock airway 7x12 ft. was driven on a 45-deg. pitch. To provide ventilation a 6x7½-ft., double-inlet multi-vane fan, belted to a 75-hp. 2,300-volt induction motor, was erected.

In driving the new slope through the sandstone formation much seepage water was encountered, but no great quantity in any one place. After the slope was finished it was found that the seepage, amounting to about 25 gal. per minute, continued to come in through the roof, sides and floor. This was no serious matter in non-freezing weather—in fact it served a good purpose for it kept the slope damp.

This locality being east of the Cascade mountains there are usually two or three months of rather severe weather in the winter, and much trouble is experienced from the ice which forms on slopes when used as intake airways. As the old slope is being maintained to the Eighth West Level as a third opening to this mine, as required by the Washington state law, some air is taken in that way, the quantity varying with the outside temperature, being more in summer than in winter, as the top of the old slope is 120 ft. higher than that of the new one.

As the fan was still in place at the mouth of the old airway it was decided to force all the ventilating current down the old slope during freezing weather. This was accomplished by opening a crosscut between the old airway and the old slope near the fan, building a stopping in the airway just below the crosscut and installing a door in the mouth of the old slope. Now by operating the old fan as a blower at 100-r.p.m., 80,000 cu.ft. of air per minute is forced down the old

Slope in Roof Rock Decreases Maintenance Cost, Shortens Haul and Lowers Hoisting Lift

slope onto the Eighth West Level whence 78,000 cu.ft. is taken through the mine by the new fan acting as an exhauster, the remainder, 2,000 cu.ft., passing *up* the new slope to the outside. Having been warmed by its passage down the old slope it prevents ice from forming on the new one.

The new fan is driven by an alternating-current motor by purchased hydro-electric power, as ordinarily no power is generated at either of the mines now being operated by the Northwestern Improvement Co. in this field. However, at No. 7 mine, which is located about one mile east of No. 5 mine, there is a 300-kw. steam-engine driven generator which is kept ready for emergency service at all times, consequently the old fan at No. 5 mine has been equipped with a 550-volt direct-current motor, the idea being that in case the power from hydro-electric sources fails the old fan motor can be supplied with power from the steam-driven generator at No. 7 mine and ventilation in No. 5 mine be maintained. It having been found that with the new fan shut down and the old fan running as a blower, all the change that is necessary to maintain ventilation is to close the steel fire door at the mouth of the new slope to keep the air from escaping at that point. The air then travels through the mine in the same direction as it does with the new fan running and passes out of the mine through the new fan.

British Battery Charging Is Often Wasteful

With Celluloid Cases In Use It Is Dangerous To Draw Current From Lighting Circuits Unless Contacts Are Good and Leakage Prevented

By L. Fokes
Walton-on-Thames, England

MOST of the collieries in Great Britain have miners' lamps which, of course, have to be charged daily. The lamps are not, however, always charged in the safest and most economical way. Lamp rooms are often left in charge of more or less unskilled hands, yet the need for careful and intelligent treatment is perhaps more important than with many other forms of electrical apparatus.

Safety-lamp batteries usually are charged in batches which are connected in series. A favorite method in the British Isles is to make use of the electric lighting supply, connecting the cells in series with a number of lamps which act as a resistance. British mine managers apparently seldom realize how wasteful of electrical energy is this crude method of charging batteries and how dangerous is the practice with battery cases made, as is often the practice in Great Britain, of celluloid, which is an inflammable material.

The voltage employed for different systems of lighting varies considerably. In some instances, the pressure may be as high as 250 volts. There is a distinct danger of fire when charging cells on these higher voltages. Some manufacturers have abandoned the use of celluloid, but it is still widely employed for this purpose. Cells of this kind, of course, require the most careful treatment.

Quite mistaken ideas are prevalent as to the actual effect of introducing a resistance in series with batteries, which are to be charged from an electrical circuit the voltage of which much exceeds that of the cells connected for charging. It is often imagined that lamps or other forms of resistance reduce the voltage. They do nothing of the kind. They merely prevent the current exceeding a predetermined limit. Take for example

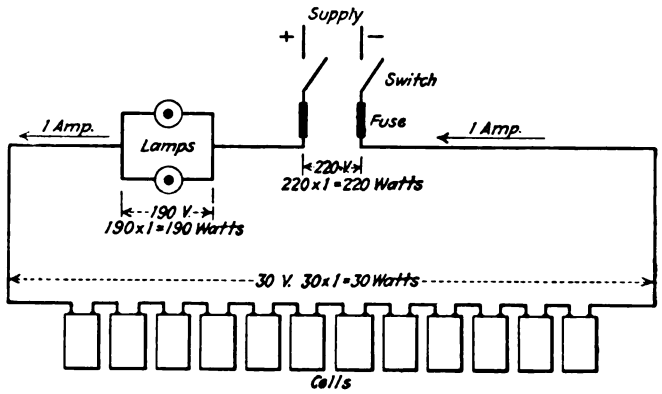

Fig. 1—Simple Charging Arrangement
Many people mistakenly think that lamps or other resistance reduce the voltage. In a case like this they merely prevent the current exceeding a predetermined limit.

a simple arrangement as shown in Fig. 1. It will be noted that the pressure of the supply is 220 volts, and twelve cells are connected for charging. The voltage of the cells in series when first connected may be between 20 and 24 volts. Obviously one or more 220-volt lamps—if more than one they will be connected in parallel—must be placed in series with the cells, the combined current of the lamps being equal to the charging current which may be assumed in this instance to be one ampere.

Now the voltage necessary to pass this current through the cells naturally must exceed that of the cells themselves, and a voltmeter connected across them when the current is passing might show 30 volts. If now the voltmeter be connected across the lamps the reading —assuming the wires have negligible resistance—will be the difference between 30 and 220, that is, 190 volts. Notwithstanding the fact that the pressure across the cells is 30 volts with current flowing, a broken connection in the batch of cells as indicated in Fig. 2 not only interrupts the current, but across the break there immediately exists the full supply voltage. It will thus be seen that a bad contact will give rise to arcing which might generate sufficient heat in the cell terminals to ignite the celluloid of one or both of the cells between which the defective contact has occurred.

Fire Destroys Celluloid Cases

Further, if there is a complete break and the cell cases and charging stand are dirty or covered with a film of acid, the full pressure of 220 volts is sufficient to cause surface leakage, and many instances are on record of the complete equipment being destroyed by fire originating from this cause.

There are circumstances, of course, in which there is no practical alternative to this method of charging. In these cases the maximum of safety from fire can be obtained only by insuring that all terminals and contacts on charging stands are cleaned and secure. The stands themselves should be free from dirt and acid. A thin layer of fish oil will give effective protection against such leakage. Still it is unwise to leave altogether unattended cells that are being thus charged.

Nor is it generally realized at British mines how ineffi-

Digitized by Google

cient is the ordinary method of charging batteries from a lighting supply. The distribution of the power consumed in the simple charging circuit of the type described is shown in Fig. 1. Now the power in watts in a direct-current circuit is equal to the product of the voltage and the current passing. Thus in Fig. 1 we have a current of 1 amp. circulating through lamps and cells. The voltage across the whole of the cells equals, say, 30 volts as shown; therefore the actual power being absorbed in charging the battery is $30 \times 1 = 30$ watts.

Across the resistance formed by the lamps there exists $220 - 30 = 190$ volts and therefore the power absorbed in this part of the circuit is $190 \times 1 = 190$ watts. Thus we see that for every single watt consumed in charging the battery, more than six watts are wasted in the resistance.

On a similar circuit with the same number of cells the proportion of power wasted remains the same regardless of the capacity of the cells and their charging current.

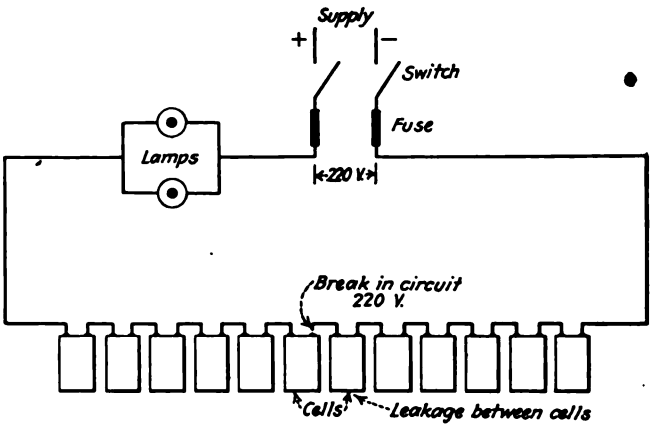
It may be argued that the whole of the energy might be utilized in a 220-volt circuit by connecting in series, where a large number of lamps are employed, a sufficient number to absorb the whole voltage and dispense with anything but a small resistance for minor adjustments.

FIRE RISK WITH SHORT CIRCUITS

It would be extremely unsafe, however, for short circuits would have serious results, and fire risks would be extremely great. In general, it may be taken that no single series of cells should contain so many units as to require in excess of about 50 volts equivalent to, roughly, 18 cells. When a large number have to be charged they should be connected in parallel groups of 18 in series. For instance, in an installation where, say, 250 cells are charged for each shift these would be connected in 14 groups, and if each required a charging current of 1 amp. the total current will be 14 amp.

To charge these from 220-volt circuit under the conditions specified would give a distribution of power consumed in charging the cells and in the resistance respectively as follows: (1) In the cells 14 amp. $\times$ 50 = 700 watts. (2) In the resistance 14 amp. $\times$ 170 = 2,380 watts. In other words the actual charging would consume per hour 0.7 kw.-hr., and would waste 2.38 kw.-hr. This does not appear much on the face of it, but if this loss continues over say 4,000 hours a year the loss would be important in these days when coal-production costs have to be reduced to the minimum.

Undoubtedly the most efficient and in the long run the most economical method of charging miners' electric safety lamp cells, is that customary in the United States and in some mines of Great Britain—by the use of the motor-generator set. Thus, if the supply is 220 volts, the set would be made up of a suitable motor to run on that voltage coupled direct to a motor giving a 50-volt current. Where, say, 250 cells are to be charged at once as in the case just considered, the energy required to charge the cells was 700 watts. If the combined efficiency of dynamo and motor is placed at 70 per cent, the motor would take about a thousand watts and, therefore, the power consumed in charging for say 4,000 hours would be 4,000 kw.-hr. as against 9,520 kw.-hr. charging direct from the supply in series with a resistance, or a saving of 5,520 kw.-hr. a year.



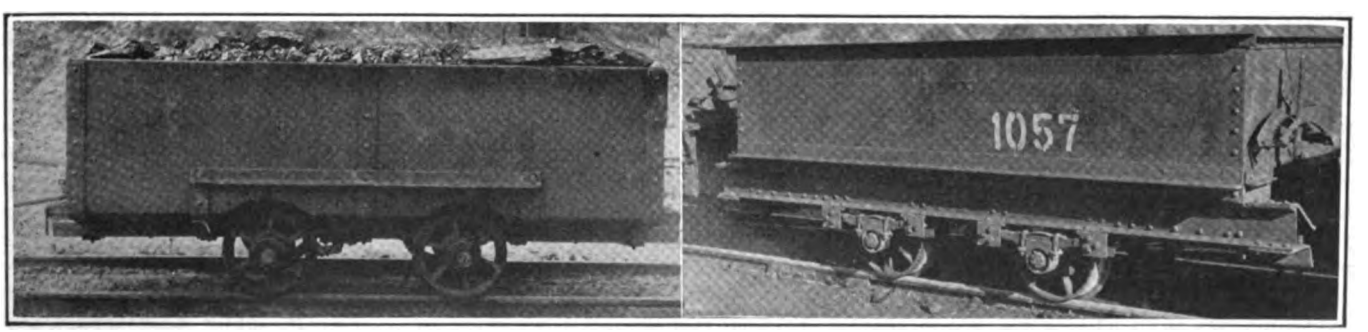


Fig. 2—Danger Develops Here

A broken connection in the batch of cells interrupts the current and across the break there exists the full supply voltage. Arcing might generate enough heat in the cell terminals to ignite the celluloid battery cases such as are often used in Great Britain.

The depreciation on a motor-generator of this kind would be small, and its cost would be saved in two or three years, depending on the cost of power. In addition the voltage would be that most suitable to the work to be performed and even with celluloid battery cases almost complete security against fire. It should be stated that with a motor-generator set similar to the one described it is necessary to connect a rheostat in the shunt field of the motor for regulating the speed and in that way the voltage generated by the motor-generator set. This is because a somewhat higher voltage is needed to maintain the full charging current when the voltage of the cells begins to build up and opposes that of the motor-generator set. This may be obtained by slightly increasing the speed of the motor generator.

Steel Cars Are Coming into Their Own in Phelps Dodge Corp. Mines

The company, which operates a group of highly modernized properties at Dawson, N. M., has put 30 of these two types of cars into service and hopes to standardize on certain styles. The one at the left has a capacity of 90.3 cu.ft. level full, and the other one of 90 cu.ft. Each type is equipped with roller bearings. That on the right is spring-mounted with spring bumpers.

Coal Not a Suitable Agent For Ice Removal

The editorial of March 4 on "Coal as an Ice Remover" should cause no undue excitement among city officials concerned with snow removal for it has no real possibilities of usefulness.

Melting snow and ice by the application of artificial heat with different types of devices seems to present theoretical possibilities which never have been realized in practice.

As a youngster I recall the elaborate snow melting apparatus at Cooper Union, New York City, way back in the winters when Colonel Waring was boss of the white wings. Heat did melt the snow and ice, but apparently it was cheaper and quicker to haul the material by trucks to the waterfront and dump it into the East River. Next season the Colonel with his white uniform and fiercely waxed mustachio told the engineers at New York University about the unsatisfactory results of tests on melting snow.

Many Unsuccessful Trials

Every time a big snowstorm blocks traffic and the newspapers reflect public impatience with street-cleaning methods, new devices and old friends in new dresses take pot shots at the impotent street cleaners trying to beat nature in her own sphere —not possible when the old lady is on a rampage.

Melting snow with steam, gasoline, fuel oil, electricity, hot water and salt have been tried time and again but with little success in New York. Salt is quite successfully used in Great Britain but climatic conditions are adverse in this country—our storms are more frequent and fiercer, temperatures before and after the storm are lower. Heat in various forms of application is a favorite panacea for "removing the snow as fast as it falls."

In reference books snow is quoted as weighing 5 to 12 lb. per cubic foot, but actually it weighs much more, so it is not safe to base any computations for heat treatment on anything less than solid ice. Again fresh snow is an excellent non-conductor, of the air-cell type and the specific heat as well as the latent heat of liquefaction of a mound of snow on the street may be quite different from that of a laboratory sample. Whether this is actually true or not, the theory that it is seems to agree with practical failures to remove snow expeditiously and cheaply by the application of heat.

Vaults Already Under Walk

Your suggestion about melting snow on sidewalks looks reasonable, casually considered, but apparently would require special and expensive new types of sidewalks because most large buildings in New York City already utilize the space under the sidewalk as vaults, many of which are heated. Sidewalk vault covers of steel supplied with heat from the building do not seem to melt snow and ice. There is something wrong with the theory of melting snow and ice by means of heat. It does not work in practice.

It would be interesting to design and estimate the cost of completely equipping two main thoroughfares in New York City for removing snow as fast as it fell. Better, however start with an outlying street without subways, water pipes, electric conduits, telephone ducts, pneumatic tubes, sewers, fire-alarm signals, etc., etc., and create a heat-conducting base and wearing surface for the pavement. No, I do not mean to be a joy killer—any possible improvement in speed and economy of snow removal in congested city districts is worthy of engineering thought and action but snow removal after all is more a matter of *organizing* and *managing available forces and equipment* than of creating special apparatus for emergency use—hardly ever justifiable economically or practically for snow removal.

New York City has drifted into the habit of spending five or six million dollars per snowstorm and why not? The newspapers recently quoted one of the District Attorney's staff as saying that half the six million was wasted or lost through grafting. Personally, I can hardly credit this statement, but it was published and nobody got "het up" over the situation. "What's the use?"

Having graduated from street cleaning to mining, I must say that the chances for expanding the coal or salt markets for snow removal do not seem to be bright, though queerer things have happened in this odd world of ours.

Trolley Installations Also Have Upkeep Charges

I read with much interest the editorial on "The Battery Locomotive," recently published in *Coal Age* and was greatly surprised to note the statement that *many* battery-equipped gathering locomotives were being converted into cable-reel type.

In my judgment the editorial is biased and not at all fair to the builders of battery locomotives or to the manufacturers of storage batteries, or even to the mining men who would take the statement as being one of fact. One would suppose from what is said that the day of the storage-battery locomotive in coal mines would soon be past; whereas the reverse is true, some of the leading coal companies of the country are doing away with trolley and reel and cable equipment and operating so-called wireless mines. In fact, such applications of battery locomotives are on the increase.

Battery Units Increasing

When the editorial remarks that "many battery equipped gathering locomotives are being converted to the "cable-reel type," it misuses the word "many." Let it be granted that there are a few isolated cases. What of that? The new equipment by far outnumbers the equipment being converted. I know of one builder of storage-battery locomotives who last year did more business than in any year since 1920.

You state the major reason for the change is the lump sum nature of the upkeep cost. I gather that you mean battery replacements. Would it not have been better to have gone a step further and explained that, by side-stepping the issue of the battery replacements, owners had better go slow or they would be jumping from the frying pan into the fire, as there are many daily operating costs which go hand in hand with reel and cable and trolley equipment. There is the constant purchase of

Digitized by Google

trolley-line material, bonds, the cost of installing the latter and the daily maintenance which this class of feeder demands. We then have an added expense of safeguarding the trolley wire at all passing points which, if not protected, will always prove a great hazard to the employees.

Eminent electrical engineers have made exhaustive tests and proved beyond doubt that storage-battery locomotives, from a power consumption standpoint, are the most efficient equipment ever designed for coal-mine service. By the use of trolley locomotives we have in most fields increased power bills and incurred a maximum demand charge. These costs coupled with the purchases of locomotive feeder cable, will ordinarily about equal the battery depreciation cost.

IS CLEANLINESS A NEW VIRTUE?

The editorial says that cleanliness is the secret of low cost of battery maintenance. Is not that the case with all classes of equipment? Why pick on the battery? As a matter of fact, a pail of water, a little soda and fifteen minutes' time, coupled with a reasonable degree of horse sense, applied each week will keep the batteries clean.

Give the battery locomotive sufficient capacity with which to do its work and I feel sure that in the majority of cases, it will win out over the reel and cable equipment, if all credits and charges are placed where they should be. One could go on further and bring out many operating features of an economic nature declaring the advantages of storage-battery locomotives over the reel and cable type, but to what end—they have been hashed and re-hashed in the very magazine that contains the editorial I am criticizing.

In conclusion, I would say that it has been my pleasure to operate fifty storage-battery locomotives for the past nine years and during that period this equipment has been the least of my troubles. Of course, the depreciation of the batteries is taken care of in a business-like way. Battery renewals are anticipated and the monthly depreciation costs allowed. Why use up the profits obtained by the use of such equipment for other purposes? Do the operators of reel and cable locomotives wait two or three years to pay their cable bills and maximum demand charges? No, they pay for them monthly and any wide-awake operator will also take care of the monthly battery depreciation in the same manner. I write this as an expression of my personal point of view and not as being an official of a coal company.

Electrical Engineer
Glen Carbon Coal Co.,
Glen Carbon, Ill.

Battery Locomotives Increasing

The editorial appearing in the Feb. 11 issue of *Coal Age* entitled "The Battery Locomotive," in my opinion is liable to be misunderstood. The actual facts on the use of storage battery locomotives, according to figures which we have carefully compiled each year, have shown that there has been a consistent increase in such equipment and the number of battery locomotives in service at the end of 1925 is 13 per cent greater than the number in service at the beginning of 1923, and, furthermore there are more storage battery locomotives in use today than at any time in the past. Tests have proved that they will gather in the same time and under the same conditions more tonnage than cable reel locomotives and at a lower cost.

QUESTIONS SUBSTITUTION

During the past year there have been few instances, found by our staff, of operators changing from battery-locomotive haulage to another system. If you know of any such instance and will make a complete investigation you will no doubt find, as we have, that the change is due either to misapplication or to gross neglect and abuse of the equipment, which is certainly not a reflection on the equipment itself. There have been a number of instances reported of mining companies changing from reel motors to battery motors. For instance, the Calumet & Hecla Mining Co. recently changed five reel gathering locomotives to battery locomotives; the Valier Coal Co. of Valier, Ill., changed two reel locomotives and we are informed that they expect to change several more before the end of the year. Reports that we have received indicate that more cable-reel motors are being changed into battery motors than is the reverse.

Don't Use Acetylene to Form Cap of Safety Lamp

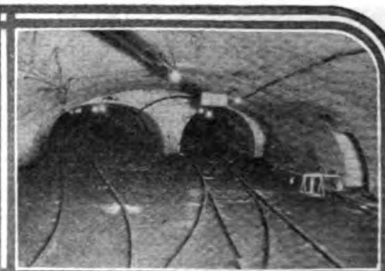
Your Feb. 11 issue of *Coal Age* on page 233, contains a short illustrated article describing an apparatus to aid in training firebosses in testing for gas. If methane were the gas to be used, the device and the idea could be heartily approved, but the use of acetylene as the testing medium introduces an unnecessary hazardous element.

The ignition point of acetylene and air is considerably lower than that of methane and air, the temperature range being 760 to 824 deg. Fahr. for acetylene and 1,202 to 1,382 deg. Fahr. for methane. Moreover, the oxyacetylene flame from 1 unit by volume of acetylene and 1.7 units by volume of oxygen has a temperature of 6,300 deg. Fahr., thus constituting one of the hottest flames that is used in industry.

ACETYLENE FLAME PASSES GAUZE

Under certain conditions, the acetylene passing through the gauze of the safety lamp will ignite and will produce a flame hot enough to heat the gauze, which in turn will ignite the gas outside the gauze but within the glass box, and an explosion will follow.

This is exactly what happened when a professor in one of our universities was demonstrating the principle of the safety lamp in a mixture of acetylene and air. The professor was knocked down and slightly injured, and the two observers were knocked across the room. The professor's apparatus differed from that described in *Coal Age*, in that a box that had contained permissible explosives was used. A small section of glass was introduced into one side of the box for observation. The explosion occurred almost as soon as the safety lamp was placed in the box, and the claim that the heat from the lamp caused the nitroglycerin absorbed by the box to explode is not worthy of serious consideration.



There will always be the hazard that a violently explosive mixture of acetylene and air may be present in the glass chamber and the introduction of the flame safety lamp is almost certain to ignite the mixture with disastrous results to those in the immediate vicinity.

Underground Operation

When Ventilation Stops, Temperature Rises, Seams Expand and Emit Gas

Gas Gathers When Fan Is Run with One Opening in Mine Closed—Steam Pipes Cut Roof—Ribs Spall with Reduced Air

By F. C. Cornet
Brussels, Belgium

Many years ago, at the time of the firedamp investigations made in Great Britain under the direction of Henry Hall, Inspector of Mines, numerous experiments were made to ascertain the influence of barometric pressure on the emission of gas at the working face. With the idea of creating an artificial atmosphere in a certain mine, the intake shaft was closed as tightly as possible by a wooden platform covered with tamped clay. The fan, an exhaust one, was kept running at its usual speed, thus maintaining unchanged the usual water gage, which was 2.36 in.

After 7 hours, when the air current had been so reduced that the anemometer did no longer revolve it was observed that the barometric pressure in the mine was only 0.157 in. lower than when the proceedings commenced. The emission of gas, however, had increased in the proportion of 235 to 100. This increase was considerably greater than the investigators had ever had occasion to observe in the same mine when, from natural causes, the mercury had fallen to the point where it was brought artificially by the means described above.

NOT DUE TO PRESSURE FALL

It is evident that a factor, not thought of at the time, added to the decrease in barometric pressure to cause the large increase in gas emission observed by the British investigators. This factor, I am now inclined to believe, was the marked increase in temperature that must have made itself felt in the mine, especially along the working faces, due to the long interruption of the ventilating current.

That an increase of temperature at the working face may result in stimulating the emission of gas would have seemed a bold assertion a dozen years back. But at the present time, the idea is being accepted by an ever-increasing number of engineers who have had occasion to gain experience in the mining at great depths of gaseous seams of coal. The following array of proved facts may convert others to the same belief. Operators of deep mines well know how variations in temperature affect the cost of maintenance of underground openings. Despite the regulating effect of a deep intake shaft, the air reaching the bottom is always warmer in summer than in winter, causing more falls of roof, more caving of ribs, more swellings of bottoms.

HEAT DESTROYS MINE

In a deep mine I know well, in the region west of Mons, Belgium, the cost of maintaining the haulways, which are all in the intake, was reduced in the proportion of 40 to 100 when electricity was substituted for steam to drive a certain underground pump. The steam was sent from the surface through a pipe placed in the intake shaft. This heated the air going down into the mine, with disastrous effects on the maintenance of the roads. That pipe is still there, but they use it only when electricity fails them.

On every such occasion, there is a prompt and marked increase in the cost of keeping the roads in good order. In other words, there is an immediate return to the old conditions. I might cite several other similar cases. One will suffice. It must be noted here that, always, when for any reason, there is an increase in the temperature of a mine, all places affected by it bear their share of the resulting trouble: the strongly timbered roadways maintained through the gob and all the other places, timbered or not, driven in solid coal, or across the measures from seam to seam.

It would certainly be a difficult matter to explain scientifically why an increase in temperature is followed rapidly by an increase in strata pressure, but whatever the unknown cause may be, its effect has, long since, been recognized.

The rapidity with which the effect follows the cause is sometimes so great that a short interruption of ventilation may result in considerable damage. The fan must be kept running at working-day speed on Sundays and idle days when no one is occupied underground. Even in time of strike, ventilation must be maintained in full, in order to keep down the temperature of the workings.

The following test made recently for the benefit of a group of mining students is not different from similar experiments made in the course of every year for the same educational purpose. Nor does it reveal conditions worse than in the majority of the mines in the Mons region.

LESS AIR, MORE GAS

The current ventilating a 360-ft. face was reduced, by short-circuiting, from 6,300 to 840 cu.ft. a minute. When the experiment began, little gas was issuing from the coal, although the seam is one subject to blowouts. The place was quiet and silent. In less than three hours, the timbers began to crack and bend, showing a heavy increase in strata pressure. The face became fissured from end to end. Gas was emitted abundantly, making a noise like that of running water. From time to time, splinters of coal, some weighing over a pound, were violently projected into the gob back of the

Digitized by Google

timbers. A student was painfully cut on the head by one of those flying missiles. Before the air current was short-circuited, a temperature of 68.6 deg. F. had been observed along the face. When the timbers began to crack, the thermometer showed 92.5 deg. F. Half an hour later, just before ventilation was reestablished in full, the temperature was 96.7 deg. F.

One hour and twenty minutes later, all was quiet again along the face, although gas continued to ooze in some abundance, but silently, from the cracked and partly crushed, coal.

This experiment shows clearly, I believe, the mechanics of the heated strata. The increase in temperature has no direct effect on the gas contained in the seam. It is the increased movement of the strata that causes the coal to act as it does. The expansion of the seam which, previously, was slow, perhaps unnoticeable, became accelerated by the increased heat and that acceleration of seam expansion resulted in an acceleration of gas emission. In a previous article, one on gas blowouts (*Coal Age* of March 1, 1923), I have shown what relation seam expansion and gas emission have to each other and why, the more rapid and complete expansion or crushing of a seam will be, more rapid and complete the emission of gas will also be.

Hazardous Way of Shooting Coal Bottoms

In many mines the lifting of "coal bottoms" or "machine scrappings" (the coal left under the machine cut) is assisted by the use of explosives. Where this is the practice, holes are often dug with a pick and in each of these may be placed from one to two sticks of dynamite, this charge being generally covered with slack. The firing of thirty to forty shots consecutively in a single place is not unusual.

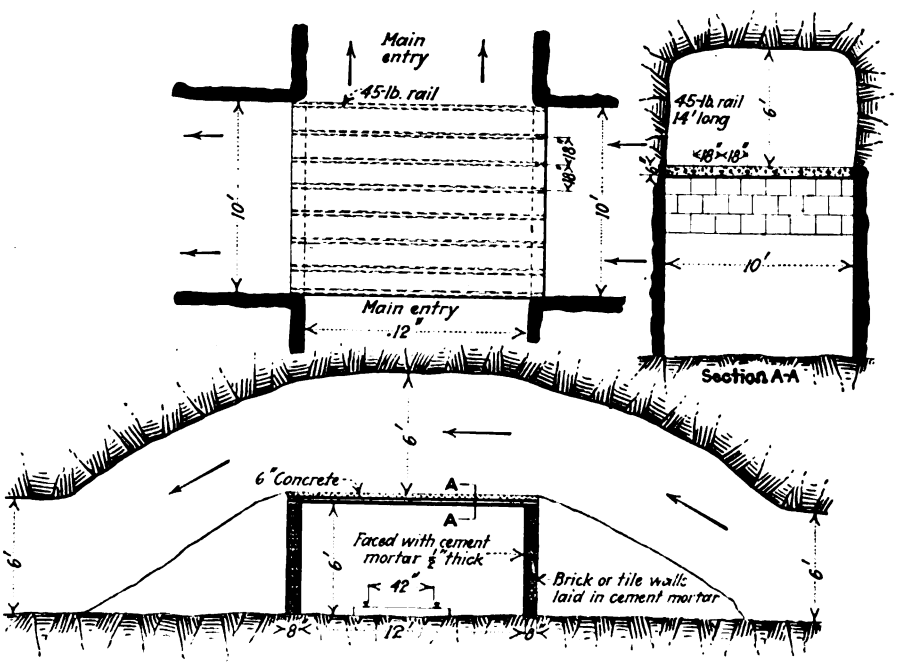
Some permissible powders when completely detonated in a drillhole, produce 158 liters, or 5½ cu.ft., of carbon monoxide for each 1½-lb. charge. Dynamite will produce several times that quantity of gas when exploded in a hole dug by a pick and lightly covered. Such shooting is scarcely to be differentiated from what might be termed shooting in the open. It is possible that 150 to 300 cu.ft. of carbon monoxide might be produced in a single place by detonation at short intervals of the number of shots mentioned. That the concussion from dynamite shots is far greater than that produced by black powder is known to be a fact.

Therefore, to a greater degree the dust in the immediate vicinity is suspended in the air. This combines with a large volume of carbon monoxide in an explosive mixture which under the circumstances is cocked and primed for an explosion. When dynamite is fired it produces more or less flame, so that it is indeed surprising that under the conditions explosions do not occur with greater frequency, particularly seeing that so many mines follow the practices described.

ONLY IF RIGHTLY USED

In the opinion of the Bureau of Mines permissible powder is permissible or safe only when properly tamped with non-combustible material and completely detonated in a drillhole. The shooting of dynamite in dug holes which are covered with dust and slack is extremely dangerous. Where bottoms or scrappings are lifted by shooting, the explosive should be placed in holes which are properly drilled and tamped with clay.

Furthermore, men should not be permitted to break slate by dynamiting in the open. Instead short holes should be drilled in the slate and these properly charged and stemmed, which practice is better and safer than shooting without confinement. I know of two explosions which were caused by what is termed "dobing rock."



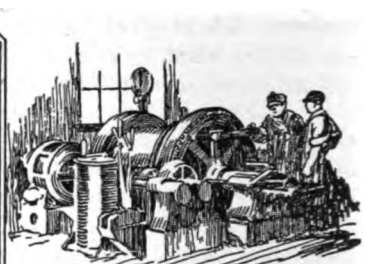
THOMAS G. HOYE.

Huntington, W. Va.

Every Mine Should Build Its Overcasts to Standard

Most mines utilize much the same kind of materials in the construction of overcasts—hollow tile or brick, mortar, concrete, steel rails and sometimes reinforcing wire mesh. But the design of overcasts varies considerably. More or less uniformity or standardization in the construction of overcasts should prevail, for the duty of these air crossovers is the same in every mine except for a difference in the volumes of air which are handled. Here are shown standard plans for the overcast construction in the mines of the Northwestern Mining & Exchange Co. near Dubois, Pa. They are so clearly detailed as to require no explanation.

The value of standards is that they prevent slovenly work by establishing a proper way to do everything by which actual accomplishment can be tested. Most overcasts need such a standard for as usually built they do much to interfere with the passage of air through the mine workings.



Standard Overcast of Northwestern Mining & Exchange Co.

Overcasts get little inspection, but they are of immense importance in mine ventilation. It is well to have a standard, so that poor work when discovered can be condemned as not according to schedule and there can be no rebuttal to the statement made. This overcast has a 6x10-ft. airway over the overcast and 6x12-ft. below. Apparently the upper airway carries only a part of the air circulating in the main roadway and does not need to be as generous in dimensions.

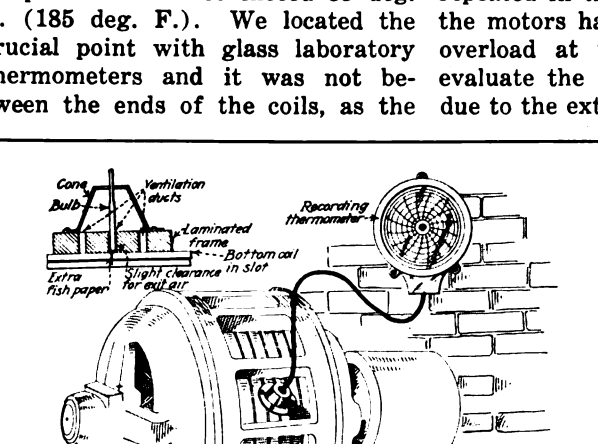
Practical Pointers For Electrical And Mechanical Men

Recording Thermometer Indicates When Load on Motor Is Safe



In our plant, says L. W. Cutler, in *Power*, there are two 50-hp. motors, which drive important machines, located where the room temperature is 40 deg. C. (104 deg. F.) in the summer and 21 deg. C. (70 deg. F.) in the winter. These machines are rated at 50 deg. rise above room temperature at full load and frequently are called upon to carry all the overload safely possible. In the winter we have little trouble, but in the summer it is evident that the over-all temperature is at the breaking-down point of the insulation. The usual method of limiting the current to full load rating or a conservative overload, by means of fuses or relays, could not be used, since the safe point would vary with the outside temperature.

Since the temperature of the hottest part of the winding was the governing factor, we located the specially shaped bulb of a recording thermometer there and told the operators to carry all the load they needed at any time, so long as the temperature did not exceed 85 deg. C. (185 deg. F.). We located the crucial point with glass laboratory thermometers and it was not between the ends of the coils, as the manufacturers suggested. The hottest point was in one of the exit ventilation ducts in the center. Here the thermometer bulb could be placed in contact with a bar in the bottom of a slot. The instrument makers made a special bulb which was a nice fit to the ventilation duct. As there must be a limited relation between the volume of the bulb and that of the tube, we limited the length of the tube to 3 in. so as to reduce the size of the bulb. At that, the smallest thermometer stuck out of the duct about 1 in.

Cone Retains Hot Air

A cone covering three ducts was fastened around the upper part of the thermometer. Thus, the protruding portion of the thermometer was bathed in the hot air coming from all three ducts.

Unfortunately, one of the motors was burned out before the thermometer was installed and the total cost of the repair must have been $350. The accident has not been repeated in three years, and I know the motors have carried 40 per cent overload at times. It is hard to evaluate the increase in production, due to the extra power available.

Recording Equipment

The hottest point was found to be in a ventilation duct. A special thermometer was built to fit it and a cone made to protect the protruding end of the instrument. Temperature is not allowed to exceed 185 deg. F.

Spare Parts for Oil Immersed Switches and Starters

After finding one plant of large size without any oil circuit breaker or starter parts worth considering, and a much smaller one with a stock of repair parts large enough for the larger plant and realizing that this condition probably arises from a lack of proper information more than from any other reason, I will here try to give some plans for checking up on spare parts and the number required.

Some men do not realize the importance of keeping spare parts on hand for even the little oil switches and starters. Many a time a delay of several hours may be prevented by having available small oil switch parts that only cost a dollar or so, each when the delay might cost hundreds of dollars, or at the rate of hundreds of dollars per day.

Power plant breakers are not opened often but they are opened under extremely severe conditions, usually on overload, and nearly always with at least full load. As they are not operated frequently no large supply of fingers and contacts need be kept on hand. The number of switches in a plant that have the same amperage capacity should be set down and each switch that is not interchangeable with the others should also be tabulated. Each individual switch for 3-pole service, which is the type most used, should have at least one spare wood connecting rod and from one to three movable contacts, this number depending on the size of the breaker and the service to which it is put. Some companies make switches that have the movable contacts cast solid. In this case it is well to supply a full set of these contacts, so that the burned ones can be removed and be built up by the welding process, after which they may be ground down to template. They may then be kept for repair parts. Of course, breakers of this type are intended for severe service such as is encountered in

Digitized by Google

rolling mills. All the stationary contacts generally burn or pit about the same time and consequently need renewal almost simultaneously. The contact fingers are fitted with springs that deteriorate and these, of course, must not be heated by welding. The number of fingers required for individual switches generally amount to a full set. It is a good idea to keep a few contact screws and bolts on hand in case any should be broken. From one to three porcelain bushings may also be kept on hand but these are seldom needed except in lightning cases. Lightning bursts bushings quite frequently especially those used in connection with large transformers.

Where a number of switches are of the same amperage capacity the number of repair parts carried per switch may be materially reduced. One complete set of contacts and two or three wood connecting rods will suffice for several switches. Of course such switches should be examined at least every three months.

INSPECT SWITCHES MONTHLY

Power plant switches should be inspected about once a month and contacts that are burned should be filed down while any that are badly damaged should be replaced, or removed and smoothed up with a mill file. The condition of the oil in the breakers has a great deal to do with the burning of contacts. Dirty oil increases arcing materially. Oil in low-voltage breakers can be strained through a clean muslin cloth and used over again, but that employed in high voltage breakers (above 600 volts) should be filtered if used a second time. Some companies put in new oil every once in awhile and use the old for lubricating slow speed line shafts and small mill bearings. However, this oil has only small lubricating value.

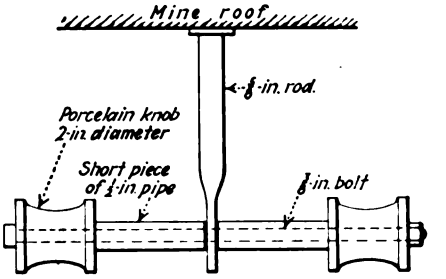
Oil-immersed auto-starters generally have more contacts than the average switch. The starting contacts as a rule pit and burn oftener than do the running contacts. In one manufacturer's equipment the movable contacts are usually of the segment type. These segments are fastened by small tapered-head screws, a supply of which should be kept on hand, because they have to carry the current and burn so badly that they are hard to loosen or tighten when replacing contacts. A full set of movable contacts also should be kept on hand as well as several fingers.

The Westinghouse company is developing a starter that has the least contact trouble of any that I have seen. This is the type "A 2 starter." With a pushing, rolling effect, the contacts on this device give little trouble. A few spare contacts will suffice for this starter, and the bolts that hold the contacts never burn.

Each new part as it arrives should be tagged with the nameplate reading of the breaker to which it is adapted as well as the number of breakers of this type operated and the circuits that they control. This facilitates repairs. It is advisable also to keep a record of parts used on switches and the dates when they were installed.

GRADY N. EMERSON.
Birmingham, Ala.

Scrap Gasoline Locomotive Used to Advantage

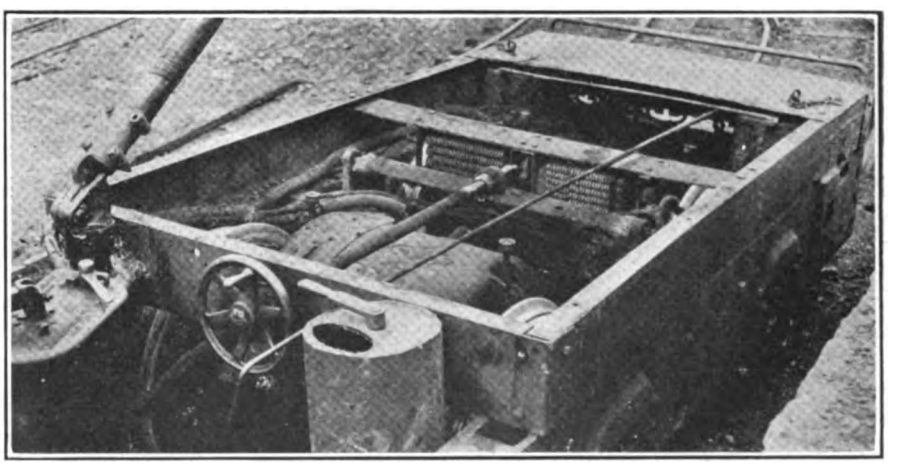


During the last three or four years much equipment has been scrapped and replaced by machines of more efficient type. This, of course, was due to the urge for lower operating cost; and the same urge has caused many companies to utilize parts which previously had been thrown into the scrapheap.

The accompanying illustration shows how the Empire mine of the De Bardeleben Coal Co., Empire, Ala., utilized an old 7-ton gasoline locomotive by installing electrical in the place of the internal combustion equipment. Two 28-hp. motors, with single-reduction gears, were mounted in the old frame.

Except for the sandbox it would hardly be suspected that the locomotive is a "half breed." This box is made from a short piece of 10-in. standard pipe. The bottom and top plates are secured in place by electric weld. The valve rod works in holes in the centers of these plates. The men at the mine are highly pleased with the performance of the locomotive and rate it as one of the best in their fleet.

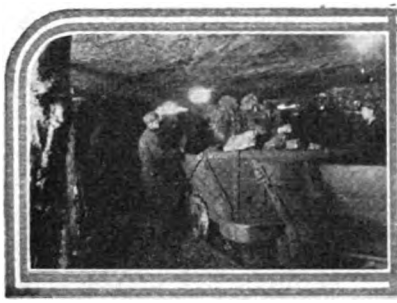
Alabama Mine Uses Neat Hanger for Wires



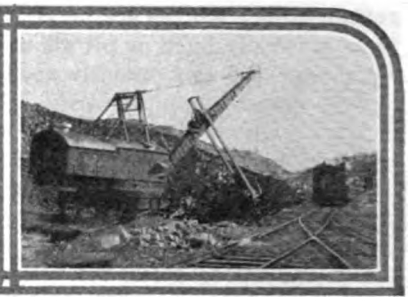
For telephone lines inside mines, bare wire seems to be used more widely than insulated. A disadvantage of using two bare wires, as compared with an insulated twisted pair, is that twice the number of insulators are required and likewise twice as many holes must be drilled unless some form of multiple hanger is adopted.

Support for Telephone Wires

This type of home-made hanger for supporting both wires from one roof bolt is used extensively in mines of the Woodward Iron Co., of Alabama.



The accompanying sketch shows the arrangement used in the Mulga mine of the Woodward Iron Co., Mulga, Ala. The hanger is fastened in the mine roof and the wires carried on grooved knobs. The ⅝-in. rod forming the center support is flattened at the lower end and a hole drilled through the flattened portion for the ⅝-in. insulator bolt. When available, scrap pipe is used to make the spacing bushings. The hanger is neat, inexpensive and serviceable.



Gasoline Equipment Replaced by Electric Motors

When an additional locomotive was needed at the Empire (Ala.) mine of the DeBardeleben Coal Corp., a scrapped 7-ton gasoline locomotive was rebuilt by installing two 28-hp. 250-volt motors. When the photograph was made the locomotive covers were removed to show the inside arrangement. Single-reduction gearing is used.

News Of the Industry

Federated Union Flops to U. M. W. As Strike for Jacksonville Scale Fizzles at Pittsburgh Coal Co.

The Federated Miners' Union of Western Pennsylvania, which was formed among employees of the Pittsburgh Coal Co. in western Pennsylvania, where the company is operating on the 1917 scale, voted to disband on March 18 and affiliate its membership with the United Mine Workers after calling a strike of its members. This action followed the alleged refusal of the Pittsburgh Coal Co. to accede to the demands of the Federated for the restoration of the Jacksonville wage scale.

Last Thursday night, officials of the Pittsburgh Coal Co. announced that the strike call would have no effect on its working forces, and this was borne out Friday morning, when a total of 1,855 men reported for work in the eight mines working, which was 10 more men than had worked the day before, when the strike was called.

The Federated Miners' Union was formed at a meeting in Pittsburgh on Dec. 22, 1925. A disavowal of allegiance to the United Mine Workers was the high spot of the organization. W. T. Harris, of Whitsett, Pa., was elected president, and John L. Hoffman of Van Meter, Pa., secretary.

P. T. Fagan, president of District No. 5, United Mine Workers, has welcomed the members of the dissolved organization into his union with open arms.

In a statement, the Pittsburgh Coal Co. said:

"The majority of our miners had refused to join the Federated Miners' Union. Any influence which Mr. Harris may have had with these men will be lost when they learn that he has delivered the organization which he formed to the United Mine Workers.

"The action of Mr. Harris in causing to be absorbed in the United Mine Workers the organization which he had formed in mines which were strictly understood to be operating independent of the United Mine Workers speaks for itself.

"The men who passed the resolutions were in no way representative of the miners working for the Pittsburgh Coal Co.

"The Pittsburgh Coal Co. permitted the official of the Federated Miners' Union to attempt to organize that union in their mines in the belief that Mr. Harris was sincere and that the miners desired an independent union. Events have proved that they do not want another union nor to pay dues to such a union.

"There can be no better proof of the utter failure of the Federated Miners' Union and its entire lack of influence among the miners than in the answer to this alleged strike call."

Secretary Hoffman, of the Federated Union, in a statement said, among other things: "The company has refused permission to the officers of the union to take up grievances in behalf of employed members and to pay the rates for extra work provided in the 1917 wage scale."

On Saturday, March 20, the company announced there were 89 more men in the mines than on previous Saturdays. On the other hand, P. T. Fagan, president of District No. 5, United Mine Workers, said that at least 500 miners in the eight mines of the company had laid down their tools and joined the union.

Ohio Operators Ask Cut In Union Wage Scale; Lewis to Defend Policy

A meeting of representatives of 200 coal operating companies in the Hocking Valley was held at Nelsonville, Ohio, on March 17 to devise ways and means of bringing about a reduction in the union wage scale in order that operations can be resumed at many of the mines in this section. Operators feel that unless a reduction is granted by the miners' union, the coming summer will see still further curtailment in production in the field. A committee consisting of Walter Wolf, Nelsonville; C. C. Sharp, Nelsonville; P. C. Morris, New York Coal Co.; N. D. Monserrat, Monserrat Bros., Columbus; O. C. Newton, Sunday Creek Coal Co., Columbus; G. S. Jones, Ohio Collieries Co., Toledo, and Dr. T. R. Biddle, Poston Consolidated Coal Co., Athens, was named to confer with John L. Lewis, president of the United Mine Workers, and other national officers in order, if possible, to obtain concessions in the scale.

Co-operation of the southeastern Ohio operators with those of the central and northern fields was recommended by W. H. Haskins, Coshocton, who reported an unsuccessful effort made by operators in the Coshocton field to get wage concessions.

The operators of the central and northern fields suggested to Mr. Lewis a return to the $5 per day wage for daymen and the selection of a central committee of miners and operators to sit in Indianapolis and telegraph prices of coal back to the mines until non-union competition of West Virginia and Kentucky was met. James R. Pritchard, formerly commissioner of the Southern Ohio Coal Exchange, desired that a conference be sought with President Lewis, believing that by such action responsibility for the future could be placed at the door of union officials.

Eastern Ohio Joins Movement

Eastern Ohio operators met at Bridgeport on March 20 and formally joined the movement to persuade the union to agree to accept a cut in wages from the Jacksonville agreement in order to meet competition from the non-union fields of West Virginia and Kentucky.

The James Paisley interests, of Cleveland, are reported to have sent a telegram to John L. Lewis, stating that unless concessions were allowed at once it would be necessary to close six mines of the company—three in Belmont County, Ohio, and the others in the union region near Morgantown, W. Va.

John L. Lewis is making a personal effort to stem the tide of dissension and rebellion against his stand-pat policy in the Pittsburgh district, advices from that field state. Philip Murray, international vice-president, recently conferred with representatives of the operators in the Ohio No. 8 field, at which time he was told of the serious plight of the Ohio operators who are bound by the Jacksonville scale. He was asked that the union do something to relieve the situation. It was at Mr. Murray's request that Mr. Lewis is taking an active personal part in the situation.

This is exactly the procedure followed a year ago, when a committee of Pittsburgh and Ohio operators requested a modification of the Jacksonville scale. Mr. Lewis at that time refused to consider the matter, and it is understood that he recently told Illinois and Indiana operators that he will give no consideration to such proposals.

The largest operator in the Pittsburgh district, the Pittsburgh Coal Co., which is running its mines on the November 1917 scale on an open-shop basis, has announced its intention of going ahead on that basis irrespective of what the union may do. A few of the mines in the Pittsburgh district that were able to operate and pay the Jacksonville scale during the anthracite strike have closed down. The Pittsburgh Terminal Coal Corp. is an exception and a few other properties are working a day or two a week.

British Coal Commission's Report Favors Labor, Says U. S. Economist; Legislation Will Be Forthcoming

By Paul Wooton
Washington Correspondent of *Coal Age*

Although the British mine workers did not get all they asked, the report of the Royal Coal Commission, if a victory for anybody, is a victory for labor. The necessary legislation to put into effect the recommendations of the Commission is sure to be forthcoming, as Premier Baldwin is said to have given assurances that he woulld put through any program on which the Commission would agree unanimously.

These are the opinions of I. Lubin, of the economic staff of the Institute of Economics at Washington. He sat through the thirty-one days of public hearings before the Commission and kept in close contact with the leaders on both sides of the controversy. A report from an eyewitness is of particular interest in this country, as the recommendations in regard to royalties are likely to be reflected in demands on this side of the ocean.

There is no thought that the British are out of the woods as a result of this report. In fact, Mr. Lubin believes they are only entering the woods. Meanwhile there seems no escape from the continuance of the subsidy for an indefinite period. Prospects favor a continuance of indirect subsidy in the form of guaranteed loans to the operators.

General Strike Now Unlikely

The only recommendation really displeasing to labor was that proposing to reduce the wages of some of the better paid workers. That some way will be found to prevent that recommendation from becoming effective is expected, although the mine workers no longer have the full sympathy of labor in other trades. They recently have lost ground materially in that direction. All danger of a general strike is believed past, although an effort to enforce the wage cuts probably would cause a walkout with the prospect of support from the railroad and dock workers.

Valuation proceedings under the report necessarily will move very slowly. Existing leases will have to expire. For these reasons none of the benefits of the recommendations, except the wage reduction, will produce any immediate economies. In the long run, however, Mr. Lubin believes large efficiencies will be effected. In fixing the terms for new leases the government should be in a position to require the use of machines to any extent it desires. The high-cost operations might even be abandoned to a large extent and where they are essential the profitable seams might be made to pay the deficit.

All of the economies of consolidation can be effected. Large savings will be made through the use of common shafts and by systematic drainage plans. In one case, for instance, three seams, one above the other, are being worked through three separate shafts. Under the proposed plan the government will have the whip hand over such inefficient operations. It will be able to put a stop to the extortions of land owners who collect large sums for running under their land, even when no coal is involved. Great savings will be effected in dictating the terms of the new leases.

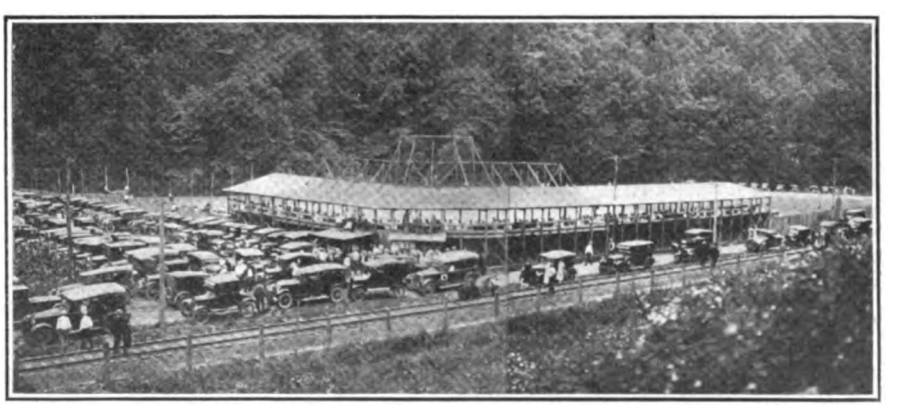
The royalty owners will fight the proposed plan to the last ditch, but their opposition is certain to be overridden. The Church of England and the Duke of Northumberland are the two largest interests that will be affected and neither has the backing of public sentiment in wanting its speculative profits protected. There is no thought that royalty owners will not receive a fair price for the present valuation of their holdings.

Another heavy expense that will be saved under the new plan will be in the elimination of the so-called pioneer lease. New seams usually are opened by prospecting companies, which then lease them to regular operators. The plan contemplates breaking up the practice of railroad-car ownership by individual mines. Decided economies in transportation can be effected by drawing all wagons from a common pool.

Heretofore it has been thought the operators were not greatly concerned with what happened to the royalty owners, but the negotiations just concluded have revealed just what is in the hearts of the operators. Under the new plan their liberty of action will be greatly curtailed. The low-cost producers naturally opposed bitterly any plan of contributing to the support of the weak sisters. The operators, without success, tried to establish before the commission that machines are being used to the extent that they are profitable. They tried to belittle the economies of amalgamation and gave the impression throughout the hearing that they have no plan of their own other than lowering labor costs which would begin to meet the situation. Their objective apparently was to maintain as nearly as possible the existing status.

Railway Fuel Men to Discuss Conservation Problems

The eighteenth annual convention of the International Railway Fuel Association will be held at the Hotel Sherman, Chicago, beginning May 8. The meeting will last three days, divided into seven sessions, at which a number of important papers and interesting committee reports will be presented.



Among the addresses on the program are the following: "Operating Factors in Fuel Conservation," by W. R. Scott, president, Southern Pacific Lines; "Engineering Factors in Fuel Conservation," H. R. Safford, vice-president, Missouri Pacific R. R.; "Mechanical Factors in Fuel Economy," C. E. Brooks, chief of motive power, Canadian National Rys. Other speakers will be President J. W. Dodge, superintendent of fuel conservation, Illinois Central R.R.; C. H. Markham, president, Illinois Central R. R.; M. L. Gould, president, National Coal Association, and Eugene McAuliffe, president, Union Pacific Coal Co., who will present the committee report on cooperation with the American Railway Association.

Committee reports will be made also on "Storage of Fuel and Oil," by Glenn Warner; "Inspection, Preparation and Analysis of Fuel," Malcolm Macfarlane, and "New Locomotive Economy Devices, Coal and Oil," E. E. Chapman.

Merger of Mine Stations Meets Opposition

The proposal to consolidate experiment stations of the Bureau of Mines has produced a decided reaction throughout the West. A large number of letters are being received by the Bureau, some supporting this recommendation of the advisory committee and others in opposition to it. These letters are being analyzed carefully, and no action on the recommendation is likely before midsummer.

Secretary Hoover probably will confer again with the advisory committee before taking final action on that portion of the committee's report. The committee probably will not be called together until the return to this country of Chairman Reynders. He probably will not be back from the Caucasus before July 1.

Baseball in the Mountains of West Virginia

This park is on the property of the Consolidation Coal Co., near Coalwood, McDowell County. The scene indicates that the life of a coal miner is not "all work and no play." Finding a level spot sufficiently large for a ball park often is very difficult in the mountain towns.

Heavy Coal Output and Outlay for Modernization, U. S. Steel Report Shows

Coal produced by the United States Steel Corporation during 1925 totaled 31,475,568 tons as compared with 27,738,007 tons in the preceding year, in increase of 3,737,561 tons, says the pamphlet report of the Corporation made public March 22. Of this tonnage 23,692,607 tons was used in the manufacture of coke and 7,782,961 tons was used for steam, gas and all other purposes. In 1924 21,041,573 tons was used in the manufacture of coke and 6,696,434 tons for steam, gas and all other purposes.

The Corporation manufactured 3,289,905 tons of beehive coke and 13,011,319 tons of byproduct coke, a total of 16,301,224 tons, as compared with 14,408,041 tons in the preceding year.

Expenditures on the Corporation's Pennsylvania coal properties for electrification aggregated $1,008,263. Additional outlays covering a wide range of improvements were made in this field and in the Pocahontas, Kentucky and Illinois fields for modernizing and economizing the cost of operations, says the report. Purchases of sundry additional coal and timber areas were made in the Pennsylvania, Illinois and Alabama fields, at a total expenditure during the year of $881,460.

The employees on the coal and coke properties of the Corporation numbered 25.920 during 1925 as compared with 26,054 in 1924, a decrease of 134.

The value of coal, coke and other fuel as inventoried on Dec. 25, 1925, was $11,546,885 as compared with $12,153,798 on Dec. 31, 1924.

The Corporation owns 438,354 acres (bed area) of coking coal, 320,495 acres (bed area) of steam and gas coal; 16,427 beehive coking ovens, of which 13,305 are active and the balance inactive, and 3,284 byproduct ovens.

Engineers and Operators To Co-operate in Research

Co-operation of the mechanical and the mining engineers of the country, through their national organizations, with bituminous coal operators in research work designed to bring substantial benefits to coal producers and consumers is planned through a committee appointed last week consisting of Dr. H. Foster Bain, secretary, American Institute of Mining and Metallurgical Engineers; Harry L. Gandy, executive secretary, National Coal Association, and Calvin W. Rice, secretary, American Society of Mechanical Engineers. Walter Barnum, president of the Pacific Coast Coal Co., Seattle, Washington, was authorized to name this committee at a meeting in New York of officials of the two engineering societies and the National Coal Association.

The research program to be outlined by this committee will embrace the outstanding problems of the coal industry and will deal with the development of the mechanization of coal mines, which is a significant movement in the industry on the score of economic and social considerations, as well as from engineering and operating viewpoints.

Hoover Cites Importance Of Foreign Trade

"The immediate purpose of those engaged in foreign trade is remunerative adventure for the trader," said Herbert Hoover, Secretary of Commerce, in an address at New York City, March 16. "But it has a far wider national importance than this and the men engaged in it are engaged in a far more significant mission.

"Foreign trade has become a vital part of the whole modern economic system. The war brought into high relief the utter dependence of the life of nations upon it. The major strategy of war is to crush the enemy by depriving him of it. In peace time our exports and imports are the margins upon which our wellbeing depends. The export of our surplus enables us to use in full our resources and energy. The creation of a wider range of customers to each production unit gives to that unit greater stability in production and greater security to the workers.

"And we may quite well view our exports from the other side of the trade balance sheet. They enable us to purchase and import those goods and raw materials which we cannot produce ourselves. We could probably get along as a nation if we had to suppress the 7 to 10 per cent of our production which goes to export but our standard of living and much of the joy of living is absolutely dependent upon certain import commodities."

Railroads Save $46,000,000 On Coal in 1925

The average cost, including freight charges, of coal used by class 1 railroads of the United States in locomotives in transportation train service during December was the same as during the preceding month, according to a statement prepared by the Bureau of Coal Economics of the National Coal Association from monthly reports furnished by the railroads to the Interstate Commerce Commission. The average cost by districts was as follows: Eastern district, $2.66; Southern district, $2.20; Western district, $2.93; entire United States, $2.63. In comparison with similar averages for December, 1924, there was a decrease of 20c. per ton in the Eastern district, 17c. per ton in the Southern district, 16c. in the Western district, and 19c. in the country as a whole.

The average cost per ton of locomotive coal, which represents the invoice price at the mine, plus freight charges, during the year 1925 was $2.72 per net ton, a reduction of 31c. from the year 1924. As the railroads in the United States during the year 1925 consumed at least 150,000,000 tons of bituminous coal, it is apparent that the bituminous coal industry contributed the round sum of $46,500,000 to the prosperity of the railroads during the past year.

Grant to Address Retailers At New England Convention

Richard F. Grant, president of the Susquehanna Collieries Co. and the man who succeeded in bringing operators and striking miners together when all other efforts to end the anthracite strike had failed, will be the featured speaker at the annual convention of the New England Coal Dealers' Association to be held at Worcester, Mass., April 7-8. Mr. Grant will talk on "Clear Thinking."

Harry L. Gandy, executive secretary, National Coal Association, will make his début before the New England retailers at the same convention. Another speaker will be C. Willing Hare, vice-president of the Anthracite Coal Service, who will match Mr. Gandy's bituminous address with a talk on what the anthracite industry is doing. "Loss and Damage Claims" will engage the attention of Col. A. N. Payne, of the Boston & Maine R.R. Harry E. Davis, national councilor of the New England association, will discuss the work of the Chamber of Commerce of the United States.

The headquarters of the association during the convention will be at the Hotel Bancroft, where the annual banquet, presided over by William A. Clark, president of the organization, will take place. The business sessions will be held at the State Armory.

Research Study at Illinois

Applications for appointment to research graduate assistantships maintained by the Engineering Experiment Station of the University of Illinois will be received until April 1. Appointees receive an annual stipend of $600 and freedom from all fees except matriculation and diploma fees, graduates of approved universities and technical schools who are prepared to undertake graduate study in engineering, physics or applied chemistry being eligible.

Research graduate assistants devote one-half time to engineering research and the remainder of their time to graduate study. The training they receive gives excellent preparation for engineering teaching, engineering research and the profession of engineering. Additional information may be obtained by addressing M. S. Ketchum, director, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Merritt to Address Retailers

The speakers at the banquet to be held in connection with the eighth annual sectional meeting of the New York State Coal Merchants Association, New York group, this evening (March 25) at the Hotel Pennsylvania, New York City, will be Walter Gordon Merritt, general counsel for the Anthracite Operators Conference, and Captain Irving O'Hay, U. S. A., retired. The meeting will open with a luncheon at 1 p.m. at which the speaker will be Martin King, of Alabama. The program for the business session to follow was printed in *Coal Age* of March 18 (p. 406).

Comprehensive Program Arranged For American Mining Congress and Machinery Exposition at Cincinnati

All sails are set and the course plotted for the Cincinnati meeting of the American Mining Congress, May 24 to 29. As in former years the National Exposition of Coal Mining Equipment and Machinery—at which will be exhibited new and improved mine equipment of all kinds—will be staged in conjunction with the meeting. Operating officials and bosses representing every live coal company in the country, who will make the trip to Cincinnati this year for the big event, will find available a greater wealth of information than ever on developments in equipment and operating practices.

The meetings will be devoted to practical discussions of conveyors, loading machines, mine layouts, roof control, transportation with reference to track and mine-car design; cutting and shooting, drainage and safety problems, including rock-dusting and the sealing of mine fires.

The problems which will be discussed have been chosen by the operators themselves. The entire country was canvassed for suggestions as to topics and speakers, under the direction of Newell G. Alford, of Pittsburgh, who is secretary of the program committee. This committee is composed of operating officials from each of the major coal-mining states, headed by George B. Harrington, president of the Chicago, Wilmington & Franklin Coal Co., as chairman. A meeting of representatives of this committee was held in Pittsburgh on March 20, at which the returns of the canvass were reviewed. From them were chosen those topics which were thought to have the greatest appeal to the majority of those who will go to Cincinnati. In the absence of Mr. Harrington the meeting was presided over by Ezra Van Horn, general manager of the Clarkson Coal Mining Co., of Cleveland, Ohio.

Will Discuss Drainage

The exposition will open on Monday, May 24, and the meeting on Tuesday, both continuing until Friday, May 29. The first session on Tuesday will deal with mine drainage, at which the following topics will be discussed: "Relation of Mine Drainage to Stream Pollution"; "Costs of Correcting and Rendering Harmless Drainage from Coal Mines"; "Economic and Legal Aspects of Stream Pollution"; "Restrictions of Stream Pollution." The chairman of this session will be Samuel A. Taylor, president of the American Institute of Mining & Metallurgical Engineers.

The Tuesday afternoon session will be devoted to the following topics on the cutting and blasting of coal: "Recent Experiences in Shearing and Blasting;" "Blasting Coal for Mechanical Loading—Cutting and Shooting Practices Designed to Facilitate Machine-Loading through Elimination of Refuse in Shot-Down Coal"; "Shooting with a Gas Cartridge"; "Results from Cushion Blasting." W. L. Affelder, assistant to the president of the Hillman Coal & Coke Co., will preside at this session.

All day Wednesday will be assigned to mechanical loaders and their application. Under the chairmanship of Eugene McAuliffe, president of the Union Pacific Coal Co., the following topics will be discussed in the morning: "Progress in Mechanization of Coal Mines"; "Mechanical Loaders That Have Operated Successfully at the Face and Their Operating Costs"; "Typical Machine-Loading Failures and Reasons Therefor"; "Methods of Adapting Present Standard Mining Systems for Best Results with Mechanical Loading"; "Getting Mine Cars to and from Mechanical Loaders."

To Study Machine Loaders

James Elwood Jones, general manager of the Pocahontas Fuel Co., has been chosen as chairman of the Wednesday afternoon session, at which these topics will be discussed: "Suggested Procedure for the Small Mine Investigating Possibilities of Machine Loading"; "Methods for Mining Thin, Flat Seams with Mechanical Equipment"; "Mechanical Loading in Rooms and Entries," including discussions of (a) "Driving Narrow Places in Thick Seams with Loading Machines" and (b) Recent Developments in Machine Loading Equipment and Applications"; "A Symposium on Mechanical Brushing of Top and Bottom Rock in Entries."

The Thursday morning session, under Dr. L. E. Young, general manager of the Union Collieries Co., will cover the following problems of underground conveying: "Inside Mine Conveyors"; "Mechanical Conveying of Coal from the Face Which Has Reduced Mining Costs"; "Underground Conveyors in Use with Mechanical Loaders"; "Mining Plans for Different Types of Conveyors"; "Conveyors in Longwall Work —Adaptation of European Underground Conveyor Practice to American Mines."

Safety of mines will be the general theme of the Thursday afternoon session, with J. J. Rutledge, chief of the Maryland Department of Mines, as chairman. Rock-dusting and the sealing of mine fires will be covered by the following topics: "Proven Advantages of Rock-Dusting"; including discussions of (a) "Successful Application of Rock-Dusting" and (b) "Recent Manifestations of Rock Dust in Checking Coal Dust Explosions"; "Sealing Fires in Gaseous Mines." This general topic will be broken down into three parts: (a) "Current Practices," (b) When the Fire Is Small" and (c) "Territory Required."

Howard N. Eavenson, consulting engineer, will preside over a session on Friday morning, at which the following topics on roof control and mining methods will be discussed: "Elements of Roof Control"; "Roof Control on Long Faces"; "Long Face Mining with Jacks"; "Control of Roof in the Eagle Seam" (this seam, in West Virginia, is overlaid by a very rotten shale, than which few roofs are worse); "Recent Developments in Roof Control."

The last session, on Friday afternoon, will cover underground transportation. A. R. Beisel, general manager of the Island Creek Coal Co., will be asked to serve as chairman of this session, which will include the following topics: "Planning Track Layouts —Importance of Good Track"; "Track Work Details and Maintenance"; "Selecting a Mine Car Design"; "Control of Long Hauls—Electric Gathering and Haulage in General"; "Comparative Costs of Mule, Storage-Battery and Cable-Reel Gathering."

All Will Hear Easily

Incidental arrangements are being made to alleviate some of the disadvantages of the ordinary convention. Speakers will be asked to deliver their talks from notes. Microphones will be installed to carry every word clearly to all corners of the convention hall. A film on rock-dusting which was taken by the Chicago, Wilmington & Franklin Coal Co. in its Orient No. 2 mine will be shown for the first time in public and a new film on mine safety, prepared by the Peabody Coal Co., also will be presented. An informal dinner will be held on Thursday evening, at which a prominent speaker will cover some important phase of the industry.

Fuel-Oil Tax Disallowed In British Columbia

The coal mining industry of Vancouver Island in particular, and of British Columbia, as a whole, received a sharp setback on March 10 when Justice Morrison in the Supreme Court of British Columbia, pronounced the fuel-oil tax to be *ultra vires* (beyond power) of the provincial Legislature. In 1923 the provincial Legislature enacted a bill providing for the imposition of a tax of one-half cent per gallon on all fuel oil purchased in British Columbia, and the tax went into effect at the beginning of 1925. Though the tax ostensibly was enacted as a revenue measure, there is a belief in some quarters that it was brought forward at the behest of the mine operators and miners of Vancouver Island, who had been feeling keenly the competition of foreign fuel oil. The Canadian Pacific Ry. and the Union Steamship Co. of British Columbia, the two largest users of feul oil in the Province, resisted the tax on the ground that it was illegal, whereupon the Attorney General brought action in the Supreme Court against the two companies to enforce payment.

Since the imposition of the tax the government has collected $206,000 from it, but had the defendants in this case paid the tax it is said that more than $400,000 would have been collected.

Canadian Committee to Probe Coal Supplies

A special committee of the Dominion House of Commons will investigate Canadian supplies of anthracite and bituminous coal. A resolution by J. E. Armstrong, Conservative, of East Lambton, to this effect was adopted after a heated discussion March 17. There was reference to the coal movement from Alberta. Charles Stewart, Minister of the Interior, spoke of the recent conference on the freight rate on Alberta coal, remarking that the provinces seemed to be unable to agree on the matter.

T. L. Church, of Northwest Toronto, charged that Sir Henry Thornton, president of the Canadian National Rys., was one of those responsible for failure to get Canadian coal into the central Canadian markets. Mr. Church declared that the proposal to raise the rate for bringing Alberta coal to Ontario from $7 to $9 a ton was nothing but one more victory for "The American coal baron." Mr. Church urged an embargo on imported coal.

W. F. Maclean (Conservative, South York), advised Nova Scotia to nationalize her coal mines, cut the profiteering out of production and apply it to the reduction in the price of coal. He thought that Ontario and Quebec would be willing to make a contract for Nova Scotia if this suggestion was followed.

Charles Stewart, Minister of the Interior and Mines, said the government would welcome such an investigation because it would clear up many misapprehensions about the fuel situation. He was not sure that he could agree that the time had come to nationalize Canada's coal mines. It would be a solution for many problems if central Canada could be supplied with coal from eastern and western Canada. He pointed out that the development of water power in central Canada and also the growing tendency to use oil were cutting into the demand for coal.

New Chicago Coal & Dock Co. Ready for Business

The South Chicago Coal & Dock Co., having offices at 39 South LaSalle St., Chicago, which was incorporated with a capital of $750,000 a few weeks ago, will soon be in active operation. The company has purchased from the Hedstrom-Schenck Coal Co. its dock property at 95th St. and the Calumet River, having an area of 470,000 sq.ft., and will install modern coal-handling machinery. Avery Brundage is chairman of the board; D. S. Harding, president, and T. F. McCarthy, manager of sales.

The Great Lakes Transportation Co., Valley Camp Coal Co. and the George Hall Coal & Transportation Co. are allied with the new concern, guaranteeing it not only dependable sources of coal but also its transportation by water to Chicago. Subscribers, according to a statement by the company, include James Playfair, president of the Great Lakes Transportation Co. and the George Hall Coal & Transportation Co. and vice-president of the Valley Camp Coal Co.; James Paisley, president of the Valley Camp Coal Co., and C. W. Kraft, president of the Kraft Shipbuilding Co. and the Kraft Coal & Fueling Co.

Trust Problem Looms as Tendency to Merge Grows

An increasing tendency on the part of American business to combine and consolidate gives evidence that this country is on the verge of a trust problem, and vastly adds to the labors of the Department of Justice, Assistant Attorney General E. F. Myers, told the House Appropriations Committee Feb. 26 in the course of hearings on the Department supply bill before the House Appropriations Committee.

"You can not pick up a paper without reading of some merger in business," he said. "And, as you know, unless it appear that the merger would result in restraint of trade within the decision in the steel case, or unless it is brought about by stock acquisition which results in elimination of competition between two companies within the meaning of Sec. 7 of the Clayton act, there is not now any legislation covering the situation.

"Whether the people of the country want Congress to provide against that sort of merger is something outside our province. I know that we have been criticized, but, with the arms at our command, I think we are doing everything the law enables us to do."

Canada Coke Output Mounts Slightly in January

Output of coke in Canada advanced to 155,700 short tons in January, 1926, as compared with 152,173 tons in December, and 101,132 tons during January, 1925, according to a report to the Department of Commerce from Assistant Trade Commissioner Walter J. Donnelly, Montreal. Ovens in the Providence of Ontario led with a total production of 74,655 tons followed by those of eastern Canada, which reported an output of 60,510 tons.

Imports of coke into Canada during January last totaled 114,724 tons as against 131,276 tons in December. Exports aggregated 3,237 tons, the apparent consumption in Canada during January being 267,187 tons, a decrease of about 4 per cent from the previous month, when 279,048 tons was used.

Of the 239,750 tons of bituminous coal used for coke making in January, 150,520 tons was imported, against the use of 89,230 tons of Canadian bituminous coal.

Navy Seeks Coal Bids

Proposals for the supply of 2,000 net tons of run-of-mine bituminous coal for the naval air station at Pensacola, Fla., will be opened at noon April 1 by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C.

Three West Virginia Firms in $2,500,000 Merger

Three West Virginia coal firms, the Blue Ridge Coal Co., of Brush Creek, Boone County; the Swiss-By-Product Coal Co., of Swiss, Nicholas County, and the Export Coal Co., of Quinnimont, Fayette County, have been consolidated, according to an announcement made in Charleston on March 19. The new company will operate under the name of the Superior Fuels Co., and the capital stock will be $2,500,000,

The combined production will aggregate 4,000 tons a day. The coal produced at the Blue Rridge plant will be disposed of to malleable iron and clay product plants; the output of the Swiss company mine will be consumed by yard interests in the northwest and the Export mine will ship its coal to consumers in New England. Those in charge of the consolidation say the entire output is already provided for.

T. S. Jones of Steubenville, Ohio, is president and J. Jay Ross, of Huntington, is the operating manager. A. D. Williams, former state highway commissioner of West Virginia, will be consulting engineer for the company, with offices in New York City. He conferred with the company officials in Charleston on March 19.

The addition of several Pennsylvania mines is said to be contemplated.

Still No Illinois Machine Scale

A meeting of the joint committee of Illinois coal operators and representatives of the United Mine Workers was held at the Great Northern Hotel, Chicago, on March 17, for the purpose of working out an agreement on wages to be paid operators and helpers on loading machines. The meeting was of brief duration and no announcement was made at its conclusion except that another conference would be held at an early date.

Eccles Inquest Postponed

The inquest on the explosion of March 8 at Mines Nos. 5 and 6 of the Crab Orchard Improvement Co., near Eccles, W. Va., has been postponed from March 24 to April 7 because of delay in cleaning up the mine. Sixty-five feet of concrete partition between intake and return airways was shattered by the explosion and ventilation has not been restored to more than a quarter of the mine, which probably will be in operation again in a month.

The Anthracite Operators' Conference on March 18 elected the following officers and committees for the coming year: Chairman, Samuel D. Warriner; Vice-Chairman, Danel T. Pierce; Committee on Economics, W. H. Williams, Allan C. Dodson, Thomas Dickson, G. N. Wilson, C. S. Goldsborough; Committee on Labor, W. J. Richards, C. F. Huber, W. W. Inglis, E. H. Suender, A. M. Fine; Committee on Publicity and Education, Percy C. Madeira, W. J. Richards, Eliot Farley, J. M. Humphrey, J. L. Cooney; Committee on Public Relations, W. S. Jenney, C. F. Huber, Otis Mouser, A. B. Jessup, S. B. Thorne.

News Items From Field and Trade

ALABAMA

The Chickasaw Shipbuilding & Car Co., a subsidiary of the Tennessee Coal, Iron & Railroad Co., is reported to have been awarded a contract for 1,000 hopper coal cars as its proportion of the recent heavy equipment contract let by the Southern Ry. The Birmingham plant of the Virginia Bridge Co. will build a large number of steel underframes also.

The Alabama By-Products Corporation is installing electric lights and water connections throughout its camp at Flat Creek, in the western part of Jefferson County. It is reported that the company will build a number of new dwellings for its employees at this operation.

Frank H. Crockard, president of the Woodward Iron Co.; Howard J. Thomas, general superintendent of the Sloss-Sheffield Steel & Iron Co., and Frank G. Morris, general superintendent of coal mines of the Republic Iron & Steel Co., compose the program committee for Alabama in the assignment of papers to be read before the Cincinnati meeting of the American Mining Congress, May 24 to 28. A large delegation of mining officials, mining and mechanical engineers and others interested in the mining industry from the Birmingham district will attend.

Two Joseph A. Holmes safety chapters were organized at Flat Top convict mine of the Sloss-Sheffield Steel & Iron Co. on March 14 by representatives of the U. S. Bureau of Mines, Alabama Mining Institute and State Mining Department at the request of the State Convict Board. The white chapter, which was named the Jones G. Moore Chapter, has 92 members, and the negro chapter, named the C. R. Davis Chapter, has 422 members.

ARKANSAS

Owners of the Ohio mine, on Hall mountain, have installed pumping machinery and are pumping the water out of the mine in preparation for resumption of mining this spring.

The engine and boiler rooms of Western Coal & Mining Co. mine No. 6, at Denning, were blown up by dynamite early the morning of March 16. The mine had been operated since Aug. 4, 1925, under lease by C. L. Melton, with non-union labor. Ten sticks of dynamite, unexploded, were found beneath the cylinder of the shaft engine.

Fire, believed to have been of incendiary origin, destroyed the coal tipple, warehouse and several cars of coal of the Bernice Anthracite Coal Co., at Russellville, last week with a loss of $100,000.

ILLINOIS

Mine No. 1 of the Chicago, Wilmington & Franklin Coal Co., known best as "Old Orient," and Mine No. 1 of the Bell & Zoller Coal Co., two of the largest in the southern Illinois field, have resumed operations after having been shut down for several weeks. Old Orient is located at West Frankfort and had been closed down for four weeks while undergoing repairs. It employs 1,000 men. The Bell & Zoller mine closed down apparently for the season several weeks ago. It will employ its 1,100 workers on a 40-per cent basis for the time being.

One of the largest operations in the Madison County district, the Lumaghi Coal Co. mine No. 2, at Collinsville, which employs about 1,200 men, is working only one day a week at present.

The shaft at the No. 1 mine of the Mt. Olive & Staunton Coal Co. caved in early this month, and as a result the hoisting tower is a wreck.

The Marion & Eastern R.R., a coal road from Marion to Paulton, a distance of 12.5 miles, is to be sold to the Missouri Pacific and operated as a part of that system. A contract for the sale has been entered into by the Missouri Pacific and H. E. Barber, principal owner of the Marion & Eastern. The Interstate Commerce Commission and the Illinois Commerce Commission will be asked to approve the transaction. The Marion & Eastern is about fifteen years old and had been operated profitably until recent months when the excessive cost of shipping coal over two roads forced several of the mines served by the road to cease operations. With direct rail facilities into the St. Louis market, however, it is expected that these mines will resume.

The Radium Coal Mining Co., Belleville, which is supposed to be a subsidiary of the Aluminum Ore Co., is expected to suspend operations April 1, unless the miners will permit the loading machines in the mine to operate the same as in other mines in that district, because the company can buy coal cheaper from the non-union West Kentucky fields than it can produce it.

The Lumaghi Coal Co., of St. Louis, is reported to have announced that it will give preference to the sale of non-union west Kentucky coal over that of its own union mines in Illinois.

INDIANA

One hundred and eighty-six employees of the Old Knox Coal Mining Co., of Bicknell, now in the hands of a receiver, have filed suit in Circuit Court at Vincennes to foreclose workmen's compensation liens on the mine property to recover their wages for the last two weeks worked. The total indebtedness of the company to its employees is more than $16,000.

KANSAS

May 22 was selected as the date for the annual Kansas first-aid and mine-rescue meet at a meeting of operators, miners and state mine officials in Pittsburg, March 10. The meet will be held on the athletic field at the Kansas State Teachers' College, Pittsburg. Teams already are being organized.

Central Coal & Coke Co.'s mine No. 51, in the southeastern Kansas field, was closed March 12 as a result of the weak demand. The mine employed more than 300 men. The Central company now has only one shaft—No. 45—operating in Kansas.

KENTUCKY

The Kentucky Legislature of 1926, which adjourned on March 17, treated the coal industry quite well. Bills to place a tonnage tax on coal, a washhouse act for mines, and other adverse legislation were killed in committees as a rule, or didn't get very far. One bill killed a few days ago provided for the creation of a boiler commission to inspect boilers, with a fee system to inspectors, which would have been costly to boiler owners, especially those who have insurance and obtain inspection as a part of the insurance service.

Through suit filed in the federal court at Hazard Judge Cochran on March 16 named John P. Gorman as receiver for the Kentucky River Coal Mining Co., operating at Heiner.

Politicians have been making a hard fight in the U. S. Coal & Coke Co.'s privately owned town of Lynch, in Harlan County, a bill having been introduced in the Legislature to force incorporation of the city, on the ground that the company controls the votes of its workers, numbering several thousand.

The Elk Horn Coal Corporation had a record production of 2,082,408 tons and the highest net income since 1920 of $311,802, equal to $2.37 a share (par $50) on $6,600,000 preferred stock in 1925. Output was 774,322 tons, or

Digitized by Google

60 per cent above 1924 and 628,182 tons, or 43 per cent above the previous record year of 1920, and net income compared with 38,445, equal to 29c. a share on preferred in 1924. With 401,271 tons mined by lessees, total tonnage produced from Elk Horn properties in 1925 was 2,483,679 tons, compared with 301,524 tons mined by lessees and aggregate tonnage of 1,618,-612 tons in 1924.

In western Kentucky the Monro Warrior interests have plans for a big new power house, and additional equipment at both strip and underground mines for getting out larger production at smaller cost.

It is reported from eastern Kentucky that the Elkhorn, Jr., Coal Co., at Millstone, is completing a modern new tipple and installing other equipment for larger production.

J. L. McCormick, of the Mineral Development Co., of Philadlephia, recently was in eastern Kentucky, inspecting company properties in Letcher County, but no announcement was made regarding any development plans.

The Dawson Daylight Coal Co., of Louisville and Dawson Springs, organized three or four years ago and running coal from strip mines for more than a year, has rebuilt a burned tipple, and also is developing some underground mines to reach coal in the deeper veins and not practical to mine by stripping.

MISSOURI

Howard & Sons, of Prairie Hill, are to open up a mine near Salisbury soon. A 4-ft. seam of coal, within a mile and a half of Salisbury on the Wabash Glasgow branch, is to be mined. Workmen are busy sinking a 154-ft. shaft. Howard & Sons subleased the property from R. E. Davis, of Salisbury.

St. Louis coal men are working on plans for a Coal Research Bureau in an educational campaign to present to the public facts about coal as a fuel and to develop other measures that will give to the coal user information as to proper sizes and consuming conditions.

OHIO

M. S. Connors, general manager of the Hocking Valley Railway Co., announces that 2,700 loaded cars of coal are at Walbridge, adjacent to the Toledo docks on his road waiting for the resumption of loading for lake traffic. Ample bottoms to take care of this tonnage have been tied up at the Toledo docks during the winter and these will be loaded ready to move when navigation is opened. It was feared that the recent cold spell might cause the formation of additional ice in the upper passages, but reports show that conditions are good and it is belived that lake traffic can be opened to the head of the lakes by April 15, which is the tentative date set for the opening.

The North Hill Coal Co. has closed its mine near Chauncey, which gave employment to about 150 miners. The mine will remain closed until market conditions warrant its reopening.

Homes of Employees of the Kingston Pocahontas Coal Co., W. Va.
This inviting location affords the employees of the Kingston Pocahontas company's Exeter Collieries a delightful environment for their homes. The buildings are of brick construction and modern in every respect.

PENNSYLVANIA

At the Pennsylvania Coal Mining Institute meeting in Johnstown on March 19, Edward H. Johnson, mining engineer, of Columbus, Ohio, delivered an address on mechanical mining and loading. His lecture was illustrated with lantern slides. The annual banquet will be held on May 20. Archie Miller, Loyalhanna Coal Co. superintendent at Cairnbrook, was elected president, succeeding Charles Enzian, of the Berwind-White company, of Windber. William Flemming, of Riverside was re-elected secretary and F. J. McKernan was retained as his assistant. The vice-presidents are D. J. Boyle, Penn Public Service Corp., Johnstown; B. C. Leonard, South Fork; Nicholas Evans, Johnstown; A. C. Cook, Windber. Vincent Stanton of Johnstown is treasurer.

The Westmoreland Coal Co. for the year ended Dec. 31, 1925, reports surplus of $745,728 after charges, taxes, depreciation and depletion, equal to $3.73 a share earned on $10,000,000 capital stock (par $50). This compares with $38,520, or 19c. a share, in 1924.

Joseph J. Walsh, Secretary of the Department of Mines, has announced a special examination for candidates for appointment as anthracite mine inspectors to be held at Wilkes-Barre on March 30, 31 and April 1. The special examinations are to be held because none of those who took examinations recently qualified for inspector. At the present time there are seven inspectorships in the anthracite region vacant.

James M. Black, Ellsworth, has been appointed a mine inspector in the State Workmen's Insurance Fund board, Richard H. Lansburgh, Secretary of the Department of Labor and Industry, has announced. The work has to do with the insurance plan. The appointee is not an anthracite or a bituminous mine inspector.

In the will of the late Mrs. Eckley B. Coxe, known as the "angel of the coal fields," further provision was made for the future of the Freeland Mining and Mechanical Institute. This institute was founded by Mr. Coxe with the idea of giving miners' sons a chance to rise in the world. When it first opened there were only four students enrolled. Now there are 170. Prof. W. R. Bray, formerly of Lehigh University, is in charge of the Freeland institute.

George J. Cochran, of Johnstown, a stockholder in the Conemaugh Coal Mining Corp., on March 6 petitioned the court at Ebensburg for the appointment of a receiver for the company. The court named the Johnstown Trust Co., the Title Trust and Guarantee Co. and Attorney John H. Stephens. In his bill Mr. Cochran sets forth that in an effort to finance the company certain indebtedness is about due; that if payment of this indebtedness is pressed at this time it will necessitate the closing of the mines, with great loss to the stockholders. He believes receivers will be able to put the company on a firm financial basis.

The Pittsburgh Coal Co. reports a new peak in weekly output from the eight mines in western Pennsylvania working on the 1917 scale. In the week ended March 13 a total of 36,246 tons was produced. A maximum daily production of 6,668 tons was attained during the week.

The report on Pittsburgh river transportation for February by United States Engineers shows that 1,469,004 tons of coal was moved on the Monongahela River in addition to 33,465 tons of coke; on the Ohio River in this district, 152,994 tons of coal and on the Allegheny River, 13,900 tons of coal.

Injunction proceedings were instituted March 18 at Washington, Pa., against the Pittsburgh Terminal Coal Corp., of Pittsburgh in which it was charged that the company permitted dangerous practices at a mine near Avella, known as Meadowlands No. 1. The action was brought in the name of the state through Attorney General George W. Woodruff and Mine Inspectors P. J. Callaghan, John J. McDonald and John F. Bell. Hauling of coal by locomotive operated by an electrical

Digitized by Google

trolley in portions of the mine known to be gaseous, specified as Butts Nos. 27, 28 and 29, and promiscuous firing of shots without observance of the requirements of the state mining laws are specifically charged. The mine employs about 400.

The Hazle Brook Coal Co. has announced that a new breaker will be erected on the company's properties at Tremont. It is expected the breaker will have a capacity of 1,000 tons of coal daily.

Wilkes-Barre school officials are making a survey of local conditions to determine whether a sufficient number of mine workers are interested in the establishment of a mining school there. If the survey indicates enough students will enroll the school board intends to organize classes immediately.

Acme No. 1 and No. 2 mines of the Bethlehem Mines Corporation, located on the M. & W. branch of the Pennsylvania R.R. between Monongahela and Bentleyville, are to reopen soon after being closed more than a year. Approximately 1,000 men will be employed. As the corporation pays the 1917 wage scale, it is expected these mines will open on the same basis.

Judge Dailey at Huntington, last week appointed Andrew S. Webb and Walter L. Haehnlen, of Philadelphia, temporary receivers for the Huntington & Broad Top Mountain Railroad & Coal Co.

The Hazelkirk and Ellsworth No. 2 mines of the Bethlehem Mines Corporation will be opened within the next 30 days, according to plans of the company.

TENNESSEE

The Marion Coal Mining Co., of Chattanooga, has leased 3,000 acres of land between Whiteside and Shellmound and will develop it.

UTAH

The Sweet Coal Co. reports that its mine in the Gordon Creek district of Carbon County, now being developed, contains coal of an excellent coking quality. The seam is reported to be 9½ ft. thick. A number of tests have been made and at present a Chicago concern is making an oven test. The company recently constructed a small beehive oven at the mine for the purpose of carrying on experiments. Utah has so far developed but two coal properties of coking quality, one at Sunnyside by the Utah Fuel Co., and the other by the Utah Steel Corp.

The Consumers' Mutual Coal Co. has awarded the Pittsburgh Boiler & Machine Co. a contract for building a tipple at its mine in Carbon County. The structure will be of steel with a capacity of 4,000 tons in eight hours. It will be equipped to handle all grades of coal. The contract must be completed in five months, a bond having been given guaranteeing this.

The Spring Canyon Coal Co., with offices in Salt Lake City, has started an action for an accounting of funds in connection with its workmen's compensation insurance with the State Compensation Fund up to the time it became its own insurer. It is held that the company is entitled to certain dividends. Officials in charge of the fund have announced their intention of filing a cross-suit asking for the return of dividends already paid, thereby, they say, testing the law at both ends.

VIRGINIA

Three suits growing out of operations of the Tidewater Coal Exchange at Norfolk during and immediately after the close of the World War have been brought in the U. S. District Court in Norfolk by Andrew W. Mellon, as director general of the American railroads. The suits are against three local coal concerns, then members of the exchange. The New River Coal Co. is sued for $7,500; West Virginia Coal, $5,000; Eastern Coal & Export Corporation, $5,000. The suits are for the purpose of clearing up disputes over demurrage claims of long standing.

The Virginia Fuel Corporation, of South Norfolk, manufacturers of "Certified Coal" briquets, made from half soft coal and half anthracite slack, has shipped its first cargoes abroad, consisting of three small lots consigned to England. The company has obtained a through rate to New England, and is now working its plant to the full capacity of 15 cars a day for the first time since it began operating.

WEST VIRGINIA

Reports were current in southern West Virginia last week that eastern capitalists are making an effort to purchase the old Hartford City property at Clifton, Mason County, consisting of an old salt mill, a quantity of coal land and 350 acres of surface.

The Camp Fork Coal Co., which recently was organized by G. R. Krebs, of Charleston, and others, has acquired the Greendale mine of the Concordia Coal Co., at Greendale, Nicholas County, and will operate it to take care of the summer trade.

The mine of the Davis Creek Land & Coal Co. on Davis creek in the Kanawha field has closed down.

The H. T. W. Coal Co. of Huntington, has increased its capitalization from $20,000 to $50,000.

Loss estimated at several thousand dollars was sustained when a blaze believed to have originated from a short-circuit destroyed the carpenter shop and electrical repair shop at the Kingmont mine of the Hite interests, at Fairmont, March 13.

Directors of the Island Creek Coal Co. on March 17 declared a dividend of $4 a share on the common stock and the regular quarterly dividend of $1.75 a share on the preferred stock. On Jan. 1 last a dividend of $5 a share was paid on the common stock.

Coal production in West Virginia in 1925 totaled 125,434,130 tons, an increase of 21,451,128 tons over 1924, according to figures made public by A. O. Wilson, statistician of the Kanawha Coal Operators' Association.

Output in southern West Virginia, the statistics showed, aggregated 87,642,551 tons, an increase of 16,050,588 tons compared to 1924, while in the northern part of the state the output was 30,691,534 tons, an increase of 5,400,540 tons compared to 1924.

The Consolidation Coal Co. reports total earnings of $19,839,109 in 1925 against $19,263,184 in 1924. After allowing for all expenses and charges for depreciation, depletion and interest the net profit was $225,606, against a loss of $2,125,650, after similar deductions, in 1924. The profit for 1925 was equal to $2.25 a share earned on the $10,000,000 7 per cent. preferred stock outstanding. The surplus carried to profit and loss was $50,606. During the year the company and its lessees mined 10,794,903 tons of coal, compared with 10,075,068 in 1924.

CANADA

The United British American Coal Co., of Vancouver, has acquired 900 acres of coal lands at Deep Valley, 4½ miles from Princeton, B. C., and has started to develop the property.

The Canadian Pacific Ry. has placed an order for 400,000 tons of coal with the McGillivray Creek Coal & Coke Co., and is negotiating with other operators in the Crows Nest Pass district of British Columbia for a further supply.

The North Pacific Forests & Mines has been organized to take over and develop the Slate Chuck coal mine and surrounding timber limits, situated at Skidegate Inlet, Queen Charlotte Islands, B. C.

The South Okanagan Collieries, near Princeton, B. C., which had been idle for some time, has re-started development work, new capital having been obtained in Vancouver.

In its annual report for the year ended Dec. 31, 1925, the International Coal & Coke Co. reports operating profits of $124,659, in addition to sundry profits of $18,008, or a total of $142,667. This record compares with an operating loss of $9,582 in the preceding year. During the last year the company's mine in Alberta worked 156 days, employing an average of 344 men. Total production was 178,542 tons.

Miners at the Minto Coal Co.'s mines at Minto, N. B., have gone on strike, and the mines are completely closed. The strike arose from the failure of the company to accept a new wage agreement outlined by the miners.

A scheme of unemployment relief for the 470 families at Sydney Mines, N. S., who are suffering as a result of prolonged inactivity of the colleries, is being undertaken by the town, the Canadian Government, and the Provincial government. All three bodies will grant equal shares.

Intense excitement prevails at Port Simpson, B. C., where the Indians are said to have discovered an outcropping of coal on the reserve. The whole property has been staked and steps taken to record it. No work on it has been done yet, but the Indians are very hopeful. The whole of the United Church mission property is included in the blocked-out area. Port Simpson is on the British Columbia coast at the mouth of the Skeena River, south of Prince Rupert.

Personal

J. O. Colley has been appointed superintendent of the Flat Creek Division of the Alabama By-Products Corp. coal mining operations, succeeding Edmund Ewing. **Frank House**, former superintendent of the Porter Coal Co., at Porter Mine, has been made superintendent of the Alabama By-Products Corp.'s Praco operations. He was succeeded at Porter Mine by **John Rutledge**. **W. C. Paxton** has been appointed superintendent for the State of Alabama at Banner Mines, of the Alabama By-Products Corp., where convict labor is employed.

B. M. Chaplin, well-known coal-operator of Morgantown, W. Va., who has just returned from a six weeks business sojourn in Florida, has decided to locate in Florida and engage in the contracting and construction business. Mr. Chaplin has long been identified with the Chaplin Collieries Co.

James L. Davidson, secretary of the Alabama Mining Institute and prominent industrialist, was named on the board of governors at the recent meeting in Memphis of the southern division of the American Mining Congress.

W. P. Barrick recently resigned as superintendent of the Macbeth (W. Va.) mine of the Thurmond Consolidated Coal Co.

H. A. McAllister recently resigned as manager of the Logan (W. Va.) division of the West Virginia Coal & Coke Co.

P. C. Thomas, assistant general manager of the Helen (W. Va.) mine of the East Gulf Coal Co., which was absorbed by the Massachusetts Gas Co., has resigned.

Sandy Marshall, superintendent of the Monitor and Yuma Coal & Coke Cos., at Wilkinson, Logan County, W. Va., resigned recently.

John Sincock, of Uniontown, Pa., who has for several years been general superintendent for W. J. Rainey, Inc., operating six of the largest coal and coke plants in the Connellsville coke region, has resigned that position, to take effect at once. Mr. Sincock will be retained by the Rainey company as consulting mining engineer. No statement has been made as yet as to who will succeed Mr. Sincock as general superintendent, but the place is being filled temporarily from the New York office.

William Heitzman, who for the past six years has been general western sales manager for the Central Pocahontas Coal Co., has resigned effective April 1 to go into the real estate business in Cincinnati, where he has large holdings. He has been succeeded by S. E. Butler, who has been in charge of the Detroit office of the company for the past five years.

Howard Stutchbury, Industrial Commissioner of Alberta, has returned to Alberta following a month spent in Eastern Canada in an endeavor to promote the use of Alberta coal. Mr. Stutchbury advocates an extensive campaign on the part of the Alberta Government to popularize Alberta coal in Ontario and eastern Canada.

W. M. Wilshire

William M. Wilshire, recently elected president of the West Virginia Coal & Coke Co., as successor to C. E. Hutchinson, who resigned, will make his headquarters in Cincinnati, it is said.

Obituary

Lochren Donnelly, general superintendent of the coal-mining operations of the Northwest Improvement Co. at Colstrip, Mont., died March 17 at Glendive, Mont., after a short illness of heart disease. He was 29 years old. Mr. Donnelly was the son of Charles Donnelly, of St. Paul, Minn., president of the Northern Pacific Ry., which controls the Northwest Improvement Co. The younger Mr. Donnelly had been connected with the organization for about six years and had been in charge of the mining operations for two years. Burial took place in Seattle, Wash.

Traffic

Central Pennsylvania Accepts Challenge on Rates

Central Pennsylvania coal operators have accepted the challenge of the southern West Virginia, Virginia and eastern Kentucky coal operators in the matter of freight rates. The Southern operators have petitioned the Interstate Commerce Commission to reopen Docket No. 15006, originally begun as an investigation into and concerning anthracite rates and which later by order of the Commission was made to include rates on bituminous coal from Southern coal fields to all-rail destinations in Northeastern states.

By order of the Commission certain rates were temporarily established from mines in the Southern fields to the above-named destinations. These rates were to expire April 30, 1926. The Commission stated these rates were to take care of an emergency due to the anthracite strike. The so-called emergency is now passed and certain interests in New England are asking that the rates be made permanent and be extended to all sizes of coal, mine-run and slack as well as prepared sizes for household fuel, to which the temporary rates only applied.

In the answer made by central Pennsylvania coal operators to the petitions of New England and the Southern coal fields it is contended:

(1) That the combination rates in effect on Southern coal previous to the temporary rates are not unjust or unreasonable and should be maintained on Southern coal.

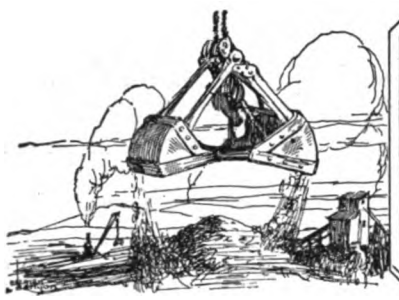
(2) That the temporary rates were established to take care of an emergency without full and complete hearings. There now exists no reason why these rates should be extended as the anthracite strike has been settled, and if extended would involve the Commission in a breach of faith, relied upon by the central Pennsylvania operators in good faith that these rates would be temporary rates only.

After asking for a denial of the petitions of the New England interests and the Southern coal operators, the central Pennsylvania operators say:

"Protestant prays also that should the Commission grant further hearing in this proceeding, such further investigation and hearing should embrace by appropriate supplemental orders of the Commission, the reasonableness, the relation, and the propriety and lawfulness otherwise of all rates, including tidewater transshipment rates, on bituminous coal from all producing districts in Pennsylvania, Maryland, West Virginia, Virginia and eastern Kentucky to all destinations in Virginia, the District of Columbia, and in the Middle Atlantic and New England states."

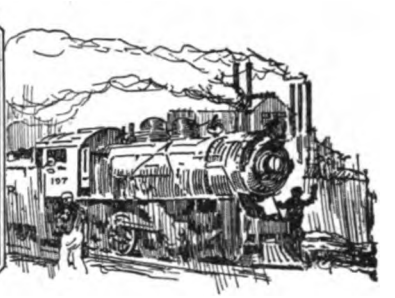
Suspend Proposed Rate Changes From Illinois Mines

By an order entered March 6 in Investigation and Suspension Docket No. 2621, the Interstate Commerce Commission suspended from March 8, 1926, and later dates until July 6, 1926, the operation of certain schedules as published in tariffs issued by various carriers publishing rates on coal from Illinois mines and Lake Superior ports.



The suspended schedules propose to increase rates on bituminous coal from Illinois to destinations in Minnesota on the Minnesota Western R.R. and to reduce rates on bituminous coal from Lake Superior ports to the same destinations. The following rates in cents per net ton are illustrative:

To	Present	Proposed
Lake Lillian, Minn.		
From		
Duluth, Minn.	303	261
Springfield, Ill.	404	441
Herring, Ill.	434	471



Penna.-Ohio Operators File Briefs in Lake Case

Briefs in behalf of the Pennsylvania and Ohio bituminous coal operators who are seeking a reopening of the lake cargo case have been filed with the Interstate Commerce Commission. Opponents have ten days in which to reply, after which the Commission will take the application for reopening under advisement. Operators from the southern fields opposing an increase in the freight rate differential, and hence opposed to reopening the case which was decided in their favor last year, met in Washington March 15 in a conference over the situation, with particular reference to division of the expense of defending the case.

Production And the Market

Union Fields Move to Meet Non-Union Competition In New Coal Year; Contracting Lags

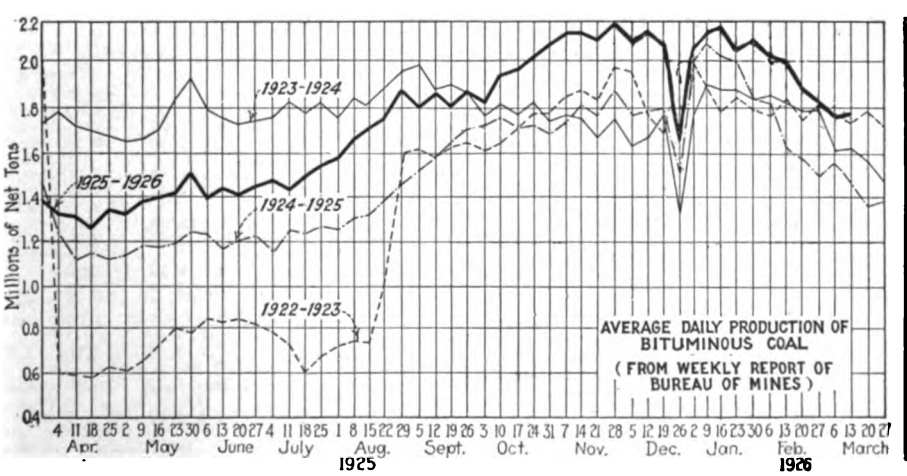
The labor situation again has assumed a commanding position in the bituminous coal trade of the country. That and the indifferent success attending the attempts of producers to hurry contract renewals far overshadow the superficial developments in spot trading as the coal year draws to a close. These developments have nothing to distinguish them from the season-end changes and minor upsets of other years.

The labor situation is pressing forward on two separate fronts. In Illinois and Indiana interest centers about the program of certain large producers to sell non-union western Kentucky coal in markets in which they have heretofore put tonnage from their own mines. This movement, initiated by the Peabody Coal Co., is, it seems, to be followed by two other—and possibly more—well-known operators in Illinois and Indiana.

In this change of front, the operators in question are duplicating a policy followed by certain producers in Ohio and Pennsylvania, who have tried to meet non-union competition by becoming non-union operators or sales agents. Ohio, however, is now going a step further and is reviving the campaign to force a downward revision of the Jacksonville scale. Unless this is done, the union is warned, there will be further indefinite suspensions at union operations.

Fight Shy of Contracts

While these struggles are in the formulative stages, producers elsewhere are redoubling their efforts to persuade consumers to renew contracts. Some business, notably that of the Norfolk & Western, has been closed at approximately last year's basis. For the most part, however, buyers are pursuing their traditional policy of waiting. In the East they have been fortified in this campaign by the large tonnage of slack available while demand for bituminous lump and egg was heavy and by the distress tonnage seeking a purchaser after the anthracite strike ended.



A suspicion that some of the canny purchasing agents have been further improving their position by buying up low-priced coal at the mines is strengthened by the production estimates for the week ended March 13. The total output that week, according to the Bureau of Mines, was 10,691,000 net tons, an increase of 231,000 tons over the preceding week. This was the first check in the decline which set in two months ago.

Prices Well Stabilized?

On the whole, the price situation appears to be fairly well stabilized—particularly in the Middle West. Pool quotations along the Atlantic seaboard also are less wobbly than a few weeks ago. This degree of stabilization is probably due to the fact that in most cases spot quotations have sunk as low as possible with safety to the seller. *Coal Age* Index of spot bituminous prices on March 22 was 167 and the corresponding price was $2.02.

Anthracite demand is broadening. Production the second week of the month totaled 1,966,000 net tons, as compared with the pre-strike average of 1,825,000 tons. Chestnut still leads in popularity, with stove and egg contending for second place. Pea also enjoys a good demand, which is made more apparent by the fact that the mines have no storage piles to draw on to fill orders.

The Connellsville coke market is featureless. There is little call for spot furnace coke and less disposition to hurry into the negotiation of second quarter contracts. Foundry coke has been in moderate demand.

Estimates of Production

Non-Union Coals Gain in Middle West

Day by day trading in the markets of the Middle West at the present time attracts less attention than the plans being made for handling business in the future. The most significant development is the proposal of Illinois and Indiana operators to go into the jobbing of non-union coals upon a large scale. The Peabody contract to handle the output of a number of western Kentucky mines was the first open move in that direction. At least two other well-known producers have made similar arrangements. Their theory is that the biggest job confronting them is to hold their customers; if they cannot do it with coal from their own mines they propose to do it with cheaper coal from non-union mines.

The adoption of such a policy, of course, means further shutdowns in the Illinois and Indiana districts. Current spot movement for the past few days has been confined largely to domestic coals. The weather has been the key to this movement. Nevertheless, "no bills" can be found in all fields. Standard prices, however, have been well maintained; the greatest uncertainty is in quotations on stripping coal for railroad business. Contract buyers, for the most part, still turn deaf ears to pleas for early renewal of expiring agreements.

Local domestic trade at both Chicago and St. Louis was more active last week as a result of weather demand. Retailers generally are more interested in cleaning up stocks on hand than in ordering forward fresh supplies. As for some time past, smokeless coal is in slight demand at St. Louis and the resumption of hard-coal mining has brought no sharp call for anthracite tonnage. An increasing percentage of the lump trade in the St. Louis territory is going to western Kentucky.

Kentucky operators and sales agencies are pressing reluctant industrial consumers to close 1926-27 contracts. Some buyers fight shy of renewing at the old figures, feeling that a period of slack demand and lower prices is at hand. The sellers scoff at that idea, emphasizing the broader market for western Kentucky all-rail coal in the Middle West and the Northwest and the prospects of a heavy lake movement from eastern Kentucky.

Kentucky Spot Trade Good

On the whole, the current spot business has been good. Cold weather has kept up domestic demand in odd lots; curtailed production has kept up prices on screenings and mine-run has shown unusual strength. Some choice eastern Kentucky block still is quoted at $3 or better, but the general range is $2@$2.75, with 2-in. lump at $2@$2.25; nut and egg, $1.75@$2. Western Kentucky block is $1.75@$2; egg and lump, $1.50@$1.75; nut, $1.35@$1.50; mine-run, $1.10@$1.50; screenings, 85c.@$1.

Compared with February, shipments from the docks at the Head of the Lakes have fallen off. The movement,

however, is large enough to convince operators that they will enter the new shipping season with no great surplus on hand. Stocks as of March 1 were officially reported at 2,875,000 tons of bituminous and 17,000 tons of anthracite, as compared with 2,818,000 and 255,000 tons, respectively, a year ago. It is estimated that stocks will be reduced to approximately 2,000,000 tons by the opening of navigation.

Smokeless Weaker at Superior-Duluth

Smokeless coals, which had the call during the anthracite strike, are weakening. Dock quotations on lump, egg and nut have been shaded 50c. and it is reported that some coal can be had at figures still lower. Mine-run and slack, on the other hand, are strong at $5.25 and $4.25. The bituminous list, too, is unchanged. There is considerable diversity of opinion as to how much of the hard-coal business smokeless will be able to hold next year. Dealers have been anxious to get anthracite, but the effect of the price differential between the two coals has not yet been measured.

Unusually cold weather has helped the domestic trade in the Twin Cities, but most of the buying is of the hand-to-mouth variety. Some all-rail anthracite has been shipped to St. Paul and Minneapolis. The steam coal trade is draggy. Receipts of anthracite at Milwaukee are increasing slowly and they are still insufficient to meet the brisk demand from householders. There also is a good call for all grades of bituminous coal despite moderate weather.

As the market in the Southwest grows weaker, more shaft mines in Kansas are closing down and crusher activity at the stripping operations is growing. Much of the business ordinarily taken care of by shaft-mine screenings is now going to crusher mine-run. Lump prices range from $4 to $4.50; screenings and crushed mine-run are firm at $2.50. Little improvement in Arkansas production is expected before the summer storage season starts.

Far Western Domestic Trade Drags

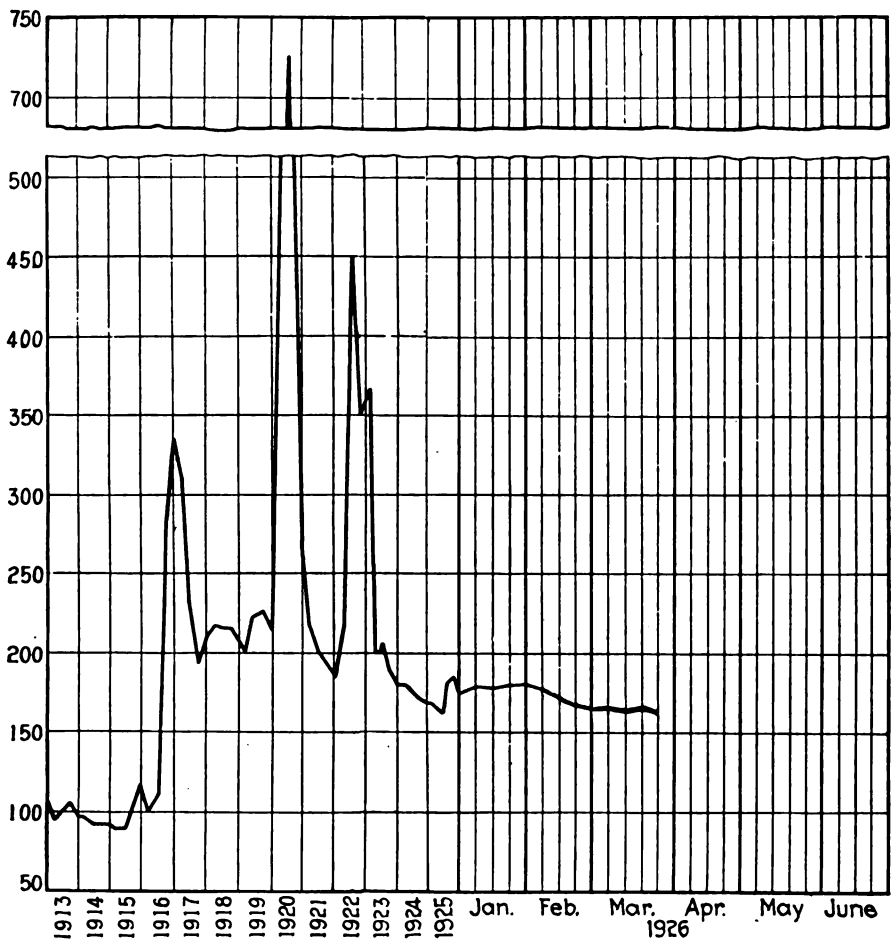
Unseasonably mild weather in Missouri River territory has had a disastrous effect upon domestic demand at Colorado mines. Operations have been cut to a 50 per cent basis. Another factor in holding back orders has been the reduction in list prices which went into effect on Monday of this week. The weather also has taken toll of lump business in Utah. Large lump is now quoted at $4, the same price asked for 3-in. coal; the former price was $4.50. Screened slack has been advanced from $2 to $2.25 and straight slack from $1.25 to $1.50.

In the Cincinnati market the annual contest between lake buyers and producers is running true to form. After trying to beat down a $1.50 figure to $1.35@$1.40, however, these buyers are swinging into line. They also are showing interest in slack at $1. The fact that the Norfolk & Western Ry. has renewed its contracts upon practically the same basis as last year has had a tonic effect upon the situation. Cold weather and reduced production, too, are helping.

The low-volatile shippers still are trying to readjust themselves to changed conditions. A $3 quotation on lump and egg now is forecast for April business. Nut has slumped to $2.50, but mine-run holds at $2.25. How to raise slack to a point where it will carry more of its share of the cost load is a problem. Current quotations range from $1.25 to $1.50.

Struggle to Move Prepared Coals

It is a struggle to move prepared low-volatile coals. Some of the large Logan County producers have cut lump to $2 and shrewd buyers are able to shade that 15c. Hazard lump is $2@$2.25. Egg is extremely soft. Steam business, however, helps the mine-run situation and byproduct coals are stronger. Slack, on the other hand, has lost some of its recent firmness and some fair grades can be bought around 75c.



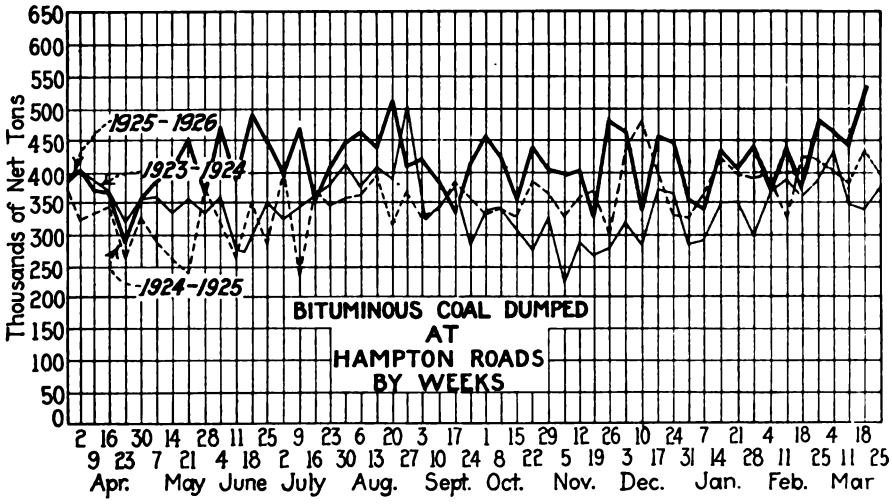
Movement of coal through the Cincinnati gateway, according to the latest weekly report of the American Railway Association, totaled 10,971 cars, an increase of 488 cars over the preceding week and a gain of 2,157 cars over last year. The largest increase was on the Louisville & Nashville—364 cars; the Norfolk & Western was second with an increase of 111 cars. A heavier movement of empties to L. & N. mines brought the empty interchange to 17,084 cars, an increase of 728 cars over the preceding week.

River business has been excellent. For April delivery it is understood that the retail trade will ask $8.50 for smokeless lump, $5.75@$6 for mine-run, $5.75@$6.25 for bituminous lump.

Central Ohio Steam Trade Puzzles

To a certain extent the steam trade in central Ohio is an enigma. General industrial conditions seem to have improved, but demand for coal has not reflected any increase. The contract outlook is uncertain. Railroads have asked for bids on substantial tonnages, but no awards have been made. Certain other large consumers also have made contract inquiries, but many are still out of the market. In the spot market there is a better tone to screenings—due solely to decreased production.

Weather, of course, is the controlling factor in the domestic trade. March retail business has been above the average, but wholesale buying has been in small lots. Consumer buying, too, has been for limited quantities. Smokeless is retailing at $9.50@$10; West Virginia splint and Kentucky block, $7@$7.50; southern Ohio, $6@$6.50.



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	Mar. 22	Mar. 15	Mar. 8	Mar. 1	Mar. 23	Mar. 24
Index	167	168	167	169	163	176
Weighted average price	$2.02	$2.03	$2.02	$2.04	$1.97	$2.13

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average of the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

Southern Ohio production again has declined. No increase is looked for until the lake season is in swing. A considerable tonnage already has been loaded in bottoms tied up at the lower ports awaiting the opening of navigation.

There has been no change in spot prices in the Cleveland market. The steam trade is weak and domestic demand dull. There is more distress tonnage to be had than inquiries for fresh shipments. Production in the eastern Ohio field for the week ended March 13 approximated 250,000 tons, or 36 per cent of capacity. Compared with the preceding week this was a decrease of 8,000 tons; compared with a year ago, it was an increase of 4,000 tons.

No Joy Pierces Pittsburgh Gloom

Optimism apparently is a stranger to the Pittsburgh district at the present time. Demand is growing weaker and weaker; few contracts are being renewed and more mines plan to close down on April 1. The labor situation is again in the limelight as the result of the dissolution of the district labor organization formed shortly after the Pittsburgh Coal Co. began reopening mines at the 1917 scale. Following the refusal of the company to restore the Jacksonville scale, the defunct union called a strike and went over to the United Mine Workers. The strike appears to have failed before it was started.

Central Pennsylvania is finding its annual seasonal dullness made more bitter by comparison with the business enjoyed during the anthracite strike. Little progress has been made in reducing the accumulation of 1,800 "no bills." Prices on all coals are easier. The Broad Top, Clearfield and Cambria County fields seem to be hit the hardest in the present slump.

Buffalo is running Pittsburgh a close second for unrelieved pessimism. Industrial spot buying is niggardly. Cold weather has given some aid to distributors of domestic bituminous, but most of the demand from householders is for anthracite, which is now coming in in quantities sufficient to meet requirements. Aside from a scarcity of nut, Toronto retailers are experiencing no difficulty in taking care of orders for hard coal. Demand for low-volatile bituminous and coke has dropped.

No Improvement in New England

The New England steam coal market is not only sluggish; it is distinctly weak. Spot buying is slow and the few orders placed are for small tonnages. Spasmodic efforts have been made to interest consumers in contracts and it was rumored last week that certain public utilities were on the point of closing. The price most commonly mentioned is $1.75 net, mines, for high-grade smokeless.

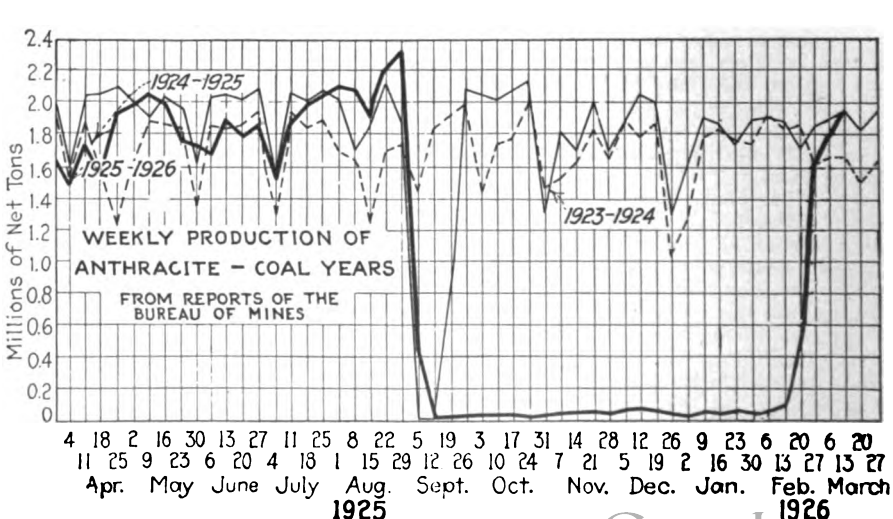
Spot prices on Navy Standard coal on cars at Boston and Providence have sagged to $5.70@$5.85 per gross ton. Terminal facilities are blocked with unsold coal. Accumulations are still the order of the day at the southern loading piers, where coal is now offered at $4.30@$4.50. Unless there are further drastic cuts in the output, the decline in prices will continue.

Prepared smokeless coal is practically a drug on the market. Shippers with rejected tonnage on hand can place it only with great difficulty. In many cases the coal has been sold for freight and demurrage. Other substitutes for anthracite are faring little better. Several cargoes of foreign coke and ovoids are being diligently hawked about, but retail buyers are indifferent.

New York Working Toward Normal

The bituminous situation at New York is slowly approaching normal. Distress tonnage is coming down, but there still are about 4,000 cars standing at the piers. Spot buying, except of distress coal, is not brisk either at tidewater or in the line trade. Contracting, too, is backward, although some business has been closed at figures approximating those carried in last year's agreements. On contract some shippers are quoting pool 9 at $2.05@$2.25; pool 71, $2.40@$2.50 and pool 1, $2.75 @$3. Late last week, however, it was reported that 125,000 tons of pool 9 quality had been closed at $1.70.

Philadelphia sales agencies are endeavoring, with no great success, to induce steam buyers to sign on the dotted line for next year and to take a little extra tonnage on the expiring agreement. Leading factors say they are holding to $2.65@$2.75 on contracts, but there have been a number of offers of good trade coal at less. The railroads have bought so much bargain-counter tonnage since the anthracite strike ended that they are as reluctant as the general industrial consumer to tie up on contracts for the new season.



Conditions at Baltimore differ in no important detail from those now controlling at New York and Philadelphia. Few inquiries looking toward contract renewals have been made by the buyers. The poorer grades of steam coal are a drug on the spot market and the better grades are only in fair demand. All gas coals are sluggish. The only ray of immediate hope is in the faint revival of export movement.

Birmingham Has Weather Flurry

A sudden drop in the thermometer was responsible for a brief buying flurry in the Birmingham domestic market last week. Producers expect to announce their spring prices within a few days and contracting on a liberal scale is forecast. It is rumored that the new schedules will show some advances in the contract prices of the better grade coals.

Black Creek, Cahaba washed and mine-run and other standard grades from the Warrior field are still in good demand for industrial, coking and bunker fuel. Shipments against contracts continue heavy, with the railroads and public utilities taking their maximum quotas. Poorer grades are less active and mines producing such coal are curtailing their output.

Reduction in the tonnage of "substi-

tute" fuels in New York retail yards has increased the demand for anthracite in the metropolitan district. Old line companies are prorating their output among customers who have not felt the urge to buy large quantities of independent tonnage. This has prevented large premiums on the latter coal as the demand is just sufficient to keep prices steady.

Chestnut Leads in Demand

Most independent shippers are pressing buyers to take either egg or stove with chestnut. The last named size still leads in demand. Stove lags behind egg, which is growing stronger. Pea coal is moved without difficulty—an unusual situation for this time of the year. The steam coals are holding firm.

Complaint of insufficient receipts of anthracite is common in the Philadelphia market. Most of the coal is moved out of the retail yards as fast as it is unloaded. As at New York, chestnut is leading in popularity. Egg, however, is outranked by stove, but retail dealers accept it unhesitatingly. Pea, too, is enjoying an unwonted demand and there are no storage piles at the mines to quiet appeals for speedy shipment.

The steam market is absorbing the production sent to Philadelphia—but there is no excess of demand. On the contrary, there is evidence that some of the tonnage is coming from the breakers faster than the consumers throughout the anthracite steam-coal area as a whole are willing to take it.

At Baltimore the situation is still one of demand exceeding the supply because the retailers are adhering to their refusal to augment company shipments with purchases of high-premium independent anthracite. Retail prices are on a pre-strike basis, which excludes paying $12@$15 at the mines for coal.

Connellsville Output Tobogganning

Week by week the Connellsville ovens are continuing their efforts to bring beehive coke output in line with consumer requirements. During the week ended March 13, according to the Connellsville *Courier*, furnace oven production was cut 2,300 tons and merchant oven output 8,260 tons. The total production for the week was 188,990 tons, of which 100,400 tons came from furnace ovens.

Blast furnaces have shown little interest in the market and there is not much second-quarter business in the offing. Ovens talk $3.50 for furnace coke and the furnacemen talk $3.25. Spot tonnage is to be had at the latter figure. Foundry coke has been in moderate demand, with standard tonnage at $4.50@$5. A fair run of buying by miscellaneous consumers also has helped the market.

Railroads Use Less Fuel Oil During 1925

A total of 59,355,000 barrels of fuel oil was consumed by locomotives of the principal railroads in the United States in 1925, compared with 61,738,000 barrels in 1924, according to returns received from railroads by the American Petroleum Institute. These figures include fuel oil consumed in all classes of service.

The largest consumption of fuel oil was shown in the Middle Western and Southwestern district, totaling 27,386,000 barreles in 1925 compared with 29,153,000 barrels in 1924. Consumption in the Southwestern Pacific district totaled 22,940,000 barrels in 1925 compared with 23,924,000 barrels in 1924. In the Northwestern district 6,637,000 barrels were consumed in 1925 compared with 7,060,000 barrels in 1924. In the Southern district locomotives consumed 2,278,000 barrels in 1925, compared with 1,470,000 barrels in 1924. In the Eastern district the consumption totaled 114,000 barrels, compared with 131,000 barrels in 1924.

Canada's Coal Output and Consumption Drop in 1925

Canada's consumption of coal during 1925 fell short of the level of the previous two years and amounted to only 90 per cent of the average for the five years 1920-24 inclusive, according to figures recently prepared by the Dominion Bureau of Statistics and received in the U. S. Department of Commerce. Of a total of 29,000,000 net tons made avaliable for consumption last year almost half is accounted for by domestic production.

Nova Scotia led in the mining of bituminous coal with 3,800,000 tons, followed by British Columbia with 2,700,000 and Alberta with 2,100,000. Alberta also produced 3,200,000 tons of lignite and 570,000 tons of sub-bituminous coal. Labor troubles occasioned by strikes were given as the cause of production falling below the 1924 total and the average for the preceding four years. Nova Scotia, which suffered particularly in this respect, had a yearly output amounting to only 64 per cent of the average for the period 1920-24.

Exports also experienced a decline to 786,000 tons, or 45 per cent of the five-year average for 1920-24.

Utilities Consume Less Coal But More Oil in January

Public utility power plants in the United States consumed 3,738,006 net tons of coal in January, compared with 3,801,372 tons in the preceding month and 3,471,524 tons in November, according to the U. S. Geological Survey. Fuel-oil consumption bv utilities in January totaled 1,016,316 barrels, as against 811,777 barrels in the preceding month and 790,734 barrels in November.

The average daily production of electricity by electric public-utility power plants in January was 197,300,000 kw.-hr., a little less than the revised daily rate for December but nearly 10 per cent larger than the output for January, 1925. The amount produced by the use of water power was 15 per cent larger and the amount produced by fuel power was 7 per cent larger.

Foreign Market And Export News

Welsh Trade Unsettled; Export Market Uncertain; Newcastle Still Sluggish

Though the tonnage situation has improved with better weather, the Welsh steam coal trade is still unsettled as regards early shipments. Coal has accumulated to a considerable extent and operators are still engaged in clearing their cars, until which time regular working of the pits is impossible.

The prospects of improved export of Welsh coal are not altogether good because shipping is still short of requirements and freights are heavy. On the other hand the operators have plenty of orders in hand and the ruling high freights will no doubt attract shipping before long.

The best contract to report is one for 32,000 tons of best Admiralty large for the Palestine Rys. for delivery for six months from April to Haifa. Beyond this there seems to be little inclination on the part of either buyers or sellers to enter into negotiations pending the developments in the industry after May 1. So far the returns show a discrepancy of 3s. 2d. per ton between the cost of production and the selling prices, the discrepancy, of course, being on the wrong side of the balance sheet.

The Newcastle market is dull and cheerless and the prospects for the next month are anything but favorable. Newcastle is still losing business to Germany and Silesia.

Output by British collieries during the week ended March 6, according to a special cable to *Coal Age*, totaled 5,285,000 gross tons, compared with 5,370,000 tons in the preceding week.

French Market Marks Time

Paris, France, March 4.—Demand for industrial fuels continues satisfactory, but the consumption of domestic grades has been greatly reduced. British imports of household fuel have been sharply reduced.

Belgian sellers of sized coal have decided to apply to the March deliveries in France the same price estimate as for last month. Owing to the rate of exchange this means an increase of 6@10 fr. per ton. Russian anthracitic is a drug on the market in the Paris district; cobbles can be used only for central heating purposes. In Rouen, Russian nuts, 25/55, are quoted at 380 fr. and cobbles 55/80 at 370 fr. These prices are out of line with Welsh anthracite, quotations of 390@435 and 380@410 fr., respectively, for the same sizes.

During the first twenty days of February, the O.H.S. received 354,900 tons of coal, 187,000 tons of coke and 24,900 tons of lignite briquet from the Ruhr.

The O.H.S. new price list for indemnity coals, effective March 1, increases the price of coal delivered by sea 5 fr. The price of industrial coal delivered via the Belgian frontier is increased 3 fr., on unscreened 20/25 and 5 fr., on unscreened 30/40.

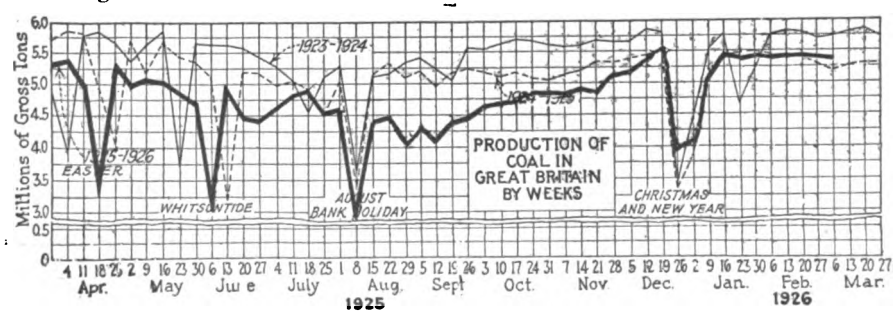
Belgian Trade Holds Position

There was no material change in the Belgian coal market the first week of the month, reports Brussels under date of March 4. Orders have been reduced for some grades of both steam and domestic coals, but prices generally are well maintained. The exception has been in the quotations on certain domestic coals for which demand has almost disappeared.

French imports are below last year's figures, but the difference between January, 1926, and December, 1925, was only about 5,000 tons. British and Dutch arrivals are more irregular. Receipts of free German coal are near a vanishing point. On Jan. 31 Belgian stocks were down to 1,398,180 metric tons, as compared with 1,558,120 tons a month earlier.

There is a good demand for industrial lean coals. Semi-bituminous steams are not much sought after, but the 5x10, 6x8 and 10x15 grades are strong and prices have been increased 2@4 fr. per ton in both the Borinage and Liege districts. Screened sizes are almost unprocurable and coking smalls are firm. Duffs for brick-making are held at 66 fr.

Current quotations are as follows:



Anthracitic: 80x120, 180 fr.; 50x80, 200 fr.; 30x50, 215 fr.; 20x30, 175 fr.

Semi-bituminous: 80x120, 140@145 fr.; 50x80, 150@155 fr.; 30x70, 175 fr.

Bituminous: 80x120, 135@140 fr.; 50x80, 150@155 fr.; 30x70, 155@160 fr.; 20x30, 130@140 fr.

The demand for briquets has improved a little, but it is still unsatisfactory. The prices of patent fuels rise in proportion with the price of pitch.

Belgium received 312,632 tons of reparation fuels (including 11,266 tons of coke) from Germany in January, as against 275,875 tons in December.

Chile Mines 1,473,000 Tons

Chile's coal production during 1925 has been estimated at 1,473,000 metric tons by the geological section of the Chilean Ministry of Agriculture, Industry and Colonization. Although this figure is 40,000 tons less than that for 1924, it is still considered unexpectedly high, as a number of mines worked only part time a large part of the year.

Coming Meetings

Lehigh Valley Section, A. I. E. E. Sterling Hotel, Wilkes-Barre, Pa., March 26, 6:30 p.m. Secretary Wilkes-Barre section, E. B. Wagner.

New England Coal Dealers' Association. Annual meeting, State Armory, Worcester, Mass., April 7 and 8. Secretary, E. I. Clark, 141 Milk St., Boston, Mass.

American Welding Society. Annual convention, 29 West 39th St., New York City, April 21-23. Secretary, M. M. Kelly, 29 West 39th St., New York City.

California Retail Fuel Dealers Association. Thirteenth annual convention at Del Monte, Calif., April 22-24. Secretary, J. B. Muir, Oakland, Calif.

National Retail Coal Merchants' Association. Ninth annual convention, New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

Electric Power Club. Convention at The Homestead, Hot Springs, Va., May 24-27. Secretary, S. N. Clarkson, B. F. Keith Bldg., Cleveland, Ohio.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, in conjunction with the annual meeting of practical operating officials. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. The fourteenth congress will be held in Madrid, Spain, commencing May 24, 1926. From May 5 to 22 excursions of interest to the visiting delegates will be arranged. Information concerning the congress can be obtained from the secretary of the organizing committee, Enrique Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

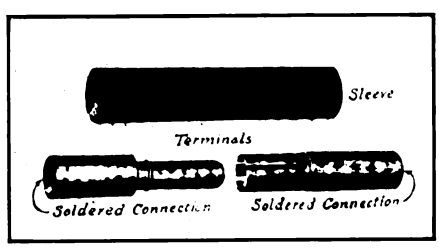
Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.



American Society of Mechanical Engineers. Spring convention at San Francisco, Calif., June 28-30. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

New Equipment

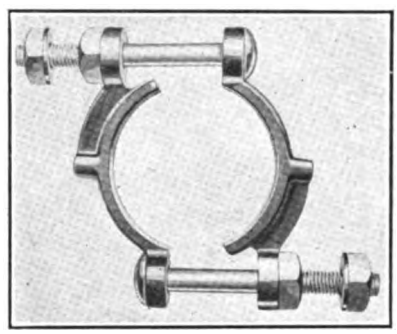
Insulated Connector Affords High Current Capacity

Small diameter, high current capacity, a lack of screws or bolts, the ability to hold against considerable tension before pulling apart, and provision for quick connection and disconnection are highly valuable attributes of any motor lead connector. The new cable connector of the Ohio Brass Co., Mansfield, Ohio, embodies these features.

This connector is intended for use on motor leads and trolley-pole connections of mine locomotives as well as for general use on stationary and portable motors. The terminals, which are of phosphor-bronze, have a double-spring contact. The slotted end of the male connection is compressed by the solid part of the female portion, and likewise the slotted end of the female element grips the solid portion of the male. One excellent detail of the design is the raised ring or boss on the solid portion of the male element. This fits into a corresponding groove in the spring or slotted part of the female element and gives the connector its ability to withstand considerable pull before coming apart.

Easily Made but Tenacious

The two terminals are soldered to the cables to be connected. A push forces the two parts together and the ring on the one fitting into an internal groove on the other holds them in place. A rubber sleeve spans the completed connection and insulates it.



The cable ends are soldered into the tinned sockets of the connector. In application the cable insulation is trimmed back just far enough so that when the connector is snapped together the distance between the ends of the insulation is slightly less than the length of the tight-fitting rubber sleeve which spans and covers the metal sleeves. In this way a well-insulated joint is attained without the use of tape.

Trolley Guard-Board Support

A simple clamp that makes it possible to install guard boards after a trolley line is in place in a mine is a recent development of the Ohio Brass Co., of Mansfield, Ohio.

Often when haulageways are extended it becomes desirable to add guard boards to the trolley line. This simple device consisting of two clamping pieces and bolts, can be fastened around the skirt of any insulated trolley hanger having a diameter ranging from 3¼ to 3¾ in. After the two clamping pieces are rigidly attached to the hanger, it is a simple matter to slip suitably drilled guard boards over the extended clamping bolts. A nut and washer on the outside of each guard board holds it in place.

This fitting is said not to affect the installed trolley hanger or clamp and can be readily removed and reinstalled in another location when desired.

Fastens Board to Insulated Trolley Hangers

This clamp may be slipped around the skirt of hanger. The clamping bolts are then passed through holes in the guard boards. Both trolley and guards are thus suspended from the same hangers.

A New Recording Pyrometer

Charles Engelhard, Inc., 30 Church St., New York City, has recently brought out the Type S recording pyrometer illustrated in Figs. 1 and 2, in which have been embodied a number of improvements, principal among these being the mercury contact switch shown in Fig. 3.

The outer case of the instrument is made up of two castings, the back half, which forms the base of the instrument, being made from cast iron and the front half or cover, from cast aluminum. The mechanism is assembled on a sub-base that is secured to the casing by four bolts.

Fig. 1—Type S Recording Pyrometer

Digitized by Google

The galvanometer-moving system which is mounted on the back of the sub-base responds to the electromotive force applied to the terminals of the instrument, and its deflection from the low-scale division is a measure of the electromotive force, which in most cases is calibrated directly in terms of temperature. A clock mechanism drives

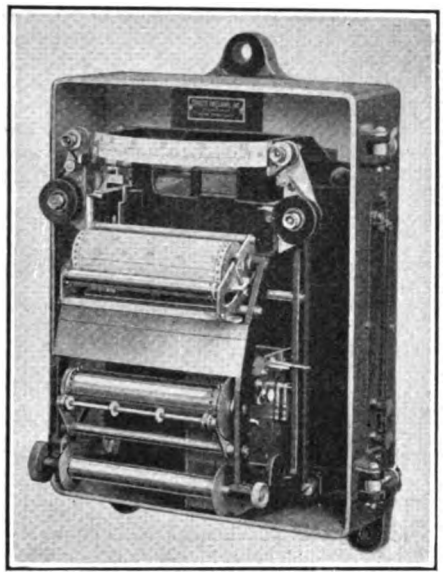


Fig. 2—View of Pyrometer Mechanism

the chart at a fixed rate of speed. A depressor bar above the pointer is operated intermittently from the power unit. When the depressor bar is lowered, the pointer presses the inked ribbon against the chart and records the pointer's position.

The power unit is controlled from a contact switch mounted on the clock. Each time that a circuit is established through this contact switch, the power solenoid is drawn down and drops the depressor bar against the pointer.

The recording chart is of the ribbon type and approximately 100 ft. in length, the over-all width of the chart being 6⅜ in. This chart is held against the driving drum by a series of rollers that are mounted in a separate frame, hinged so it can be swung outward while the rolls are being changed. The

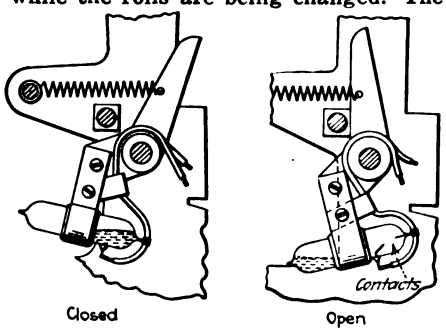

Fig. 3—Mercury Contact Switch

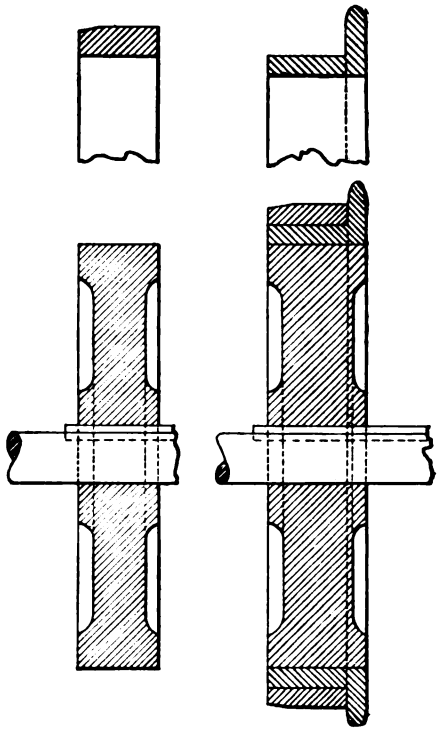
driving drum for the chart is connected to the gear train by an adjustable clutch.

The electric clock for the unit is designed for alternating current and is of the Warren type. The mercury contact switch previously referred to is furnished on the multi-record instrument and forms part of the power unit. This switch consists of levers mounted on a spindle and spaced from one another. To the lower ends of the levers is attached a small glass tube containing mercury and sealed-in electrodes. The normal position of the levers is such that the bulbs are tilted and the mercury is not in contact with the electrodes. Opposite each lever on a revolving spindle that is connected to the pinion of the power unit is a stud that throws the lever forward when turned to the right position. This action tilts the switch bulb so that the mercury completes the circuit between the two electrodes as shown in the closed position, in Fig. 3.

Automatic Re-centering Motor Bearings

Many of the troubles experienced with electric motors are the result of bearing wear permitting the rotor to rub on the stator. To insure a continuous uniform air gap in motors, the Howell Electric Motors Co., of Howell, Mich., has brought out a complete line of motors with anti-friction bearings, in which any looseness in the bearing, caused by wear or otherwise, is instantly and automatically taken up, so as to keep the rotor of the motor continually centered. This is done by using a Timken tapered roller bearing, shimmed with a fluted wire spring which acts as a compression spring.



The inner race or cone of the roller bearing is fitted on the shaft with a light press fit. The outer race or cup is fitted into the housing of the motor end bell with a sucking fit which allows creeping of the outer race. The spring is held tight against this outer cup by the outer grease cap; pushing the cup tightly against the rollers and keeping the bearings tight at all times. This type of bearing is put in each end of the motor. The roller bearing is made of nickel-molybdenum steel.

Two-Piece Locomotive Tire

In the accompanying illustration may be seen a new type of locomotive tire recently patented by J. N. Abbott, superintendent of Mine No. 3 of the Columbus Mining Co., of Christopher, Ky. In this construction the tire is made in two parts, the inner one carrying the flange and the outer acting as the tread proper.

When the tread wears, as all treads do, it can be replaced without incurring the expense incident to a complete tire renewal. In order to change locomotive tires at most mines it is necessary to withdraw the drivers and their connecting axle, remove the gear and send the balance to the machine shop where the tires are ground or turned down. This consumes much time and keeps the locomotive out of commission for at least one shift.

With the construction here shown it is claimed that a change can be made much more quickly. It is merely necessary to raise one end of the locomotive and cut off the worn tread either with a hammer and chisel or with the acetylene torch. The new tread having been previously heated may then be slipped into place, and allowed to shrink. It is claimed that replacement of a worn tread may be accomplished in a few minutes time and that one flange will outlast several treads.

Cross-Sections of Wheel and Tire

As may be seen the tire is made in two parts the flange being part of the inner band and the outer one serving as the tread proper. Inasmuch as the tread wears much more rapidly than does the flange it is well that the former can be removed without making a renewal of the flange necessary.

Clamp Holds Angle Iron Trolley

The use of the bulldog trolley clamp principle has been extended by a recent development of the Ohio Brass Co. to include an application where angle iron is employed as the trolley contact. The adaptation consists in the substitution of clamping jaws shaped to grip a standard 2½x2½-in. angle, in place of the customary wire clamping jaws. With this device the bulldog line is said to include suitable clamps to handle practically any form of trolley contact and feeder suspension.

Angle Iron Clamp with Strong Holding Jaws

Trolley lines made of angle iron can now be supported by a type of clamp commonly used for mine trolley suspension.

COAL AGE

The World's Accepted Authority on Coal Mining

McGraw-Hill Publishing Company, Inc. **April 1, 1926** Price Twenty Cents Per Copy

Inviting Bids—

on mine cars is just ordinary business. But placing orders for mine cars is as interesting and as important as any other work an official is called upon to do.

Hyatt equipped cars are used by all of the large producing companies, one group having more than ten thousand Hyatt equipped cars. Continued patronage is a true indication that when *"to be equipped with Hyatt bearings"* appears on prints and in specifications that a company is seeking large, low cost production by the use of durable and dependable mine car running gear.

Please specify Hyatt bearings *by name* in your inquiries and on your drawings. If you desire, we will help you choose the proper bearings and axles for your particular cars. Also, we will send any responsible executive a full size Hyatt bearing for office study and examination. Ask for it, advising size car, wheel diameter and the number of cars you expect to buy and from whom, and when.

There are no strings tied to this offer—no obligations to buy, but we believe that if you can hold a "he-man" Hyatt bearings as you study the propositions that you receive from the various manufacturers, you will know why so many mining heads have such implicit faith in the performance of Hyatt mine car bearings.

An Exide-Ironclad-equipped motor hauling a heavy trip up a steep grade at W. R. Gallagher & Bros. Coal Company, Houtzdale, Pa. An Exide-Ironclad Battery always has plenty of power in reserve for grades or extra heavy loads.

How many cars did you load and ship today? Many mines that have tried Exide-Ironclad Batteries have found the smoothness and efficiency of their haulage service so increased that more tons go over the tipple.

The empties are ready, but where is the motor? When an Exide-Ironclad is on the job empties are hustled in and the loads brought right out—without delay.

* * *

The motor is ready to take the empties in and the motorman is giving the Exide-Ironclad a "boost" while he eats his lunch. The battery takes its charge quickly, easily, and with little waste of current.

The miner and his helper rarely have to quit work for lack of cars, when the gathering motors are equipped with Exide-Ironclad Batteries.

Hauling more coal for less money

MORE and more are the important coal mines of this country standardizing on Exide-Ironclad Batteries for haulage service. They are doing so because they have found this battery handles the most coal, in the quickest time, at the lowest cost.

It does this because its first cost is reasonable, its life long, its power and speed great, its charging efficiency high, and its repair and maintenance cost negligible.

It will pay you to know more about Exide-Ironclad Batteries. A representative from our nearest branch will gladly call, or you can write for free booklet No. 1791, "Facts for Consideration in *Selecting a Battery* for Locomotive Service."

Inching Toward Safety

Coal Age is specializing on mine accidents, for only by due consideration of the causes of these can we attain safety. The Minister Stein explosion will be described next week and its causes discussed. No gas had even been found where the explosion took place, but it may have been there in sufficient quantity to ignite when the shot that blew up the mine was fired. It was only a small shot, and some will wonder if mine officials and the state authorities were right in visiting it with the blame when there were so many other possibilities present. But the story of the explosion, even if the cause has been wrongly assessed has several morals for all of us to draw, and M. Touwaide, the author has a lucid way of presenting them.

Taking the Dirt Out of Coal

What shall be done with bone coal? Some believe that if the operator can't use it himself, he can't afford to waste it and should send it to market in the fine sizes. Much coal has to be wasted to lower the ash content materially after once the segregated slate is removed. But whatever the operator does decide, it should be based on the facts and not on a guess as to the ash analysis he prefers. He should be able to get a mathematical figure to show just what he can afford to throw away and what he is obliged to market. He should enter those markets only that are adapted to his coal. The article helps him to decide on the dividing line.

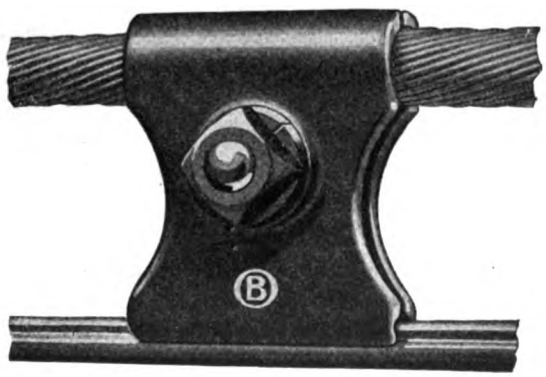
A Flexible and Economical Construction



It is obvious that flexibility in the overhead prolongs the life of the trolley wire and fittings themselves, and reduces the wear and tear on trolley wheels and bushings. Mining practice is tending toward catenary construction for high grade, permanent work. But heretofore, the lack of a simple method with inexpensive fittings has delayed progress.

O-B has now contributed the solution of this problem.

O-B Bulldog Cable Clamp

A cable sling with clamping jaw, which grips the cable tightly and will not let it slip. It is screwed onto the standard hanger. Uses the familiar Bulldog clamping principle—a turn or two with an ordinary wrench supplies ample grip on the cable.

O-B Catenary Clamp

Using the feeder cable as the messenger wire, these catenary connectors are installed between the hangers, affording perfect suspension for the trolley without rigidity at any point.

Volume 29 | NEW YORK, APRIL 1, 1926 | Number 13

Time for a Showdown

ONE OF THE LEGACIES of the late anthracite tie-up has been the accumulation of orphan cars of bituminous coal and coke rejected by consignees after hard-coal mining had been resumed. At one time there were 1,200 such cars blocking railroad sidings in and around New York. While less has been printed about conditions in other cities, the rejection evil has been felt with varying degrees of intensity all along the Atlantic seaboard.

Consignees who have blocked traffic in this manner allege in justification of their action that the coal and coke rejected was of inferior quality. That there have been cases where the greed of producers or intervening middlemen has led them to send forward fuel unsuited for domestic consumption is no doubt true. In such cases, assuming misrepresentation, refusal to accept the shipments was the proper course to be followed by the consignees. Nobody has the temerity to suggest, however, that, if the hard-coal suspension had continued, rejection on that or any other ground would have been the fate of most of the tonnage filling railroad terminal tracks.

Where coal has been refused so that the consignee might escape the burdens of a bargain made bad by changed conditions, such action constitutes sharp practice which cannot be too severely condemned. The strange part of the case, however, is that many producers who are the victims of such practice condone by a policy of inaction the unscrupulousness from which they have suffered. They decline to invoke the processes of law to compel observance of their contracts of sale. They seek relief in fulmination where they should seek redress at the bar of justice.

Such an attitude is hardly more defensible than the rejection of tonnage without just cause. Such a policy injures not alone the shippers directly involved but also those retail distributors who lived up to their purchase obligations even when they knew that it meant accepting tonnage which could be resold—if at all—only at a substantial loss. Condonation of sharp practices reflects upon the whole industry and makes sound merchandising and fair dealing that much more difficult.

If, as has been suggested in some quarters, loose methods in handling orders militate against a successful action at law, then the sooner the coal trade embarks upon a campaign of self-reformation the better it will be. There is something to be said upon the opportunities for confusion, misunderstanding and evasion inherent in a lack of fixed, uniform standards of sizing and quality in the different producing fields. It is a subject worthy of further attention as a step toward improving merchandising in the future.

That, however, should not be set up as a bar to action in the present cases. Shippers of rejected tonnage who resort to technicalities to excuse their failure to defend their good name place themselves in the unenviable position where their own sales practices and integrity appear properly objects of suspicion.

Coal Dust at Lower Landings

MANY OPERATORS are gravely concerned over the quantity of coal dust suspended in the air at the working face and are searching for feasible schemes of eliminating this hazard. But at the mines of many of these same operators, coal is dumped in the path of the intake and tons of this dust are daily sifted into the air at the bottom of shafts and slopes, without much thought of the danger involved. The hazard of this practice is too great to be excused and is so important that it would justify the great expense involved in the construction of a third opening. In all cases the mine bottoms in which are installed dumping equipment should be neutral as to ventilation, on a separate split or on the return. Furthermore, possible agents of ignition should be kept away from this location.

It is true that an arrangement in which the air in the bottom is neutral would stop the travel of dust and allow it to accumulate within narrow confines, but the accumulation would be large enough to be exceedingly dangerous and the dust would have to be removed at frequent intervals. As some means should be provided for carrying away the coal dust as quickly as it is suspended in the air, and as air itself is no doubt the most convenient of the two, the separate split is the more logical provision. The arrangement might well involve a hood over the dump, from which could be led a suction pipe to the outside where a dust collector might be located.

In either event permissible electric motors or air should be used to operate the dumping equipment. Pneumatic power is peculiarly suitable to the operation of mine-dumping equipment, in which also it is fairly efficient.

Public Opinion and the Coal Industry

PUBLIC OPINION is rated by many students as the most effective force in the world today. Certainly that applies to the United States, and to the coal industry. When did John Lewis lose the recent anthracite strike? When he failed to enlist public good opinion and support, which he had counted on and which had not failed him in former campaigns. But when the public frowned and stiffened its back against Lewis' pressure, the game was already up.

But let us not imagine, on that account, that the coal industry is popular. It is not; it is unpopular. The unanimity of opinion of the men on the street is striking in this respect. It was not that the public

Digitized by Google

loved the coal operators more; it was that it loved Lewis less.

One who is curious to learn just why the public has this uniform prejudice against the coal industry can ascertain, as a result of many desultory conversations, that it has its basis in the direct dealings of the average man or woman with the industry, and these, of course, are to a great extent, the individual purchases of fuel for domestic heating. The popular grievance with this particular part of the business is fairly uniform and turns upon two features in the preparation of coal for the market, and the marketing. It is universally stated that an unstandardized product with a widely varying proportion of incombustible material is forced upon them at uniform prices; and that such is the organization of producers and retailers that they have no chance to shop around and get a better grade or a lower price. There is no other commodity, the complaint runs, where a man cannot buy discriminatingly; where he cannot, as the phrase goes, "get a run for his money." Therefore the general conclusion that retailers and producers alike are "robbers." Statements showing the unfavorable returns of many coal companies and the fair profits of others have no effect on this frame of mind. The average individual does not grudge profits, small or large, as, for example, to the automobile manufacturers; but in buying an automobile, he insists he knows exactly what he is getting and has a competitive field from which to select.

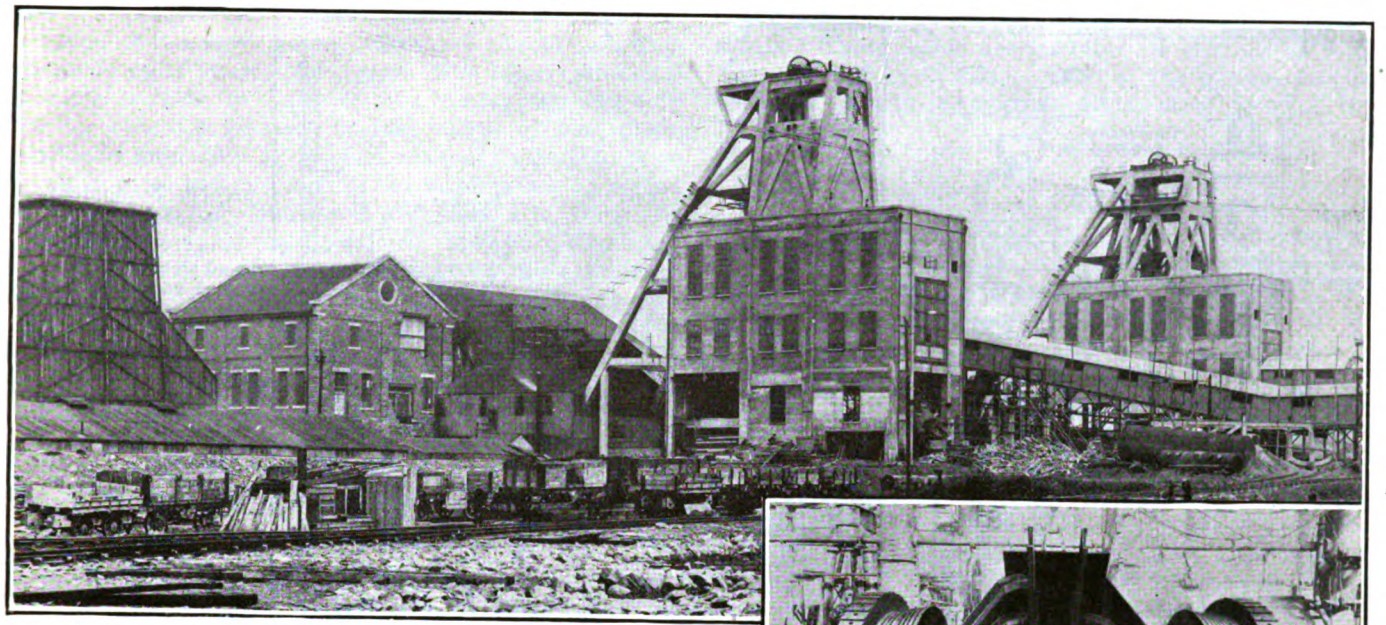
The coal industry should consider how far the public's grievances are justified, and how to rectify them—how to please the public, in short. It would probably make more rather than less money by so doing. It also would build up public goodwill which would stand in good stead in future discussions as to government regulation or labor domination. And, in addition, a policy of openness and frankness on the part of the industry with the public would be disarming. The arguments as to the relative merits of open and secret diplomacy are extensive, but experience in the United States is that placing the cards face up on the table is the best way to play the game. What is only surmised invariably is suspected. The coal industry might well spend a little money on publicity and indulge in a little honest program of educating the public as to the inherent facts and problems.

The Only Way Out

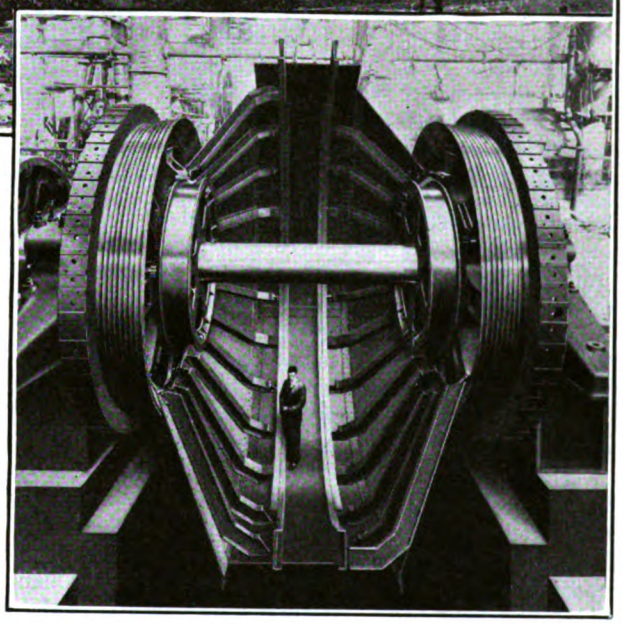
THE ANNUAL REPORT of the Pittsburgh Coal Co. for 1924 so clearly foreshadowed the financial results of the past calendar year that the net operating loss of $1,266,940 in 1925 comes as neither a surprise nor a shock. The latest report, however, is more than a mere chronicle of past disaster. It is a heartening record of courage to face the future—not with blind resolution but with a well-considered plan to overcome some of the tremendous difficulties confronting the bituminous coal industry. The key to that plan is modernization.

Acting upon the report and recommendations of nationally known consulting engineers, the company last year dismantled thirteen of its older operations "found to be uneconomic, wasteful of labor and unprofitable in competition with modern plants." This scrapping of obsolete plants and equipment meant the writing off of $1,385,902 from its surplus account. The company also consolidated several existing plants and is considering further consolidations and the complete modernization of all its operations in the Pittsburgh district. "These projects," states the report, "will involve large capital expenditures which, however, in the judgment of your officers, will be justified by the increased efficiency and lower production costs so attainable."

The Pittsburgh company is not the only operator that has adopted such a program. Neither is it the only producer that should invite the attention of engineering skill. There are probably hundreds of mines which stand in the need of drastic rehabilitation. Many, unfortunately, lack the courage to acknowledge their shortcomings. Many that are willing to confess their weaknesses have not the financial resources to effect modernization. If these latter cannot attract capital, they will drop out of the competitive race. The same fate awaits those that delude themselves with the idea that plants which were the last word in efficiency a few years ago can stand up against the newer, larger units. Modernization is a continuing process. Only the company that is ready at all times to scrap something good for something better can hope to survive.



Of course, no small measure of the troubles of the Pittsburgh company since 1923 has been due to rigid union wage rates. In recent months that company has launched upon an expensive experiment to free itself of that drawback. The importance of wage rates is not to be denied. Nevertheless, the labor question may profitably be subordinated when a modernization program is to be considered in its broadest aspects. It is a reasonable assumption that the uneconomic wage rates must inevitably find an economic level. When that condition is reached, the necessity for modernization will be still greater because business naturally will gravitate to the operators who can profitably produce the best prepared coal at the lowest cost. A common wage rate places a premium upon efficient operation and skillful management.



Despite the sad wailing of the professional mourners, the bituminous coal industry is not going to the dogs: it is the thousand-and-one brightly labeled political panaceas which have failed. Operators with courage are looking ahead, not back, and are working out their own economic salvation through modernization that starts underground and travels from the tipple to the sales department. They are breaking the path to a stabilization that will be effective because it is based upon sound operating policies and a sound merchandising program.

Profiteering in Brick

BRICKMAKERS declare that the high price of brick is due to the increased cost of coal. One cannot see any justification for such a claim. If by chance before the strike they burned anthracite they could easily have replaced that fuel by bituminous coal and kept their prices down. Now brick is coming to America from England, France, Belgium and Holland and there is a loud cry for a tariff, for which there is no real reason. If the prices are set right the American manufacturer has adequate protection, for brick is costly to load and unload, delaying shipping and absorbing precious wharf space.

Flywheel Equalizes Hoist's Demand for Steam

Small Turbine Operates Large Hoist Through Flywheel—Dynamic Braking Employed — Double-Cylindro-Conical Drum Reduces Excessive Load Peaks

By C. H. S. Tupholme
London, England

IN MOST coal regions the mine output must be hoisted to the surface either up a shaft or through a slope. The power demand of the hoist motor is not only intermittent but fluctuating. Heretofore it has not been deemed feasible to correct this inequality and make the demand for steam on the generator constant. This has been practically accomplished, however, at the Harworth Colliery in England, and although British hoisting practice varies radically from that normally followed on this side of the Atlantic, this installation will prove of interest to American coal men.

The Harworth Colliery, owned by Barber, Walker & Co., is located about 20 miles east of Sheffield. It is provided with two shafts, each 22 ft. 4 in. in diameter and about 2,940 ft. deep to the coal, being sunk to the Barnsley seam, which is the measure worked. These shafts, which were put down by the aid of the cementation process, are lined with concrete throughout the entire thickness of the water-bearing strata penetrated or to a depth of roughly 800 ft.

In selecting a suitable hoist equipment for these shafts, the following considerations were taken into account:

The upper illustration forming the headpiece of this article is a general view of the upper works of the Harworth Colliery. Two shafts have been sunk, and coal will be hoisted through both. Both tipples as well as the headframes serving them are built of reinforced concrete. On the right is a view of the interior of the drum during erection. The huge size of the drum (its outer diameter is 26 ft.) can be judged from the size of the man standing within it.

Total depth of hoist	3,000 ft.
Output per hour	300 tons
Net load per hoist	7½ tons
Weight of cage and chains	10 tons
Number of cars per cage	9
Weight of empty car	840 lb.
Diameter of hoisting rope	2½ in.
Type of rope	Locked coil
Decking period	10 sec.

When both shafts are in operation the colliery will be capable of producing about 4,000 tons per 7-hr. shift. The power necessary to carry the load other than that consumed in hoisting, such as pumps, haulages, compressors, ventilating fans, preparation screens and coal-washing equipment, totals approximately 1,500 kw.

Several schemes for obtaining the necessary power were investigated. These included steam hoists fitted with mixed-pressure turbines to carry the auxiliary load; a main power station where electrical energy for all purposes would have been produced by high-pressure turbo-generating units and the purchase of electric energy from a public utility. The Stubbs-Perry system was finally adopted.

By this system advantage can be taken in mine hoisting of the direct application of the high-speed condensing turbine, with its well-recognized economy, reliability and small size. Furthermore, this system entails a minimum of electrical equipment and assures precise and smooth operation. The consequent reduction in

Digitized by Google

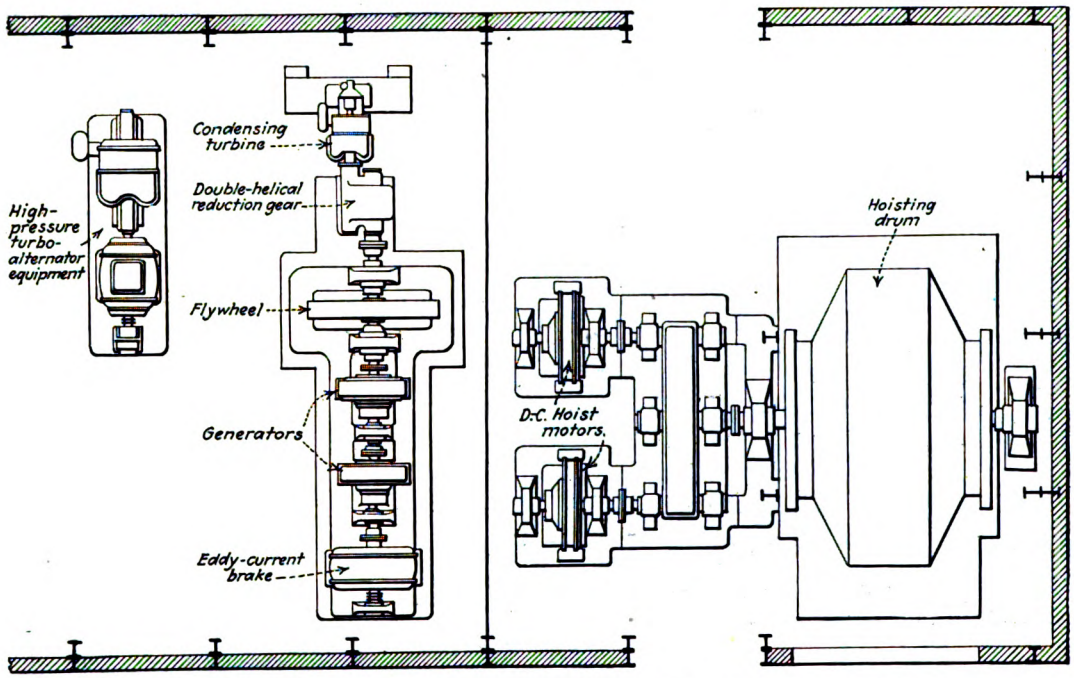

FIG. 1

Hoist Equipment

This shows the relative positions and sizes of the various pieces of apparatus. It makes a compact layout and one which could probably all be operated by one man or at the outside two. Labor charges for operation are thus reduced to a minimum.

boiler capacity, cooling towers and the possibility of using modern high-pressure boilers has enabled many improvements to be obtained, with a corresponding reduction in the initial expenditures.

Theoretically the system affords the following advantages: (1) Complete isolation of the hoist-equipment load from the remainder of the power demand. (2) Elimination of large fluctuations either in the form of electrical energy or of high steam demands.

With these broad advantages in mind, it is easy to perceive that the equipment may be arranged to suit the widely varying conditions found at collieries. Thus Fig. 1 shows an arrangement adapted to a large mine operating in a country district beyond the range of existing power lines. It should be noted that the eddy-current brake forms a means for absorbing all regenerative energy above that required to return the flywheel to its normal speed. In other words, the only energy absorbed by the eddy-current brake is regenerative energy returned to the flywheel set during a trip in which material is being lowered into the shaft. This brake is automatic in its operation and is controlled by the turbine governor. In effect, such as installation operates like a Ward-Leonard equipment, drawing its power from a large centralized supply.

Fig. 2 shows the hoisting equipment installed at Harworth, comprising a 14x26 ft. bi-cylindro-conical drum. Each of the hoist motors geared to the drum is of 1,200 hp. The arrangement is shown in Fig. 5. The two motors are connected through flexible couplings to pinions meshing with a common double helical gear secured to the drum shaft. Both motors, the gearing and two of the drum-shaft bearings are mounted on a massive cast-iron bedplate of box section and form a self-contained unit in themselves. At the other end of the drum shaft the bearing pedestal is cast integral with the bedplate. Both the pinion and drum-shaft bearings consist of four-part cast-iron shells lined with white metal and capable of adjustment by wedges.

To the right of the headpiece may be noted the

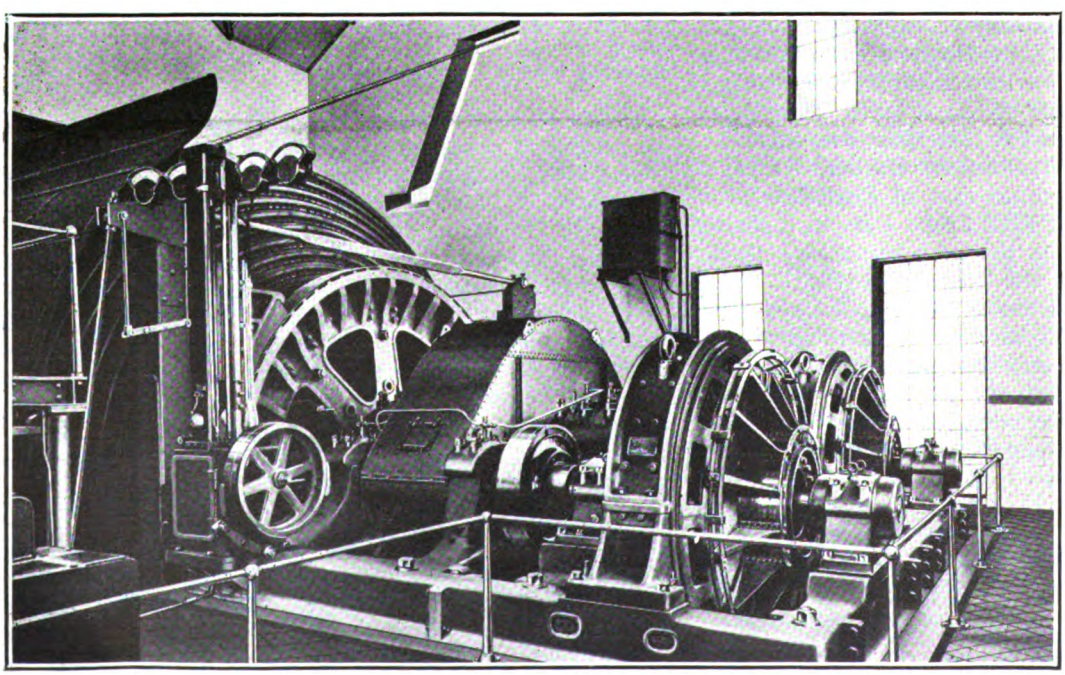

FIG. 2

The Hoist

A general view of the two motors geared to the hoist shaft. All the bearings on this side of the rope drum are attached to a common bedplate of heavy box section affording great rigidity of construction and assuring correct alignment of all shafts. The outboard bearing on the farther end of the drum is carried in a pedestal cast integral with its bedplate. The overwinding and overspeeding device practically forms a part of the depth indicator. It is so connected with the engine control as to assure safety.

Digitized by Google

internal construction of the drum itself. With the exception of the cheek pieces, which are of cast iron, this drum is built up of steel plates. The large cylindrical portion is 26 in. in diameter over the lagging and 6 ft. 2¾ in. wide. It is made of four pieces of 1-in. plate, stiffened internally by 15x4-in. channels placed back to back in pairs and fastened to the scroll plates by means of 6x6-in. angles. The scroll plates are ¾ in. thick and each is made up of eight sections. These are connected to each other, to the drum cheeks and the cylindrical part of the drum by 8x8-in. broad-flanged beams, two 8x6-in. beams being used as intermediate stiffeners on each section. The drum cheeks each have eight arms which are cast integral with the brakeways and the small-diameter cylindrical portion of the drum. They are cast in halves and held together by two 4-in. bolts and four shrunk keys recessed into the bosses, which are of 46-in. diameter and 28 in. wide.

TEN TURNS FOR ACCELERATION

Scroll iron is riveted to the scroll plates and carries the rope from the small to the large diameter of the drum in 10 turns. Of the eight convolutions of rope on the small cylindrical portion of the drum three are dead. Two cast-iron spare-rope reels, each having a capacity for 300 ft. of rope are mounted on the drum shaft. These reels, which are made in two parts, are clamped to the drum cheeks during winding operations, but may be rotated by hand-operated spur gearing when it is necessary to pay out or take up rope. The drum sides are securely stayed by large tie bolts and nuts. The large cylindrical portion of the drum or barrel is lagged with well-seasoned oak secured by bolts with countersunk heads.

Brakeways are placed on each side of the drum. These are 16 ft. in diameter and 12 in. wide and are ventilated on the underside. Twin brakes of the post type are employed. These consist of 24 in. x 7½-in. I-beams reinforced with flats. They are applied by means of a weight and released by an air-brake cylinder 14 in. in diameter with an 18-in. stroke.

The drum shaft is built in two parts with the spur wheel sandwiched between them. This shaft is of 26-in. maximum diameter and 32 ft. 10 in. long. The maximum diameter lies within the drum cheeks, the shaft being only 24 in. in diameter in the center of the drum. A 4-in. hole is bored through this shaft from end to end.

The double helical gearing by means of which the drum is driven is of particular interest. The pinions

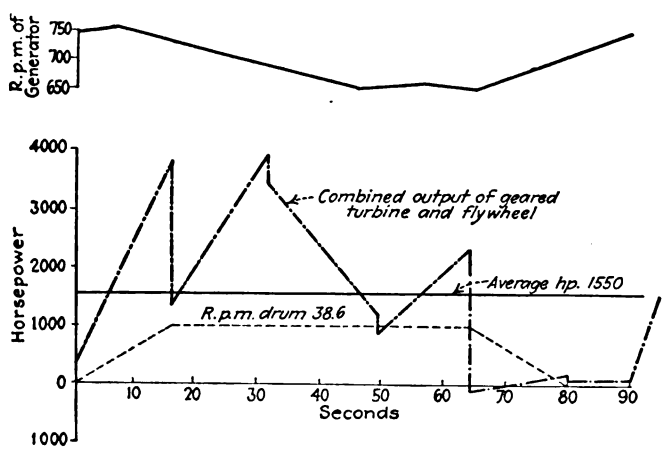

Fig. 3—Motor Duty Cycle for a Coal Hoist

This is a horsepower-second diagram showing that a complete hoist takes about 1½ min., and consumes a maximum of roughly 4,000 hp. Although three distinct peaks are apparent none is large.

are of oil-tempered nickel-steel forged integral with the shafts. These latter are mounted in journals of 9-in. diameter and 19 in. long. Each of the pinions carries 38 teeth of 1.15-in. circular pitch, meshing with the

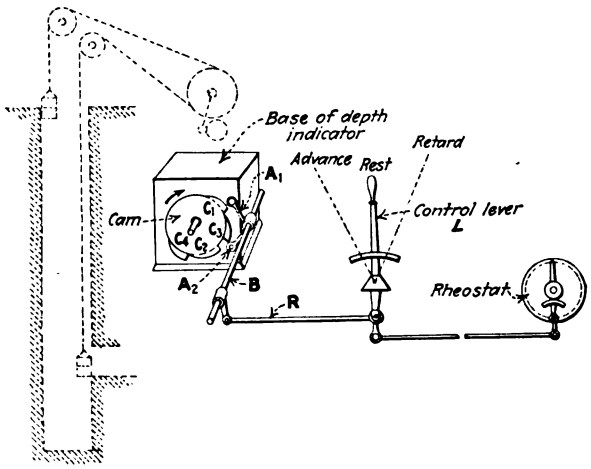

Fig. 4—Diagram of Safety Control

By a system of shafts, levers and links the overwinding and overspeeding device which is geared to the depth indicator is attached to the hoist-control lever in such a way that the machine would be stopped automatically should the hoistman mismanipulate his levers at the beginning or end of a hoist.

gear wheel which has 345 teeth. This wheel has a cast-iron center provided with a forged-steel rim, which is securely shrunk and pegged to it. In order to minimize shrinkage stresses, the spider rim is slit across in four places, make-up pieces being inserted in these openings. This wheel has a pitch diameter of 10 ft. 6½ in. and an over-all width of 39 in., the effective width of face being 36 in.

Fig. 3 shows the variation in horsepower throughout a complete coal hoist. It will be noted that the beneficial effect of using a double-cylindro-conical drum is pronounced, inasmuch as the diagram shows a moderate peak load instead of one with a high acceleration, as the load gets under way on the small diameter of the drum. A secondary peak appears as the rope mounts the cone, but this also is of moderate height, thus reducing the cost of hoist motors in proportion.

The maximum energy exerted by the motors during a normal coal hoist is slightly over 3,000 hp., but the motors are capable of exerting a momentary peak of approximately 6,000 hp. The electrical control of this hoist is normally effected by the driver by means of a single lever from the control platform. Under certain conditions, however, the machine is controlled automatically and quite independent of the hoist engineer. This is accomplished by means of a cam gear which operates in conjunction with the depth indicator.

DEPTH-INDICATOR DESIGN

The depth indicator is gear-driven from the drum shaft, and on its shaft is mounted a cam wheel as shown diagrammatically in Fig. 4. The arms *A1* and *A2* are both keyed to the shaft *B* and carry rollers which engage with the cams. The cams and arms are so arranged that the cams *C1* and *C2* engage with arm *A1* and cams *C3* and *C4* with arm *A2*. The control lever can thus be operated from the cam wheel through the rod *R*.

Suppose that the hoist is running at full speed with a cage approaching the dumping point, the control lever and controller being then in the forward position with the cam wheel revolving in the direction of the arrow. Should the hoistman neglect to reduce the speed at this

Digitized by Google

point by returning the control lever toward the off position, the cam *C1* will come into contact with the roller arm *A1* and the control lever will be returned automatically toward the off position, thus bringing the cages almost to rest. The hoist, however, is not quite stopped at the decking level, but will creep past that point at a slow speed.

It will be observed from Fig. 4 that when the controller is in the off position the rollers on arms *A1* and *A2* are clear of their respective cams. It is possible for a careless hoistman to start the machine from rest in the wrong direction, but no harm would result should the overwind switch be brought into operation and the emergency brake applied, as the hoist moves off in either direction at an extremely low speed. It will be observed from Fig. 4 that at the beginning of the hoist the operator must keep the roller pressed against the cam in order to obtain the correct rate of acceleration.

The duty of the mechanical brake, under normal conditions, is not to bring the hoist to rest but to hold it after it has been stopped by electrical braking. The wear on the brake blocks is thus reduced to a minimum. The safety device is added to provide a means for automatically stopping the machine in case of overwind, overload, failure of current, or overspeed of the flywheel set. It is so arranged that it may be tripped by the driver in case of emergency.

Safety Devices Always Ready

This safety device comprises a field-discharge contactor and discharge resistance, as well as an emergency brake and solenoid contactor. It is designed to operate under the following conditions: (1) By hand (in case of emergency), by means of a push button or hand lever; (2) in case of overwind by means of the overwind limit switch; (3) on overload by means of a relay operating in the main Ward-Leonard circuit; (4) by overspeed of either the hoist motor or the generator set; and (5) on failure of the power supply. Should any of the above conditions arise, the safety device causes the emergency brakes to operate, at the same time taking the load off the hoist motor by open-circuiting the exciter field.

The eddy-current brake shown on the left in Fig. 6 absorbs regenerative energy when materials or men are being lowered. It is arranged to operate at a function of the turbine speed. Thus, assuming that the turbine flywheel equipment is running at its light-load speed and that a load is being lowered into the shaft, the regenerative energy returned to the flywheel equipment will have the effect of increasing its speed. Immediately this takes place the mechanical arrangement connected with the turbine governor operates a contactor system which energizes the field of the eddy-current brake, thus holding the speed of the turbine flywheel equipment within safe limits.

In capacity this brake is such that the maximum load possible may be lowered with safety and may be held electrically in any position. In installations where auxiliary electrical power is available an induction motor may be installed in place of the eddy-current brake. Such a motor operates in exactly the same way as the brake described, but in addition may on occasion be used as an induction motor, the turbine being unclutched meanwhile. This feature greatly increases the flexibility of the installation. It provides an alternate means of operating the hoist engine, thus enabling the turbine and steam plant to be shut down for extended periods. It also offers certain economies during off shifts when the equipment may be operated electrically.

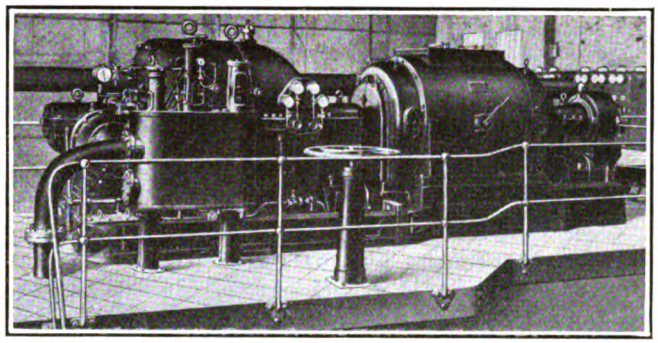

Fig. 7—Turbo-Generator Carrying Colliery Load

This alternating-current generator shoulders all of the colliery load except that of hoisting. This machine has a capacity of 1,500 kw. and is installed in the same room with the direct-current flywheel unit shown in Fig. 6.

At Harworth power for the hoist engine is supplied by means of the turbo-flywheel equipment shown in Fig. 6. This consists of two 875-kw. direct-current generators, a solid cast-steel flywheel weighing 22 tons, the eddy-current brake and a 1,550-hp. high-pressure steam turbine, designed to operate on 170 lb. of gage pressure and 200 deg. of superheat and to exhaust into a 27.68-in. vacuum. This machine operates at a speed of 4,500 r.p.m. and with its condenser occupies an extremely small space considering its capacity. The direct-current generators and flywheel operate at 750 r.p.m. and naturally are driven through reduction gear-

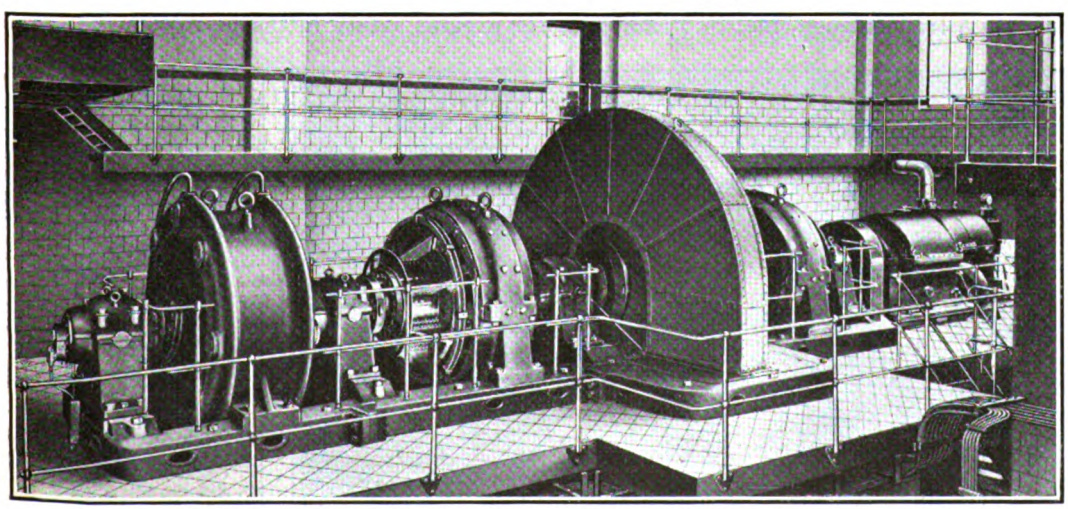

FIG. 6

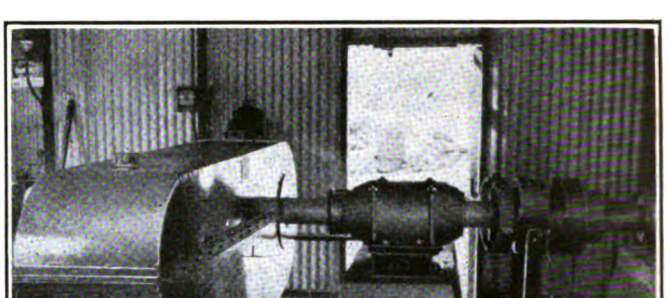
Flywheel Turbo Set

Flywheel motor-generator sets furnishing power to hoist engines are fairly common but here is a turbo-generator set fitted with a flywheel. By this means the steam demand of the turbine is nearly equalized and rendered almost constant. The turbine is connected to the generator shaft through a reduction gear.

Digitized by Google

ing, the ratio being 6 to 1. The arrangement is such that during peak loads the turbine decreases its speed, thus allowing the flywheel to give up its stored energy and equalize the demand for steam imposed on the boilers.



At this mine the auxiliary load is carried by a 1,500-kw. 3,000-r.p.m. high-pressure turbo-alternator erected in the new power station shown in the background of the general view of the colliery. This alternator also is shown in Fig. 7.

At the present time the upcast shaft only is in operation so that the power-house building is only half completed. The other half of the hoisting equipment or that for the downcast shaft is being put together at the factory.

As the output of this colliery increases automatic decking arrangements will be installed, and the coal will pass along covered galleries to the screening plant. This is designed to handle 4,000 tons of coal in 6 hr. 40 min.

Barber, Walker & Co., owner of this colliery, is building a modern village for its employees. This will eventually consist of 1,000 to 1,200 houses, together with the necessary shopping and recreational facilities. At present about 600 of these dwellings are completed and occupied. The village has been laid out on generous lines, the houses being supplied with water and electric light and placed in such a manner that the surrounding grounds may be utilized for gardens and lawns.

I am indebted to the Metropolitan-Vickers Electrical Co., Ltd., for the data upon which this article is founded and the photographs accompanying it. This firm designed and installed the system here described.

A Restricted View in the Motor House

The short "belt center" possible with silent-chain drive cuts down the size of building required. The inclosing casing of this chain can be seen at the left. At the right is the square-jaw clutch on the fan shaft.

Mulga Mine Has Three Fans Using Common Intake

Mine ventilation, as one of the factors pertaining to safety, receives its full share of attention at the Mulga mine of the Woodward Iron Co., at Mulga, Ala. To the ventilating equipment, which until recently consisted of two fans pulling over 175,000 cu.ft. of air through the mine, there has been added a new fan, with a rating of 160,000 cu.ft. per minute at 5-in. water gage. All three fans are operated on a common intake. An auxiliary drive forms a part of the equipment at each fan. The two old fans which are located close to the tipple and power plant can be operated either by steam engine or motor. Electric power for the latter is available from two sources: the local plant and a transmission line.

The new fan, an 8x3-ft. multivane unit rated at 275 r.p.m., was installed at a recently-completed escapeway located in a secluded hollow a long distance from the tipple. The regular drive of this fan is a 200-hp., 435-r.p.m. motor of the wound-rotor type. A silent chain connects this motor to a short drive shaft, which in turn is connected to the fan by means of a square-jaw clutch.

The auxiliary drive is a four-cylinder fuel-oil engine having a rating of 200 hp. at 285 r.p.m. It was purchased second-hand and is not one of the latest type. Starting is by means of compressed air furnished by a small gasoline unit. The large engine is direct-connected to the fan through a square-jaw coupling of the same type as is used on the motor side. A tank of approximately 10,000 gal. capacity, erected close to the fan stores a supply of cooling water.

Because of the remote location, an attendant is at the fan at all hours. At regular intervals he starts the engine in order to assure its being constantly in working order. With such precautions as taken with the fan equipments at the Mulga mine, any interruption to ventilation because of fan trouble is unlikely.

APPROXIMATELY 140,000 workers in the mineral industries have now been trained in mine rescue and first aid methods by employees of the Bureau of Mines, according to the 1925 report of the director. The chief purpose of the Bureau's recently organized safety extension service will be to give advanced training in rescue work and bring to the attention of mine officials the latest advances made in the prevention of mine fires and explosions and in the conduct of rescue operations and disasters. The Bureau has also recently begun a campaign for greater safety in the petroleum industry.

Construction View of Fan at Mulga

The regular drive is a 200-hp. motor installed in the small building at the right. The auxiliary drive, a fuel-oil engine of the same power, is in the large building at the left. Cooling water for the engine is stored in the tank back of the motor house. The fan is a multivane unit 8 x 3 ft., having a rated capacity of 160,000 cu.ft. per minute at a 5-in. water gage.

Coal Men You Should Know

Robert Grant

By J. S. Burrows

THE RECENT merging of some of the larger smokeless mines under the ownership of the Massachusetts Gas Companies has brought to the front rank of the smokeless industry, Robert Grant, as president of the several companies now controlled by this Boston corporation. Mr. Grant is a man whose talent for efficiency in organization and management has carried him from the lower clerical positions of a large city gas office to the active direction and management of important public-utility companies and other corporations, embracing high- and low-volatile coal producing properties, gas plants, byproduct coke ovens, iron furnaces, steamships, towboats, and barges, which it may be added includes nearly all the important coal-consuming industries. Mr. Grant is now president of the E. E. White Coal Co., the East Gulf Coal Co., the Pemberton Fuel Co., the Prince Wick Coal Co., the Long Branch Coal Co. and the Glencoe Coal Co. of West Virginia. He is also president of Castner, Curran & Bullitt, Inc., of New York—a well-known selling organization with branches in Boston, Chicago, Cincinnati, and other cities.

Robert Grant

Mr. Grant was born and educated in Glasgow, Scotland. He came to the United States when a young man and entered the employ of the New England Gas & Coke Co. Shortly after joining this organization, and while he was employed as a junior accountant, the company was placed under a receivership and the auditor of the company resigned. Mr. Grant was placed in charge of the accounting department at this most important time and when a reorganization came about and his company was taken over by the Massachusetts Gas Companies, Mr. Grant was placed in charge of the accounting department of the greater Massachusetts Gas Companies. In the years that followed his special organizing ability brought additional responsibilities and recognition. Mr. Grant was made an executive of the parent company early in its career and has been closely identified with its expansion program from the beginning. He has supervised the formation of all the subsidiary companies acquired in recent years. In 1915 he became president of the "Commercial Companies" of the Massachusetts Gas Companies such as the New England Coal & Coke Co., New England Fuel & Transportation Co., Mystic Steamship Co., etc., and was elected vice-president of the parent company in 1918. Mr. Grant is an indefatigable worker, a fine example of the sturdy stock from which he comes and a great lover of his native game, golf. He has always found time to keep in close touch with his subordinates and the thousands of employees of the companies he directs. He is not only personally acquainted with most of these people, but is deeply interested in their individual welfare. As the directing head also of the Federal Mines near Fairmont, W. Va., Mr. Grant has had practical operating experience in coal mining and is well-known in that part of the state as a successful operator. His entry as an operator into the southern West Virginia field foreshadows a successful, efficient mining organization of which its members may be proud. Such organizations have been the life-work of Robert Grant.

The steady growth of the smokeless coal industry of West Virginia—so often attributed solely to the high quality of its product or to the fact that the mines are non-union—could not have been brought about without an aggressive marketing policy, which from necessity has been developed within the industry itself.

These fields, lying in the southern counties of West Virginia, were actually hewn out of the wilderness by the pioneering type of operator as far back as the early eighties and lacking a contemporaneous growth of coal consuming industries nearby—as for example, the Pittsburgh region—they have remained in an isolated position hundreds of miles from any markets.

As the smokeless industry is vitally dependent upon long-haul transportation by rail and water and as it must derive its sustenance from many kinds of consumers in distant markets both at home and abroad, it is plainly a business which can succeed best when conducted on a large scale, which under modern conditions means corporate ownership of properties under experienced men like Robert Grant.

By Mechanical Loading an Attack Is Made on the Largest Cost Items of Coal Mining

Miner Should Favor Mechanization as It Makes for Better and Easier and More Social Working Conditions—Doubles Tonnage per Man and Reduces Room "Rent"

By Nixon W. Elmer
Consulting Engineer, Quincy, Mass.

Nixon W. Elmer

IN EVERY industry there is a natural tendency to do things as every one else in the same industry is doing them, each individual concentrating his efforts on doing them a little better than the other fellow. No general change of methods takes place in any industry in a brief space of time, except under the spur of necessity, usually furnished by bitter competition.

I think that you will agree with me that such necessitous conditions exist in the bituminous coal-mining industry today. Reacting to this universal stimulant, necessity, the coal-mining industry has studied its standardized practice and customary sequence of operations with an open mind and a searching eye.

After repeated study of operations and cost data, man after man in widely separated districts has apparently come to the same conclusion, namely that the opportunity for a major saving lies in one place only. This is at the face and as far back as the haulage entry.

Here is located the greater part of the labor item in mine coal cost. Much of this is hand labor, in fact it is safe to say that more than 95 per cent of all the coal used by the industries today, has been manhandled about as follows: Dug out of the side of a pile in semi-darkness with a shovel, carried an average of one step on the shovel, lifted higher than the miner's shoulders and placed in a car, not in place to receive it more than 75 per cent of the time.

Of course the miner does not need to shovel coal for 8 hr., but the 2 hr. he loses are generally speaking, during the time when he must shovel coal because the face is not ready to work on till the free coal is cleaned up. This means that he either wastes this time or uses it uneconomically in moving the more distant coal closer to the place where the car will be, thus handling this part of the coal twice.

A commonly expressed, though perhaps not a very thoughtful viewpoint, has been that the miners generally work on a tonnage basis and will demand and receive double wages, at the expense of the operator, if their output is doubled by mechanical means, the corollary of this thought being that in this event the individual miner will work but half the time that he would if he did not receive this assistance. The point missed is that, with group machinery, there is no longer any possibility of individual tonnage payment, the very machinery itself will force tonnage work to be of the group type, and with group work provision for an average number of absentees can always be made and their places can be filled without loss of production.

Furthermore, in setting such new group-tonnage rates it is not probable that these new rates will be such that the miner who had formerly made $10 per day, for example, would be raised to $20 per day for the same time and easier work. As a matter of fact most of such work now going on is being done on a day-rate basis, and the men like the idea and take to it, both because the work itself is easier and because of the element of social intercourse thus introduced into lives that are notably barren in this respect. The logical development would seem to be in the direction of day labor with a group bonus for group-tonnage production. The factor just mentioned, namely the social element introduced into the miners' lives in this way, is an intangible, and so seems an airy nothing to the man in a busy office seeking privacy, but to the miner underground it seems to be of real importance. When we stop to think, this in understandable. Men always prefer to do manual labor in gangs rather than individually or in pairs. Those of us who have passed through a stage of being paid for muscle alone should be able to remember this.

Many an otherwise thoroughly competent engineer or executive has failed to make a success of a carefully planned and mechanically correct project, through

MR. ELMER declares that with mechanization, individual tonnage payment becomes impossible, making group payment or the day wage essential. He declares that to mechanize is to Americanize. He avers that when mechanization is complete men will load at least twice as much coal. He urges that one improvement only should be made at a time and that conveying should precede machine shoveling, making enough profit to pay for complete mechanization.

Article entitled "The Mechanization of Our Coal Mines, from the Viewpoint of the Material-Handling Engineer," read March 11 in New York City before the Material-Handling Section of the American Society of Mechanical Engineers acting with the National Coal Association.

Digitized by Google

neglect of such human preferences—the likes and dislikes of the man behind the shovel.

Though I, for one, cannot claim to have foreseen this result, and more time will have to pass before it can be said to be proved generally, still it is interesting to note that, even with no increase of wages, these better, easier and more social conditions are attracting a higher and more intelligent grade of labor underground. This is certainly important and will mean much to the industry, if general experience parallels individual experience in this respect. Broadly speaking, does not the history of other industries teach us that to mechanize is to Americanize?

To get back to the general subject of mechanizing the hand-labor operations from the face; let us ask ourselves two questions: (1) What is the order of magnitude of the possible savings at this point? (2) What means are in sight that appear as possible or probable means for achieving such savings?

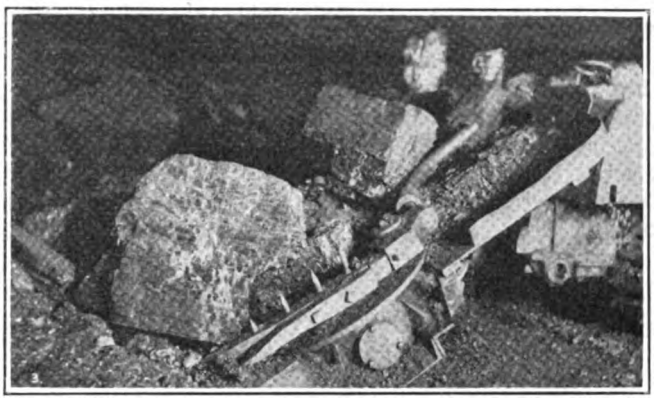
Taking up the first question: "What is the order of magnitude of the possible savings over present hand-labor methods from the face out to the haulage entry?" Please note that this question deals solely with the possible saving in hand labor, without defining the particular mechanical method to be used.

No One Best Method of Loading

Though larger figures have been given on good authority, the figures I am going to give are based on personal experience. I do not believe, however, that the use of this or that particular method or means should affect these results materially, provided the method selected fits the conditions in the particular mine. This is a new thought to many and deserves to be emphasized. There is not and never has been one best method of handling bulk materials mechanically. Success follows a wise selection of mechanical means, where the machine and the method are respectively so modified and co-ordinated that they work together to the best advantage under the special conditions in the particular mine.

Where a certain group of workmen average 10 tons per 8 hr., laying their own track at the face and their own drilling and shooting, under a suitable and carefully planned mechanizing system, these same men can and do handle from 20 to 30 tons per 8-hr. shift, depending upon how much shooting, drilling and moving of equipment they are required to do.

The actual tons quoted are not significant, it is the proportional increase obtained that has a real meaning for us. The means used for mechanical handling to which these figures apply were mostly chain conveyors. I have seen, and others here can relate, similar results with belt and apron conveyors. In such cases, shovels, man-handled, are used as of old; merely the conditions under which the shovelers work, are changed.



Under other mining conditions, cable drags have successfully replaced the shovelers entirely with equal or better results, and where lumps are not large belts will undoubtedly find their place in the future. Circumstances frequently call for a combination of two or more of these methods, but the results to date fall within the limits mentioned of two to three times the normal room-and-pillar output for the same individual.

The mining methods used in these various applications run the whole gamut from straight room-and-pillar, through modified room-and-pillar, modified long-wall to longwall. It does not require a prophet to see that some of these applications, useful as they are in themselves, are merely half-way stations furnishing the necessary background for a still more substantial success with loading machines.

It has seemed to me sometimes that the cart frequently preceeded the horse in much of our experimenting with loading machines. A suction dredge without a discharge pipe would be analogous to a loading machine without anything in which to load. Like most machinery, loading machines can earn no dividends when they are idle.

We are now ready to attempt the answer to our first question: "What is the order of magnitude of the possible savings through mechanizing the operations from the face to the haulage entry?" On the face of the results quoted, this would appear to be not less than 50 per cent of the direct labor.

Please note that we are speaking of the possible saving. The actual saving to date has usually been less than 50 per cent of the direct labor, particularly at the start. This is not surprising, because the mechanical details of the various types of equipment have not had time to go through the normal cycle of improvement and the operating forces have not had time to develop the technique of operation.

Lifting Large Lumps to Level of a Mine Car

Looking at these heavy masses of coal being carried to a mine car by a mechanical loader will convince anyone that the miner's opposition to the machine where it exists will be of short duration and be followed by a demand for its universal adoption.

Under almost every conceivable mechanizing scheme, the unit becomes a group instead of one or at most two individuals. This means that one consequence of the complete mechanizing of any mine must be to reduce greatly the area developed for a given production. Concentration of working areas of the order of magnitude of 10 to 1 are to be expected.

On paper your mine foreman can show from this a saving of general underground overhead labor of from 20 to 25 per cent, but this saving will not appear on the cost sheets till the whole mine is mechanized, the idle parts closed, and the unnecessary portion of the overhead labor pried lose from its hereditary jobs and absorbed in the productive labor. This takes time.

It took the Government five years to reduce their departmental organizations in Washington, after the war! When this reduction has become accomplished, this item of savings in overhead labor should fully balance the extra men used to handle and operate the machinery employed in the mechanizing. Then the possible saving will become the actual saving. At first we will have to be satisfied with about half the possible.

We now come to our second question: "What means are in sight that appear as possible or probable means for achieving such savings?"

Digitized by Google

In some of the early efforts, the assumption was made that the mining system would have to be altered radically to fit the mechanizing means. In the light of present experience this seems to have been unnecessary, because the available means for mechanizing are so numerous and various that suitable means can be and have been adapted to almost every type and method of mining.

On the other hand, it is often more economical in the individual case to change the mining system, where this is allowable. There are two main reasons for not changing a mining system, where money will be definitely saved by doing so: One is the safety of the workmen and property, and the other is mental inflexibility on the part of the management; of course either may function separately or both together. Where the mining system cannot be changed, it is reasonably certain that some form of mechanizing can be adapted and modified to fit existing conditions.

It is well to bear in mind that equipment already developed above ground should form the basis for the development of similar underground equipment; but that the mere transplanting of such equipment bodily, without suitable modification, will always prove unsatisfactory. In making such modifications to fit underground conditions, full advantage should be taken of the years of experience gained above ground with similar coal-handling equipment. This is where the material-handling section of the American Society of Mechanical Engineers may individually or collectively be made of use to the mining fraternity.

Too Little Use Made of Experience

The two or three statements about the use of above-ground experience below ground, sound so self-evident that they hardly seem worth saying, but they certainly need to be taken to heart because the facts are that our general practice seems to have been almost the exact opposite. That is to say, we have not generally made use of above-ground coal-handling experience underground, and we have attempted to transplant bodily equipment developed above ground to the work in our mines. In these two mistakes may be found the reason for many of our failures.

What means are in sight which are capable of achieving important savings near the face? As this is to be a verbal, not a visual, table, I will simplify it by restricting myself to conveying methods, and assume, for the reasons already stated, that the loading machine should follow rather than precede the conveyors. The more promising of the efforts with which I am acquainted, may be grouped as follows:

- Longwall
  - Cable scraper or hoe
  - Chain conveyors
  - Apron conveyors
  - Combined mining and conveying
  - Jigging conveyors
- Modified Longwall
  - Saw-tooth or Y
    - Apron conveyor
    - Chain conveyor
    - Cable scraper or hoe
    - One or more of these combined with belts
    - Jigging conveyors
  - V-Type
    - Apron conveyors
- Room-and-Pillar (Modified)
  - Cable scraper or hoe
  - Chain conveyors
  - A combination of either or both of these with belts
  - Belt conveyors alone.

Each of these conveyor types has its strong and weak points. Salesmen will present the former, but unless we familiarize ourselves with the inherent weaknesses of each type we cannot hope to select and adapt wisely, except by some more or less fortunate accident.

The logical line of development of the heavier type of apron conveyor will be to improve it so that it can come closer and closer to the face to be shot. This will leave little opportunity for the use of loading machines. On the other hand, the next and obvious step with most of the other types of conveyor (except the cable scraper) is to adapt a suitable loading device to caterpillar traction and develop a successful continuous feed therefrom to the conveyor and thus eliminate most of the hand-shovel labor, already materially reduced by the conveyor.

Make One Change at a Time

This, you will notice, assumes that the loader is introduced into the scheme after the conveyor application has been fully developed, has paid its way and reached a state of reasonable working perfection. It does not pay to attempt to introduce two separate but interdependent improvements at once. The reason that the conveyor should precede the loading device is that the conveyor installation will pay its way as it goes, and nothing will have to be undone when the loaders are later introduced. Also the cleaning problem is postponed.

Below ground as above, there is no one best type of conveyor; some types have received more attention than others and their underground development has proceeded farther, but each has its own strong points and weaknesses which must eventually determine its individual field of usefulness. It is inevitable that in many cases the best results will only be obtained by a judicious combination of types, each with its own proper function to perform.

The idea of cutting, mining and conveying at one and the same time and with one and the same machine is interesting many and should lead to important results. The cable drag or hoe is being tried out in many places, but under an unnecessary handicap. The device looks ridiculously simple, and, therefore, many operators are making the same mistake their brethren above ground made ten or fifteen years ago. They are using home-made outfits, and a good device will get a bad name in this way.

Any mechanizing system will be at a premium which favors the pillar-drawing part of room-and-pillar work, because of the large area of standing pillars throughout the country. In room-and-pillar work, retreat lags behind advance so that rooms frequently stand for years.

Make the Rooms Pay "Rent"

The rooms of a house or office either cost or earn money, which is called "rent." I have found it useful to charge standing rooms with a yearly rent, so-called. This underground room "rent" is obtained by dividing the cost of retimbering, relaying track and clearing up falls at the end of the period, by the number of years the room will have to stand before the pillars are drawn. The effect of this in interesting the local authorities to reduce this time element is astonishing. Such "rent" may amount to as much as a dollar a day per room, though this would be exceptional. Such information may be unpleasant, but it certainly helps to have the facts known and kept before the superintendent and foreman.

It is not unusual to hear not too thoughtful criticism expressed of the conservatism and resistance to change met with around coal mines. We should understand

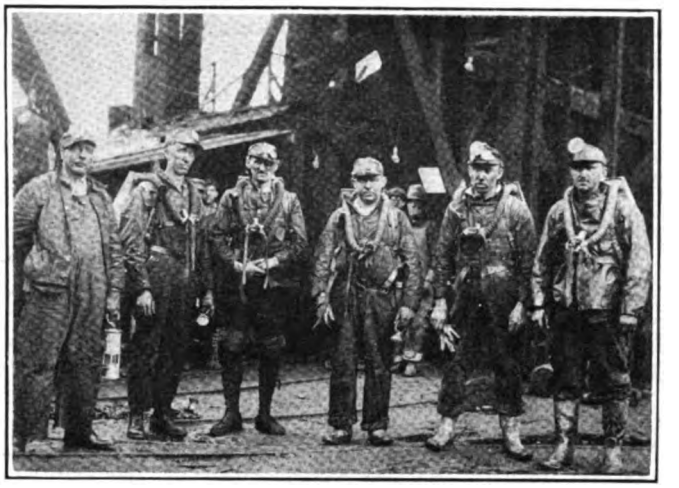
Digitized by Google

and appreciate that such an attitude is not only natural, but inevitable, and, in many ways, desirable. Life itself below ground depends upon the correct interpretation of the signs and sounds, and the man who has learned the meanings of these warnings under a given system will naturally and rightly resist any changes which may lessen the value of his hard-won experience.

In conclusion, let me say that the interest in all this to the community at large lies in the stabilizing effect which a general success in mechanizing the mines will have upon the coal-producing industry. The beneficial effect on the industry from reduced costs, both direct and indirect, is obvious, but perhaps it would mean still more if the number of companies operating were materially reduced. It is logical to anticipate that machine loading will reduce the number of companies operating, for several reasons: (1) Many "snow-birds" will drop out, because of the decreased margin available under which they can work. (2) Competition will gradually eliminate those mines which are unable to make improvements in their methods for any reason, physical, mental, or financial.

From the point of view of the bituminous-coal industry, such stabilizing of conditions would be of incalculable value. The interest of the general public therein has been well put by the Engineering Council: "In the last analysis it is the consumer who will profit most by any improvement in coal procurement."

Believe Cutting Machine Caused Blast at Eccles Mine



Barricade in Long Room Saved Ten Lives—Three Men Leave to Meet Death—One Man Killed in Upper Seam

IGNITION OF GAS by a cutting machine is thought to have been the cause of the explosion on March 8 of the No. 5 shaft mine of the Crab Orchard Improvement Co., Eccles, Raleigh County, W. Va., in which nineteen men were killed. Thirteen men who were at work in the southwest-entry section barricaded themselves in a room. Twenty-five hours after the explosion, ten of these men were rescued. Three of them met death in an attempt to leave the mine before the arrival of the rescuers. An explosion in the mine on April 28, 1924, killed 180 men.

The mine is in the Beckley seam and is served by a hoisting shaft which is 535 ft. deep. It connects with the No. 3 mine at the same horizon, about 270 ft. below the No. 6 mine of the company, which is working the Sewell seam. The coal from all three mines is hoisted in the one shaft mentioned. At the time of the explosion thirty-six men were at the upper level, that, namely, in No. 6 mine. All but one of these men reached the surface safely.

The explosion occurred at 6:50 p.m. An hour and a half after the explosion, No. 2 truck from the state rescue station at Mount Hope arrived on the scene with Inspector Robert Lilly who took charge until the arrival of Chief Inspector Lambie two hours later. These men were assisted in the rescue work by volunteers, including a team from the New River Co. at Scarbro, another from the McKell Coal & Coke Co. and a third from the E. E. White Coal Co. at Glen White.

Recovery was attempted, shortly after the explosion, through the upper level or No. 6 mine. In this operation thirty-five men were led to the surface through an auxiliary shaft. The explosion doors on the fan over the air compartment of the main hoisting shaft were blown off by the explosion and the air escaping through this vent was so charged with foul air that the men working at this replacement were required to wear gas masks. As the main force of the explosion was expended through this shaft, the curtain wall, buntons and guides were materially damaged. For this reason some time was lost in patching the shaft before a clear passage to the bottom was effected.

Rescue Team, White Oak Coal Co., Arrives First

This team started work at 10 p.m. cleaning and repairing shaft. At 6 a.m. of Tuesday morning the team entered the mine and advanced, in one shift, ¾ mile, building stoppings as it went.

DEBRIS HINDERED OPERATIONS

About 40 ft. from the bottom landing much debris was encountered, which, it was estimated, would have required about 48 hr. for its removal. The decision was reached, therefore, to stop the fan of No. 5 mine and to reverse the fan of No. 3 mine, on the same level, in the hope that the afterdamp would be pulled away from the southwest entries. The rescuers suspected that the men who were at work in this territory might still be alive.

At 7.30 p.m. of the following day the rescuers found a board in the southwest section, on which was chalked the information "Come to Second Right." Following this advice, they found a brattice barrier at a point 600 ft. inby, behind which were found ten survivors.

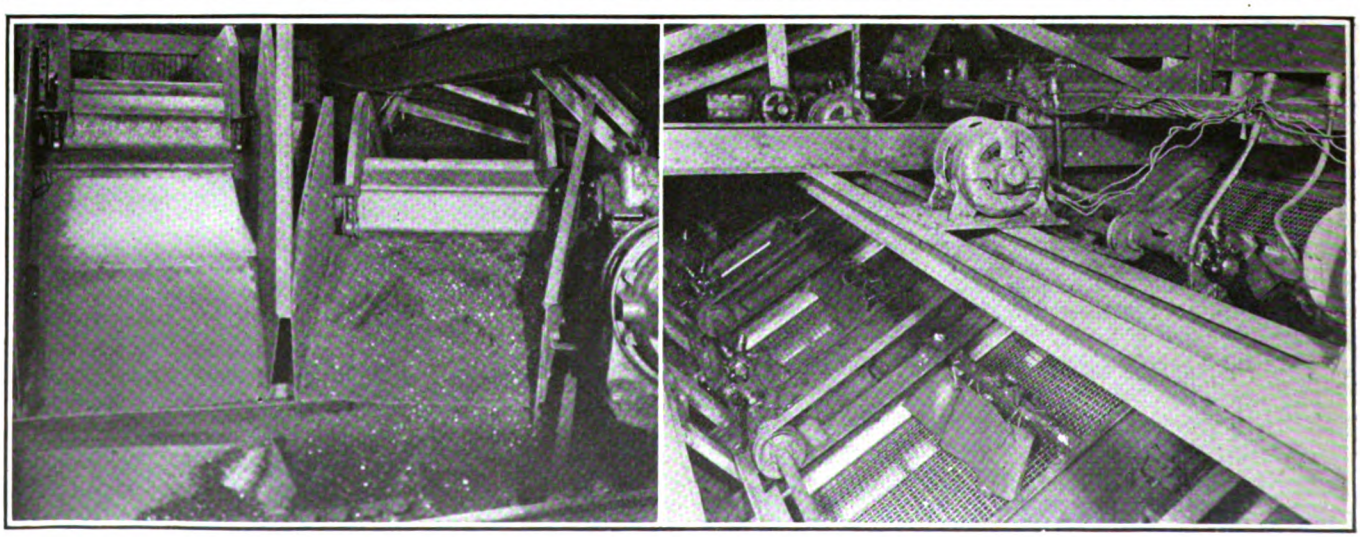
His Energetic Action Saved the Barricaded Men

Robert Lilly, district mine inspector, veteran fire fighter who had entire charge of recovery work till the arrival of Chief Lambie, and later subject to Mr. Lambie's direction. The car in the rear is one of the new West Virginia rescue trucks, two of which were rushed to Eccles following the explosion.

Digitized by Google

Those Who Directed the Rescue Operations

From left to right, Robert Lilly; Ralph Taggart, vice president Crab Orchard Improvement Co.; R. M. Lambie, chief, West Virginia Department of Mines, and Stockton Garvis, West Virginia state rescue man. Lambie was overcome by carbon monoxide but Taggart and Garvis administered oxygen from their own tanks and brought him out saving his life.



These men and three others, who subsequently died in an attempt to leave the mine, had erected a barricade of canvas and boards sealed with clay and refuse, at the mouth of a room, 1,000 ft. outby of the face. The room was 190 ft. long and had a volume of 11,000 cu.ft. In the barricade was built a small door and it was through this door that the three victims of afterdamp left the inclosure.

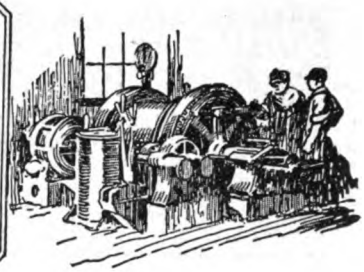
The survivors say that they had begun to grow impatient toward the end of their siege and were on the verge of attempting an exit when they were rescued. Throughout their work prior to reaching the barricaded men, the rescuers were as fearful that they would arrive too late as were the entombed men themselves. It was argued that, though the barricaded miners might escape the afterdamp, they might succumb to a shortage of oxygen caused by the liberation of methane and by the absorption of oxygen by the freshly-cut coal. The rescuers believed that the men had probably walled in a small area inby the last crosscut of an advancing entry. "The survivors," Chief Lambie said afterwards, "chose the location of their barricade with much wisdom," at a point that is far enough removed from the advancing entry faces.

Out of the explosion comes a new sense of the importance of selecting the proper place for erecting a barricade and of choosing the materials for its construction. In the light of experience at this mine disaster and at a recent explosion in the No. 8 mine of the Jamison Coal & Coke Co., Chief Lambie will outline the proper procedure in erecting barricades in a paper to be presented to the safety clubs of West Virginia, of which 250 are already organized.

In this explosion as in that at No. 8 mine of the Jamison Coal & Coke Co., was demonstrated the wisdom of an act of the last state legislature by which rescue trucks were provided for the use of the department of mines. In each case one of these trucks brought equipment and men to the scene soon after the explosion occurred. Governor Howard M. Gore, who is deeply interested in safety in mining in his state, played no small part in bringing about this arrangement and in co-ordinating the activites of the varous departments so that immediate aid is rendered at the scene of a mine disaster. The coroner's inquest will be held in Beckley on April 7.

ONE OF THE OLDEST electrified coal mines in existence recently closed down after 30 years of continuous operation. This was No. 22 Eureka colliery of the Berwind-White Coal Mining Co. in the Clearfield district of Pennsylvania. This mine was opened in 1894 and was the first plant installed in the district having electric haulage. There was not a mule or horse used in the mine. The mine cars were small and, when full, carried one gross ton of coal. From 1895 to 1901 the mine averaged 180,000 tons a year.

Handling the Coal on Part of Its Course Through Mt. Union Plant of the Rockhill Coal & Iron Co.



At the left are shown apron conveyors discharging onto a shaking screen. Two transfer conveyors of the apron type carry the coal from the narrow-gage railroad pits to a shaker screen within the transfer plant. This shaker, only a few openings of which may be seen, divides the coal into two products—over 4½ and under 4½ in. The oversize is picked and loaded over a picking-table loading boom and the undersize is carried by a conveyor into the coal-cleaning plant.

At the right is a battery of four vibrating screens. Each of these screens is driven independently by a 3-hp. motor. They are actuated through small throw eccentrics driven at high speed, and are composed of two decks. Each deck is made up of two screens in tandem. The upper screens separate a combination of furnace and range sizes from the stoker sizes and the lower screens separate sized stoker coal from stoker fines which are not washed. Each unit will handle a feed of 100 tons an hour. These screens are said to have the highest capacity of any in existence, each handling 100 tons per hour.

Practical Pointers For Electrical And Mechanical Men

Battery Watering Device Slides Along Cable

Method in the flushing of mine locomotive batteries will well repay the time and thought involved in its accomplishment. Water can be poured into the cells from a pitcher, but that is poor practice, for the reason that almost invariably much water is spilled on the cell covers. This moisture helps to collect dust and results in current leakage. A hydrometer syringe can be used, but filling by this process is slow and also usually results in a certain amount of spillage.

The best method is to use a small rubber hose with some sort of valve near the end. The supply to which the hose is connected can be a stationary tank, but this usually necessitates the use of a hose of cumbersome length. The accompanying photograph shows the convenient arrangement for watering batteries in the Nuttallburg, (W. Va.) mine of the Fordson Coal Co. In this charging station sufficient top has been taken down to leave room for suspending the water vessel above the locomotive.

Batteries Are Readily Charged in This Station

Above the track is a messenger cable located about 2 in. from the roof and stretched tightly. On this is hung the water tank, and the alarm box which indicates when the cells have been filled to the proper height. The outfit can be moved along the wire to either of the two locomotives on the track. At the left are charging panels for three locomotives.

A ⅜-in. galvanized steel messenger wire is stretched above the center of the track, close to the roof, between two anchor bolts. The battery watering tank can be slid to any point along this wire. With this arrangement one man can flush the cells of several locomotives in much less time than he would take were he to use any other method.

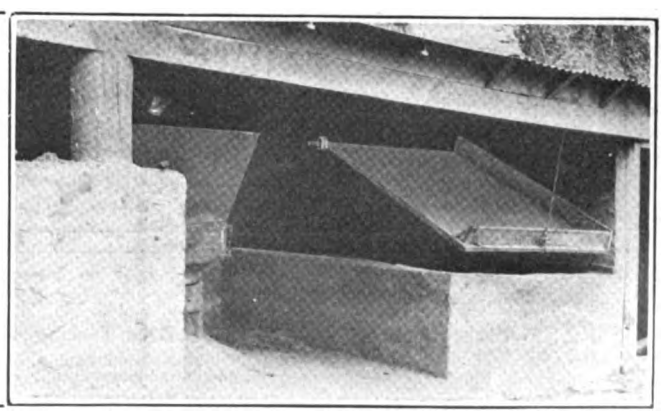
Screen Above Dry-Sand Bin Can Be Swung Clear

Often the sand-drying and handling arrangement at a mine is not as efficient as it should be. The fact that usually an extra man is required for this work and has time to spare is not a good excuse for continuing to use an unhandy and inefficient layout. If the drying can be arranged so as to take up but a small portion of a man's time, other productive labor can usually be provided for the other portion.

Considering the natural limitations of space, a handy and efficient sand-storing and drying outfit is that used by the Fordson Coal Co. at Nuttallburg, W. Va. This is shown in the accompanying illustration. The raw-sand bin is at the left, the dryer in the center space, and the dry-sand bin at the right. The mine supply track parallels the front of the shed.

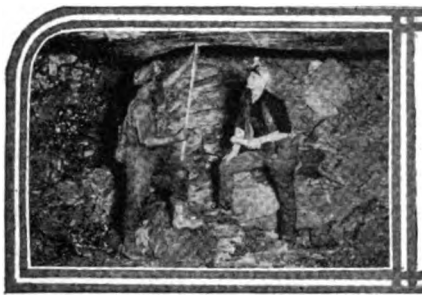
The screen above the dry-sand bin is pivoted at the back end and is counter-balanced at the front end by a weight hung on the supporting cable. When dried sand is being put into the storage bin the front end of the screen is pulled down to a position somewhat lower than that shown in the photograph. The sand is shoveled on to the sloping screen which takes out any foreign material that is large enough to cause trouble. When sand is to be handled out of the bin and into the mine car the screen is raised out of the way, making it possible to get down in the bin and shovel out the sand over the end wall without inconvenience.

Shoes Outlast Wheels in Alabama Mine



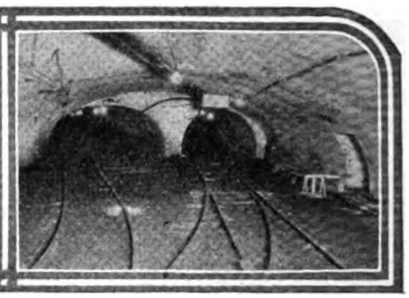
Trolley wheels lasted less than a week on a heavy-duty main haulage locomotive in the mine of the New Castle Coal Co., at New Castle, Ala. Now a shoe is used in place of a wheel, and the life is approximately three months.

M. G. Launius, superintendent, explained that recently they have started the practice of greasing the trolley wheels once a week with engine oil, and expect that this will greatly lengthen the life of the shoes.



At the time that a *Coal Age* representative was in the mine with Mr. Launius, some of the locomotives were still equipped with trolley wheels. When watching the loaded locomotives pass, it was observed that seldom was there any arcing from the shoe, but that there was much arcing from the trolley wheels, especially at each hanger.

Sand House



The screen above the dry-sand bin is pivoted at the back end, the front end being supported by a wire rope which passes over a pulley and to a counterweight.

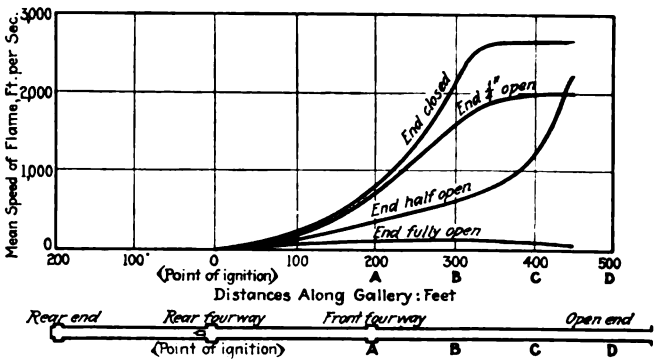
Underground Operation

Effect of Confinement on Violence of Coal-Dust Explosions

British Ascertain Effects of Exploding Coal Dust in Open Steel Tube and in One with a Partly Closed End



For some time it has been believed that coal-dust explosions are more severe if they occur at dead ends, with the charge, so to speak, ignited at the breach of the gun rather than at the muzzle; and recently the results of experiments made by H. P. Greenwald and R. V. Wheeler of the "Safety in Mines Research Board" confirming this belief have been published by that Board in Paper No. 14.

Briefly, the steel tube or gallery used was composed of boiler shells bolted together to form a straight tube of an internal diameter of 7½ ft. and 750 ft. long. One end was open and the other could be completely closed by a steel blank bolted in place. Except for fourway pieces inserted between adjacent boiler shells, one 200 ft. and the other 400 ft. from the rear end of the gallery, the tube was without side openings. There were no obstructions of any kind other than the rivets and the overlapping of the steel shells. In the experiment chosen for description, these fourways were closed by steel blanks. A series of wooden shelves was fastened along the gallery, five in each side. They extended from the open end to within 200 ft. of the rear end.

The explosions were started by a blown-out shot of 28 in. of black powder tamped with 8 in. of slightly damp clay, fired from a cannon having a 2-in. diameter borehole 34 in. deep. This blownout shot was fired into an open-ended tube 3 ft. in diameter and 10 ft. long, forming what will be known as the "impetus tube." This rested on the floor of the gallery in such a position that the end distant from the cannon was at the edge of the first fourway. Fig. 1 shows a plan of the gallery, giving the position of the cannon and impetus tube and of the two fourway pieces.

End Open and Closed

When fully open the flame travels at low speed, but when the end is closed it speeds along the tube at a velocity of 2,660 ft. per second.

The dust used was pulverized nut coal, ground so that 85 per cent would pass through a 200-mesh sieve. This was distributed as evenly as possible along the gallery at the rate of 1 lb. per linear foot. Twenty pounds of dust were strewn within the impetus tube, and an additional quantity was deposited on a plank, 14 ft. long and 15 in. wide, immediately in front of the tube. Beyond this plank the dust was thrown in the air by hand, right and left to settle on the floor and sides of the gallery and on the top of the shelves. No dust was strewn behind the cannon, so that there was a dustless zone 185 ft. in length between the cannon and the "rear" end of the gallery. The coal used for the experiment was Thorncliffe Silkstone having the following average analysis: moisture, 1.90; volatile matter other than moisture, 32.92; fixed carbon, 63.67 and ash, 1.51 per cent.

By the use of blanks at the "rear" end the degree of closure was regulated so as to entirely close, half-close and quarter-close the opening. The blanks in the last two cases had concentric circular holes bearing the relations indicated to the size of the full opening.

The results obtained by the explosion are as indicated in the graph Fig. 2 and in the table.

In one of the experiments with the rear end entirely closed the shell at the open end of the gallery was ruptured. When the rear end was left completely open the burning of the dust cloud was so slow that its progress could easily be followed by the eye, for the speed of the flame did not exceed 130 ft. per second, and the pressure developed was no more than 2 lb. per sq.in. at any point along the gallery. In one test with the rear end completely open, there was a strong west wind opposing the progress of the flame which sufficed to snuff it out before it could reach the end of the gallery.

Flame issued from the rear end of the gallery in all the experiments in which an opening was left there, and no inrush of air could be observed at the rear until the flame had passed out at both ends of the gallery. It was noticed, however,

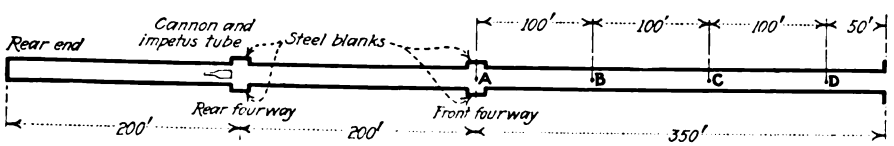


Fig. 1—Experimental Tube at the British Testing Station, Eskmeals

Tests at this station showed the not-too-astonishing fact that a cannon open at the breach or leaky along the bore does not show any real expulsive force when fired. Why didn't we think of this before?

Digitized by Google

Effect of Openings in Gallery 200 Ft. Behind Point of Ignition on Development of Coal-Dust Explosion

Condition	Mean Speed of Flame (Feet per second) O–A	A–B	B–C	C–D	Maximum Pressure (Lb. per sq.in.) B	C	D	Flame Extension
End closed	240	1,310	2,660	2,660	39	68	73	Out at open end of gallery
End ½-open	195	1,175	1,940	2,000	22	37	70	Out at both ends of gallery
End ¼-open	175	515	825	2,270	15	18	48	Out of both ends of gallery
End open	90	130	110	95	2	2	2	Out of both ends of gallery

that when the speed of the flame was slow, as a result of the opening at the rear being large, its motion was markedly vibrating, the column of dust and air preceding the flame being expelled from the gallery in puffs rather than in a continuous stream and the flame itself could be seen to issue from one of the openings two or three times, a slight inrush of air occurring between each appearance of flame.

Briefly it may be said that when the gallery was closed at the rear end and openings made in the fourway in front or behind the impetus tube, the results in general were similar but when the rear fourway was closed and the front fourway was open with the impetus tube in the position in which it is placed in Fig. 1, the pressures and flame speeds were much higher, showing that the opening behind and beside the point of ignition do more to retard the progress and violence of an explosion than when some considerable distance in front of the point of ignition. With the front fourway fully open so as to give an opening 64 per cent as large as the cross section of the gallery the pressure averaged only 6 lb. at D as against 73 lb. with the rear end and fourways all closed.

Machine Undercuts Big Rock Band Which After Wetting Is Barred Down

In the lower section of No. 3 mine of the Phelps Dodge Corporation, Stag Canon Branch, Dawson, N. M., a rock roll has been encountered which is being successfully removed by the method outlined in Fig. 1. The rooms are driven 37 ft. 6 in. wide on 75-ft. centers. The face is advanced on an angle of about 51 deg., to a depth of 300 ft.

An arcwall slabbing machine, with an 8-ft. cutter bar, advancing as shown in Fig. 1, makes a kerf 6 ft. deep. After the completion of the cut, the face and kerf are thoroughly sprinkled. The rock, which is a hard sandy shale, is friable and fractures readily upon the application of water. The entire band to the full depth of the cut is removed by means of bars, and gobbed, as shown.

The section of the seam below the rock band is then drilled, shot and loaded out, after which the top section is removed.

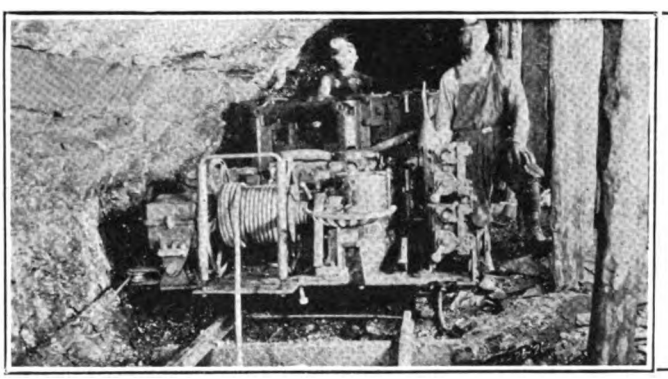

FIG. 3
Rear View of Cutter
View from the rear showing cable reel and drag line working its way across the inclined face.

Steel ties are used under the rails at the face, in order to save height and avoid brushing. The track from the curve to the end is made up in short sections convenient for advancing.

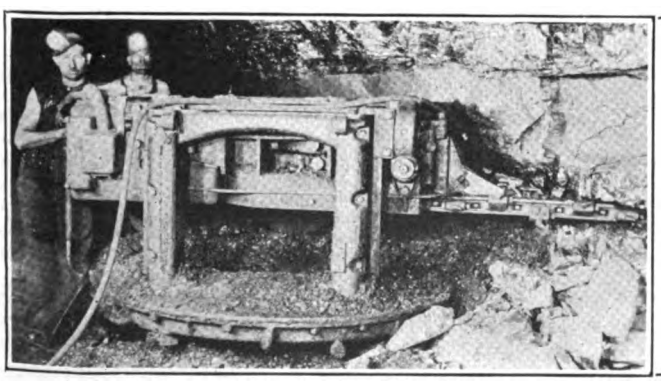

FIG. 2
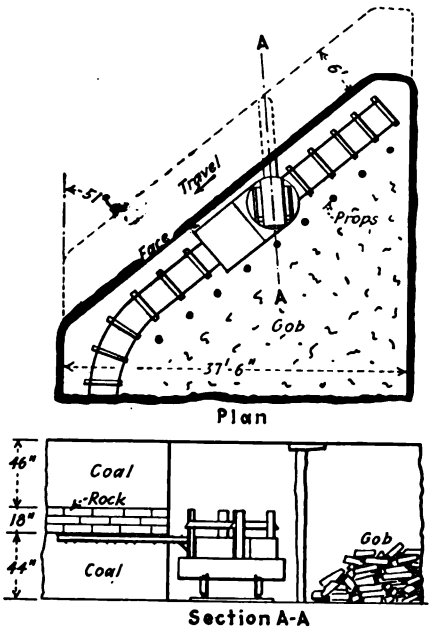
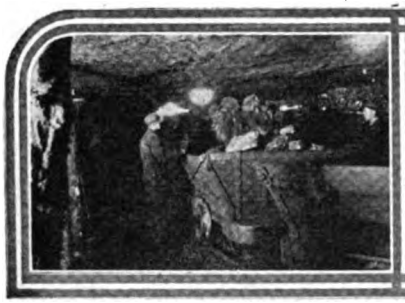
Undercutting Rock Band
Shows the nature of the thick parting of rock, which, when undercut and wetted, can be readily pried down with bars.

Big bands of rock have usually marked the end of mining in the United States especially if they are larger than can be removed by a cutting machine. In Great Britain this is not so; thick rock bands are quite frequently mined and tossed in the gob, but the cost of mining is greatly increased where such bands are encountered. The question frequently arises whether to cut the band itself or to undermine it. The Gay Coal & Coke Co. mines the rock, but the Phelps Dodge Corporation undermines it.

In the Western country whether in Illinois or in the far West the measures are often quite dry, and watering breaks up the rock and clay more than in the East where water is usually present and where the measures have lost those chemical substances that are soluble in water. This may account for the readiness with which the rock band at No. 3 mine disintegrates when wetted and is so readily removed by bars.





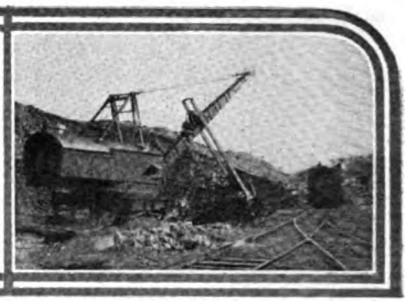


FIG. 1
Face Made Oblique to Afford Capacity
When bands can be mined or undermined they can be readily removed and then the shooting of the coal is light and easy, for the seam is in two masses instead of one.

News Of the Industry

Coal Legislation Barrage Opens in Congress; Treadway Urges Laws Based on Coal Commission Report

(Special Dispatch to Coal Age)

Washington, D. C., March 30.—The opening gun in the campaign to revive congressional interest in coal legislation was fired today when Representative Treadway, of Massachusetts, appeared before the House committee on interstate and foreign commerce to urge that the recommendations of the United States Coal Commission be enacted into law. Congressman Treadway, the only witness heard during the session, directed his remarks to proposals to give the President emergency powers to seize and operate mines when strikes threaten and to compel continuous fact-reporting. Under a barrage of questions, however, he receded from his position on emergency control to the extent of agreeing with Congressman Newton, of Minnesota, that such a provision might encourage deadlocks and that for that reason it might be well to withhold such legislative action until the need developed.

Although declaring that the prices charged for bituminous coal and coke during the recent anthracite strike was warrant for including soft coal in the legislative program, Representative Treadway stressed heavily the interest of New England in anthracite. The State of Pennsylvania came in for caustic criticism on three grounds: The miners' certification law, the anthracite tonnage tax and royalties. Questioned by Congressman Wyant, of Pennsylvania, as to how he could change the anthracite tax in view of the Supreme Court decision upholding the imposition, he retorted that constitutionality did not necessarily imply moral justification and that it might be possible to shame Pennsylvania into a repeal.

Pressed by Congressmen Newton, of Minnesota, and Rayburn, of Texas, as to the exact powers he wished conferred upon the President, the witness fell back upon the Coal Commission report and the Coolidge messages of 1923 and 1925 and said the President's advisers and the committee's counsel could work out that problem. He insisted, however, that more recognition should be given to the public interest and that the public should sit in in coal disputes. He put great faith in the strength of public disapprobation in correcting unfair situations.

Costs, profits, wage rates and earnings, he argued, were no longer to be treated as matters of private business. The operators, he continued, had assured the public that they were resisting the miners' demands to increase costs. Nevertheless, he alleged, since the strike the price to the public has been boosted a dollar a ton, which meant, according to his figuring, an additional tax of at least $300,000 daily on the consumer. Compulsory, continuous publicity, he continued, would be an antidote for price gouging and would discourage the sale of premium coal. Much of the latter, he charged, was company production seeking the high dollar through a middle agency.

The sharpness with which some of the questions were flung at him provoked Congressman Treadway at one stage of the hearing to blurt out that he had been told the committee was packed against him. Upon protest, he said he made that accusation in a jocular vein and the remark was expunged from the record. There were so many interruptions from committee members that Chairman Parker, of New York, several times intervened to ask that cross-examination be deferred until the witness had concluded his direct statement. When the cross-examination by the committee was over the hearing was adjourned until Wednesday morning.

Old Ben Acquires Holdings In Non-Union Fields

The Old Ben Coal Corp., with offices in Chicago and large coal operations in southern Illinois, recently acquired extensive mining properties in West Virginia and established connections in eastern and western Kentucky, all in non-union fields. This move, it is reported, was to guard the company's business against the harassment of union labor troubles incident to the increasing depression in the Central Competitive Field, which is attributed to the Jacksonville agreement. The Peabody Coal Co. announced a short time ago that it had taken over several lines of west Kentucky coal.

In its official announcement, issued March 26, the Old Ben corporation stated that the step was made in order "to meet all competitive market conditions and to reduce strike interruptions to the minimum."

Senate Confirms Woodlock; Reed Placated

Thomas F. Woodlock, of New York, was confirmed by a vote of 52 to 25 as a member of the Interstate Commerce Commission after five hours of heated debate behind closed doors in the Senate March 26.

Soon after Mr. Woodlock was nominated, on Jan. 26, 1925, the insurgents of both parties began warfare against him as a representative of "Wall Street," though nobody questioned his ability or integrity. Senator Reed, usually ultra-regular Republican, was especially hostile, complaining bitterly that Pennsylvania had been denied proper recognition in Railroad Commission patronage.

Senator Reed was suddenly converted to Mr. Woodlock when the White House announced last week that Pennsylvania would be favored for the next commission vacancy.

Mr. Woodlock has been sitting as a recess appointee since April 2, 1925.

Hard-Coal Strike Reduced D. & H. Earnings

The adverse effects of the anthracite coal strike on the earnings of the Delaware & Hudson Co. in 1925 is reflected in the annual statement for 1925 released for publication this week. The report shows net income of $4,907,708 after all charges, or equal to $11.54 on the capital stock of the road, against $5,818,376, or equal to $13.69, in 1924.

Railway operating revenues declined $3,243,497 to $41,769,491. Freight revenues decreased $3,843,306, or 10 per cent. There was a reduction of $5,192,946 in revenue from anthracite traffic, which was partly offset by an increase of $647,368 from bituminous coal traffic. The net reduction in freight receipts from coal amounted to $4,535,578, or 20 per cent.

Railroads Use Less Coal In January; Price Drops

Class 1 railroads of the United States consumed in locomotives in freight and passenger service 9,155,429 net tons of coal in January, 1926, according to a report by the Interstate Commerce Commission. This compares with 9,102,555 tons in December and 9,209,439 tons in January of the preceding year.

The average cost of coal per ton by districts decreased 1c. in the Eastern and Western districts and 2c. in the country as a whole.

Government Accepts Commission Plan To Adjust Britain's Coal Difficulties; Seek Measures for Lasting Solution

Stanley Baldwin, the British Prime Minister, announced on March 24 that the government has decided to accept the report of the Coal Commission, submitted March 10, and to pass such legislation as may be required to give effect to its recommendations for reorganization of the coal industry, provided the operators and miners agree to accept the report and carry on the industry on the basis of the recommendations.

The Premier made the government's decision known to representatives of owners and miners who had been invited to meet him in Downing Street. The government, he said, had not reached this decision without careful consideration of the report, and he indicated that acceptance of its recommendations required of the government the setting aside of certain preconceived opinions.

"The conclusions reached by the Commission," said Mr. Baldwin, "do not in all respects accord with the views held by the government, and some of the recommendations contain proposals to which, taken by themselves, the government are known to be opposed."

The Prime Minister said the government, however, had made its decision in the hope that, with the co-operation of all parties, it might be possible to find "a lasting solution of the problem."

Herbert Smith, president of the Miners' Federation, put a question which led the Prime Minister to make a statement in regard to the coal subsidy. This subsidy was granted last August for nine months, and is due to terminate at the end of next month. The Commission recommended that it should be abolished, and the government's acceptance of the report includes acceptance of that recommendation.

"But I recognize," said Mr. Baldwin, "that in some districts, if a settlement is to be reached, the sacrifice that might be required would be heavy, and if an agreement can be reached by May 1 I shall be willing to consider what temporary assistance may be required to ease the situation."

The Premier stressed two points in connection with further financial assistance from the government. In the first place, the amount of money available in the present condition of the country's finances is limited, and in the second place, the period for which further assistance is given also must be limited. The Prime Minister suggested that it be three months.

"Not one ton of coal will be handled throughout the country" if the government's decision in the coal controversy is unsatisfactory to the miners and they have to strike May 1, said A. J. Cook, secretary general of the Miners' Federation, in a speech at Westminster March 24.

"We also have made sure that no coal shall enter this country from America or Germany," he added. "We are not going to be slaves any longer. The miners will starve before they accept any reduction in wages."

The speech of Mr. Cook was delivered after he had been present at the two-hour conference between Premier Baldwin and the miners and operators' representatives.

Sale of Coxe Bros. Probable

Roger Shale, of Washington, D. C., has been appointed by the U. S. District Court to succeed the late Thomas R. Marshall as trustee, with James Neale, of Coxe Brothers & Co., Inc., coal subsidiary of the Lehigh Valley R.R. In some quarters this is seen as a step toward the separation of the coal company from the railroad. With two active trustees, railroad men believe that the next move will be an invitation of bids for the coal company. Mining engineers have gone over the property and submitted a report to the railroad company regarding its value. It is expected that Coxe Brothers will be sold outright.

Miners Discuss British Coal Commission Report

Herbert Smith, president of the British Miners Federation, is shown in the act of telling what he thinks of the findings of the Royal Commission. In the front row are W. Richardson, Tom Richards, Mr. Smith and A. J. Cook, secretary general of the Federation.

Industry Has Coal Supply For 35 Days

During February industrial consumption of bituminous and anthracite coal increased slightly over the preceding month, according to statistics compiled by the National Association of Purchasing Agents. The estimated consumption was 43,747,367 tons. Because of the depleted stocks of anthracite, the industries reporting showed an increased consumption of bituminous coal. The total consumption, however, is approximately eight million tons above that of the February (1925) mark.

Stocks of coal in the hands of industrial consumers on March 1 totaled 60,014,527 tons, compared with the Feb. 1 figure of 66,190,000 tons. Stocks on hand March 1 were sufficient to last 35 days at the February daily consumption rate of 1,706,424 tons. This is a drop from the figure for Feb. 1, which showed 49 days' supply on hand, and a slight drop under the figure for March 1 last year, when there was coal enough to last 38 days.

Receivers Likely to Sell Carbondale Coal Corp.

Robert P. Hobson, of Louisville, and Allen W. Mason, of Baltimore, who were named receivers for the Carbondale Coal Corp. by federal Judge Charles L. Dawson, in Louisville, have arrived in Madisonville, Ky., and taken over the properties involved. The Carbondale Coal Corp., which formerly was the Hawley-McIsaac Coal Co., has been operating coal mines in Hopkins and Ohio counties for several months.

Judge Dawson granted a receivership as result of a suit filed by the Baltimore Trust Co. against the Carbondale corporation. This action was precipitated by the corporation's failure to pay instalments on a sinking fund due upon an issue of $720,000 of bonds, according to announcement by Gordon, Gordon & Moore, attorneys.

Hobson's first move upon reaching Madisonville was to order suspension of operation at all of the plants controlled by the corporation. He was unable to say when operations will be resumed.

The Carbondale Coal Corp. owns large stripping operations at Carbondale and Nebo, in Hopkins County, and at Morrison, in Ohio County. It employed 175 workmen and produced 2,500 tons of coal daily. It is likely the properties will be sold under the hammer on court order for enforcement of the mortgage.

Federal Judge Dawson has postponed the sale of the D. B. Gore Coal Co., Providence, Ky., recently declared bankrupt, until April 6. The original order called for a sale on March 24, but because of unavoidable delays a postponement was found necessary, according to the announcement. The Gore company has been operating a stripping plant near Providence. It owned large undeveloped acreage.

N. Y. Retailers Discuss Outlook for Soft Coal and Coke as Anthracite Rivals

Sharp differences of opinion as to the permanency of the markets won by bituminous coal and coke during the anthracite strike marked the discussions forming the major part of the program of the regional group meeting of the New York State Coal Merchants' Association at the Hotel Pennsylvania, New York City, March 25.

Walter R. Morris, Seaboard By-Products Coke Co., tracing the growth of byproduct coke production in recent years, was confident that coke as a domestic fuel was here to stay and warned the retailers that unless they co-operated in the distribution the coke ovens would find other means of selling to the consumer. Charles A. Owen, president, Imperial Coal Co., forecast a slow but steady gain for high-grade bituminous coal, particularly in the suburban communities and among those consumers to whom price was the controlling consideration. The natural increase in population also would be a factor in developing such a market because anthracite production could not keep pace with such an increase.

Say Anthracite Will Come Back

On the other hand, Arthur C. Wadley, president, Shanferoke Coal & Supply Co., in a paper read in his absence by Roderick Stephens, vice-president, Stephens Fuel Co., saw no barriers to the triumphant return of anthracite. Oil, he held, must be a lessening factor because of cost, uncertain supply and danger. Byproduct coke can compete only on a price basis and the increased costs of handling through the retail yards because of its bulk makes it unattractive to the retail coal merchant. Bituminous competition was too insignificant to be considered seriously. The incidental damages to property, menace to health and the methods required to burn it successfully all militated against its use.

Speaking from the retailer's standpoint, Hiram Blauvelt, vice-president, Comfort Coal & Lumber Co., urged vigorous merchandising methods to check the inroads of oil and praised the co-operation possible through the Anthracite Coal Service in meeting oil competition. He also pleaded for more stability in the merchandising policies of the operators, citing the situation in pea coal to illustrate his point. Responding to producers' appeals two or three years ago, his company had built up a consumer demand for pea coal which today it cannot fill because it cannot get enough of that size.

Mr. Blauvelt criticized the failure of the operators to take the retailers into their confidence as to price changes far enough in advance to permit them to map out adequate merchandising programs. In this connection he suggested that prices be changed on May 1 by a $1 reduction, with 25c. increases each month until the winter basis was reached. Such a basis, he felt, would offer a greater incentive to early buying than the old 10c. monthly discount system.

Lignite as Locomotive Fuel

Texas Lignite is being tested by the Missouri Pacific R.R. as a locomotive fuel in one of its locomotives running out of Palestine, Texas, on the International Great Northern. The engine has pulled as many as ninety-six cars, and as a steam producer the lignite is said to have been a success. The greatest fault of lignite in tests in Wyoming, Montana and Colorado is said by Kansas City operators, interested in those states as well as in the Southwestern district, to be sparks spread over the right of way and adjoining fields by the forced draft. The Missouri Pacific on some of its northern runs is now using northern Montana lignite, while the Rock Island is burning lignite in Colorado to a limited extent.

The meeting closed with a dinner at which Walter Gordon Merritt, general counsel for the Anthracite Operators' Conference, was the principal speaker. Mr. Merritt's subject was "The Public Stake in Anthracite." He declared unequivocally that the new wage agreement carried no provision, expressed or implied, for the check-off. The contest, he said, has taught the United Mine Workers that a strike can be lost and has demonstrated to the operators that a strike can be won. The politician has learned that meddling is undesirable and the public now knows that anthracite is not a necessity.

The Missouri Pacific R. R. applied to the Interstate Commerce Commission on March 25 for authority to acquire control of the Marion & Eastern R.R., a coal line extending from Marion to Paulton, Ill., a distance of 11.5 miles. The stock of the road is valued at $190,000. The Marion & Eastern through consolidation with the Missouri Pacific would have direct outlet to St. Louis and other coal markets.

N. C. A. Names Delegates to U. S. Chamber Meeting

Delegates of the National Coal Association to the annual meeting of the Chamber of Commerce of the United States were appointed March 23. The members of the delegation are engaged in the production of bituminous coal in the states of Colorado, New Mexico, Wyoming, Indiana, Kentucky, Ohio and Pennsylvania. They are: M. L. Gould, president of the Linton Coal Co., Indianapolis, Ind.; W. M. Ritter, Washington, D. C., chairman of the board of the Red Jacket Consolidated Coal & Coke Co., of Red Jacket, W. Va.; Whitney Warner, Cleveland, vice-president of the Warner Collieries Co., with operations in Ohio, West Virginia and Kentucky; John M. Jamison, Greensburg, Pa., president of the Jamison Coal & Coke Co.; G. P. Bartholomew, New York City, general manager of the coal department, American Smelting & Refining Co., with operations in Colorado and New Mexico; R. J. Ireland, Amityville, N. Y., president of the Owl Creek Coal Co., Gebo, Wyo.

Mine Inspectors' Institute Plans Live Program

The Mine Inspectors' Institute of America will hold a meeting May 11 to 13 at the Seventh Avenue Hotel, Pittsburgh, Pa., according to an announcement by G. B. Butterfield, secretary. The program, which is not yet complete in detail, will include the following subjects: "The Single-Entry System"; "Comparative Fatality Rates"; "Comparative Policies of Federal and State Mining Activities"; "Recent Coal-Mine Explosions"; "Regulations Governing Safety in Mines"; "Regulations for the Use of Permissible Explosives"; "Approved Electrical Mining Machines"; "Self-Rescuers"; "How Dust is Controlled by Watering in Alabama." A banquet has been arranged and a committee of six has been appointed to devise other entertainment features.

Men Who Took Part in Drafting Program for Cincinnati Meeting Of American Mining Congress

As the program committee is constituted chiefly of operating officials representing all coal centers of the country, questionnaires were sent out inviting each to contribute suggestions as to topics and speakers for the Cincinnati meeting. From the returns were selected the most weighty and attractive suggestions by the above group which met in Pittsburgh on March 20. They are, from left to right: Sitting, C. W. Wilson, S. A. Taylor, Ezra Van Horn, E. J. Newbaker and A. P. Cameron; standing, Alphonse F. Brosky, J. F. Callbreath, Newell G. Alford and George F. Osler. L. E. Young, of St. Louis, who also attended this meeting, was absent from the room when this photograph was taken.

Increasing Statistical Work Among Coal Associations Presages Plans To Meet End of Jacksonville Pact

By Paul Wooton
Washington Correspondent of *Coal Age*

A revival of statistical activities among the local coal associations is noted by the Bureau of Coal Economics of the National Coal Association. An idea of the present extent of statistical reporting among the local associations may be gained from the following:

Stover's Smokeless Coal Bureau represents the smokeless fields of southern West Virginia. Its reports cover a rather wide range. There is a daily report showing by companies, for each of five subdivisions of the smokeless territory, the number of hours worked each day by each mine, the number of tons mined and the tons mined to date. A weekly distribution report of carload shipments classifies such shipments under ten grades and thirty-one destinations. Finally it publishes a weekly sales report of past transactions showing for each price the number of cars shipped at that price during the week for each of eight grades of coal and to each of six general destination groups.

For some months the Operators Association of the Williamson Field has been carrying on statistical work through a bureau of coal statistics which is finally intended to cover the high-volatile fields of southern West Virginia, eastern Kentucky and Virginia. Kanawha has joined forces with Williamson and they have opened a central statistical office at Huntington, W. Va., known as the Bureau of Coal Statistics of the High-Volatile Fields of Southern West Virginia, Eastern Kentucky and Virginia. The Logan district is about ready to join forces with Kanawha and Williamson.

Record Seam that Coal Is From

The Williamson reports as they have been issued show day-by-day sales at different prices grouped under seven grades, four destinations and five classes of use. They also show the particular seam in which the mine is located, whether the sale was spot or contract, whether it was to a jobber or a consumer, and the average price per ton spot sales and contract sales separately.

The Harlan County field of Kentucky issues a daily report showing the number of cars sold at each price during the day, grouped under six grades and four destinations. It also indicates whether the sale was spot or contract.

The Virginia Coal Operators' Association publishes a similar report based on daily shipments. It indicates the number of cars shipped at each price grouped under seven grades, twelve destinations and four classes of use. The reports also show whether the sales were spot or contract and, if the latter, the date when the contract was entered into.

The Southern Appalachian Coal Operators' Association recently inaugurated a daily sales report in which individual prices and number of cars shipped at each price are shown under eight grades, two destinations and four classes of use. The report also indicates the particular part of the field in which the mine is located and, for everything except spot sales, the date on which shipments are to be made.

The first weekly past sales report of the Brackett Statistical Service, operating in the northern West Virginia or Fairmont territory, was issued as of Feb. 16, 1926. This report differs from those already described in that it does not give the price of each individual transaction, but average high and low prices. The transactions are grouped under four grades and six destinations. Sales to brokers and to consumers are shown separately. The report covers both spot and contract sales.

The Alabama Fuel Association recently launched a past sales report which shows the number of cars sold at each price day by day. The seam from which the coal comes is indicated. The sales are grouped under ten grades and seven destination points. In some instances the date on which the coal is to be shipped is shown and in some cases it is indicated whether the sale was spot or contract.

Movement Is Spreading

The Central Pennsylvania Coal Operators' Association has made arrangements for inaugurating a similar statistical report. West Kentucky is actively engaged in formulating plans for similar work. The Southwest Interstate Coal Operators' Association also is considering similar plans.

Other associations are giving the matter of statistical reports active consideration.

These highly needed activities suggest the desirability of drawing together the results of local statistics into a comprehensive summary for the country. The Bureau of Coal Economics of the National Coal Association was designed for just that type of work. Its head, Alan H. Willett, is an economist and statistician of national reputation.

It is the hope of various officials in Washington who are interested in coal that the industry will undertake a constructive fact-finding program of its own. This will give the federal government an opportunity to concentrate on problems that industry will not undertake to solve.

Statistical work is expensive and the coal industry is poor as never before, so there are financial objections which will have to be overcome, but it is believed the wisdom of expenditures for such purposes is fairly well established among the producers, at least. Outlays in that direction ought to pay handsomely in promoting more efficient distribution; in avoiding shortsighted flooding of markets with unsold coal; in making possible a wiser program of production and in allowing the formulation of definite plans for future development.

In this connection consideration also should be given to the fact that the end of the Jacksonville agreement is only a year away. Its termination promises a period of uncertainty and stress, a period of controversy and public discussion. The industry must be ready to justify its case, both with the miners and with the country. The agreement may be renewed on the same terms. It may be renewed with different terms. The union districts may decline to renew at all.

Regardless of what happens it is perfectly plain that the coal producers will be in a position where they must have their case well prepared. The time is coming within a year when there will be desperate need for statistical data. A good start is being made. The clearing house exists, but as yet has not the support necessary to function on a scale commensurate with the increased activities of the local associations.

Labor Studies Records Of Congressmen

The executive council of the American Federation of Labor is making a study of the legislative records of members of Congress affecting labor measures. When records have been completed the Federation will send them into each Congressional district to be used in the elections next autumn. William Green, the Federation's president, said that 90 per cent of the 35,000 local unions in the country have formed non-partisan political campaign committees to participate both in the primaries and general elections.

Union Labor Starts Battle Against Injunctions

The American Federation of Labor made its first move in a national drive against the use of injunctions in labor disputes, at Albany, N. Y., March 26, when Assemblyman Frederick L. Hackenburg, Democrat, New York, introduced a bill defining combinations and conspiracies in trade and labor disputes and proposing that issuance of injunctions be prohibited in industrial controversies.

The bill, according to Mr. Hackenburg, is intended to "end the present abuse of discretionary injunction power by courts to inject themselves into labor disputes, arbitrarily."

Briefly reviewing the history of labor's campaign against issuance of this type of injunctions, the Assemblyman declared that the power of the first was employed after the railroad strikes in the latter part of the nineteenth century, and that since the American Federation of Labor has conducted a fight in every state, and at Washington, against the injunction power.

The New York Legislature, he added, is the first in which the present bill has been introduced, but that it will follow this year or next in legislatures of all the states.

Machine Scale Ratified in Kansas; Loaders Get 90c.; Operators, 25c. per Ton

A machine mining scale for District 14 (the Kansas coal field) was formally ratified in Pittsburg, Kan., March 22, after having been agreed to two days earlier at the conclusion of negotiations extending over six weeks.

The machine rate is divided into the following differentials:

Ninety cents a ton to the miner for loading.

Twenty-five cents a ton to the machine runner and helper for undercutting the coal.

Ten cents a ton to the operators for furnishing the electrical machinery and other equipment.

The rate is based on $1.25 a ton. Although the miner receives 90c., or 35c. less per ton than the pick miner, the larger tonnage per day will equalize this, according to a statement issued for the Southwestern Interstate Coal Operators Association by W. L. Johnson, general commissioner.

In pick mining much of the coal is removed from the solid wall by blasting, resulting in approximately 50 per cent slack, but machine mining will give a larger percentage of lump, operators say.

At intervals for several years operators and the union officials had made efforts to agree on a scale. A representative of the international union was present during the negotiations, which were held in Pittsburg and Kansas City. Twenty-seven machines are now in use and consummation of the contract is expected to increase the number.

The machine scale will go into effect at once and expires March 31, 1927, at the same time the present pick mining scale expires. The contract provides that either party to the contract may within 90 days reopen negotiations if it deems an adjustment of the scale for dead work necessary.

Pittsburgh Coal Co. Omits Preferred Dividend

Dividend payments were suspended on the preferred stock of the Pittsburgh Coal Co. at a meeting of directors held in Pittsburgh, March 24. The regular quarterly dividend of 1¾ per cent was due to be declared at this time. A statement issued by the company said that "the dividend was not earned and it would be inadvisable to pay it out of surplus." The accrued unpaid dividends bear interest at the rate of 5 per cent. The directors felt the necessity of conserving working capital after a year of unprofitable operations, according to reports. It was further pointed out that the policy of modernizing the properties of the company would be continued. This work is being carried on for the purpose of improving mining methods in order to overcome high labor costs.

The following directors whose terms expired were re-elected for three years: W. K. Field, D. L. Gillespie, J. D. Lyon, A. J. Miller and W. M. Knox, William G. Warden was re-elected chairman of the board.

Roads Spent Heavily for Betterments in 1925

Class 1 railroads of the United States expended $754,000,000 in the form of capital expenditures for new equipment, improvements to facilities and extensions in 1925, according to a report by the Bureau of Railway Economics to the American Railway Association. Of this amount, about 45 per cent, or $339,000,000, went into new equipment in 1925, while the remaining 55 per cent, or $414,600,000, was expended for additions and betterments to roadway and structures.

As a result of these large capital expenditures the rail carriers in 1925 operated with the greatest efficiency and economy in their history and supplied to the shippers of this country the best transportation service that has ever been offered to them.

Despite this record efficiency, which has been increasing since the railroads were returned to private control in 1920, they have not earned either on their property investment or on their tentative valuation as fixed by the Interstate Commerce Commission, the "fair return" as fixed by the Commission.

N. C. A. to Hold Three-Day Annual Meeting in Chicago

The ninth annual meeting of the National Coal Association will be held at the Drake Hotel, Chicago, June 9, 10 and 11. This was the decision of the program committee, which held its initial meeting in New York City March 23, with the following present: Messrs. Gould, Van Horn, Richardson, Mouser, Kennedy, Shirkie and W. C. Shank (representing Mr. C. F. Spencer). Telford Lewis, chairman, was unable to attend because of illness.

Research will be the major subject discussed at the Wednesday morning session, June 9. On Wednesday afternoon there will be a sectional meeting of purchasing agents, at which the successful practices of the New River Coal Operators' Association along lines of co-operative buying will be described.

There will be three sessions on Thursday, the 10th. The morning session will be given over to insurance and safety; in the afternoon there will be a sectional meeting of sales agents and sales managers of coal companies; a banquet will be held in the evening. The program for the morning session of the third day includes discussion of taxation and a paper on the banker's viewpoint respecting consolidation proposals and the like.

A program is being arranged that will be rich in material of practical value to every bituminous coal operator and it is hoped that the interest of the industry will be centered in Chicago during the week of the annual meeting. The sessions will be open to nonmember operators and to the public.

Erie Coal Holdings May Be Segregated Soon

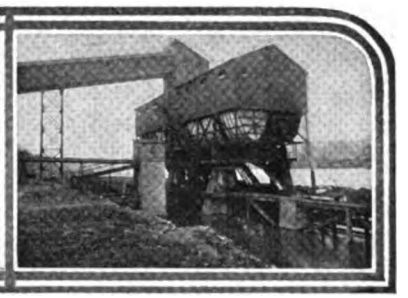
The coal properties of the Erie Railroad Co. valued at from $35,000,000 to $85,000,000 will soon be segregated, it is believed, in accordance with the ruling of the Interstate Commerce Commission. It is thought that the same plan will be followed in separating the coal properties from the railroad company as was followed in the case of the Delaware, Lackawanna & Western and the Lehigh Valley. A few years ago there was considerable opposition to the segregation by directors because it was pointed out that the road needed the income from the coal holdings, but now since the earnings from the railroad itself have increased so much they are not nearly so vital.

It is also thought that the directors will want to take some action on the separation of these properties before the inauguration of dividends on the first preferred stock. Earnings are running sufficiently well at present to permit the payment of dividends on the stock, but whether it would be advisable immediately is declared to be a question.

The coal properties are carried on the books of the Erie R.R. at $35,000,000, while the Van Sweringens testified before the Interstate Commerce Commission in the Nickel Plate hearing that they were valued at $85,000,000. Disinterested outsiders have placed the value as high as $100,000,000. The Interstate Commerce Commission in rejecting the Nickle Plate merger called attention to the fact that the properties had not been segregated.

Funds Voted for Study Of Mine Accidents

The House of Representatives, at Washington, has passed the Departments of Commerce, State, Justice and Labor appropriation bill carrying funds for the Bureaus of Mines and Standards and other bureaus as recommended by its appropriations committee. On motion of Representative Taylor (Dem., W. Va.) the House increased from $396,000 to $403,500 the appropriation of the Bureau of Mines for investigation of mine accidents. A previous amendment to fix the fund at $411,000 was defeated by a vote of 20 to 36. Mr. Taylor said that with $15,000 the Bureau could start a scientific investigation of the causes of the fall of roof and coal in mines.



May Keep Tabs on Inquiries In Trade Trend Records

Consideration is being given at the Department of Commerce to a plan under which a record would be kept in some instances of inquiries as well as orders. The current condition of industries now is judged largerly by the volume of orders. In some industries there is a considerable lag between the inquiry and the order. By plotting the inquiries over a good cross-section of certain activities some idea of the trend of demand could be had. The gathering of this information is expected to be of more value after the first year, when the curve can be compared with that of the preceding year.

News Items From Field and Trade

ALABAMA

A new coal washery of modern design is being constructed by the Porter Coal Co. at its Porter mine, near Palos, Walker County. This company has expended a large amount recently at this operation in the way of new equipment to increase production and improve preparation. The mine is owned and operated by W. C. Adams and E. J. Rowe, of Birmingham.

COLORADO

Officials of the Bear Canon Coal Co. were exonerated from all blame of the explosion in the Bear Canon mine No. 3, Valloroso, on Jan. 29 last at a hearing held at Walsenburg before the state board of examiners and the state coal mine inspector. In this explosion three men were killed outright and one died of burns at the local hospital a few days later. A number of other miners were burned, a few seriously, by the explosion.

Students taking engineering at the Colorado School of Mines in the future may have the option of taking either metal or coal mining, the school having installed a coal-mining department. A large number of students are taking advantage of the new course, it is said.

The Colorado Fuel & Iron Co.'s report for 1925 shows gross business of $34,537,134, against $39,297,320 in 1924, and net income, after all deductions, of $1,752,427, against $520,285. The net income for 1925, after preferred dividend requirements, was equal to $4.65 a share earned on the $34,235,500 common stock outstanding, against $1.05 a share earned in 1924. J. F. Welborn, president, in his report to stockholders, said the company expended $2,442,732 in 1925 for additions and improvements.

Coal production in Colorado registered a decrease in February from the figures set for the same month last year, according to the monthly report by James Dalrymple, state coal mine inspector. The report showed 749,506 tons produced during February, compared with 1,079,061 tons in January, the total for the two months, 1,832,074 tons, being 322,620 less than was mined for the first two months of 1925. An average of 12,216 men was employed mining coal in Colorado in February, the report showed.

The state Supreme Court has been asked to decide whether the state can compel a man against his own wishes to properly safeguard his own life. The question came up in an appeal from a Colorado Springs district court, where James Dalrymple, state coal mining inspector, lost his fight to compel Fred Sevcik to install safety measures in a small coal mine which Sevcik owns and operates by himself. District Judge Cornforth ruled that in this instance the state law requiring a coal mine to have a certified foreman and ventilation fans was unreasonable and unconstitutional, and issued an order preventing Dalrymple from further interference in Sevcik's mine.

The Rockvale and Fremont mines of the Colorado Fuel & Iron Co. have closed for the season, during which time extensive development work will be carried on with a small force of men. The Coal Creek mine will continue in operation and a large majority of the force from the two other properties will be taken care of at Coal Creek.

ILLINOIS

Judge George W. English of the U. S. District Court in East St. Louis, on March 24 advised the receivers for the Southern Gem Coal Corp. that an amended petition be filed with the court in April so that a sale of all the properties of the corporation may be held. This will permit a marshaling of the assets of the company and the court will then be in a position to pass on the priority of claims. Judge English took this action when requested by the receivers, N. C. McLean, of East St. Louis, and William Wilson, Pinckneyville, to give directions as to further procedure in the case.

Mine No. 1 of the Chicago, Wilmington & Franklin Coal Co., known as the "Old Orient," at West Frankford, resumed operations last week after a suspension of four weeks. This mine employs about 1,000 men. Mine No. 1 of the Bell & Zoller Coal Co., at Zeigler, also resumed operations with about 40 per cent of the 1,100 employees ordered to work. The unexpected reopening of these mines is one of the most encouraging signs of a return to normalcy in these fields in many months.

The last big mine in Grundy County ceased operations March 20 and Coal City no longer has a reason for its title. The Wilmington Company's mine No. 7 will be dismantled. Where a few years ago Coal City and South Wilmington were centers of great coal activity, now there is nothing left but small mountains of slag and slate to recall the industry. One small wagon mine is all that is left in operation in this district. There is plenty of coal in the mine, said the superintendent, Joseph Campbell, but advancing wages and freight rates had given other mining centers insurmountable advantages. The mines here had been in operation for fifty years, in which the shafts of the community produced as much as 1,500 tons daily.

INDIANA

The executive board members of 21 districts of the United Mine Workers of America went into session at national headquarters, Indianapolis, March 22 for the first time in ten weeks. The meeting was delayed by the anthracite strike. The session will continue two weeks. The first few days were devoted to appeals from decisions and routine business within the organization. The Indiana coal trouble likely will be given some official attention, it was said.

Harvey Cartwright, vice-president of district No. 11, United Mine Workers, in a recent trip to Indianapolis reported that more miners were leaving the non-union operated mines in the Evansville field and that the working force of each mine was becoming more depleted. He said everything was peaceful. He admitted, however, that no additional coal operators had signed agreements with the mine workers, the John Bull and Erie Canal mines being the only two which were operating on a union basis.

The Western Indiana Mining Co., of Terre Haute, has filed a preliminary certificate of dissolution.

A three weeks' strike at Atlas No. 1 Mine, near Petersburg, was brought to a close March 15 when the Pike County Coal Co., the owners, agreed to give employees turns at work in the mine. The working force was reduced more than 50 per cent, but the work was divided among the men so that all will get two or three days' work a week when the mine is operating at full capacity. The mine is the largest deep-vein pit in southern Indiana and has a daily output of 2,600 tons.

The American Cannel Coal Co., Cannelton, has reduced its capital stock from $50,000 to $25,000.

KANSAS

Would Coke Kansas Coal.—Dean P. F. Walker, of the engineering school of the University of Kansas, at a meeting with State Teachers College instructors, coal operators and representatives of the Chamber of Commerce in Pittsburg March 19 declared there are great possibilities for coking Kansas coal and urged that a fund be raised for experimental purposes. He warned that shipping coal by barge

Digitized by Google

from St. Louis to Kansas City on the Missouri River may take the Kansas City market away from the Kansas mines. A fund of not more than $30,000 would provide for adequate tests, he said. He said that coke now sells in Kansas for $13 or $14 a ton but that it could be produced there at a cost of $5 or $6 a ton and the by-products would be valuable.

Kansas mined 4,813,088 tons of coal in 1925, according to the complete official report of James Sherwood, state mine inspector. Output in the preceding year was 4,491,069 tons. Kansas mine employees in 1925 numbered 9,471, compared with 8,743 in 1924. Fatal accidents numbered eleven, four more than in the preceding year. Non-fatal accidents totaled 704, while in 1924 there were 813. Production by counties was as follows: Crawford (deep), 2,752,984 tons; Crawford (shovel), 338,711; Cherokee (deep), 479,180; Cherokee (shovel), 724,263; Osage, 95,227; Linn, 53,760; Leavenworth, 95,563; Franklin, 1,497; Bourbon, 17,428; Neosho, 4,475; Miscellaneous, 250,000.

KENTUCKY

The Daniel Boone Coal Corporation, of Lennut, Ky., is reported to have taken over the mines and plant of the Kentucky River Coal Co., on Lost Creek, near Heiner.

A tipple is under construction at the new Lee's Switch coal mine, near Henderson. The mine is being sunk toward a 4-ft. seam of coal 220 ft. beneath the surface. Harry Jennings and several other Henderson men are sinking the shaft.

MISSOURI

The Western Coal & Mining Co. hoisted the first coal from its new mine No. 23, near Minden, on March 18, when it made a run of 300 tons. When fully developed the mine will employ 300 men. The seam is from 2 ft. 10 in. to 3 ft. 2 in. thick and is 60 ft. deep. The Western's mine No. 22, near Arma, will be ready for operation by next fall, giving the company six large mines.

There are prospects of another by-product coke plant locating in St. Louis. Definite action is expected on this in the next three months. It probably will be located on the river and will offer rail and water transportation for both coal and coke.

OHIO

The Charter Oak Coal Co. has been formed by 10 miners, who will open a small mine in the Pomeroy field on a co-operative basis. A royalty is to be paid the mine owner.

Acting for Willis J. Richardson, former president of the defunct Richardson Coal Co., of Cincinnati, Attorney Frank Wood has offered the referee in bankruptcy for the U. S. District Court at Cincinnati to compose the indebtedness at 33c. on the dollar. The coal company was thrown into the hands of a receiver last fall. Richardson in February went into bankruptcy, scheduling $24,000 as liabilities and $700 as assets. His attorney says relatives have come to his rescue, making the settlement possible, and asks that his creditors meet and approve of the offer.

Bids will be received April 14 by the Columbus Board of Purchase for coal for city departments as follows: 12,500 tons of Ohio nut, pea and slack for the municipal light plant; 6,700 tons of Ohio nut, pea and slack for the Scioto River pumping station; 2,500 tons of Ohio nut, pea and slack for the garbage disposal plant; 500 tons of West Virginia nut, pea and slack for the coal pulverizers at the garbage reduction plant. H. C. Cain, is secretary of the Board.

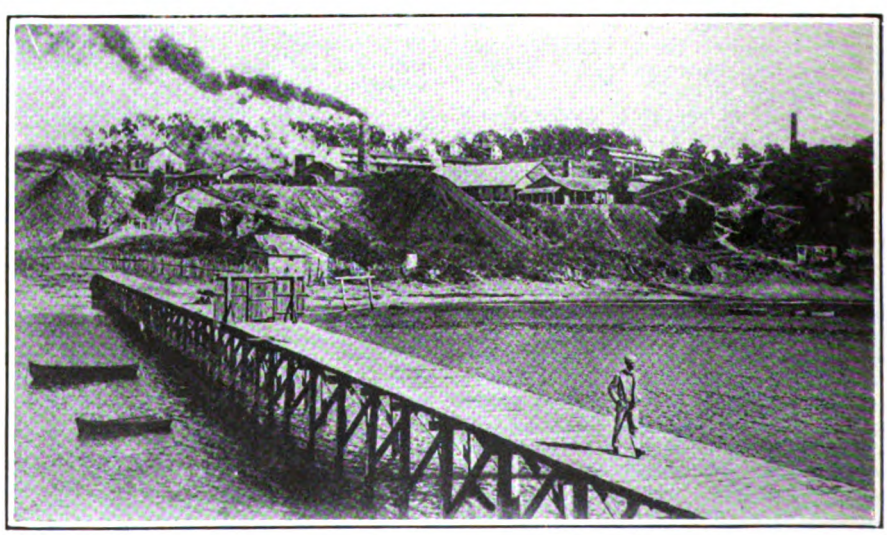
PENNSYLVANIA

Former Mayor P. B. Brown, of Pittston, has embarked in the coal business with Thomas Lynott, an experienced rock contractor. They have taken over a plot of ground on the mountain east of Pittston. It is understood that there is a coal seam 11 ft. thick at some portions of the new operation. For the present the coal is being hauled from the property to a breaker in Dunmore and there prepared for market. Later on the mineral will be shipped to Dunmore in railroad cars.

The York Farm Coal Co., which has conducted a mining operation near Pottsville for several years, is now engaged in dismantling its washery there. This action is due to the fact that the huge culm dump formerly connected with the York Farm mine of the Lehigh Valley Coal Co. has been virtually worked out. The washery machinery is being shipped to Herdnon, where it is understood that culm deposits are to be taken from the Susquehanna River.

The Clinton Iron & Steel Co., at Pittsburgh, has resumed operations at its blast furnace on the south side, which had been banked for the past three months. In order to keep this furnace supplied with coke the Snowdon Coke Co., owned by the same interests, has fired up 120 of the 200 ovens put out when the anthracite strike was settled. This company now has 220 ovens in blast.

W. J. Rainey, Inc., have put out 200 ovens at their Allison plant and have closed down their Royal plant altogether for an indefinite period, during which time their plant will be completely electrified.

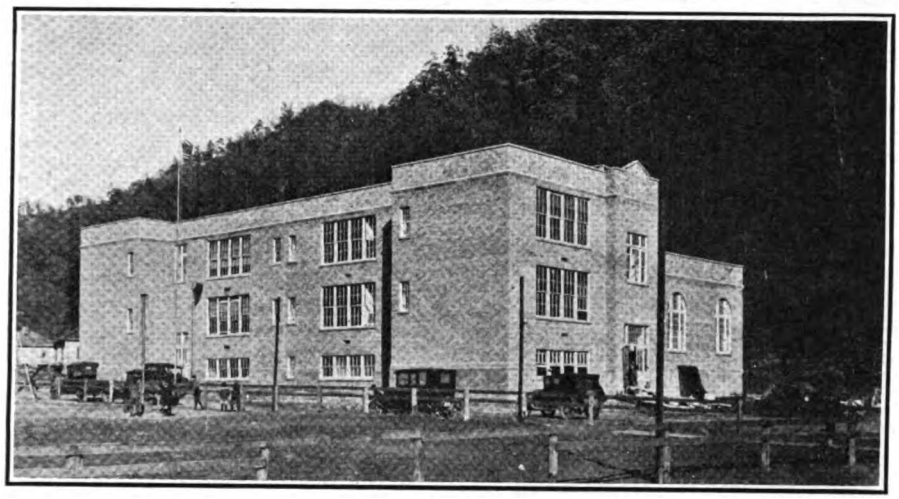


The Oliver & Snyder Steel Co. has put out 100 ovens. The H. C. Frick Coke Co. is putting out additional ovens, as is also the Puritan Coke Co.

David Thomas, a member of local union 1157, United Mine Workers, of Mocanaqua, who was suspended by the local union for ninety-nine years for his alleged part in the framing of a resolution concerning arbitration during the resent hard-coal strike, has been restored to good standing in the union. The executive board decided that the evidence upon which the suspension was based was not sufficient.

The executive board of District 1, United Mine Workers, has approved a plan to have all offices of the district organization with the exception of the legal department, located in Scranton. Attorney Roger J. Dever, who is the general counsel for the union, will retain his office in the Miners Bank Building, Wilkes-Barre. Former sub-district offices located in Wilkes-Barre will be removed to the Coal Exchange Building, Scranton.

The Spring Mountain Colliery, near Jeannesville, has been declared the most efficient of all the Lehigh Valley Coal Co. and Coxe Brothers operations. Company experts studied the records of the collieries for June, July and August last and awarded the efficiency banner to the Spring Mountain plant.



John J. Golby, superintendent of the Consolidation Coal Co. mine at Pine Hill, Somerset County, was instantly killed on March 15, when he was caught in a gas explosion in the mine. His body was badly burned and mutilated. Two other men with him escaped. Gas was detected in the mine a week before and Mr. Golby had entered the mine to

Chilean Coal Mines at Lota, First Operated in 1844

The Lota field is 280 miles, south, as the crow flies from Valparaiso or a little further than Pittsburgh is removed from Philadelphia. It lies near the city of Conception, so much at the water's edge that much of the coal extracted, if not all, comes from under the sea. The volatile matter in the coal runs from 34 to 41, the moisture from 3.6 to 4.7, the ash from 1 to 6.5, and the sulphur 0.2 to 4.8 per cent.

School Building at Caretta, McDowell County, W. Va.

This new building, which stands on property of the Consolidation Coal Co. and cost $80,000, provides space for modern equipment such as auditorium, gymnasium, manual training, and domestic science rooms.

discover the place where the gas was escaping. The body was hurled 500 ft. by the force of the explosion. He was 45 years old. A son, Thomas Golby, risked his life by going into the heading and carrying the body of his father out while a rescue crew pumped oxygen into the mine.

J. E. Kennedy, of the Kennedy-Van Sann Manufacturing & Engineering Co., New York, gave a lecture on Thursday night, March 18, to the members of the Engineers' Society of Northeastern Pennsylvania on "Pulverized Coal." The meeting was held in the auditorium of the Glen Alden Coal Co. building and was presided over by C. R. Seem, president of the society.

Judge Bailey, at Huntingdon, has decided to dismiss the temporary receivers for the Huntingdon & Broad Top Mountain Railroad & Coal Co., according to advices from Philadelphia, but will hold a further hearing on April 16, after which it is expected that action will be taken regarding the question of permanent receivers.

Secretary of Mines J. J. Walsh is expected to fix a date during the coming week for a new series of examinations for qualification of candidates as anthracite mine inspectors. The date probably will be during April. The recent examinations did not qualify men for appointment. There are seven vacancies, a larger number than has existed at one time in many years.

A loss of almost $75,000 was caused recently near Gordon, when fire destroyed the Coal Creek washery of the Hill View Coal Co. This washery was erected a few years ago and was operated at times during the recent strike, but has been shut down since the settlement.

William Lamont, of Bakerton, Cambria County, a member of the state board of mine inspectors, has announced that nineteen men passed the state examination. The tests were given in Pittsburgh. The successful candidates are Silas S. Hall, Connellsville; William G. Kneoper, Philipsburg; John Ira Thomas, Johnstown; J. F. Robey, Uniontown; James D. Walker, Butler; D. W. Wilkinson, Uniontown; Thomas J. Lewis, Punxsutawney; W. L. McCoy, Pittsburgh; F. W. Howarth, Hillcoke; Thomas Anderson, Heilwood; Patrick S. Nairn, Johnstown; William B. Wardrop, Barnesboro; James L. Maise, Uniontown; Thomas A. Stevenson, Conemaugh; William J. McGreagor, Eldersville; William Phillips, Caddy; George Stenheiser, Punxsutawney; Patrick J. Buchanan, Ellsworth, and Alexander Jack, Lilly. Three vacancies exist at present, in the Crafton, Altoona and Philipsburg districts.

WEST VIRGINIA

Plans are being made by Charleston mining men to entertain the southern West Virginia and northeastern Kentucky chapter of the American Institute of Mining and Metallurgical Engineers in Charleston on May 6 and 7. The guests will include Samuel A. Taylor of Pittsburgh, Pa., president and Dr. Thomas T. Read, of New York City, assistant secretary of the national organization. Dr. Read was formerly director of the safety service of the U. S. Bureau of Mines. Probably 200 mining men will attend. A banquet on the night of May 7 at a Charleston Hotel will be one of the features. The chapter has a membership of 200. On the afternoon of the second day the mining men will visit the industrial plants of Charleston. The local committee of arrangements is composed of J. K. Anderson, president of the chapter; C. E. Krebs, secretary of the chapter, and Carl Scholz, vice-president and general manager of the Raleigh-Wyoming Coal Co.

Operators estimate that coal production in southern West Virginia has been curtailed 25 per cent since the anthracite strike ended.

The Colcord Coal Co., of Charleston, is installing equipment at its Montcoal mine, on the C. & O., in Raleigh County, to be completed May 1 at a cost of from $25,000 to $30,000. Screens and rotary dumps are being installed and the tipple is being remodeled. The company also is buying 50 new mine cars.

Affairs of the Otto Marmet Coal Co. were in the federal court of southern West Virginia in Charleston on March 24. Otto Remelin, manager of Raymond City; Charles Strebel and other officials are trying to again obtain possession of the mine at Raymond City, Putnam County. The property was purchased by J. C. McKinley, of Wheeling, whose affairs afterward went into bankruptcy. The company seeks to resume operation at the mine as soon as the legal status of affairs is straightened out. The original company, the Otto Marmet Coal & Mining Co., also is involved in the proceedings.

William N. Cummins, general manager of the Red Jacket Consolidated Coal & Coke Co., reports that the company has completed the reconstruction of its No. 5 tipple. The improvements include a new set of modern shaker screens, picking tables, loading booms and refuse conveyors. At the No. 6 plant a new gathering motor and cutting machine have been installed.

A. J. Thompson will soon open for development a tract of coal land on the Durbin Branch of the Western Maryland Ry. at what was formerly Montes, near Elkins. Tests disclose the presence of a seam of Sewell coal. Development work will be started at an early date under the direction of Orin Kelly, who has been making the tests. It is stated that approximately 250 men will be employed once the new mine is in operation.

Increased profit for 1925 was reported by the American Coal Co., whose annual statement shows a net earning of $433,256, as against $244,001 for 1924. This is equal, after federal taxes, depreciation, depletion, etc., to $8.73 a share earned on outstanding 49,598 shares of $25 par capital stock. It was $4.91 a share in 1924.

In its report for 1925 the **Island Creek Coal Co.** shows a net profit of $2,210,949, after charges and taxes, equivalent, after preferred dividends, to $16.09 per share (par $1) earned on 118,801 shares of common stock. In 1924 the figures were $2,426,569, or $17.91 per share. The net income from coal and other operations was $3,736,620. Administrative and general expenses, miscellaneous interest, depreciation and depletion and federal taxes totaled $1,525,671. Total assets, including cash, $833,117; accounts and notes receivable, $1,683,886, and coal inventory, $73,759, were $22,727,820. Total liabilities were $15,990,163.

CANADA

Coal production of British Columbia in the first two months of the current year totaled only 350,025 gross tons, as compared with 404,467 during the corresponding period of 1925. The falling off has been chiefly in the Vancouver Island mines, which produced only 194,192 tons, as compared with 249,226 tons in the first two months of 1925. The decreased production is due to extraordinarily mild winter. C. E. Villiers, general manager for Canadian Collieries (Dunsmuir), Ltd., says the effect has been particularly noticeable at the Extension colliery, which depends on local demand. The Cumberland collieries, which have an extensive and regular bunkering trade, are not feeling the depression to the same extent.

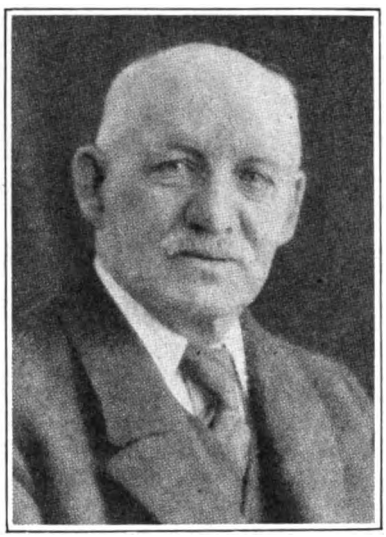
Among the Coal Men

Whitefoord R. Cole, newly elected president of the Louisville & Nashville R.R., of Nashville, Tenn., also is a coal man, being connected with mines in the west Kentucky field and at one time was financially active in the affairs of the Dealers Fuel Co., of Nashville, which had an office in St. Louis. **James B. Hill** was elected president of the Nashville, Chattanooga & St. Louis Ry., to fill the vacancy created by the elevation of Whitefoord R. Cole to the presidency of the Louisville & Nashville. Mr. Cole became the head of the Louisville & Nashville following the death of W. L. Mapother. Mr. Hill was assistant to the president of the Nashville, Chattanooga & St. Louis. He began as a clerk.

E. L. May, well known during the past few years on account of his connections with the Levy enterprises of Chicago, is now in the sales department of the Lumaghi Coal Co., of St. Louis, Mo.

Tom Mackie has been elected a director of the Central Coal & Coke Co., Kansas City, Mo., to succeed J. N. Penrod, who died last September. Mr. Penrod's place on the executive committee of the company was taken by Harry T. Abernathy, another director.

M. C. Allen, who formerly owned the store at Middle Fork, Kanawha County, W. Va., has leased the mine of the Middle Fork Block Coal Co. at Middle Fork.



J. J. Tierney, son of the late Col. L. E. Tierney, has been made manager of the Eureka Coal & Coke Co. at Eckman, W. Va., and of the Lynchburg Coal & Coke Co. at Kyle, in McDowell County,

F. R. Wood president of the Temple Fuel Co., of Trinidad, Colo., and Mayor of Trinidad as well as president of the Colorado & New Mexico Coal Operators Association and formerly State Senator, will enter the race in the primary election for the governorship of Colorado.

Vernon G. Leach, an expert on combustion, who formerly was with the Nason Coal Co., is now connected with the Peabody Coal Co., Chicago. He will devote his entire time to the promotion of power-plant economy.

Thomas Kennedy, international secretary-treasurer of the United Mine Workers, has been made a member of the tri-district executive board in the Pennsylvania anthracite field with voice and vote. The action was taken at a recent meeting of the board.

The duties of the position of general superintendent of W. J. Rainey, Inc., vacated recently by the resignation of John Sincock, are being temporarily cared for by **Robert Woods, Jr.**, assistant general superintendent, Uniontown, Pa., and **J. R. Maust**, New York, N. Y., general purchasing agent, who is spending his time in Uniontown at present. No permanent appointment has yet been made.

David Hannah

David Hannah recently was elected president of the South Wales Institute of Engineers, of which he is one of the oldest members, having joined 42 years ago when a student. Born at Mynyddislwyn in 1855, he has been active throughout his career in the South Wales coal field, where he is one of the leading mining engineers. He received his early training with the Powell Duffryn Colliery Co., later becoming acting manager of the Ocean Coal Co. In 1889 he was appointed assistant manager of D. Davis & Sons' Ferndale Collieries, and a year later general manager of all that company's plants at Ferndale and Tylorstown, a position that he retained until his retirement a few years ago. Mr. Hannah is now chairman of the Welsh Navigation Steam Coal Co., Ltd., and a director of D. Davis & Sons, Ltd., and Locket's Merthyr Collieries, Ltd. He also is a member of the South Wales Coal Conciliation Board.

Traffic News

More Ohio Interests Ask Hearing In Lake Rate Case

The Tristate Coal Stripping Association, the Wheeling & Lake Erie Ry., the Ohio Public Utilities Commission, the Attorney General of Ohio and the Eastern Ohio Coal Operators' Association filed petitions with the Interstate Commerce Commission March 23 urging a rehearing in the lake cargo rate case. The eastern Ohio operators' petition said the situation "has seriously injured and impaired the business and social life of the complaining district and caused widespread suffering and distress."

The Ohio Attorney General and Utilities Commission declared the tonnage of coal shipped to lake ports for transshipment had continually decreased from Ohio districts and had correspondingly increased from the Kentucky and West Virginia districts.

In Ohio, it said, thousands of miners were reported out of work, enormous investments were imperilled, millions of dollars had ceased to flow through the usual channels of trade, the commercial life of mining communities, where not already ruined, was stagnant, many operators had become bankrupt and others were "desperately endeavoring to avert that fate.

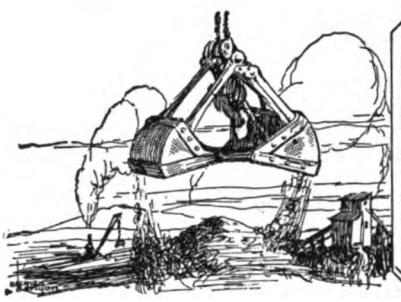
"Relief from the excessive rates charged on lake coal from the Ohio districts," the petition added, "must be had; otherwise the coal industry, which for many years has been one of Ohio's chief assets, will deteriorate into a comparatively insignificant and unprofitable business enterprise, while the Southern fields will continue to expand."

The eastern Ohio operators presented figures to show that miners' wages in Ohio had decreased from $70,994,928 in 1923 to $31,500,000 last year.

I. C. C. Studies Hard-Coal Rates To Upper New York

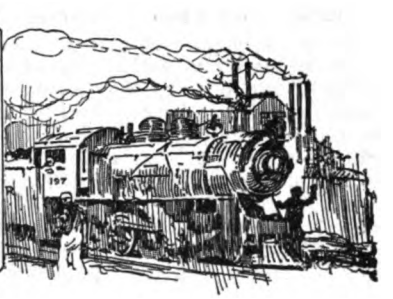
A round-table discussion was held by the Interstate Commerce Commission March 16 with representatives of carriers which are proposing readjustments in freight rates on anthracite coal from Pennsylvania to northern New York territory, which generally would result in slight increases, and representatives of communities and other interests opposing the changes. No agreement was reached. As the new schedules are proposed to become effective April 1, the Commission must decide before that date whether it will suspend the new tariffs pending further investigation or permit them to become operative and take up the matter subsequently in the form of complaints.

Complain of Colorado Rates



The Colorado and New Mexico Coal Operators Association has filed with the Colorado Public Utilities Commission a complaint charging Colorado railroads with discriminatory freight rates on coal from the northern Colorado fields on the Rock Island railroad in Colorado west of Limon. The Santa Fe, Burlington, Rock Island, Colorado & Southern, Union Pacific and Denver & Rio Grande Western were the roads named as defendants in the complaint.

Ratify New Central Coke Rate



The New York Public Service Commission has approved a new rate of the New York Central (East) on coke, coke breeze and coke dust, from Troy to stations from Ogdensburg to Rouses Point inclusive, on the Rutland R.R. of $3.20 per net ton, effective April 13, 1926. No joint rate heretofore in effect.

The Pennsylvania R.R. last week asked the Interstate Commerce Commission to deny the petition of the New England Traffic League for a further hearing in the case involving emergency rates on soft coal from West Virginia mines to Northeastern states, which expire April 30. The road's representatives declared the present temporary rates, placed in effect during the mine suspension, were too low and should not be made permanent.

Production And the Market

Market Conditions Colorless as Coal Year Ends; Bituminous Output Declines

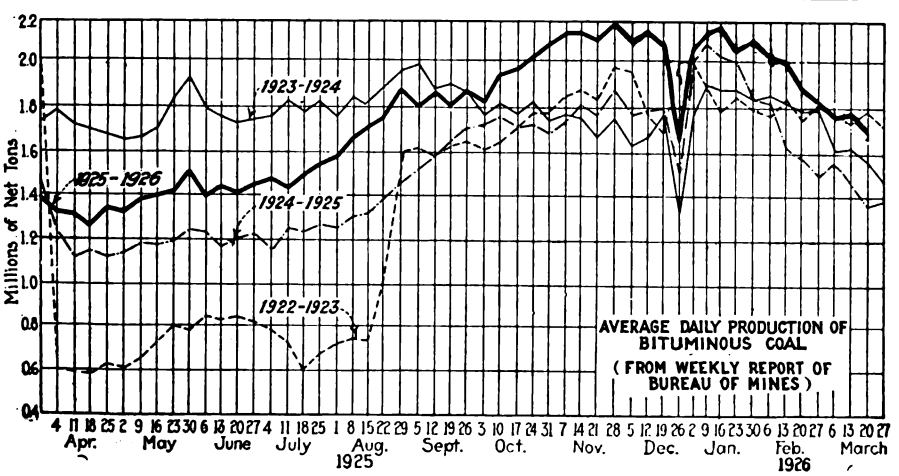
Nothing sensational or startling marked the passing of the coal year 1925-26 in either the anthracite or the bituminous markets of the country. Here and there, as on the Missouri River, for example, a brief weather flurry brought a final burst of activity to the domestic trade. Such flurries, however, were outnumbered by the slumps induced by a climbing mercury in other parts of the country. For the most part, the past week revealed merely the accumulation or the intensification of the effects of factors at work for some time.

Bituminous production, which showed an unexpected and still unexplained reversal of form the second week in March, again hit the downgrade during the week ended March 20. Output that week, according to the Bureau of Mines, was 10,273,000 net tons, a decline of 417,000 tons. Production, however, is still ahead of demand. Every mining field has its quota of "no bills" and distress tonnage has its depressing influence upon the movement at many eastern terminals.

Spot prices, on the whole, weakened—particularly in the East and upon eastern and southern coals in the markets of the Middle West. *Coal Age* Index of spot bituminous prices on March 29 stood at 163 and the corresponding price was $1.98. This was a drop of four points and 4c. when compared with March 22. Illinois and Indiana quotations were well maintained. Kentucky and West Virginia prices generally were softer and pool quotations at the Atlantic seaboard again declined.

Outlook for New Year Perplexing

Speculation as to the course the new year will take naturally holds the center of discussion, but no clear course of action has been mapped out. Those producers in union fields who have not lined up non-union connections are resigned to further suspensions of operations until such time as a modification of the Jacksonville scale can be effected. The uncertainty as to when that change will come underlies the deep pessimism in the Pittsburgh district and in the southern Ohio field.



Contracting still is backward. Nevertheless, it is probable that more activity in this connection is being conducted under cover than current reports would indicate. There are certain well-established connections involving the annual movement of large tonnages which may be counted upon to continue undisturbed. At the same time it is recognized that the existing conditions offer little incentive to the buyer to contract—especially if he represents an industry which can afford to gamble with its fuel supply.

Anthracite Output Heavy

Anthracite production continues at a high rate. There are signs, however, that the most pressing demands of the consumer have been met. Company operators are starting to store some of their steam coal output and independents find increasing sales resistance to the movement of No. 1 buckwheat. Even the retail buyers are more discriminating in their purchase of the high-dollar independent domestic.

As forecast in *Coal Age* six weeks ago, it now appears to be well settled that there will be no spring reduction in mine prices of the large sizes. Whether the prices established in February will be used as a basis upon which to build advances during the spring and summer months is a question now troubling some people. Upon this point there has been no official announcement or comment.

The Connellsville coke trade has settled into its regular groove.

Estimates of Production

(Net Tons)

BITUMINOUS

	1925	1926
March 6	9,384,000	10,460,000

Middle West Looks to Contracts

The question of steam-coal contracts is the paramount one in the markets of the Middle West at the present time. Producers who still are trying to market their own coal are fighting hard against non-union competition. Some high-grade southern Illinois slack can be had on contract as low as $1.75, and other screenings may go at $1.50 or even $1.25. Railroads are inviting tenders; they probably will be able to buy southern Illinois mine-run at $2.25@$2.50 and Indiana coal at $2@$2.25. Few contracts have actually been closed.

Domestic demand is slow. Interest centers upon the new price announcements to be made this week. Reductions in the Franklin County basis are forecast, with a sliding scale throughout the summer months—a replica of the old anthracite summer discount system. West Virginia and Kentucky shippers are seeking retail storage orders on block at $2@$2.75. Smokeless lump and egg are offered to middlemen as low as $2.50.

More mines in Illinois and Indiana are closing down. The combination of warm weather, non-union competition and the normal spring slump in demand is proving too much for the average producer, who is beset with "no bills" on everything but steam coal. In southern Illinois, operations working are getting two and three days a week. Duquoin and Jackson County are in worse shape; only the strip pits have an even break. Mt. Olive is moving little coal. There has been no change for the better in the Standard district. The St. Louis local market is colorless.

Kentucky Waits for Lake Trade

Weather conditions since the middle of March have robbed domestic demand of life in the Kentucky fields. Producers, therefore, are finding it harder to move prepared sizes and prices in the eastern section of the state have broken. No real revival in demand is expected before the lake shipping season is well under way. Steam business, too, is less active, notwithstanding the fact that the industrial outlook is good. Many purchasing agents are holding to their determination to play the open market instead of renewing expiring contracts.

Eastern Kentucky block is to be had at $1.75@$2.25, with only the best known coals commanding up to $2.50. Two-inch lump, egg and nut are quoted at $1.75@$2, with some sales at $1.60. Mine-run is $1.25@$1.60; screenings, 90c.@$1.10. The prices in the western Kentucky field, except on lump and screenings, were unchanged last week. Lump advanced 10c. and a dime was added to the maximum price on spot screenings.

Hand-to-mouth buying by both retail and industrial consumers has resulted in part-time operations at the docks at the Head of the Lakes. Mild weather has cut household consumption of fuel to such an extent that retailers fear they

will be overstocked. Industrial plants see no occasion for worry with ample reserves on the docks, railroad transportation good and the opening of navigation close at hand.

Dock Smokeless Again Slumps

Prepared sizes of smokeless coals were again the only sufferers in price. Lump, egg and nut were officially cut to $7—a reduction of $1 since the middle of March. The end of the anthracite strike and all-rail movement of hard coal to the Twin Cities are advanced in explanation of the weakness afflicting the smokeless list. In the local trade at Duluth and Superior, however, smokeless is still welcome because of the price differential under anthracite. Coke and briquets also are holding their own.

A rising mercury has slowed down demand for all grades of fuel in the Milwaukee market. Anthracite is coming in more freely; no spring reductions in prices, however, will be made. Retail prices at the present time for chute or curb delivery are: Stove, $16.80; nut, $16.65; pea, $14.25; buckwheat, $11.

A cold wave brought a slight flurry of activity to the Southwest trade last week, depleting retail stocks so much that replenishment orders were placed with the shippers. These orders, however, were not heavy enough to take a very noticeable bite out of the surplus of "no bills" which have been clogging Kansas mine tracks for several weeks and did not revive the moribund Oklahoma and Arkansas situation.

Colorado domestic business is still in a demoralized state. Demand is extremely weak and the market is glutted with unsold coal. Retailers are buying only for immediate necessities, hoping for further reductions in storage coal prices. The only size for which there is an active demand in Utah is slack and that demand is due primarily to curtailed operations at the mines. Business on the whole is subnormal.

Smokeless Given Another Blow

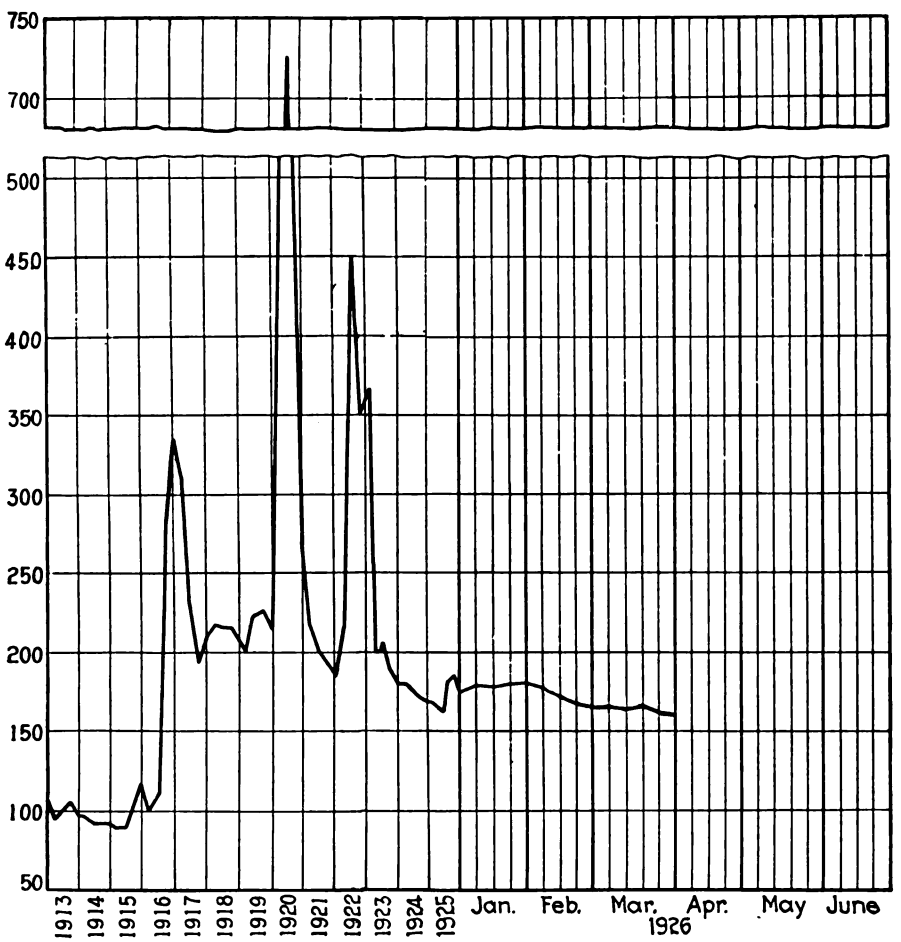
Smokeless prices have been given another jolt in the readjustment process in progress at the Cincinnati market. Egg and lump are weak at $2.50@$3. Mine-run, which had been steady at $2.25, now is offered at $2@$2.25. The campaign to bolster up slack prices appears to be making little headway. Retail prices at Cincinnati and throughout the Miami River valley have been cut from $8.50@$9.50 on lump to $7.50. Retail mine-run is down to $5.75@$6, which is the range also quoted on bituminous lump.

Traders have about abandoned hope that high-volatile coals can be moved via the price reduction route. Shrewd shoppers can buy some of the best West Virginia lump at $1.75@$2 and Kentucky at $2@$2.25. Egg is hard to sell at $1.50@$1.75. Mine-run, on the other hand, is steady. Slack has dropped back to 75c.@$1.10.

Shop talk centers around the lake business. One report, apparently well authenticated, says that a large Logan County group has sold its summer output at a $1.50 mine-run basis. Another report states that lake buyers, after a futile attempt to dragoon Kentucky shippers into a contract for slack and 2-in. coal at 80c., have offered 90c. for slack and $1.65 for 2-in. Movement through the Cincinnati gateways is within 300 cars of normal for this year and about 3,000 cars a week ahead of last year.

Ohio Also Looks to Lakes

With domestic trade out of the picture and industrial buying slow because big consumers are well stocked, Ohio producers are wondering what the lake trade will have in store. Outside of the mines with direct dock connections, Ohio expects a smaller share of the lake business than in earlier years because producers cannot meet the prices quoted on lake business in Kentucky and West Virginia. Lump at $1.60 cannot be matched by the Buckeye State.



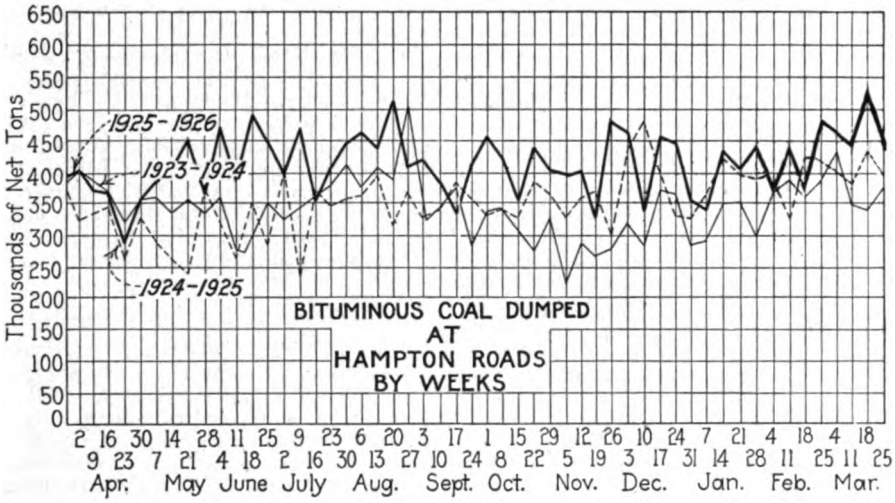
Retail dealers in central Ohio are more anxious to clean up stocks than to place fresh orders. Industrial plants are indifferent on the score of contract renewals. Railroads, however, have invited tenders, but little tonnage has been awarded. Southern Ohio production is still under 20 per cent of capacity. The No. 8 field produced approximately 247,000 tons, or 35 per cent of capacity, during the week ended March 20. Out of 120 mines in the field, only 16 are working full time and 63 operations have been down for a year or more.

Cleveland reports a steady but gradual slowing down in demand, particularly in prepared sizes. This has cut further into the tonnage of free slack and nut-and-slack available. Screenings prices were up 5@10c. last week. On the other hand, there still is considerable distress tonnage of the larger sizes to hold down quotations on mine shipments and sap consumer interest in the market.

"There Is No Joy in——"

The Pittsburgh district is stagnant. Independent operators are pegging along, working a few days a week to keep up on unexpired contracts. Many of these mines plan to close down as soon as these contracts have been completed as the prices offered on renewal make a shutdown the lesser of two evils. Prices show no real change because buyers will not pay more and operators feel they dare not sell for less. A number of Connellsville producers have been trying to break into the steam and gas coal markets, but their success has not been marked.

Central Pennsylvania production still is on the toboggan. Output the week ended March 20 was 15,572 cars, as



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	Mar. 29	Mar. 22	Mar. 15	Mar. 8	Mar. 30	Mar. 31
Index	163	167	168	167	161	173
Weighted average price	$1.98	$2.02	$2.03	$2.02	$1.95	$2.09

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average of the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

compared with 16,190 cars the week preceding. Only 118 mines are working full time. Railroads are buying up some of the distress coal in the district at bargain figures. Current quotations for shipment are: Pool 1, $2.50@$2.60; pool 71, $2.35@$2.45; pool 9, $2.10@$2.20; pool 10, $1.90@$2; pool 11, $1.70@$1.75; pool 18, $1.65.

Buffalo bituminous trade is a drab affair. Some contracts are in the making, but the prices bring no joy. Spot quotations are unchanged. Slack is the only grade for which there is a real demand. The announcement that there would be no spring reduction in anthracite prices and the possibility of advances later have caused an unfavorable sentimental reaction. Consumer demand for hard coal is slowing up at Toronto, but orders already booked and coming in will keep retail yards busy for some weeks to come.

New England Trade Dull

The New England steam coal market is dull, with no signs of early betterment discernible. Prices are sagging and coal is piling up at the mines and the southern loading piers. Contract customers are well supplied with fuel and spot buyers can find enough distress tonnage to keep them running. Navy Standard was available at $4.15 gross f.o.b. vessels at Norfolk last week. Nut-and-slack and straight slack have been offered at prices as low as any within recent years.

Navy Standard on cars at Boston and Providence was held at $5.75 at the last named point for inland delivery and under $6 at Boston. Open prices to regular customers for retail delivery in Boston is $8.50, but recent bids on the requirements of the Massachusetts state institutions show a fighting basis much lower. One proposal named a delivered price of $5.85 on New River at Charlestown State Prison.

Further reduction in the tonnage of distress coal in the New York bituminous market was effected last week. Some screened sizes in that category were offered at $3.50 alongside and some Kanawha splint at $3.50@$4 alongside. A Shipping Board inquiry for a small tonnage of standard pool 1 coal for bunkering brought a price of $5.78 t.i.b. Contracting for the new season is backward. As the distress tonnage melts, however, spot buying is slowly improving.

Micawber Comes to Philadelphia

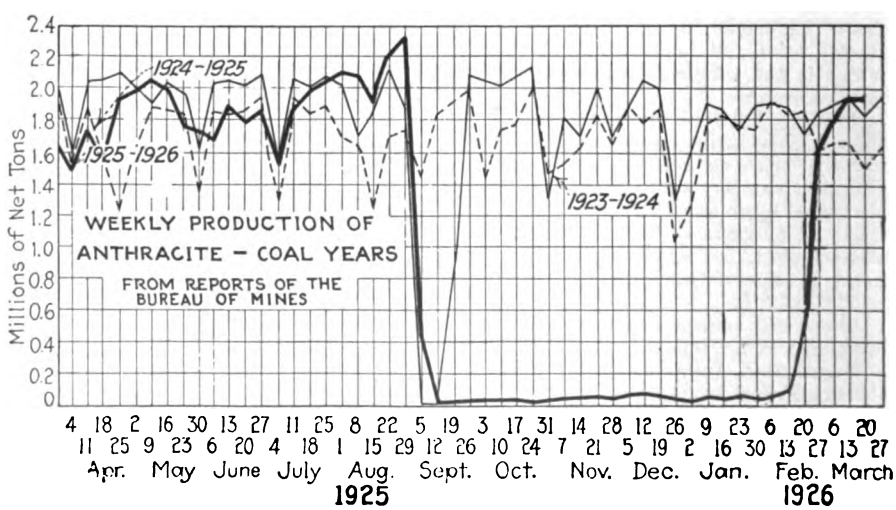
In the Philadelphia bituminous market everybody is waiting for something to turn up—not sure what it will be and not at all certain that anything will happen to better the outlook. Tonnage moving in some cases may be satisfactory, but prices realized are not. Contracting is slow. The nearest many industrial consumers are coming to signing on the dotted line is to buy a car or two here and there as trial shipments. Spot prices are unchanged. Bunker trade is holding its own.

In the main, the situation in the Baltimore bituminous market is a duplication of that at New York and Philadelphia. Aside from large consumers such as the public utilities little interest is displayed in contract negotiations. Current spot prices are so near those named in contract tenders, that many plants see no incentive to sign up. Good coals which usually command around $1.85 have been sold as low as $1.50. One recent sale of a large block of steam tonnage was made at a price 20c. per ton under actual mining costs.

The promulgation of April prices on domestic coals in the Birmingham market has been followed by an active contract movement. In fact, some producers already are sold up for the spring and early summer months. The new price basis is as follows: Big Seam lump, $1.75@$2.25; Carbon Hill lump, $2.50; Cahaba lump, $3 50@$4; Black Creek lump, $3.50@$3.75; Corona lump, $2.75; Montevallo-Straven, $4.25; Montevallo-Dogwood, $4.50; Montevallo-Aldrich, $4.75. Egg prices are 25c. less; washed nut, 75c. under the lump quotations.

Better Alabama Coals Hold Up

The better grades of mine-run and washed coals are in fairly active demand. Spot buying of the lower grades is not brisk, but there are no surplus accumulations of tonnage. Spot prices have shown no material change. The St. Louis-San Francisco R.R. has broken the ice in railroad contracting by closing agreements for approximately the same tonnage as last year and at the same prices. Most of this coal will come from Walker County.



The market for egg and nut coke is not active. Spot quotations range from $5 to $5.50 at the ovens. A number of contracts have been made on foundry coke at $5.50@$6. Spot foundry coke also is in good demand at $6.50.

Assurance that there will be no spring reduction in anthracite mine prices has had a steadying effect upon the New York hard-coal market. But retailers have announced reductions in their prices to the household consumer and their ability to take care of his orders promptly. They are, however, urging that the householder take a combination of sizes. Chestnut coal still tops the market from the standpoint of present popularity, but stove is a close runner-up. Pea also is in good demand, and some householders are looking on No. 1 buckwheat with friendly eyes.

Weather Takes Toll in Philadelphia

Spring temperatures at Philadelphia last week were reflected in a sudden easing off in consumer demand for hard coal. This, however, did not slow up the rate of ordering from the mines, although there was more hesitancy in retail buying of high-dollar coal, and occasional hints that independent egg and stove were not particularly desired.

Steam sizes are coming from the mines faster than the market will absorb them. Producers without storage facilities are working hard to place their surplus production. Some independent contracts have been closed at $2.50 for No. 1 buckwheat, $2 for rice and $1.50 for barley. One of the largest company shippers has named contract prices of $2.75, $2 and $1.60 on those sizes. Certain buyers are reluc-

tant to pay these prices, particularly on No. 1 buckwheat.

Baltimore household consumer demand has weakened with a rising thermometer and the change is welcomed by the Baltimore dealers. Orders on hand, however, will eat up all the coal running to the yards in the city.

Furnace Contracts Closed?

Although no definite announcement has been made, it is understood that the bulk of the furnace coke needed for the second quarter by buyers who draw supplies from the Connellsville region has been closed at $3@$3.25. Some business was signed up at $3.50, mostly renewals. Spot furnace coke is held at $3.25, but inferior fuel can be had for less. Standard spot foundry coke is quotable at $4.50@$5. Some April orders have been placed at $4.75.

Coke production in the Connellsville and Lower Connellsville region the week ended March 20 totaled 190,010 tons, according to the Connellsville *Courier*. The furnace ovens produced 104,600 tons—an increase of 4,200 tons over the preceding week. Merchant oven output, 85,410 tons, was 3,180 tons less than during the week ended March 13.

Seeks Bids on 25,000 Tons

The U. S. Engineer's O ce, 140 Decatur Street, New Orleans, La., will receive bids until April 22 for 25,000 tons of bituminous coal at mine for shipment to various points on the Mississippi River below Vicksburg, Miss. Further information may be obtained upon application to Frank Michinard, 107 University Place, New Orleans, La.

February Exports Increase

United States bituminous exports in February surpassed those of the preceding months, but are well below the average for 1925, according to the Department of Commerce. The total quantity of bituminous shipped abroad during the month amounted to 1,013,158 gross tons, as compared with 993,386 tons in January.

Anthracite exports increased from 6,311 gross tons in January to 37,157 tons in February. Coke exports declined to 67,697 tons.

Exports by countries were as follows:

Russian Shortage Continues

The fuel crisis is still very acute in Russia and is endangering industrial activity. The Supreme Economic Council has taken some special measures to overcome the difficulties. In the Donetz coal district a number of old shafts have been put into operation and new shafts are being dug with the assistance of German firms. Owing to the fact that large sums of capital are required for the exploitation of the coal deposits, ways and means of attracting foreign capital for mining purposes are being discussed.

Coal Bids for New York City Reveal Wide Range

Twenty companies submitted bids on 502,436 tons of anthracite and bituminous coal for the Department of Purchase of the City of New York on March 23. The opening of tenders revealed the following:

For furnishing and delivering 10,000 net tons of mine run bituminous coal to Rikers Island the prices submitted ranged from $4.13 to $4.28 per ton.

For 5,103 tons of No. 1 buckwheat coal above 59th Street, Manhattan, six bids received ranged from $4.81 to $6.28 per ton, while for 6,592 tons of the same kind of coal below 59th Street five bidders made tenders ranging from $4.84 to $6. For 7,760 tons of No. 2 buckwheat coal in Manhattan the prices submitted ranged from $4.44 to $5.20 per ton.

Prices submitted for supplying in Manhattan Borough various tonnages of broken, egg, stove and chestnut coals ranged from $11.99 to $12.59 for broken; $11.88 to $12.50 for egg; $12.49 to $13.22 for stove; $12.48 to $12.59 for chestnut, and $8.94 to $9.20 for pea coal, depending in all instances on delivery points.

In Brooklyn two bids—$4.84 and $5.22—were received for furnishing and delivering 1,673 tons of No. 1 buckwhat coal. For 15,000 tons of mixed coal—11,500 tons No. 2 buckheat and 3,500 tons soft coal—to the Kings County Hospital four bids received ranged from $4.38 to $4.94 per ton.

For furnishing and delivering to boats of the various city departments at various points 9,300 tons of mine-run soft coal there were four bids received ranging from $4.56 to $5.92 per ton. Five bids were received for furnishing and delivering 173,000 tons of No. 1 buckwheat coal in barge lots to various delivery points. These prices ranged from $4 to $4.66 per ton. For 45,600 tons of No. 3 buckwheat coal under the same conditions four bids received ranged from $3.54 to $3.98 per ton, and for supplying 28,500 tons of mine-run soft coal under the same provisions the prices ranged from $4.17 to $4.54.

Foreign Market And Export News

Surplus Stocks of Coal Depress Welsh Market; Tyne Inquiries Increasing

London, England, March 16—The Welsh steam coal trade is still very unsettled. Colliery owners are well booked and arrears of delivery are heavy, but the tonnage position is very unsatisfactory. Stocks of coal have accumulated to such an extent that irregular operation of the pits has become the rule instead of the exception.

The collieries are anxious to obtain any prompt business that may be available and in some cases are cutting prices to secure quick shipment, though their order books are well filled and they are not really in a position to accept such bookings. In South Wales the difference between the cost of production and the selling price is now estimated at 3s. 3d. per ton, without reckoning any return on the capital invested in the mines.

The Egyptian State Rys. have invited tenders for 150,000 metric tons of Monmouthshire large coal for May and June delivery. The Palestine Rys. have ordered 32,000 tons of best Admiralty large, and the Portuguese Rys. 21,000 tons of steam smalls for delivery over three months.

The Newcastle market is dull, but there is an increased inquiry for forward business. Very much, however, depends upon the attitude of the government, the operators and the miners towards the coal report, which has now been published. Prices for the most part are steady, though in one or two cases they have been inclined to waver or fall slightly. There is little actual business to report aside from certain European gas works contracts.

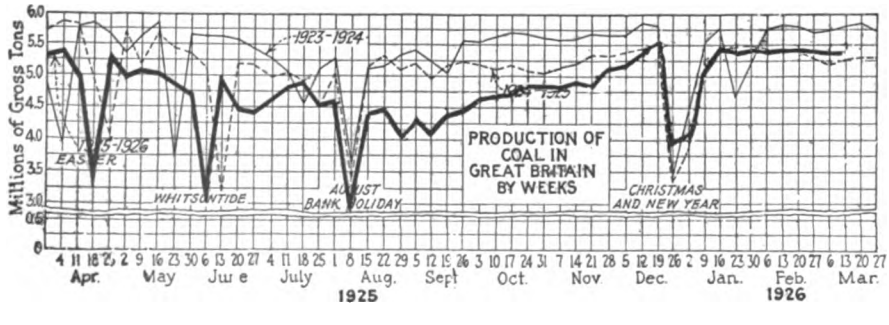
Output by British collieries during the week ended March 13, according to a special cable to *Coal Age*, totaled 5,285,000 gross tons, the same as in the preceding week.

Belgian Market Less Active; Outlook Unfavorable

Hopes of an improvement in the industrial coal market in Belgium have not been realized, reports Brussels under date of March 18. The slight advance registered in prices in February has been maintained, but there is nothing in the present outlook to indicate that further increases are possible. Small coals are in the greatest demand. Coking smalls are readily salable at 85 @87 fr. Lean smalls for brick and lime kilns command 67@68 fr., and there is some talk of raising the price to 70 fr.

The domestic market is weak. Stocks on hand are increasing as consumer demand is tapering off.

Syndicate prices on coke are 125 fr. on Belgian and 120 fr. on German coke, but outsiders are selling coke at 110 fr.



An agreement finally has been reached on first-quarter prices on coal for the Belgium State Rys. These prices, 84@88 fr., represent a uniform advance of 1 fr. per ton over November-December figures. The price on briquets, 100 fr., is an advance of 4 fr. The question of second-quarter prices is now under discussion. One order for 450,000 tons has been allocated, but the price has not been fixed. An order for 150,000 tons of briquets has been placed at 110 fr. The increase over first-quarter prices reflects the higher cost of pitch.

French Industrial Call Strong; Domestic Orders Decline

Paris, France, March 18.—The industrial demand for coal in France continues on a satisfactory basis. Further decline in the value of the franc in foreign exchange has had an adverse effect upon the rate of importation of coal from Great Britain, forcing a heavier load upon the productive capacity of the French collieries.

Buying of domestic coals is easier, but orders still are numerous enough to take care of the sized output from the French mines. Increases of 6@10 fr. in Belgian prices, due to fluctuations in the rate of exchange, also have helped the French operators. An agreement was made last week between French and Belgian interests fixing summer prices on fuel for the Parisian district, but the prices have been withheld.

The first arrivals of Polish coal have made a favorable impression although the appearance of the fuel is against a ready sale. This, however, is offset by the small degradation. The Polish coal is being sold at prices approximating those on French coals of like grade.

Coming Meetings

New England Coal Dealers' Association. Annual meeting, State Armory, Worcester, Mass., April 7 and 8. Secretary, E. I. Clark, 141 Milk St., Boston, Mass.

Canadian Retail Coal Association. Annual convention, King Edward Hotel, Toronto, Ont., Can., April 14 and 15. Secretary, B. A. Caspell, Brantford, Can.

American Welding Society. Annual convention, 29 West 39th St., New York City, April 21-23. Secretary, M. M. Kelly, 29 West 39th St., New York City.

California Retail Fuel Dealers Association. Thirteenth annual convention at Del Monte, Calif., April 22-24. Secretary, J. B. Muir, Oakland, Calif.

Mine Inspectors' Institute of America. Annual meeting, Seventh Avenue Hotel, Pittsburgh, Pa., May 11-13. Secretary, G. B. Butterfield, Hartford, Conn.

National Retail Coal Merchants' Association. Ninth annual convention, New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

Electric Power Club. Convention at The Homestead, Hot Springs, Va., May 24-27. Secretary, S. N. Clarkson, B. F. Keith Bldg., Cleveland, Ohio.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, in conjunction with the annual meeting of practical operating officials. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. The fourteenth congress will be held in Madrid, Spain, commencing May 24, 1926. From May 5 to 22 excursions of interest to the visiting delegates will be arranged. Information concerning the congress can be obtained from the secretary of the organizing committee, Enrique Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

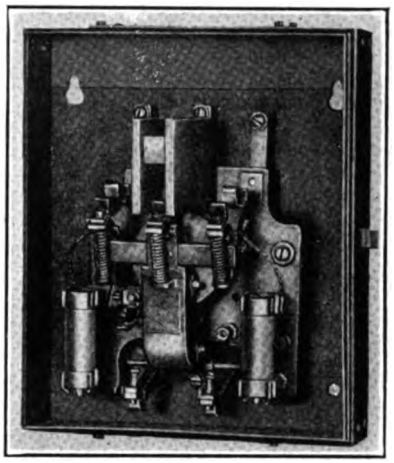
Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.



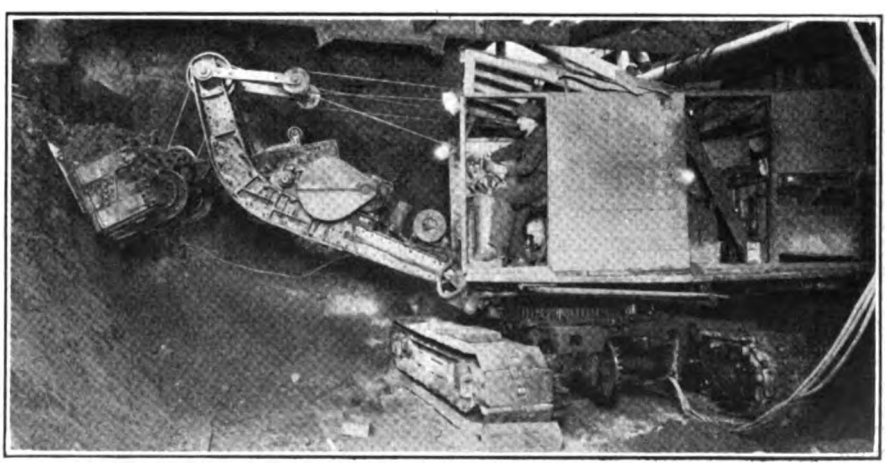
New Equipment

Across-the-Line Starters Made Easily Accessible

In the accompanying illustration may be seen one of the two new across-the-line starters which have been recently developed and are now being placed on the market by the Westinghouse Electric & Mfg. Co. of East Pittsburgh, Pa. These starters are of the reversing and non-reversing types respectively. They are of compact design and have been made easily accessible for installation and wiring. Two slotted hexagonal screws firmly hold the starter unit in place in a sheet steel cabinet. Thus the starter may be removed as a unit by merely withdrawing these screws with an ordinary screw driver, leaving all the room inside the cabinet free for attaching conduit bushings and drawing in the leads.

This starter, consisting of a 3-pole contactor with electrical interlock, is completely inclosed and is operated from a push button station that may be located at any convenient point. It thus provides safe control and eliminates damage which might result from tampering by unauthorized parties or by unskilled handling. In addition to this safety precaution, a floating armature type of 3-pole contactor is employed which provides smooth and positive contact. This is quiet in operation and the tips are kept clean by the rolling and wiping action of their closure.

Where operating conditions necessitate the protection of the starter against an accumulation of chips or other foreign matter, a door interlock may be had that makes it impossible to start the motor unless the cabinet door is firmly closed. The non-reversing starters, class 11-160, are applicable for many machine drives where dirt and dust is encountered, such as in textile mills, on machine tools, wood-working machinery, conveyors, blowers, pumps, tipple machinery and the like. The reversing type, class 11-165, embodies the same sturdy and safe construction and the same essential operating characteristics as the non-reversing type, but in addition the mechanical interlock above referred to, making it impossible for the contactors to be closed unless the door is shut. This type has its obvious advantages which need no further comment.



Starter and Cabinet

Removal of two screws permits the contactor to be removed from its steel cabinet, thus leaving the whole inside of the cabinet free for the insertion and installation of the wiring. An electrical interlock with the door may be installed rendering it impossible to close the contacts unless the door has likewise been previously shut.

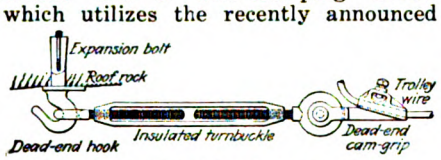
Burrowing Power Shovel

In the accompanying illustration may be seen a power shovel that is particularly adapted to low headroom such as is encountered in coal mines. This is a Marion standard type No. 21 machine fitted with a bow-shaped boom. It is built by the Marion Steam Shovel Co. of Marion, Ohio.

This machine is obviously a tunneler and has been operated underground in as little as 11 ft. of headroom. It is pointed out by the builder that because

Surface Shovel Evolves into Underground Unit

Subway and other tunnel contracting work is causing a rapid change in the upstanding steam shovel. It is learning to stoop. This one also crawls. It will work in a place only 11 ft. high and with non-combustible cab should prove fitted for thick coal beds.



Digitized by Google

of its short boom and dipper stick and the consequent shortness of its swing, it loads cars with great rapidity. The shovel in the illustration is owned by the Oakdale Contracting Co. of Brooklyn, N. Y., and is being used in subway construction. Electric shovels of this type, however should be useful in loading coal in mines where sufficient headroom is afforded.

Dead-End Assembly Saves Trolley Wire

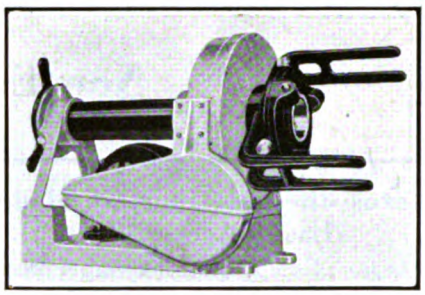
To fill the need for a simple, yet substantial and complete device for terminating trolley lines, the Ohio Brass Co., of Mansfield, Ohio, has placed on the market parts for a new dead-end assembly.

This device consists of a heavy malleable-iron hook which can be affixed to the standard overhead hanger or expansion bolt, an insulated turnbuckle and a wire-clamping device which utilizes the recently announced

Simple Dead-End Assembly

Simplicity is the key note of this device. It consists of a hook fitted with an expansion bolt that may be anchored in the roof, an insulated turnbuckle and a trolley-wire grip.

cam-type grip. This latter is of particular value in the assembly as it eliminates all the waste of wire usually entailed where dead ends are formed by bending or looping trolley wire around some rigid support.



This new dead-end assembly is equally useful for permanent and temporary installations. It can be removed with ease and used over and over as the line is extended. A material saving in time and labor is said to result from the employment of this handy device.

Portable Power Pipe Threader

Threading pipe by hand is always a more or less laborious operation depending somewhat on the size of the pipe. In any case it is slow. To obviate this difficulty the Oster Mfg. Co., of Cleveland, Ohio, has recently developed and placed on the market the new light weight model, power drive pipe threader shown in the accompanying illustration.

As may be seen, the body of this machine is made almost exclusively of aluminum allow which is not only stronger and more durable than the cast-iron formerly used, but is much lighter. The new machine weighs only 150 lb. and is therefore a really portable unit in its entirety.

Motive power for this machine is furnished by a ½-hp. reversible universal motor which automatically speeds up on the smaller sizes of pipe yet maintains the necessary speed on the larger sizes. This gives the outfit a greater productive capacity than would otherwise be the case. This motor can be run from any 110 or 115-volt lighting circuit either direct or single phase alternating current, of any frequency. Its reversibility makes it possible to

Threads Pipe with Ordinary Die

This machine is driven by a small, reversible universal motor. It will thread pipe of all sizes up to 2 in. or by the aid of an attachment up to 6 in. It may also be used to make up fittings and couplings.

use almost any die stock in connection with the machine.

This machine has the capacity to drive any die stock or pipe cutter up to 2 in., but with a special auxiliary drive shaft (which can be furnished) geared die stocks or cutters up to 6-in. may be handled. In addition to this, the machine may be used to screw up fittings as a pipe wrench can be held by its driving arms and rotated the same as a pipe die.

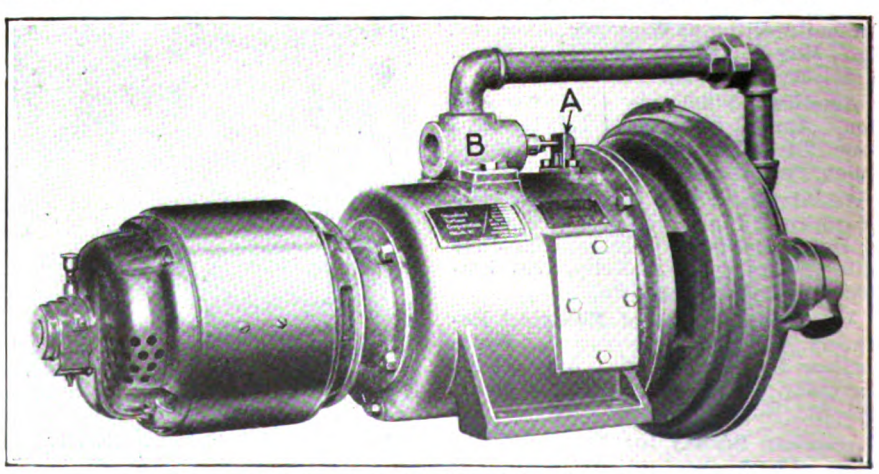
The pipe to be threaded is held stationary in a three-jawed, self-centering chuck and the pipe tools are turned by the driving arms. Self-centering universal guides in the rear of the machine assist the chuck in centering long lengths of pipe. An idea of the compactness of this device may be gained from the fact that it is only 18⅛ in. high, 14½ in. wide and 30⅛ in. long.

Splicer with Cam-Grip Holds Trolley Wire Tight

A cam-grip splicer for securing the ends of trolley wires and based on a new principle is a recent development of the Ohio Brass Co., of Mansfield, Ohio. The operation of this splicer depends upon the action of a serrated cam on the trolley wire rather than on the direct pressure of set screws. The cam or dog is of hardened steel carrying milled teeth. It is confined in a pocket in the body of the splicer and is held down against the trolley wire by means of a single heavy hardened steel set screw.

The eccentric action of this cam comes into play when the wire is pulled, so that the greater the tension on the wire, the stronger becomes the grip. The strength is not dependent on the force used in tightening the set screw but upon the wedging action of the dog when the wire is in tension.

The wires enter cored holes in the body casting and the lips are formed by a V-shaped opening in the underrun, ground to a taper toward the ends of the splicer. No peening of the lips is necessary as the opening is made for a snug fit around the wire. The cam forces the wire down against the bottom of the opening with the result that there is said to be an easy transition of the trolley wheel onto and off of the splicer.



Steel Teeth Bite Into Copper Wire with Bulldog Grip

In this splicer the cap screws do not bear on the trolley wire direct but through rocking cams provided with milled teeth. The greater the tension pulling the two wires apart the firmer the grip of these cams.

An Emergency Lighting Unit

A turbo-generator set in sizes from ½ to 10 kw., designed especially for use as an emergency lighting unit for the power station, is a recent development of the Standard Turbine Corporation, Scio, N. Y. The unit is arranged to start automatically when for some reason the regular light supply on the station fails, automatic starting being accomplished by means of an electrically operated shutoff valve in the turbine steam line.

The set is similar in construction to the regular line of small lighting sets built by this company except for the governor, which is of special design and which operates in the oil space of the bearing pedestal. The steam governing valve *B* is fastened directly to the top of the turbine and connects with the governor through the lever *A*. The generator is made an integral part of the turbine, which tends to reduce the over-all size for a given capacity.

Emergency Lighting Unit Designed for Automatic Starting

Starts automatically when regular light supply of station fails, the automatic starting being accomplished by an electrically operated shutoff in the turbine steam line.

Use—Not *Years*—Measures Value

Time, occasionally, may be a measure of quality. The age of a picture—the youth of an egg—are both indexes to desirability and value.

But in measuring the service of a mine car wheel, time is a misleading standard. One mine may demand of a car more service in five months than another will require in five years. To ask, "How *long* will wheels last?" is as illogical a question as, "How high is up?" or "How long is a piece of string?"

The only true standard of wheel service is the use it will give —which may most accurately be measured in ton miles: the weight on the wheels × the length of the haul in miles × the number of trips.

Computing on this basis is simple. Determine the average length of haul; the number of trips per year the cars make loaded with coal; the number made loaded with slate and rock; the weight of car and load in each case; and the weight of the car empty. Then work out these 3 formulas:

Number trips coal-loaded x length of haul x total weight.
Number trips rock-loaded x length of haul x total weight.
Number trips empty x length of haul x total weight.*
(**This number will be equal to the sum of the first two.*)

Summing up the three results will give you the ton miles of service per year.

A few minutes work with your pencil will show you some facts concerning your haulage equipment service that will be interesting—and may be profitable. Why not do this figuring?

Advancing to Seat of A Mine Fire

It would be easy enough to recover a mine after a mine fire if you were sure the fire was out, so entirely out that the admission of air could not fan the embers into flame and start another explosion. But the approach to the seat of a fire is always made in doubt as to whether it is asleep or dead.

At Horning there was the usual uncertainty, but the fire was found to be out. However, a good plan of campaign was arranged and everything was prepared for the advance. Had fire lurked ahead, the precautions might have saved many lives. A description by Mr. Brosky of the recovery will appear next week with an account of the damage done by the explosion and of the protection afforded by the rock dust along the roads and in barriers.

Where Will We Get Our Timber?

Instead of wondering, many firms are planting. They have the idle land and they may as well put it under timber. Next week Mr. Alford will describe the status of the forestation movement in coal mining.

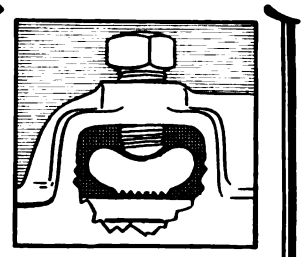
Trolley Tension Tightens it!

New O-B Trolley Splicer with Cam Type Grip



WITH this new device, O-B engineers have greatly simplified and at the same time improved current practice in trolley splicing.

Instead of depending on the direct pressure of a set screw on one little spot in the wire, the set screws are themselves used merely to hold cam-shaped dogs in place. Each dog has milled teeth which are in contact along the top of the wire. When tension is applied, the dog is pulled under the set screw bringing into play the cam or wedging effect as the diameter increases. The teeth bite further into the wire and the pressure is increased until a grip is attained which cannot be broken or worked loose.

The harder the pull, the tighter it holds.

A cored hole extends straight through the body casting. Trolley wires to be spliced are butted; the splicer is slipped onto either one and pulled as far along as needed to clear and receive the other end. The splicer is then centered and set screws tightened with a small wrench or pliers. No bending or other damage is done to the wire.

These new O-B Splicers are accurately made in sizes to insure snug fit for the several wire gauges customarily used. No peening of the lips is required because the pressure of the cam forces the wire tightly into the V-shaped opening in the underrun. Note the smooth underrun provided.

Details of cam grip

Dogs and set screws are made of hardened steel. Note the length of contact, with milled teeth against the wire.

Assuring Fan Operation

IN ALL coal-mining equipment, taken by and large, reliability is of greater importance than economy. Getting the greatest return from the fuel burned or from the power purchased is an excellent objective to keep in view and strive to attain, but in most instances it cannot be subordinated to reliability. For shutdowns and interruptions wreak havoc on production and production costs out of all proportion to their own magnitude. The indirect losses sustained from such suspensions are far greater than their direct expense.

Where the safety of the men employed is at stake, also, continuity of service is doubly essential. Thus it is highly important that the fan be kept in operation even though power may go off the line for more or less extended intervals. To this end auxiliary units, such as gasoline engines either belted to the fan through a clutch or direct-connected to a generator of sufficient capacity to drive both fan and man hoist at reduced speeds, are frequently installed. If steam must be generated to heat water for the washhouse, it is common practice, also, to employ steam engines as standbys on these two pieces of equipment.

Where storage-battery locomotives or power tanks are extensively used their batteries may be made to serve the purpose of standby power to excellent advantage. In such mines some batteries are on charge at practically all times. In order to utilize the energy stored in such accumulators it is only necessary to run a suitable line from the charging station (which is usually located near the shaft bottom or mine mouth) to the fan house and provide there a motor of the proper type and capacity. This source of power may be similarly employed for shop or repair operations on idle or off days as well as for a standby. At several mines this source of power is now being utilized for either or both of these purposes.

Stop the Repeaters

UNDER THE general subject of tracks, there appears in the Union Pacific Coal Co.'s code of standards the following paragraph:

"A record of all derailments shall be kept by the mine foreman giving date, cause, and location. Drivers and motormen must give their reports of such happenings to the mine foremen daily."

This expresses a principle which is one of the important factors underlying the high-production and low-maintenance cost records per unit of equipment at many mines. It applies to all classes of equipment.

Generally speaking the mining machinery of today is wonderfully rugged, considering the limitations of size and weight, and gives excellent service if properly lubricated and not unnecessarily abused. The problem is to differentiate between normal wear, which takes place in any machine even if properly maintained, and trouble due to preventable causes.

A record of failures forms a stairway leading to the bottom of the trouble. Every failure has a cause, and the causes are not as numerous as might be expected. In eliminating troubles which show up frequently, some companies go so far as to redesign parts of equipment which are deemed too light or not suited to the specific local conditions encountered. Usually this is necessary only in the more advanced stages of development. An improvement of installation, operating, repair or lubrication methods can be countered upon to eliminate most of the "preventable" troubles. But before a physician can treat human ills intelligently he must correctly diagnose the case. His training in diagnosis is based on records which the medical profession have been compiling for years. It is much the same in the treatment of failures of equipment. The procedure should be based on a careful and frequent analysis of operating records. Usually there is little excuse for enduring repeated troubles from a common cause.

"No Backward Step"

ORGANIZED LABOR in the coal fields, like organized labor in industry generally, came out of the World War stronger than it ever had been before in the history of the labor movement in the United States. Why that was so, need not be discussed; it is water long since gone over the dam. Among the various union groups were some that recognized the force of economic competition and willingly or unwillingly met capital on the basis of the changed conditions brought about by the post-armistice depression and, later, by the collapse of the 1920 boom.

The United Mine Workers was not among those that trimmed their demands to the unfavorable winds of depression. Under the dynamic, belligerent leadership of a new president, the executives of that organization rallied to the battle cry of "no backward step." Let wages fall elsewhere; the United Mine Workers would stand firm against all demands for a reduction and so save the country from an economic smash-up! Adhering to that resolution, the miners' union has insisted and still insists upon the continued maintenance of the highest basic wage scale ever granted it.

In 1918 the United Mine Workers controlled approximately seventy-two per cent of the bituminous tonnage produced. In 1925 less than thirty-five per cent of the output was mined under the union scale. Entire districts have been swept into the non-union column; many others have become so pockmarked with open-shop operations that the union no longer is the dominant factor in those fields. Mine after mine has closed down in the strongly organized districts, and the beginning of the present month swelled the roster of the idle union operations.

Digitized by Google

Nor is that all the picture. In the Appalachian Region, where the close proximity of union and non-union mines has intensified the competition between the two groups, the drift from union to non-union production through the exploitation of non-union acreage by operators originally identified only with the union fields has been going on for some time. This development has come to be the accepted means by which the union operator can retain his hold upon his business. The practice, indeed, has become so common that it has ceased to excite comment.

This movement, however, is no longer confined to the fringes of the Central Competitive Field. It has penetrated into the very heart of that great union stronghold. Less than a month ago it was announced that the Peabody Coal Co. had taken over the distribution of the output of a group of non-union western Kentucky mines in territory in which it might normally be expected to push the product of its own Illinois mines. And there are other Illinois and Indiana producers who have maintained friendly relations with the union over a long period of years who are taking similar action to protect themselves.

The lesson ought to be plain enough to convince even the officers of the United Mine Workers that their attempts to hold an untenable position can lead only to further disaster. "No backward step" has a vigorous ring, but the successful leader frequently retreats in order that he may advance. Has the United Mine Workers such leadership or must the real interests of its members be sacrificed in idolatrous worship of a deluding phrase?

Safety in Longwall

A LONGWALL MINE is less likely than any other to be closed by creep. Modified longwall and the slabbing methods also afford a similar assurance of mine safety. All of which does not mean that there will be no difficulty in maintaining the longwall face, especially when the first attempt is made to obtain a break. Perhaps the mine most likely to close up suddenly is the room-and-pillar mine with a 50 per cent recovery. When rooms are started and pillars not drawn or if the drawing of pillars is delayed, a squeeze over a large area is almost sure to start. In Illinois squeezes have repeatedly ridden over big barrier pillars. Unless the roof is broken the mine is in danger. The 100 per cent extraction of longwall, especially where there is no packwalling or the 90 per cent extraction of slabbing, assure complete caving if the panels are sufficiently long and wide, but the room-and-pillar method with its low recovery invites the loss of a mine in a night.

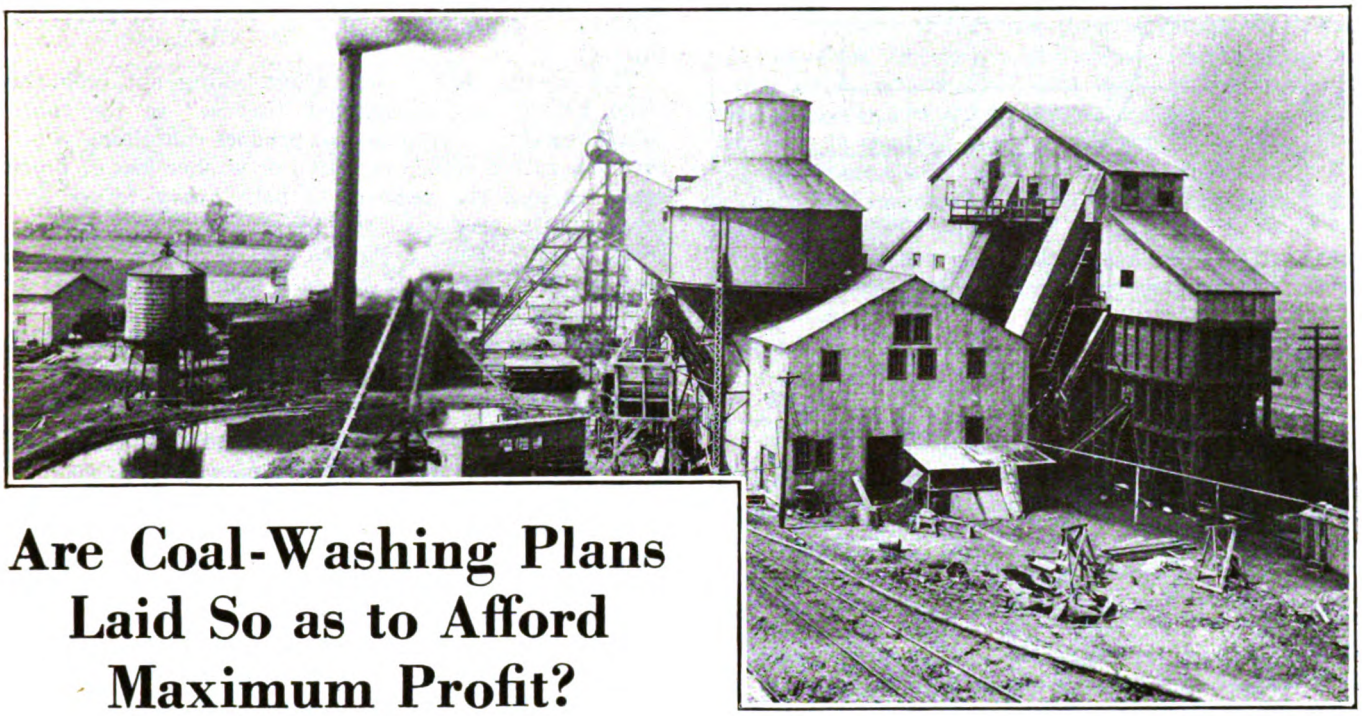
Congratulations!

A NEW ARRANGEMENT has been made for the preparation and distribution of monthly statistics of the exports of coal and coke which will place the figures in the hands of the public about two weeks earlier than has been the case in the past. Heretofore the delay in issuing this data has been the subject of criticism ranging from the profane to the ribald. After all, a good part of the value of statistics lies in their timeliness. It has hardly been flattering to our pride in American efficiency to compare the delays blocking the publication of our export figures—small as they may be—with the speed displayed by some other countries. The Minerals Section of the Bureau of Foreign and Domestic Commerce at Washington is to be congratulated on the speeding up process which makes these figures more news and less ancient history.

Minister Stein Explosion

AFTER MUCH careful experimentation and inquiry the authorities in Germany have reported on the disaster at the Minister Stein Colliery. We print in this issue an interesting article on the subject by Raoul Touwaide. Yet, though the study made was long and arduous, one cannot be assured that the conclusions of the investigators were correct.

In this mine which was kept free of gas by an unusually large air circulation, it is not surprising that an explosion occurred after a fall of rock had shut off the ventilation. The explosion may have been due to any one of many causes. Possibly the shot to which the explosion is attributed may have been the cause, but only because the gas flooded from the Ida back into the Otto seam or because the Otto seam itself made enough gas that, when the air current was shut off, the air almost immediately became gas-laden. These probabilities seem far more likely than the assumption of the authorities that the "depression" caused by the shot drew gas out of cavities which gas was ignited by the burning parts of the cartridge when they were expelled from the hole. If the cavities of the Otto seam contained methane in such quantity, the seam was surely not non-gaseous in any proper sense of that word.



The evidence that a shot caused the explosion is also dubious. It is stated that a shot was fired about the time at which the accident occurred and that the place at which it was fired was little damaged. It is argued that the damage is usually at a minumum at the point of ignition, but so it might be at the point at which the blast dies down. So this assumption may also be without warrant.

It has been noted that where explosions are known to have started, as in the face of the experimental mine at Bruceton, Pa., it is often found that large piles of planking have been projected against the face and that there has been much violence. These facts have been explained by showing that the explosion often gains in pressure as the wave advances and then throws back waves toward areas of lower pressure, with resultant lifting of material only partly ejected or wholly undisturbed by the main explosive wave. The investigators assume that there was an increase in violence as the explosion extended but apparently are unwilling to admit that this would probably, but by no means inevitably, have resulted in a return wave that would have made a place, that had largely escaped before, a point where much energy was later displayed.

We have learned from Mr. Touwaide that the shot was stemmed, but it would seem that, if it was the cause of the explosion, the shot either blew *out* or else blew *down* the material so easily as to release the burning contents into the roadway. That may be a danger with a shallow shot, the stemming may be too short or the environing walls may be too weak to prevent the issuance of flame before combustion is completed.

But if some things seem uncertain, the value of rock-dust barriers was clearly demonstrated as also the ineffectual protection afforded by water. The proof was so clear than the German authorities, who have hitherto been skeptical, seem to be so no longer.

Are Coal-Washing Plans Laid So as to Afford Maximum Profit?

Rarely Pays to Remove Middlings as Quality of Coal Is But Little Improved—Clean Coal, However, Keeps Mine Working Steadily—Review of Typical Washery Machinery

By Thomas Fraser
Assistant Professor of Mining,
University of West Virginia

IN THE STUDY of the washery problem the important consideration is to produce such coal as will afford the most profitable return. When coal is washed, so as to remove both bone and slate it usually happens that the analysis is but little bettered by the removal of the bone and a large quantity of coal is thrown away, whereas the removal of slate only will reduce the percentage of ash considerably without wasting any large quantity of the product.

The usual method of disposing of the fine coal (screenings or slack) is to place it on the market in the raw state as a cheap stoker fuel. If the coal seam contains friable impurities, the fine coal is dirtier than the larger sizes and, in many cases, use of mechanical loaders will increase the proportion of dirt in the fines. To produce a desirable grade of small coal under these conditions, the coal must be cleaned by machinery. The proper size at which to make the division between hand picking and mechanical cleaning will vary with individual conditions; but, inasmuch as the nut coal is the most difficult and expensive size to hand-pick and the easiest size to clean mechanically, it generally will be advisable to include the nut coal (2x3 in. or smaller) in the washer feed if a washery is being installed for the smaller coal. This would be the most economical procedure except where the nut coal is comparatively clean and requires only a superficial treatment.

In the extensive Appalachian and Eastern Interior coal regions washeries have been generally regarded until recently as novel appurtenances only to be found at steel-company mines. Although some plants for the preparation of commercial coal have been operated, they are uncommon. However, in the past three years there has been a marked increase of general interest in coal preparation, attended by moderate activity in actual cleaning-plant construction.

The cleaning plant and process best suited for the preparation of coal for the general market may be expected to differ materially from those designed to produce metallurgical fuel. The important considerations which influence the operation of commercial plants are: (1) Market conditions usually prohibit crushing to prepare coal for treatment. (2) Removal of heavy refuse alone usually results in a satisfactory product. (3) Only a small enhancement in selling price is available to cover operating cost and shrinkage. A simpler and cheaper plant generally can be used to prepare a general-purpose fuel than to prepare metallurgical fuel because the complete removal of bone coal and light middling products is unnecessary and usually undesirable. The essential requirements of a plant for this purpose are (1) low plant cost, (2) low operating cost, (3) simplicity of operation, control and repair, (4) minimum loss of coal in refuse, (5) applicability to a wide range of sizes.

KEEPING SHRINKAGE LOSS LOW

Inasmuch as the increased selling price obtainable for cleaned coal is often small, it is regarded as essential to keep the cost of cleaning and the washer loss or shrinkage down to the absolute minimum although, because of the ready salability of cleaned coal, it may often pay to operate a cleaning plant at an apparent loss; this bringing about, indirectly, a much greater

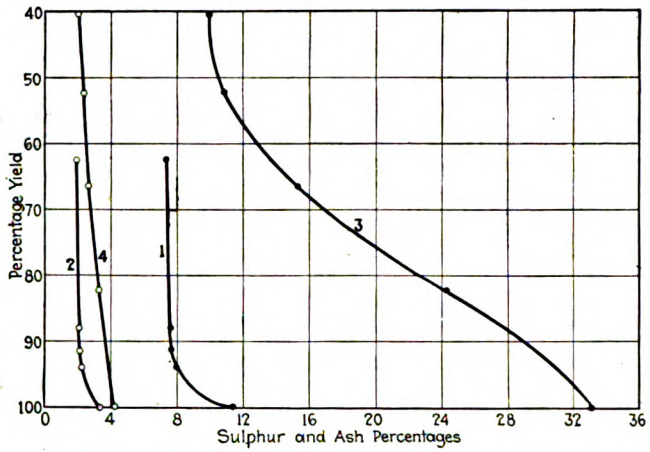

Fig. 1—Curves Show Relation of Ash to Yield

Where the curves are almost horizontal any cutting of sulphur or ash percentages is achieved without much upward progress on the curve and therefore without any marked change in the percentage yield. But where the curves are nearly vertical one can make hardly any progress horizontally without a great change vertically and a big loss in yield. Consequently it is not well to leave the curved tips of the graphs and it is well, indeed, to avoid rising too high on them.

saving through larger sales and steadier operation. Low washer loss is especially important, as every ton of material discarded as refuse decreases the tonnage shipped. Plants should usually be adjusted to take out only the clean rock and heavy bone.

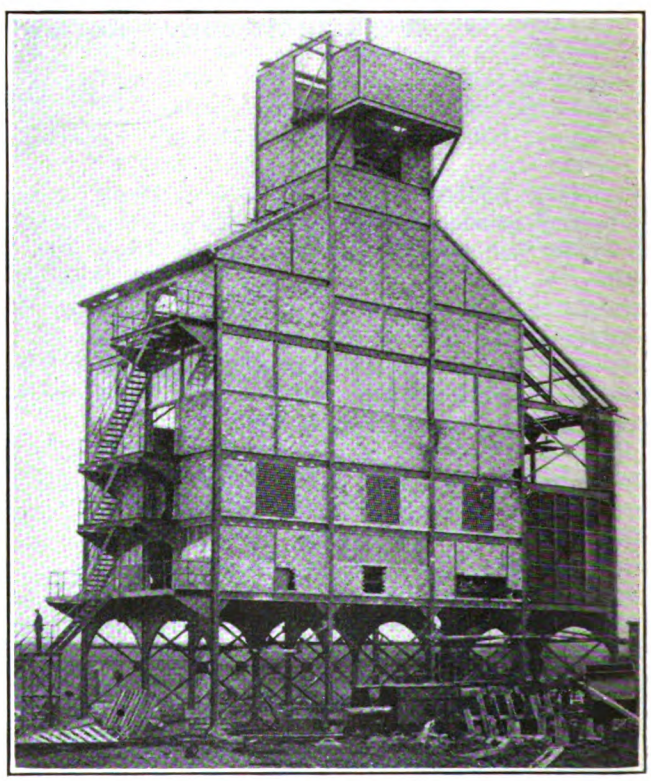
Light bone and mixed particles contain a large proportion of combustible material and rejection of these products as refuse means some loss of fuel; furthermore, because of its low-ash content, removal of bone coal is an expensive ash-reducing measure as a large rejection is necessary to obtain a relatively small decrease in ash in the cleaned coal. In any case, only enough of this bone coal and middling should be rejected to produce a cleaned product of the desired grade. Any type of washer can be adjusted over a certain range of separations; the greater the cleaning effect desired, the greater must be the quantity of material rejected as refuse.

This condition is illustrated by Table I giving the results obtained by washing a sample of high-ash Pittsburgh coal. For experimental purposes several

Table I—Results of Washing a High-Ash Pittsburgh Coal Sample

Product	Per Cent of Feed		Per Cent of Ash		Per Cent Sulphur	
	Direct	Cumulative	Direct	Cumulative	Direct	Cumulative
Raw coal	100.0	....	11.4	....	3.46	....
No. 1 washed coal	62.5	62.5	7.4	7.4	1.97	1.97
No. 2 washed coal	25.5	88.0	8.1	7.6	2.43	2.10
No. 3 washed coal	3.4	91.4	10.5	7.7	3.52	2.15
Middlings	2.6	94.0	37.0	8.0	6.80	2.28
Refuse	6.0	100.0	65.6	11.4	21.80	3.41

products were made; No. 1 clean coal; heavy high-ash refuse, and intermediate products consisting mainly of bone coal and mixed pieces, part coal and part dirt. It should be possible to adjust a commercial plant to make a separation between any two contiguous products shown in the table or at any point on the curves 1 and 2 of Fig. 1, which show the washing results graphically.



The figures in the second column, headed "Cumulative per Cent of Feed," gives total percentage of combined clean products above the individual products in question: for example, 94 per cent is the combined yield of washed coal and middling products if all are combined as one prepared product; similarly, the cumulative per cent ash (8) is the average ash content of this combined product and the cumulative per cent sulphur (2.28) is the average sulphur content of the combined product.

This means that a separation taking out only the clean heavy rock, designated "Refuse" in the table, would result in a cleaned-coal product containing 8 per cent ash with a refuse rejection or washer loss of 6 per cent, whereas the removal of both heavy refuse and intermediate products (middlings and No. 3 washed coal) would produce a cleaned coal of 7.6 per cent ash with a washer loss of 12 per cent. Thus the removal of 6 per cent of heavy slate reduced the ash content of the coal from 11.4 to 8 per cent whereas the removal of an additional 6 per cent of middlings gave a further reduction of only 8 to 7.6 per cent.

If Power Is Generated Can Wash Cleaner

As indicated by the straightening curves of Fig. 1, the further the ash-reducing process is carried the greater rejection is required to accomplish a given ash reduction. In preparing coal for the general market, rejection of light bone, which amounts to making the separation in the upper portion of the curves, is unprofitable, unless some special use can be made of this part of the reject by crushing and rewashing or by using it at the mine as a low-grade fuel.

In case the larger sizes of coal (lump and egg) are hand-picked and the smaller sizes are cleaned mechanically, coal mixed with or adhering to the rock picked

Courtesy American Coal Cleaning Corp.

Fig. 2—Wardley Plant of John Bowes & Partners, Newcastle-on-Tyne, England

Built by the Birtley Iron Co., Birtley, Durham, England, under American licenses. It has six pneumatic coal separators. The roof is glass and the walls of brick and steel. The three louvers are for the incoming air to the fans. The separators are on the floor above. The louvered extension at the end of the building contains the dust-extraction system.

out of the lump and egg can be reclaimed by crushing and washing with the nut and screenings. In this case, the larger sizes can be cleaned more thoroughly, because the coal loss in the pickings is ultimately recovered.

Digitized by Google

Although the question might arise as to whether this practice would affect detrimentally the average quality of the cleaned coal product, the washer may generally be expected to remove practically all the extraneous free impurities in the feed, reducing it to a more or less uniform base ash content a little above the inherent ash.

This would depend, however, upon the nature of the picking-belt material introduced. If a large proportion of bone coal were directed into the washery feed in this manner, a deleterious effect on the quality of washed coal might be expected, whereas, if the picking-belt refuse were made up of shale and pyrite fragments with coal attached, the washer could be expected to clean this as completely as the raw coal after crushing sufficiently to free the coal from the rock.

Results of a pneumatic-table test on high-ash refuse material containing a comparatively small quantity of merchantable coal are shown in Table II and curves 3 and 4 of Fig. 1. In this test the material discharging from the cleaning table was separated into ten graded products by means of separate narrow chutes attached to the discharge side of the table and each leading to a separate receptacle. This is similar to the method of testing explained in detail in a previous paper.*

Table II—Recleaning Test and Refuse Material Using Pneumatic Table

No. 9	15.8	82.3	66.8	24.3	5.80	3.29
No. 10	17.7	100.0	73.5	33.1	8.85	4.28

Although the raw material fed to the table contained about three times as much dirt as the bulk of raw coal normally treated in this particular washery, the cleaner products, Nos. 1, 2, 3, 4 and 5, averaged only a little higher in ash and sulphur than the average washed coal produced at the plant, and the comparatively small quantity of such coal recoverable from refuse materials would have little effect on the average quality of the washed coal.

In addition to being undesirable in most commercial operations, the removal of light bone coal and middlings is difficult, requiring such expedients as close sizing, fine crushing and retreatment. Hence the operation which aims at removal of only the heavy refuse can be performed in a much simpler and cheaper plant than is required to obtain the maximum cleaning effect.

FOUR MAIN WASHING METHODS

The coal-cleaning processes that appear best adapted to this particular service are (1) pneumatic-table treatment applied to wider combinations of sizes, (2) single-compartment, large-capacity jigs (either pan- or piston-type) treating unsized coal, (3) rising current or cone washers, (4) trough washers.

Pneumatic tables, though they require separation of the feed into sized products before treatment and thus lack the simplicity of operation that characterizes the jig and cone plants, have so many other advantages that they compensate for the expense of sizing. Furthermore, it is being found that these machines will separate coal from dirt in a wider range of sizes than was at first advocated. Specific data on the maximum range of sizes that can be effectively treated are not available —at least in the literature of this subject. This, obviously, is greatly dependent upon the kind of service to be performed, particularly upon the disposition of bone and light middling products.

For preparation of an easily cleaned coal or one from which only the heavy refuse need be removed, as is commonly the condition in commercial coal preparation, the pneumatic table should treat satisfactorily a comparatively wide range of sizes in one operation. This process, if simplified by combination of sizes treated to reduce excessive screening, is an economical means of cleaning commercial coal because it eliminates drying, thawing and water-clarifying problems incident to the operation of wet plants.

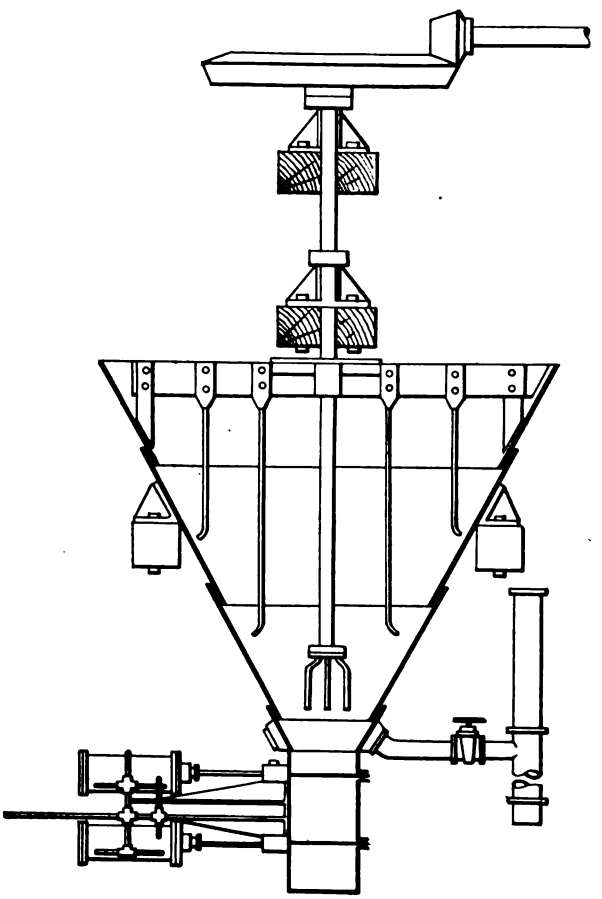

Fig. 3—Cone Washer with Hindered Settlement

Constantly rising water from the main on the right and the motion of the revolving arms enables the coal to keep afloat. The trident at the bottom keeps the bottom stirred up and free to respond to the pressure of the water. Two gates trap the slate at the bottom of the cone. This is the Robinson-Ramsay type of washer.

The wet coal-washing tables under favorable conditions will handle coal up to ¾-in. round-hole size, and if this is the largest size to be cleaned mechanically, a table plant may be used to treat the unsized raw coal. The outstanding advantage of table operation is ease of control and adjustment of the separation; the operation takes place on the table deck in plain view of the operator.

For dry-cleaning nut coal, the spiral separator is effective and inexpensive in operation. Although developed and manufactured in America, these machines

* Fraser, T.; Yancey, H. F. Interpretation of results of coal washing tests, Transactions American Institute of Mining and Metallurgical Engineers, Vol. 69 (1923), pp. 447-469.

Digitized by Google

for bituminous coal are used more extensively in Great Britain. They are especially adapted for removing flat shale and slate but are not so effective in removing bony materials that break like the coal. Separation depends upon differences in specific gravity, coefficient of friction, and shape of particles, between coal and rock. Sinnatt and Mitton give the following sizes as suitable for spiral treatment; 4x6 in.; 2½x4 in.; 1½x2½ in.; ¾x1½ in.; ¼x¾ in.

LARGE COAL DOES NOT FREEZE

Where water is available and the possibility that the coal may freeze can be overlooked, jig plants of simple design are a cheap and effective means of cleaning small coal for market. Jigs and rising-current cone washers have the great advantage, for this particular service, that they will handle larger coal than some of the other processes, and unless the coal is extremely bony and hard to wash, will treat a wide range of sizes. Nut coal up to 4-inch round-hole size has been treated in both jig- and cone-type machines, and unassorted raw coal ranging from this size down to dust may often be treated in one operation with sufficient cleaning effect to produce an entirely satisfactory commercial fuel. This depends upon the kind of impurities present and the quantity of impurities in the fines. Just how completely the very fine material is cleaned in such an operation is problematical.

A thorough study of jig performance on a rather bony Pennsylvania coal, treated at 0x1¼ in. size, indicated that particles from ¼ in. to 1¼ in. in size were well cleaned. Hancock has shown that, in a single-compartment jig treatment of Alabama coals up to 3-in. size, the material finer than ⅛ in. is not appreciably improved. In most cases the dust and very fine coal, even if not benefited by the washery operation, is sufficiently small in quantity that it will not greatly effect the average quality of the washed coal. It should therefore, wherever possible, be screened out of the raw coal before it goes to the washers and mixed in the dry raw state with the washed coal. This minimizes the coal-drying and sludge-handling difficulties and greatly simplifies the washery operation.

For simple low-cost operation, Stewart and Shannon Washeries of the pan-jig type have been very successful. They are easy to operate and repair, have few complicated parts that cause protracted delays in case of breakdown, and are built in large capacity units, usually for treating unsized coal; the water circulating system is very simple.

The Montgomery pan jig will pump its own water and some of the other jigs of this type will operate in a tank of water without outside circulation. Machines of this kind, with a settling tank and slow-moving perforated bucket elevator for draining and loading the washed coal, form a cleaning unit of low installation and operation cost and yet well suited to the service required at many commercial mines where marketing difficulties are being experienced because of the high ash in the small coal.

Large-capacity single-compartment piston jigs are also adaptable to this service. While machines of this type are a little larger and occupy more floor space than pan jigs of the same capacity because of the addition of a separate plunger compartment, this difference is of little moment. Some operators consider that the piston jig can be adjusted to make a little closer separation than the pan jig. Plants of this kind would enable the mine operator, by a small capital outlay, to meet the present demand for cleaner coal and to take care of increased impurities in machine-loaded coal.

The jig usually installed for this service is the movable sieve or pan type. The plants are comparatively simple and compact. The small coal from the main tipple shaker is elevated to a small raw-coal storage bin from which it feeds by gravity to the jig. The washed coal and water overflow into an adjacent settling tank, from which the water is pumped back to the jig for reuse, and the coal is raised by a perforated bucket elevator to the washed coal bin over the shipping tracks.

COST OF PLANT AND OPERATION

A simple single-compartment jig plant of this general type can be erected for $40 to $60 per ton of daily capacity and operated for 5 to 10c. per ton of coal handled.

The Robinson cone washer is well adapted to use in a plant similar to that just described, replacing the jig as the cleaning unit. This washer is simply a large inverted cone through which a continuous current of water rises and overflows the perimeter of the cone. Raw coal fed into the cone at the center is agitated by the vertical stirring rods and assorted by the rising water current; the velocity of the water current is so

Fig. 4

Charbonnage de Besringen

Hoist, tipple and washer. The plant is located in North Belgium near the Dutch border. The Rheolaveur system of washing is installed.

Digitized by Google

adjusted as to carry the light coal up and over the sides of the cone into the collecting launder while the heavier refuse sinks through the water and is trapped out through the double-gate, cylindrical refuse chamber at the bottom. This washer has the advantage of large capacity low operating and maintenance cost, and ability to treat a wide range of sizes in one operation. Robinson plants have been widely used in England and in the Alabama field, where they were the first style of coal cleaner to be widely introduced (1890-1910). Though they have been replaced in many coking coal plants by more elaborate systems of treatment, they are still extensively used for preparation of commercial coal where hair-splitting nicety is unnecessary.

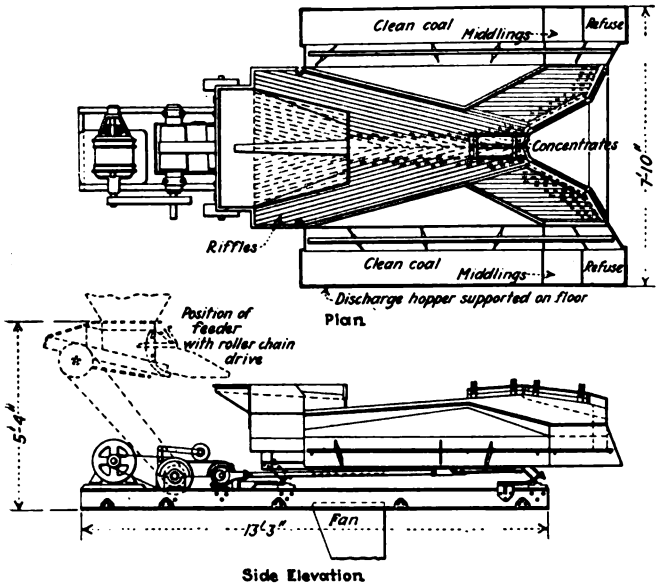

Fig. 5—Pneumatic Coal Separator of Y-Type

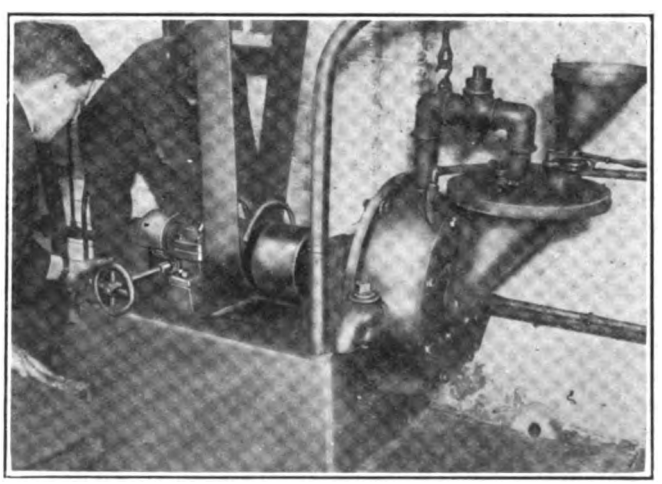
Increases the range of sizes treated by 100 per cent. In old types the coal is separated from its impurities on a single, pervious, riffled deck, the impurities being collected at one side. In the new types the refuse is collected in the central portion of the deck and the coal discharged on both sides.

Other washers that appear attractive for this particular kind of service are the Rhéolaveur and the sand-flotation process. The former is a Belgian invention which has been widely adopted in France, Belgium and England. It is an adaptation of the old trough washer and has its inherent advantages of large capacity, extreme simplicity, and absence of moving parts. The new feature, peculiar to the Rhéolaveur, is the use of small rising current classifiers as refuse traps. The classifiers form a continuous automatic means of refuse removal, assort and rewash the refuse material, and furnish additional wash water to the main horizontal classifying stream in the trough. The sand-flotation process separates coal and dirt of any size or range of sizes by float-and-sink action in an agitated water-and-sand pulp. By virtue of its large capacity and wide range of sizes treated, a sand-flotation plant, as it is now commonly used in anthracite preparation practice, is comparatively simple and inexpensive.

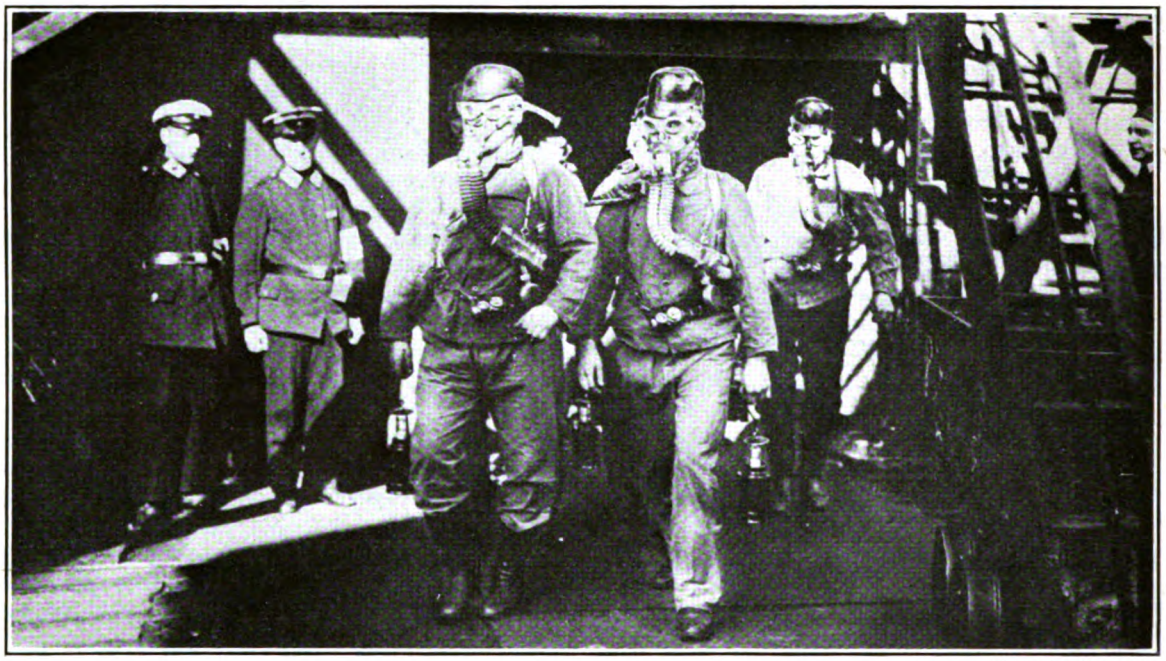


Plants of the kind herein described are best adapted to the preparation for market of coal of the type commonly found in our important coal fields. The simplest device for application of the hydraulic or pneumatic stratification principle will make a separation sufficiently complete for most cases. Therefore, the important differences in machines are matters of mechanical simplicity, sturdiness, cost and capacity.

Flame Safety Lamps Are Safe If Handled Properly

A caution as to the misuse of flame safety lamps in coal mines and a warning against the dangers of using mixed lights in such mines are given by the U. S. Bureau of Mines, in Miners Circular 29 by L. C. Ilsley, electrical engineer. The circular, obtainable on request, points out the dangers of misuse of such lamps. However, the bureau has made hundreds of laboratory tests of flame safety lamps and has never been able to get a failure of a properly designed, double-gauze, bonneted lamp, even in the most explosive mixture of gas and with strong air currents striking the lamp in any of several directions. This shows that when rightly made and rightly used the flame safety lamp is thoroughly reliable.

By tests made at the Pittsburgh experiment station the Bureau has found that some kinds of flame safety lamps are safer than others. For example: A single-gauze lamp without a bonnet is safe only in slow-moving air currents; a small-size lamp is not as safe as one of standard size; and a lamp without a bonnet is not as safe as one with a bonnet. The Bureau believes that lamps with internal relighters and magnetic locks are the safest; in fact, it has not approved and probably will not approve a key-locked lamp. The reason for this is obvious.



A flame safety lamp is the simplest device yet developed for quickly determining the approximate percentage of gas (methane) in a mine atmosphere. The Burrell gas detector under skillful handling is more accurate for small percentages, but it requires more skill and more time for a test. In fact, a fire boss could not cover the same ground with the Burrell gas detector that he covers with a flame safety lamp.

"Oil from Coal" at Birmingham University

Experiments in the Bergius method of liquefying coal in a high-pressure bomb, are being conducted at the Mining Research Department at the university in Birmingham, England. The coal is pulverized into the finest powder and is then mixed with hydrogen and passes into a bomb which raises a pressure of 7,000 lb. per square inch. Oil is produced without residue. This photograph shows the colloid mill which pulverizes the coal before it is passed into the bomb. Two assistants of the Department are adjusting the grinders inside the drum.

General Secretary
Ressaix Coal Co., Ressaix, Belgium

ACCORDING to a governmental inquiry set on foot by the Chancellor of the German Republic, the terrible accident at the No. 3 shaft of the Minister Stein mine, in the Ruhr district of Germany, Feb. 11, 1925, occurred in a gallery where no traces of gas had ever been found and where there were no old workings around that could, in any way, have released firedamp. A pocket of gas, a single cartridge shot in the rib of the road near the roof and a fall which shut off the air current are declared to have been the causes of the disaster. The explosion occurred at 8 p.m. Of the 145 men in the mine at the time, only nine escaped.

Raoul Touwaide

The Minister Stein mine is owned by the Gelsenkirchen Bergwerkes Aktien Gesellschaft, which controls much of the output of the Ruhr district. There are four shafts, and the No. 3 shaft, at which the disaster occurred, lies about a mile and a half to the south of the area that was operated from the main shaft, No. 1. As a rule the seams worked are regular, though pitching, and no faults disturb the workings. Four seams were being extracted which starting from the uppermost were Ida, Otto, Rudolf and President. Two others were being prepared for operation.

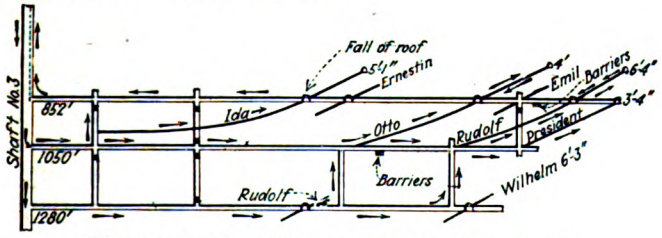
The shaft is circular with a section of 260 sq.ft. and is lined with cast iron. It has three levels, one the main return-air level, 852 ft. below the surface, and two intake levels at 1,050 and 1,280 ft. respectively. All these levels were connected by blind or inside shafts. The illustration shows these coal beds with their thickness. The beds pitch at any angle from 20 to 25 deg. There is only one shaft, and this is divided into two compartments to a depth of 852 ft., that is down to the return airway. One of these, which was connected with a fan, served as an air shaft. About 66,500 cu.ft. of air per minute were circulated through the mine. This is about 458 cu.ft. per person.

The fresh air coming in through the 1,050-ft. level went up the first blind shaft and ventilated all the sections between the upper and second level. Another split of fresh air went through the 1,280-ft. level and passed

Digitized by Google

over the developments in the Rudolf and Wilhelm beds, the remainder of it reinforcing the draft in the Otto and Rudolf seams in the upper sections of the mine.

The mine was gaseous, but owing to the excellent ventilation no traces of gas could be found in the ordinary daily inspection. It was known to be dusty, and water sprinkling and spraying were practiced. A few rock-dust barriers were provided. The management had decided to build more barriers and intended to rock-dust all entries, roads and airways. This program had been partly executed, and a milling plant had been erected and had started operation a few days before the disaster. The mine was operated with closed lights.



The explosion originated in the Otto seam, starting in the West road, above the 852-ft. level. It went through all the workings of this seam and of the Ida. The other workings of the Rudolf and President seams were spared, the explosion being stopped on both the first and second level by rock-dust barriers of the Taffanel type but slightly modified. However, all the men in those sections were killed by afterdamp, the ventilation being reversed by a roof fall which cut the communication between the shaft and the airway.

MEN AT FOOT OF SHAFT ESCAPE

On the noon shift of the day of the disaster, 145 men entered the mine, five of them to work near the shaft. A few minutes before 8 p.m., the top cager telephoned to the assistant manager that he had received a call from the 1,280-ft. level, where a few men had arrived at the shaft, declaring that they had heard a dull sound coming from the workings and that the ventilation had been disturbed. They wanted to be hoisted. Permission was immediately granted, and rescue teams were summoned.

The first rescue car arrived at 8.30 p.m., and five minutes later another twenty men were on the ground with complete apparatus. In less than four hours, 150 rescue men fully equipped, some of whom had come a distance of 20 miles, arrived at the shaft. On exploration it was found that the President and Rudolf beds had not been ravaged by the explosion but that all the men in these seams had died of carbon-monoxide poisoning. Other teams went through several rock headings and found eight men still breathing. They were brought to the shaft immediately and treated with pure oxygen but only four of them could be revived.

In all 129 men were killed outright by the explosion, seven were asphyxiated by gases, and nine men, four of whom worked near the shaft, came out alive. It should be added that above the 852-ft. level the gases were stagnant at the time of the rescue work, making exploration difficult. All over the mine many and heavy falls of roof hindered the work of the rescuers, making it, moreover very hazardous.

Where the Use of Rock Dust Justified Itself

Unfortunately, though the barriers kept the explosion from killing by violence the men who were in the Rudolf and President workings, the carbon monoxide that the explosion generated effectually did what the force of the explosion could not do. Many men would have been saved if they had taken with them small self-rescuing apparatus for use in such an emergency.

The fall that caused the disaster occurred where the roads of the Ida workings crossed the 852-ft. level. It cut the mine off from the shaft on the main airway. Examination proved that the explosion started in the West road of the Otto and that it was caused by the firing of a shot. This shot consisted of only one cartridge which had been bored in the rib of the roadway near the roof.

The inquiry proved that no traces of gas had ever been found in the gallery, and there were no old workings around that could in any way have released gas. After several tests in the Derne gallery the following report was issued: "In the roads of the Otto seam there were pockets of gas in cavities of the roof. Under ordinary conditions it was impossible to detect these. When the shot was fired, the gas was drained out of them by the resulting depression."

© Keystone View Co.

Crowd Waiting at the Mine Gates

Investigation seemed to give the company officials a "clean bill of health." Only the rock-dusting appears to have been inadequate, and the law did not require that the mine be thus protected. What little rock dust had been provided did good work, and Government officials expect to require rockdusting.

It was proved by a series of tests that, though a common charge of explosive by the force of the explosion destroys itself in the shothole and also all parts of the detonator, the paper envelope of the cartridge, etc., the firing of a single cartridge does not develop sufficient heat to destroy instantly all the combustible parts of the detonator. These are expelled still burning from the shothole and can easily set fire to gas. All the experts came to this conclusion.

Later on it was proved by means of an interferometer —an instrument that detects gas by the deflection of rays of light in the presence of gas—that gas pockets could be detected 30 ft. away from the point where the gas had been fired. The formation of these pockets of gas was demonstrated by successively stopping and restarting the ventilation, a condition that the opening of doors might cause many times daily during the coal-getting shift.

The explosion was believed to be due not to the presence of gas in a dangerous percentage where the shot was fired and ignited by the shot itself, but to the suction of gas in the road as a consequence of the depres-

Digitized by Google

sion caused by the shot and the ignition of the gas by the burning particles of the detonator seal.

The place where the explosion started was believed to have been conclusively fixed by the following observations: (1) On the body of the fireboss in charge of this road was found a book reporting the firing of a single cartridge at the time of the explosion. (2) Near the exploded shot were found the bodies of the men by which it had been fired. (3) The mechanical effects of destruction were at a minimum at this point. It has always been noticed in explosions that the damage is least where the explosion starts. Further away combustion is in evidence and, as the distance increases, the effects become worse and worse.

IDA SEAM IS VERY WET

In this explosion, it is believed the explosion went through the workings of the Otto and Ida seams, then through the Otto seam between the first and second level and from this level down to the 1,280-ft. level. The Ida seam was naturally very wet. Water constantly streamed along the faces. This, however, had no effect whatever on the explosion. A series of tests recently made in the Derne gallery have proved that, in a road completely wet, 2.14 oz. of dust per cubic yard were enough to render the air susceptible to an explosion.

In the direction of the other seams, the Rudolf, Ernestin and President, the explosion was extinguished both on the first and second levels. Here the rock-dust barriers had operated and quenched the flames. On the other side of the barriers, evidences of high temperature such as coke on props could be found but no flames passed the extinguishing cloud of rock dust that was caused by their destruction. Thus, though water had no effect whatsoever, the bar proved successful.

Barriers of the kind used, however, work only if the speed of the explosive waves is sufficiently high. An empty barrier placed a small distance from the starting point of the explosion was not destroyed, although the planks of which it was constructed were burned. This proves that rock-dust barriers alone will not afford complete immunity and that entries, aircourses, manways and rock entries should be rock-dusted.

The Dortmund Obergamt declares that the disaster will oblige the Control Commission to require rock dusting, in order that the first effects of an underground explosion may be counteracted by the neutralization of the coal dust. He adds that this rule is to be made obligatory on all the mines of the Ruhr district. He adds that "it is, moreover, necessary to forbid blasting in all gaseous sections of a mine and to make a careful study of the precautions to be taken to protect, from the action of toxic gases, men who are not directly injured by the explosion."

From this disaster many useful conclusions can be drawn. (1) Barriers are insufficient to protect a mine against a coal-dust explosion. All entries, haulageways, aircourses, in a word the entire mine, should be rock-dusted. (2) Water sprinkling and spraying systems should be abandoned, for explosions may extend long distances over roads completely wetted. (3) Rescue teams should always try to restore the normal ventilation before making any change in the direction of the air current. Had this been done many men in the Rudolf and President seams would have been brought out alive. (4) All-service gas masks if carried by the men would have given them an opportunity to escape, for the men in the Rudolf and President seams might well have reached respirable air had they been thus equipped. (5) The firing of a single cartridge is a real danger, for as proved by the Derne gallery tests the burning particles of the detonator may be thrown out of the hole thus setting fire to an explosible mixture of air and gas. (6) All cavities in which gas can accumulate should be filled, because, in case of a depression from blasting, these gases may escape into the roadway. (7) Rescue teams using pure oxygen to resuscitate victims are at a disadvantage. It was unfortunate that the rescuers in the Minister Stein explosion did not have carbogen, that is oxygen mixed with carbon dioxide, available to administer to those who were asphyxiated.

Two Horses Escape Death in Runaway

An accompanying illustration shows the top works of the Independent Coal & Coke Co.'s mine at Kenilworth, near Helper, Utah. Until 1925, when a long rock tunnel was completed, it was necessary to pull coal up from the mine to the outcrop shown high on the face of the hill in the picture and then to lower each trip nearly half a mile down a 40 per cent grade shown in the upper left of the photograph to the tipple at the

Runaway Trips Did Circus Stunts Here

right. The strain on cables sometimes proved too much and it was customary for runaways to roar down, crash through the end of the high tipple, describe a long arc through the air over the railroad and alight in a heap.

Old timers at the mines like to tell stories about what happened during some of these acrobatics by runaways. On one occasion a man drove a team of horses and wagon up near the company store and stopped the team, by chance, exactly in the spot which was bound to receive a 10-car trip of flying loads. The man went in the store. No sooner had he entered than the well-known roar sounded down the mountainside.

"Yay! There she comes," shouted somebody in the store, whereupon every one present rushed out on the porch to enjoy the show. They were horror stricken when they saw the team standing unconcernedly in the danger spot switching their tails at bothersome flies. But it was too late to do anything. The trip burst out the end of the tipple, sailed through the air and piled up with a great clatter submerging the team and wagon. When the men pulled the stack of coal and cars apart to find the mangled remains of a good pair of horses, both animals got up from their short incarceration within a prison of cars that had been built protectingly about them with a terrifying suddenness, and walked off, still switching their tails at the same flies. The tellers of this tale insist that the flies were identical.

Viewpoints of Our Readers

How Long Shall We Endure "April Fool Prices?"

It is quite unfortunate that the operators can't get together sooner and announce what anthracite prices will be, at least a week or ten days before April 1. As it is now, some of the companies send out circulars announcing their Spring prices "until further notice" while others *tell* their dealers what the prices will *probably* be and there seems to be nothing definite or permanent about the information which comes to the dealer.

For this reason he cannot prepare his advertisements for the newspapers or circulars for mailing out to his trade until the last minute, with the result that he always gets a rush job and usually a poor one. Last year we had to have an entire new circular printed up because of conditions which changed almost over night, costing us between five and six hundred dollars.

Dealers in a nearby section already had their Spring prices out in the mail when it was discovered that these had been based upon a false rumor and were too low. A frantic effort had to be made to get out a second circular contradicting the first and by the time the whole affair was closed the retail coal merchant looked nothing short of stupid and foolish to the trade he was trying to serve.

CANNOT QUOTE PRICE

Similarly last year, on April 1, we were unable to tell our customers what the prices would be, and had to accept orders with blind prices. The telephone rang all day long from nearby and fairly distant dealers, all 'phoning each other excitedly asking everyone else whether they knew what the Spring prices were going to be. There seemed to be absolutely no definite information in the retail trade. It was as if the companies did not feel that their own distributors were worthy of confidence and of receiving any advance information upon this subject so vital to the whole trade. In several localities "April Fool Prices" were published by dealers who had later to retract them.

One of the most serious phases of this recent policy of late price announcements has been that the retailer has been utterly unable to formulate his advertising and selling campaigns beforehand. These are not something which can be developed and printed over night. They require a lot of careful thought and study, with the result that last year for instance, the month of April was well under way before the retail dealer was able to launch his advertising matter effectively. This simply means that the retail consumer market responded that much later to these sales impulses and put the whole industry back in the important problem of moving coal during the Spring and Summer.

The operators ought certainly to take a definite stand upon prices *earlier*, so that the retailer can tell his consumer trade the facts and the new prices sooner as well as shoot his advertising promptly on April 1, when it is expected and most effective. This policy of procrastination in the announcement of prices, is costing us all time and money in the selling and moving of anthracite.

Failed to Establish Sinking Fund for New Batteries

In reference to what you say to the replacement of battery locomotives by reel-and-cable equipment in the editorial entitled "The Battery Locomotive" appearing in the issue of Feb. 11, would say that I believe investigation will show that in the few, not many, cases where battery locomotives have been changed to reel and cable this was due not to unsatisfactory or expensive operation but to failure to provide a sinking fund with which to pay for the renewal of the battery. The money that should have been put aside for battery renewals was diverted to lowering operating costs or taken as profit.

Had the coal business not been through such a long term of depression with its attendant financial distress, I do not think any wise coal operator would consider changing a battery locomotive to reel and cable unless he was unfortunately the victim of a misapplication such as too small a battery or locomotive.

WHEN INDUSTRY IMPROVES

I feel today that, if and when the present deplorable condition of the coal-mining industry is relieved and there is money enough available to operate coal mines in the best and most economical way, the storage-battery locomotive will stand out more than ever as one of the most desirable pieces of equipment that can be installed.

For this reason I feel that the editorial is misleading and unwise and will tend to hold back improvements in coal gathering and haulage. The opinion stated coming from such a source as *Coal Age* must and does carry lots of weight.

LOCOMOTIVE BUILDER.

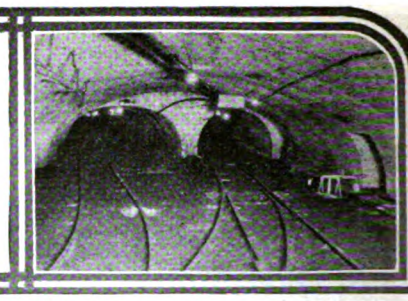
Gas Mask Does Not Provide Oxygen for Breathing

In the Feb. 18 issue of *Coal Age*, p. 263, Dr. R. R. Sayers is quoted as saying in effect, "If necessary the gas mask may be used in poisonous atmospheres or in those deficient in oxygen."

I am under the impression that gas masks are for use only in normal air contaminated with small percentages of poisonous gases and that oxygen-breathing apparatus should be used in case of oxygen deficiencies and large percentages of poisonous gas. When wearing a gas mask one should carry a lighted flame safety lamp which is in perfect condition and if the safety lamp is extinguished it is a warning that the mask may not give the desired protection.

RESCUE FOREMAN.

Battery Power and Safety



Had the editor who wrote the remarks on "The Battery Locomotive" in the issue of *Coal Age* of Feb. 11 paused to think of the unprecedented number of mine accidents that have occurred since Jan. 1 of this year, either from gas or coal dust in suspension, and the danger to life and property ever present through exposed wires and the ones from the trolley, I do not see how he could do otherwise than advocate greater safety. Yet he commends equipment that he must know would add to the danger.

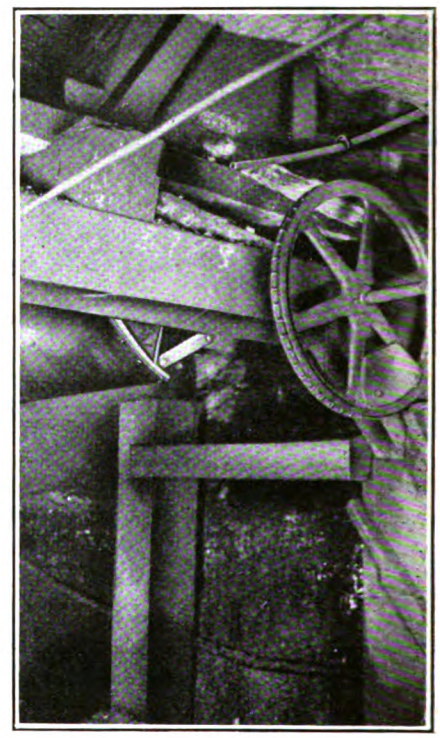
Underground Operation

Trying Out a Seam of Doubtful Value By Slopes to the Working Seam

Fearing That Roof in Upper Bed Would Be Bad, Plans Were Made to Chute Coal Temporarily From Upper to Lower Seam — Now Drift Mine Will Be Started

By J. H. Edwards
Huntington, W. Va.

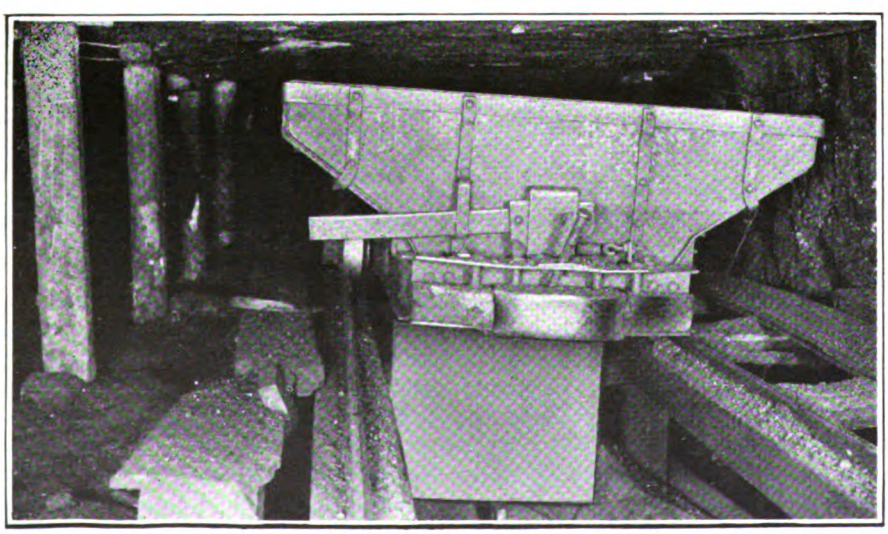
Coal in an upper seam is rarely chuted to a lower measure as a means of bringing it to the tipple, at least in West Virginia, but this is being done at a mine in the southern part of the state. Here the upper seam is 48 in. thick and lies 65 ft. above the main producing bed. At this operation, coal has been mined from the lower bed for years, but it was not until recently that the upper seam was opened. Now about 200 tons per day is being produced from this upper seam, dumped in a rock chute and reloaded into cars for transmission to the tipple.



This upper bed is known to have, generally, a rather bad roof, so it was not advisable to spend much money in the initial development. The opening was accomplished by driving two rock slopes, a few hundred feet apart, up from the lower seam.

One slope, which is equipped with track, is used for handling material and as an intake airway. This mounts to an angle of 30 deg. and is of 5x10-ft. section. The other slope, which is driven at 45 deg., is 5x8 ft. and is used as a coal chute and return airway. The chute proper is a 3x3-ft. wooden box.

UNDERCUT GATE CONTROLS COAL



The opening at the bottom is controlled by an undercut gate mounted above the track in a haulage entry of the lower seam. A trip of empties is loaded, in short order, without uncoupling. The motorman remains on the locomotive in order to spot the cars under the chute and the brakeman manipulates the gate.

The car dump at the top of the chute is nothing but a pit or hopper between the rails. In this upper seam automatic drop-bottom mine cars are used.

Undercut Gate at Foot of Slope

Above the gate frame can be seen the bottom of the wooden chute which takes up a part of the area of the slope. The remaining area is used as a return airway. After an opening is driven to the outside the slope will no longer be necessary as an airway, so will be utilized entirely as a chute and storage bin.

Drop-Bottom Car Discharging at Top of Chute

The coal averages 48 in. in thickness, and the top was found to be much better than is usual for that seam. The use of automatic drop-bottom mine cars made it possible to utilize simple dumping equipment. The hole between the rails is the only indication that this is the dumping point for the mine.

As yet there is no direct opening to the surface. Power for operating the cutting machines and for charging the storage-battery locomotives is brought up the material slope from a connection on the trolley wire of the lower mine. The slope is not equipped with a hoist. Instead, a locomotive is used to pull the material car.

At present the output of the upper seam is handled, seemingly, with an absolute minimum of investment. But the coal has been found to be of good quality and has good top, so the management is proceeding with the idea of a more permanent installation.

An airway will be driven to the surface, after which the entire area of the slope, now containing the

Digitized by Google

Brakeman Loading a Trip of Empties

From this point at the foot of the chute the coal is hauled to the surface in the same manner as is the output from the lower, or principal, producing seam. The chute acts also as a storage bin so that a whole trip of empties can be loaded in a few minutes by the motor crew.

wooden chute, can be used for coal. It is likely that an electric hoist will be installed at the other slope for handling machinery and supplies.

For Rougher Levels Why Use Slow Precision Level?

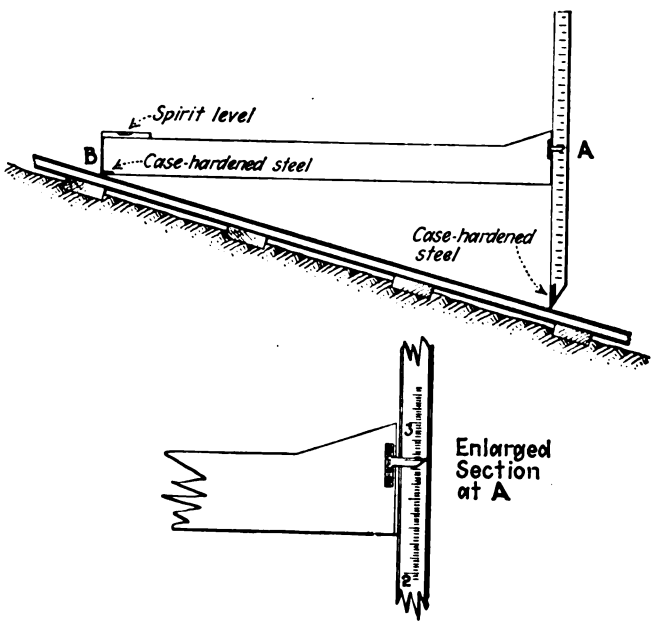
In the British coal field, especially in the northern (Scottish) area, where the dip of the strata is irregular and steep, the ascertainment underground of the variations in level from the government or "ordnance" datum presents many difficulties. On level roadways and moderately inclined planes, the dumpy level and rigid staff is generally used.

Where the inclination exceeds 10 deg., the roads are quite generally leveled by the use of the straightedge and spirit level. On inclinations above 40 deg. the altitudes are taken trigonometrically with the theodolite (or non-reversing transit).

It is surprising that where the variations such as on a "level" haulageway are only a few feet in a hundred, a dumpy level is used, and yet where the variations are greater, one finds a primitive and rough straightedge instrument employed. Work with the straightedge where the instrument is not properly designed is bristling with inaccuracies. Realizing such possibilities in this class of work, I designed a straightedge and staff some time ago and put it to use, and the results have been good. The measuring rod or staff is similar in size to the inner portion of a surface leveling rod of the old box type and is made in lengths of 3 ft., 4 ft. and 5 ft. respectively. The base of the rod is pointed and shod with a piece of case-hardened steel. Using a pointed end instead of one that is rectangular makes for correctness as there is no chance that the level to be taken will be that of first the front and then back of the rod.

If used in wet or dirty roadways, the ordinary calibrated staff in time becomes obliterated. For this reason among others, the zero reading on the staff is at a distance from the bottom corresponding to the top of the straightedge, which is generally about 6 in. deep.

The straightedge is made from well-seasoned wood in such suitable lengths as 6 ft. and 10 ft. The top and bottom are machined truly parallel and of an exactly determined length. To facilitate maintaining it of that length, the straightedge is cut short and end pieces with the grain of the wood at right angles to the length are fastened to the ends, these being smoothed till the correct length is attained. To insure that the measuring rod is at all times at right angles to the end of the straightedge, a small triangular piece of wood is placed at one end of the latter which increases the contact surface to about 9 in. On this end as shown in the sketch, a pointer is placed which is designed to swing from its projecting position when not in use. Screws capable of being adjusted to correspond with zero on the measuring rod are also provided. The opposite end of the straightedge where in contact with the rail, has also a case-hardened piece of steel inserted. The leveling tube used is of ordinary adjustable design and is fitted with a graduated tube. This may be placed either on top or mounted on an adjustable carrier on the side convenient to the person reading the staff. In use the points to be observed are: (1) That the point *B* is definitely marked and that the straightedge is placed properly thereon. (2) That the level is laid if on top, parallel to the straightedge, and not in any way at an angle thereto. (3) That the staff is plumb in both directions.

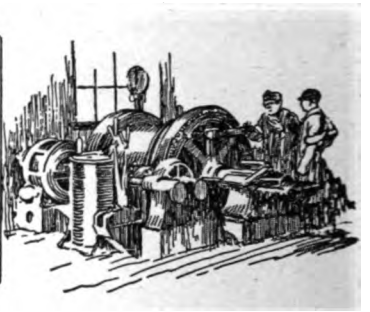


In the hands of capable assistants, quick work can be done with this straightedge and on inclined planes the results will compare favorably with any other method of taking levels.

P. W. BROWN.

View Park,
Cowdenbeath, Scotland.

Straightedge Outpaces Dumpy Level



With a straightedge like this, rapid work can be done. The steel point gives definiteness to the point being leveled. The rail at the back of a rod may be some tenths of an inch lower than in front, and the assistant may not always sense the importance of watching this discrepancy, thus vitiating the results.

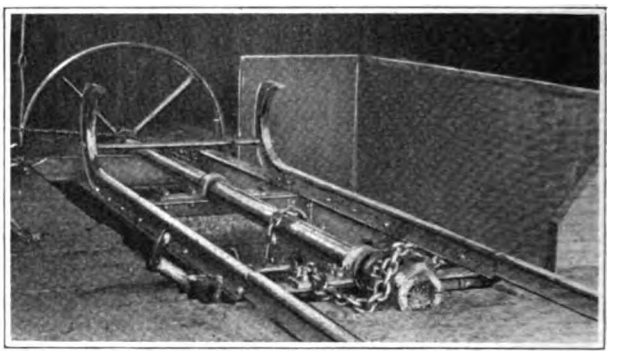
Practical Pointers For Electrical And Mechanical Men

Slate Dump Handles Cars of Several Types

At Ehrenfeld, Pa., the Pennsylvania Coal & Coke Corporation was confronted with the problem of providing a slate dump which would accommodate several types and sizes of cars from two mines. The slate cars are pulled up an incline to a point where they are dumped into a bin which is emptied by a motor-driven self-dumping larry.



The accompanying illustrations show the rather novel slate dump. This was built in the company shop at Gallitzin. The cars handled with it are of two wheel bases, 24-in. and 30-in. and are of various lengths and body shapes. The dump is of the side-tipping, gravity type, counterbalanced by suitable weights.

One end of the car is held by stationary horns engaging the forward wheels and the other by a chain which is looped over the bumper. The chain is tightened by rotating a shaft fitted with a ratchet handle. This shaft is located so that the chain pulls the cars forward against the horns and at the same time holds the back end down to the track.

At the forward end of the dump is a brake wheel for controlling the tipping, and for stopping or holding the dump in any desired position. The unbalance for the self-dumping action is obtained by having the main shaft set ¾ in. off center.

In Normal Position

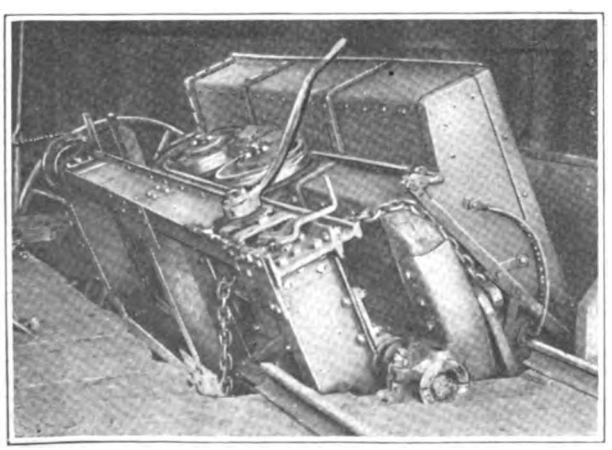
Cars of two different wheel bases and of various lengths and body shapes are handled by this slate dump which was made in the central repair shop of the company.

At first thought it might appear that the time required for placing the chain over the bumper, tightening, unloosening, and removing, would prove a serious objection to the dump. This, however, is not so. The tightening device is geared so that it requires but a few seconds to apply and tighten the chain. After the dump tips a few degrees it begins to raise a counter-balance which brings it back to the upright position.

Superintendent S. W. Blakeslee states that the dump is entirely satisfactory for the service and that its action is not influenced by the design or size of the slate car handled.

Flue Trouble Reduced by Continuous Blowing

Only the power-plant engineer who has had to "fight" boilers using hard, untreated water can appreciate what it means to be entirely rid, or practically relieved, of trouble from that source. The installation of a high-grade water-treating plant is, of course, the commonly advocated solution, but the money for such equipment is not always forthcoming. The use of boiler compounds, which require little or no initial investment, can be a great help in reducing the trouble from boiler scale.

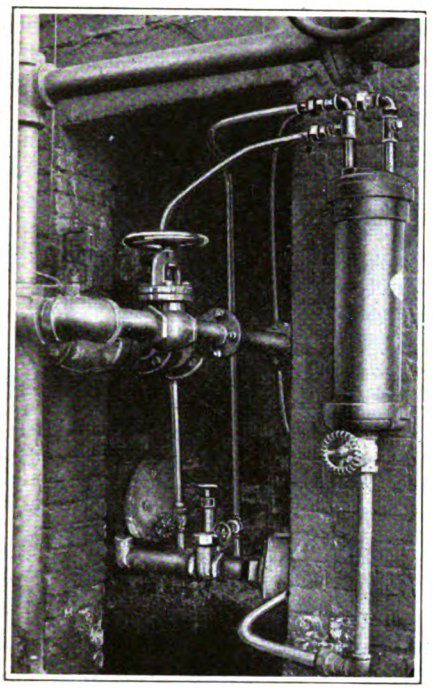


Other methods of reducing the deposition of scale are by skimming and blowing down. In many instances, however, these are used solely for the prevention of foaming. At a certain power plant in Ohio, skimmers were installed with this intention, but they also greatly reduced the deposition of scale.

Experience at the Mulga (Ala.) mine of the Woodward Iron Co. proved that continuous blowing down of a boiler also can limit materially the quantity of scale deposited. The illustration shows one of the four continuous blowoffs in use on a battery of 400-hp. vertical water-tube boilers.

No Scale Accumulated

Ninety days after the installation an inspection revealed that little or no scale had accumulated in the boilers, and in the operation there had been no indication of foaming. No boiler compound was used. According to the master mechanic, J. L. Franklin, before the installation, even when using a compound ⅛ in. or more scale would form.



It was the practice, formerly, to blow down the boilers six times in

How Car Is Held

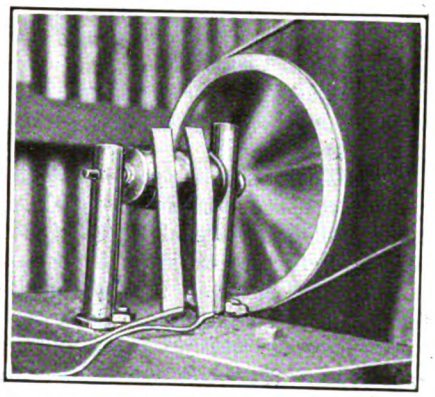
When the chain which is looped over the bumper is tightened, the car is forced against the horns and held to the track. The lever, with the handle showing above the car, operates the chain-tightening rachet.

Digitized by Google

Installation on 400-hp. Boiler

The body of the continuous blowoff is at the right. The installation is made by connecting four small lines to the regular blowoff line. The quantity of water drained continuously from the boiler is determined by the size of the special orifice used.

24 hrs., but even then scale caused the failure of from 10 to 20 flues per month in the four boilers. At the time that the photograph was made, the continuous blowoffs had been in use ten months with a record of no flue failures.



E. D. Clark, general superintendent, explained that the results in the Mulga boiler plant have been so gratifying that the company has decided to equip all of their railroad locomotives in the same way.

Improvised Flasher Gives Years of Service

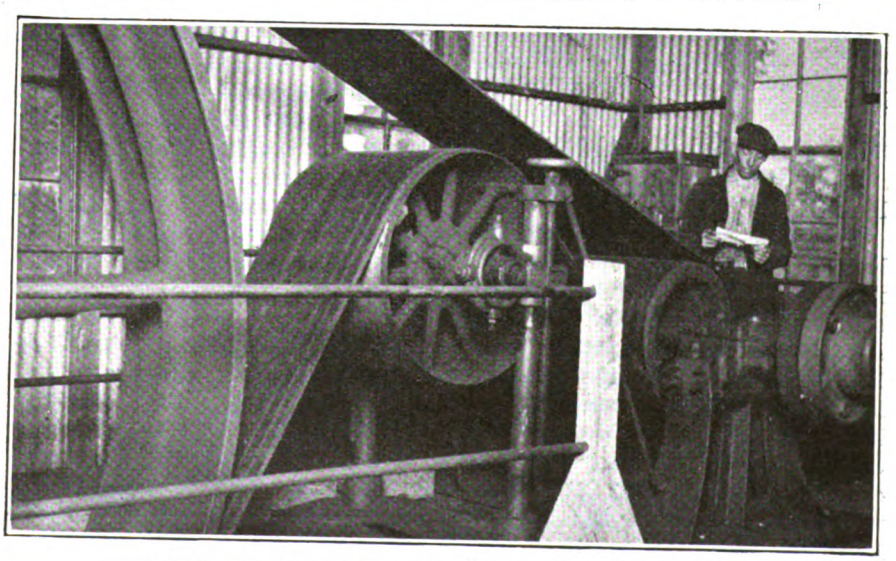
Ten years ago an explosion occurred at No. 1 mine of the Roden Coal Co. at Marvel, Ala. It is said that the fan may have stopped and thus been one of the contributing causes of the explosion. This fan, which is motor-driven, is located about 1,000 ft. from the hoist house where the starting compensator is installed. In order that there would never again be a chance for the fan to stop without showing a visible indication at the hoist house, a flashing mechanism was installed.

This flasher, which is still in use, is shown in the accompanying photograph. It consists of a part of an old controller drum with a sewing machine pully mounted on the shaft. The drive is by a round leather belt from the fan shaft. Bearings for the contact drum are holes drilled through the short pieces of pipe which form the pedestals. The drum turns at 100 r.p.m. and flashes the signal light once in each revolution.

Until a year or two ago the connections of the flasher were such as to open the circuit through the lamps. A periodic clicking in the village radio receivers was traced to this flasher, so that connections were changed in a way which eliminated the annoyance. An extra lamp was added in the circuit, in series with the main signal lamp, and the flasher connections changed so as to short circuit the extra lamp. The periodic changes in resistance of the circuit causes the desired flicker of the signal lamp.

Flasher Is Driven from Fan Shaft

This device has been operating for ten years. The contact drum is one removed from an old controller. The pulley came from a scrapped sewing machine. Interference to radio receivers caused connections to be changed so as to avoid breaking the signal circuit.



Many fans are placed where the noise of their motion is not readily audible to the men in the power house. Consequently they would not take notice if the fans should stop. A flashing light, on the other hand, is a warning that can hardly be overlooked.

An Idler Pulley Should Be of Large Diameter

In a number of instances short-center belt drives have proved successful on mine fans, generators, air compressors and so on. In some cases, however, such drives have been found unsatisfactory. Short belt life and trouble with idler bearings were mentioned as objections in several instances.

Usually such troubles can be traced to the fact that an idler pulley of insufficient diameter was selected. This causes a severe reverse bend in the belt and makes the idler pulley operate at a high speed. Vibration, and lubrication troubles attendant with high speed, cause the bearing trouble.

An example of a well selected idler pulley is shown in the accompanying illustration. This is on the drive of a 150-kva. alternator which until a few years ago was used regularly, but now serves as a reserve to purchased power at the plant of the Roden Coal Co., Marvel, Ala. Although the alternator pulley is but of 22-in. diameter, the idler pulley is 30-in. This is a contrast to many cases where idler pulleys are used which are considerably smaller than the small pulley of the drive.

With Big Idler, Less Vibration and Belt Curvature

The drive of an alternator at the Marvel mine of the Roden Coal Co. A 30-in. diameter idler is interposed between the steam engine and a 150-kva. alternator equipped with a 22-in. pulley. Often the success of an idler drive depends on the diameter of the idler. The larger the better, so long as the small pulley has sufficient belt contact.

Book Reviews

Outcrop Fires and Glaciation Make North Dakota Mining Troublous

Some of the matters which are taken for granted in Eastern coal fields are not all to be regarded as certainties in dealing with the North Dakota coal fields. This is due to the character of the Tertiary beds in which the lignites of that state are found. In common with the coals of most Western regions, aridity has made the beds subject to spontaneous or other combustion along the outcrops. Few of the thicker beds have wholly escaped burning.

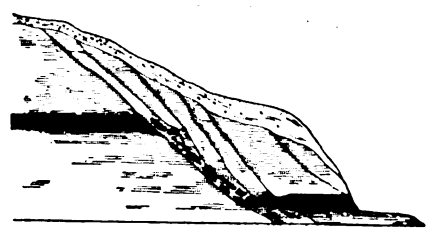
Some were doubtless set on fire by man, others may have caught fire from prairie conflagrations, but it would seem that spontaneous combustion has been the chief cause. The burning of the coal beds has doubtless been going on for thousands or tens of thousands of years, ever since the erosion of the overlying strata brought them near the surface or exposed them in bluffs or buttes.

Lignite Burned at Crop

The scoria may be 60 ft. thick where the coal is 35 or 40 ft. in thickness. One can be almost sure that the base of the cinder pile is at the bottom of the bed, but how far in the hill the operator must go before the lignite will be found unburned is uncertain. Whole townships of the thickest lignite, centuries ago perhaps, passed away in smoke.

As an example the Bowman coal bed of Bowman and Slope counties may be cited, this thick 35-ft. coal bed having been burned over many townships so that its former extent is known largely by the clinker it has formed. Lignite beds, however, less than 4 ft. thick do not burn, except under unusually favorable conditions. A 10- or 12-ft. coal bed will often give clinker beds 20 to 30 ft. thick.

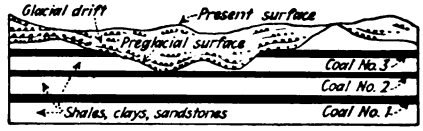
If the overburden is very porous, slow combustion may have proceeded beneath 20 or 30 ft. of cover, resulting in pits or depressions on the surface. Clinker from a lignite bed 10 ft. thick may attain a thickness of 30 ft. and from a 35- or 40-ft. bed may be 50 or 60 ft. thick with much fused or slag-like material. Masses of such clinker of 10 to 20 tons weight are not uncommon.



Big Landslides Annoy

This is not all, where the beds have been deeply eroded the face of the bed has occasionally slumped down. This may lower, almost unaffected, a large area of the bed and there is a risk that the man who opens a mine in the slumped fringe of the coal area may work in it for a while and then find the bed has disappeared.

Investigation will prove that the rest of the bed which has not been disturbed lies several feet higher requiring for its exploitation a new opening and needing somewhat different surface works from those that were planned and provided in the expectation that the whole deposit was lying at the level at which the slumped fringe was found. So caution is necessary when opening an outcropping bed.



There is also trouble from glaciation. Of the 28,000 square miles of workable lignite beds—there are 32,000 square miles in all—about 15,000 are covered more or less by glacial materials deposited during the epoch of continental glaciation, the debris ranging from fine silt to large boulders.

This glaciation, taking place in beds imperfectly consolidated, has created much erosion, the depth of which is not determinable on the surface as is the erosion of contemporary rivers and streams. The glaciated material has filled up the channels it has created, and the surface of the ground may show little of the damage that has been done. When, however, the beds are worked, the glaciated materials are encountered, the signal for caution being the softening of the coal. If this warning is not heeded the drift may be tapped, and then trouble will be encountered in handling the large quantities of water the drift contains.

Where the Outcrop Slumps

When the lignite is eroded, and also the measures under it, a large slip, slump or fault occurs and the bed is thrown down. Expensive surface equipment should not be built until drill records show the exact position of the coal.

Glacier Has Destroyed Lignite

On approaching the drift the coal gets soft and if mining is continued large quantities of water stored in glacial drift will pour in.

But the operator is not without advantages. Royalties are low. The Federal Government and the Northern Pacific R.R. will lease lignite for 5c. per ton or some slightly higher figure. (Under the present law there is no way in which state or school lands may be leased). The beds also are quite level and subject apparently only to the difficulties mentioned.

Stripping Cover Not Heavy

Furthermore in removing cover for strip mining there is little difficulty in digging the overburden as it is not so hard in these Tertiary as in the Carboniferous rocks. This overburden is in many places not heavy. In 1924 about one-half the lignite mined was excavated by stripping and the average cover did not exceed 3.5 times the seam thickness, ranging as it did from two to five times the cover, whereas in the United States in general the cover is 6.04 times the seam thickness, in Illinois it is 3.86 times and in Oklahoma 10 times the thickness of the coal. There are several hundred millions of tons of lignite in North Dakota such that the ratio of overburden to coal does not exceed three.

The general complaint that lignite weathers is offset by a large size of the lumps which can be obtained by proper mining. If this lignite is stored so that air is largely excluded as in cellars, concrete or brick bins or in root cellars when neither the summer's sun nor wind can dry it out, it will slack somewhat but not

Digitized by Google

enough to do otherwise than bring it to a size that is best suited for burning. Excessively large lumps are not desirable for furnace firing.

The percentage of moisture in the lignite in a number of samples as received at the laboratory of the School of Mines of the University of North Dakota ran from 25.34 to 43.47 per cent, with probably higher values at the mine, the volatile matter ran from 22.97 to 30.34, the fixed carbon from 24.39 to 34.11, the ash including sulphur from 2.90 to 20.68, the sulphur from 0.09 to 14.03 and the thermal capacity from 5,516 to 7,130 B.t.u.

The statements made are based on an interesting report, Bulletin No. 4 of the North Dakota Geological Survey, produced in co-operation with the School of Mines, College of Engineering, University of North Dakota, containing 228 pp. with 21 plates and 18 illustrations.

Industrial Museums Needed In the United States

No country perhaps has done more to promote industry than the United States, yet few have done less in their museums to make record of their achievements. There are few places in the United States where historic machinery can be sent for public exhibition, and even there when it arrives it will be housed with collections of an entirely different type.

The reviewer wonders if the coal industry would be considered so sleeping and unprogressive if in some national museum, where it could be seen without dirt and discomfort, were placed some of the wonderful mechanisms by which coal is mined, loaded, conveyed, transported, hoisted, sized, cleaned and prepared for market.

Critics Might Learn

Those learned critics who believe coal mining to be an ancient art without any modern development might be apprised of the actual facts or at least their children might be. The present generation is almost beyond conviction. The public might also note that nearly every modern development from rails to pumps, from steam engines to locomotives took their initial steps in the darkness of the mines or within shadow of its heapstead.

A book of 117 pages measuring 6x9½ in. has been published by the Macmillan Co. on "The Industrial Museum" the price of which is $3. The author, Charles R. Richards, director of the American Association of Museums, has toured Europe for the General Education Board of the National Society of Vocational Education to see the excellent work of the European museums of industry. He finds much to praise and much to condemn. Beginning as the United States would from the ground up and not being confronted for a while with the need of expansion, it might build better museums as to housing, arrangement and convenience, but perhaps it would be long acquiring the historic machines which the European museums exhibit. If we are going to rival their treasures we must make a beginning; or rust, moth, decay and the depreciations incident to age will destroy many valuable opportunities.

It is well said that in early ages industry was performed in the open. Today it is hidden behind closed doors. The public has only a hint of what is going on. But nevertheless, people in general are quite inquisitive. Any one can note that fact on passing an excavation, the building of a roadway or the construction of a building or a railroad. It must be admitted, however, that the public though inquiring is not any too well informed. We have done marvels without such exhibitions. What may we do if we have them! The spirit of progress will be greatly aroused when we view them.

Industry Behind Closed Doors

Mr. Richards' analysis in this volume is keen. We can scarcely avoid quotation. His treatment of the subject is adequate and the illustrations in full-page plates are excellent. We can only hope that what he is striving for will be accomplished for all the larger cities, thus preserving our past, accelerating our future and creating a knowledge of what we are, each in his own sphere, performing. All industry is related and an industrial museum will keep each part of industry in step with the best and most available in the rest. It is well worthy of note that the ventilation engineers were in wonderment when the mining engineers at the recent meeting of the American Institute of Mining & Metallurgical Engineers descanted on a certain article as the last word on the ventilating art. The science of ventilation has for many years had little attention from mining men and the mastery of the subject now lies with the heating and ventilating engineer.

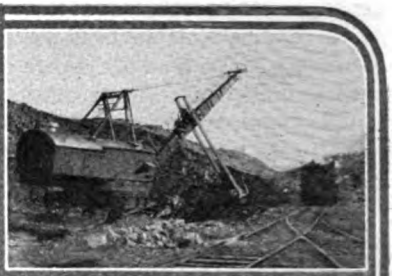
Recording Watt-Meter of Human Progress

Some fifty of the learned societies for the study of science, politics and industry have combined to prepare a record of 1925, entitled "The American Year Book." About 270 men and women have contributed, over ninety of whom have had a part in more than one section. This annual was first published in 1909 but in 1919, under the unfavorable circumstances following the war, was discontinued. This year with a splendid co-operation from the learned societies it is issued once more. It contains eight parts—Historical, American Government, Governmental Functions, Economics & Business, Social Conditions & Aims, Science Principles & Application, The Humanities, Chronology & Necrology. The publisher is the Macmillan Co., 60 Fifth Ave., New York City, and the price is $7.50.

Chemistry's Industrial Side

A two-volumed book entitled "Industrial Chemistry" has appeared with Allen Rogers, supervisor of the Industrial Chemical Engineering Course and Head of the Department of Industrial Chemistry at Pratt Institute, Brooklyn, N. Y., as editor. The first volume is said to be devoted to inorganic chemistry, and it seems somewhat odd to find 22 pages on "Fuel and Power Generation" and finally fertilizers of an organic character under that head. As regards the first, it may be said that, in the use of coal, oil and wood, we use the materials as if they were inorganic and rather wish we had pure carbon and pure hydrogen to deal with. The second book is marked "Organic" and covers in 136 pages city gas, industrial gases, coal tar and its distillation products. The two volumes which contain in aggregate 1,267 pages measuring 6 x 9½ in. are published by D. Van Nostrand Co., of 8 Warren St., New York City. The book sells for $12.00 net.

Publications Received



Possibilities for the Commercial Utilization of Peat, by W. W. Odell and O. P. Hood. Bureau of Mines, Washington, D. C. Price, 35c. Bulletin 253. Pp. 160; 6x9 in.; illustrated.

Report of the Massachusetts Special Commission on the Necessaries of Life. The Commonwealth of Massachusetts, State House, Boston, Mass. House No. 1250, January, 1926. Pp. 187; 6x9 in.; tables and diagrams. Numerous references to coal are included.

News Of the Industry

White House Favors Early Action; Jacobstein Would Encourage Mergers To Settle Coal Industry's Troubles

The campaign to induce Congress to enact some form of coal legislation at the present session is gaining ground. Although most Washington observers—including some who favor action—feel that Congress will adjourn without formally considering any specific proposals to make the coal industry the subject of federal regulation, interest in the question has been growing since the House committee on interstate and foreign commerce began hearings on March 30.

Before the hearings actually commenced it was common talk in Washington that the threat of coal legislation was as dead as the anthracite strike. Even after the hearings were announced there were some who dismissed them as a gesture made to soothe the members of Congress who had presented half a hundred bills during the time the hard-coal mines were idle. Last week, however, the flat statement was made that the committee intended to report out a bill. Still later the hands of proponents of legislation were strengthened by the announcement that the White House favored action before Congress adjourns.

Precedent received a severe jolt the first day the committee met. Reversing the usual practice of having witnesses direct their remarks to the provisions of specific bills before the committee, Chairman James S. Parker, Republican, of New York, asked the witnesses to discuss the theory justifying legislative action and the economic necessity for coal-trade regulation.

President Desires Action

President Coolidge, it may be stated, is of the opinion that it is very desirable to have Congress take action at this session. Whether the President's message to Congress last December is to be construed as a blanket indorsement of all of the recommendations of the United States Coal Commission and a suggestion that those recommendations be enacted into law is a question upon which the views of the White House are not known. Spokesmen for the President will go no further at the present time than to say that two points are to be considered essential:

(1) To enact legislation enabling the President to appoint a mediation board in the face of an actual or a threatened strike.

(2) To set up machinery for coal administration in the case of a shortage.

Only two witnesses were heard by the committee last week—Representative Allen Treadway, of Massachusetts, whose testimony was covered in the preceding issue of *Coal Age*, and Representative Meyer Jacobstein, Democrat, of Rochester, N. Y. According to the latter, the basic troubles in the anthracite industry go deeper than a recurring deadlock between capital and labor. The fundamental deadlock is economic. Ownership and location are highly concentrated; labor is a monopoly.

Scores High-Cost Mines

Thirty to thirty-five per cent of the output, said Congressman Jacobstein, is mined at high costs and low profits; 50 per cent at low costs and high profits. The bulk of the high-profit coal was controlled by the major producers, who, he said, restricted their output in order that a market might be found for the high-cost coal. In that way the industry was using the high-cost mines to keep up prices and to keep down wages.

The witness admitted that the big companies named mine prices lower than those charged by the independents, but argued that the difference was made up in transportation earnings of affiliated railroads and in profits accruing to separately established selling agencies. Congressman Walter H. Newton, Republican, Minnesota, wanted to know whether increased production by the big companies would not drive the independents out of business and create a complete monopoly. The witness conceded that that would be true, but added that such a development would bring "the monopoly" out into the open and, if the monopolistic powers were employed against the public, compel strict regulation.

Later in his testimony it was brought out that one of the remedies Mr. Jacobstein had in mind to put the whole coal industry on a proper basis was a modification of the Sherman anti-trust law which would encourage consolidations and combinations. He would combine strong companies with weak ones in somewhat the same manner proposed for railroads in the Transportation Act of 1920. To enjoy relief from the Sherman law, however, the industry would be compelled to assent to federal licensing and control.

Representative Ashton C. Shallenberger, Republican, Nebraska, inquired whether the existence of high- and low-cost operations was not common to all industry. The witness agreed, with the reservation that only in coal was production restricted to foster the high-cost operations. He declined to admit, when questioned by Mr. Newton, that labor was in anywise responsible for restricted output.

Part of the trouble with labor, he contended, was due to the belief of the worker that labor was not receiving its share of the profits. The actual investment in anthracite, he stated, approximated $450,000,000; book values approximated $620,000,000 and the valuation placed on the properties by coal company engineers exceeded $900,000,000. Labor wanted to know upon what basis profits were to be figured.

Urges Publicity of Facts

Turning to the question of remedies for conditions which he asserted the people insisted must be changed, Mr. Jacobstein proposed, first, compulsory fact-finding and publicity to prevent exorbitant prices and compel fair wages. Such publicity, he said, should include figures on actual costs of production, sales realization, profits, wage rates, transportation charges, interest on investments, capital structure and interlocking directorates. He also would require reports from wholesalers because middlemen were sometimes "a screen" behind which the producers concealed their real earnings.

Mr. Jacobstein critized the failure of the operators to make the usual spring reductions this year. He said they had assured the public they were opposing increased wage demands so that prices might be held down, but that the failure to make the spring cuts meant an average increase of 30c. per ton to the consumer. The recent hard-coal agreement, he added, could in no sense be considered a permanent

Water Works Switches From Oil to Coal

The Kansas City Water Works, which has been using oil as fuel for about six years, recently closed a contract to install pulverized coal-burning equipment and expects to save $30,000 a year by using southern Kansas coal as fuel instead of oil. About 90 tons of coal will be consumed daily.

Digitized by Google

solution of the difficulties in the anthracite region.

In his discussion of the bituminous situation the witness began by contrasting the diffusion of interests and the wide area underlain with soft coal with the concentration of control and deposits in the anthracite field. Quoting Secretary Hoover's charge that the bituminous industry was "one of the worst functioning" in the United States, he declared that it was overdeveloped and overmanned, carrying an excess of 200,000 workers who demanded high daily wages to compensate them for broken running time.

The shift from union to non-union production, he observed, is menacing the existence of the United Mine Workers and forecasts serious disturbances when the Jacksonville agreement expires next March. Unless Congress acts now, it may reassemble next March too late to prevent a strike which would interfere with interstate commerce. The industry, he thought, was woefully backward in the use of machinery.

Representative Adam M. Wyant, Republican, Pennsylvania, wanted to know how overproduction affected prices. The witness conceded it led to bad breaks. He was not, he explained, arguing for legislation which would deny profits. Mr. Shallenberger interjected that present prices were high. Mr. Jacobstein retorted that prices should be higher than in prewar days because in those days the industry did not make a fair profit. Representative John G. Cooper, Republican, Ohio, mentioned the losses in output in the Central Competitive Field. The witness thought there was a more economic use of labor in the non-union fields, viz., lower daily rates and higher weekly earnings. Mr. Wyant insisted freight rates had something to do with the shift.

Opposes Government Ownership

Mr. Jacobstein was questioned closely on his theory that coal should be regulated because it was a quasi-public utility. Representative Schuyler Merritt, Republican, Connecticut, asserted the witness' proposal to limit the opening of new mines would take away property values in undeveloped acreage. To follow a "do nothing" policy, answered the witness, means to imitate the ostrich. Mr. Jacobstein declared he was opposed to both government ownership and to price-fixing.

He modified his position on price-fixing, however, when questioned by Representative Sam Rayburn, Democrat, Texas. Mr. Rayburn did not think Congress would modify the Sherman law unless a great public benefit would flow from such action. If the government controlled production, wouldn't price-fixing and other forms of control follow? Mr. Jacobstein answered that he was not afraid of price regulation in a natural limited monopoly. Control, he admitted, would have to extend to the selling agencies. Such control was better than the present anarchy, which is unfair both to operators and workers.

"When you control production," asked Mr. Rayburn, "won't you have to assure the producer a reasonable profit?"

"Yes."

"Then, wouldn't you have to touch prices and distribution?"

"Eventually we might have to."

"Could we write anything into the law to insure continuous production?"

"No, and I would not if I could because the public will not support the idea of compulsory labor."

Despite this admission, Mr. Jacobstein believed legislation would help prevent strikes because with all the facts known he did not believe labor could hold out for an unfair settlement. A statement by Representative George Huddleston, Democrat, Alabama, that it was just a question of time before there would be a tremendous convulsion in the non-union fields was seized by the witness as another proof that legislation was needed.

Hearings were resumed Tuesday morning with Representative Robert Luce, of Waltham, Mass., on the stand. He urged that standards of quality be set up to apply to all shipments of domestic sizes of anthracite. He expressed the opinion that it would be entirely practicable to require that a certificate be attached to each bill of lading indicating the size of the coal and certifying that the non-combustible content of the coal is not above a certain specified percentage. He would vest supervision of coal shipments in the Bureau of Mines.

It is expected that the hearings, which were resumed on April 6 after an adjournment from April 2, will last another ten days. Following testimony by Congressmen, representatives of the operators, the wholesalers, the retailers and the American Federation of Labor will be heard. It is understood that Secretary Hoover also has been invited to appear.

Keystone View Co.

Representative Meyer Jacobstein

Turner Urges Rock-Dusting

Director Turner of the U. S. Bureau of Mines has issued a statement advocating rock-dusting of bituminous coal mines to prevent explosions. "More than 90 per cent of bituminous mines in the country have not yet adopted rock-dusting," he said.

Five Union Mines Close Near Pittsburgh, Unable To Pay Jacksonville Scale

Coming almost simultaneously, the action of a number of coal interests in the Pittsburgh district working on the Jacksonville scale in closing down their mines recently is construed as a final abandonment of the attempt to operate at the higher rate in competition with Southern fields and other companies working on the 1917 rate in this district.

Mines in the Pittsburgh district that have shut down, all of which operated on the Jacksonville scale, follow:

Scott mine of the Montour Collieries Co., at Imperial.

Hazel mine of the Chartiers Creek Coal Co., near Canonsburg.

Bulger mine of the Bulger Block Coal Co., near McDonald.

Two mines of the Carnegie Coal Co. —the McDonald and Atlas, the latter at Atlasburg.

The Carnegie Coal Co. has started operations at a small mine, the Cedar Grove, near McDonald, to offset the other two closed.

Among the so-called independent commercial operations the Pittsburgh Terminal Coal Corp. is about the only sizable concern that continues to work on the Jacksonville scale.

Lewis Deplores Ohio's Plight But Denies Help

The special committee of operators, representing a great majority of mines in the southeastern Ohio field, recently appointed to confer with John L. Lewis, president of the United Mine Workers, which reported at a mass meeting of operators at Nelsonville, Ohio, April 1, held out no hope of a solution of the difficulties in the field being gained through concessions by the United Mine Workers. The committee, which consisted of Walter Wolf, Nelsonville-Murray Coal Co., Nelsonville; C. C. Sharp, Big Bailey Coal Co., Nelsonville; P. C. Morris, New York Coal Co., Columbus; N. D. Monserrat, Monserrat Bros., Columbus; O. C. Newton, Sunday Creek Coal Co., Columbus; G. S. Jones, Ohio Collieries Co., Toledo, and Dr. T. R. Biddle, Poston Consolidated Coal Co., Athens, reported obtaining practically no satisfaction from the conference with the union miners' chief.

The committee quoted Lewis as admitting that he did not know how to relieve the mining industry in the southeastern Ohio field. Lewis asserted that he could not see how the miners could work on any scale in competition with non-union fields. He agreed that conditions were deplorable but that he had nothing to offer. He frankly admitted that he felt extremely sorry for the plight of the miners, but could see no way out of it at this time.

After hearing this report the operators proposed a tentative plan to take the case to the miners direct. The committee which conferred with Lewis was directed to confer with committees of other districts in the state on a plan looking to the adoption of a scale to be substituted for the Jacksonville agreement.

Wants Public to Know What Industry Will Do To Insure Steady Coal

By Paul Wooton
Washington Correspondent of *Coal Age*

To learn what the industry itself is doing to insure the public a continuous supply of coal is one of the principal objectives of Representative James S. Parker, of New York, in the investigation which he is directing in Congress. Mr. Parker is chairman of the Interstate and Foreign Commerce Committee of the House of Representatives. It has been his observation that heretofore the attitude of both operators and miners toward proposed legislation has been purely negative.

Mr. Parker believes the country wants to know, and is entitled to know, exactly what the industry proposes to do toward guaranteeing a steady supply of this necessity of life. He points out that other businesses manage to settle their troubles without plunging whole sections of the country into famine.

Before recommending legislation Chairman Parker feels that an opportunity should be given the industry to make such constructive suggestions as it has to propose.

"I have given no small amount of thought to the best way of approach to the coal problem," Mr. Parker said in discussing the situation with this correspondent. "At most of the coal hearings during the past several Congresses a bill has been set up and industry has been invited to attack that particular measure. I feel that perhaps a better way would be to start out, as we have done, with no preconceived plan and ask those in the industry what constructive suggestions they have to offer. We have begun by hearing the members of Congress who have proposed coal legislation. Full opportunity will be given any other representatives of the public who desire to be heard. Then we hope to hear what measures of assurance the operators and the miners are willing to give that there will be adequate supplies of coal at all times.

Would Encourage Self-Reform

"It is my opinion that business should be encouraged to reform itself. There can be little question that there is need for reform in the coal industry. There must be some way to adjust differences without going to war every two years. Whether this is done by removing the causes of controversy before they become acute, as the steel industry seems to do with some success, or whether it is done by special machinery for conciliation, such as the railroads are proposing to employ, is of little concern to the public. The people are not particular as to the method so long as a way is found to maintain production."

Mr. Parker is anxious to correct any impression that may have been gained from certain statements in the newspapers that the committee has no serious intention of reporting a bill. "These reports show a strange conception of members of Congress. They are too busy to spend days and weeks listening to witnesses if there is no intention of taking action. We expect to listen patiently to any who are qualified to represent the different points of view. Then we will weigh the evidence and agree on a bill which we will recommend to the House."

While Chairman Parker would not attempt to lay down a detailed plan for the conduct of the hearings, it seems probable that operators representative of all the principal districts will be invited to appear. They will be asked what assurances they can give of maintaining a continuous supply of coal and what steps they propose taking to prevent biennial strikes. Similar questions probably will be asked of representatives of the United Mine Workers.

© Harris & Ewing
Representative James S. Parker

John Fritz Medal Awarded To E. D. Adams

The John Fritz gold medal was bestowed on Edward Dean Adams with appropriate exercises at the Engineering Societies Building, New York City, March 30. The award was made for great achievements as "engineer, financier, scientist, whose vision, courage and industry made possible the birth at Niagara Falls of hydro-electric power." Dr. Frank B. Jewett, past president of the American Institute of Electrical Engineers and now chairman of the John Fritz medal board of award, presided.

Addresses were made by James M. Beck, former Solicitor General of the United States, and Dr. A. E. Kennelly, of Harvard University. Major Fred J. Miller, past president of the American Society of Mechanical Engineers, made the presentation. Mr. Adams responded in an interesting address in which he traced the development of the Niagara Falls Power Co. from its inception to the present time.

At a dinner given to Mr. Adams prior to the presentation exercises short speeches were made by W. H. Onken, Jr., editor of *Electrical World;* L. B. Stillwell, chairman of the Engineering Foundation, and Prof. C. F. Scott, of Yale University.

New Orient Shuts Down; Will Be Developed Further

Following the series of mine shutdowns in the southern Illinois coal fields recently, New Orient, at West Frankfort, Ill., the largest mine in the world, suspended operation indefinitely March 29. The closing of this mine placed eleven hundred men out of work. The Chicago, Wilmington & Franklin Coal Co., which owns the mine, plans to continue development work during the summer, using about three hundred men in driving entries and getting the mine to capacity production stage by next fall.

Normally the mine employs fourteen hundred men. The world's hoisting record of 12,825 tons in one day is held by the "New Orient" and officials say the mine is capable of producing fifteen thousands tons daily and providing employment for eighteen hundred men.

New Orient has been producing coal since Dec. 1, 1922, this being the first suspension.

Hudson Coal Co. Reorganizes Operating Staff

Reorganization of the operating division of the Hudson Coal Co. took place at a recent meeting of colliery superintendents and foremen conducted in the main office at Scranton, Pa., according to reliable reports. A series of resignations, promotions and transfers resulted.

Company executives declined to discuss the changes but it is understood that the changes will be as follows:

Samuel Oakley, superintendent of the Marvine colliery—resigned.

Karl Hughes, superintendent of Clinton colliery, Vandling — promoted to superintendency at Marvine.

Thomas Steele, superintendent of the Dickson colliery—resigned.

Seth Reese, assistant superintendent of Marvine colliery—promoted to superintendency at Dickson.

James F. Loftus, foreman at Eddy Creek colliery—promoted to assistant superintendent under Superintendent L. H. Weichel at Olyphant.

Harry Williams, foreman at Baltimore colliery, Wilkes-Barre—promoted to assistant superintendent under Mr. Weichel.

Mr. Oakley, who resigns the superintendency of the Marvine operation, has been in the employ of the Hudson firm forty years, rising in the ranks from coal cutter to the post of superintendent.

Mr. Hughes, successor to Mr. Oakley, has been in continuous service with the Hudson firm for years, serving for a time as chief colliery engineer at the Powderly colliery, in Mayfield. Later he worked as superintendent at the Vandling operation.

Previous to his appointment as superintendent at the Dickson colliery, Thomas Steele supervised operations at Legitt's Creek company plants.

Mr. Loftus and Mr. Williams, who have been advanced to positions of assistant superintendents under Mr. Weichel, will have under their jurisdiction the Olyphant, Eddy Creek, Miles Slope and Grassy Island operations.

Deadlock Again Looms in Britain's Coal Situation; Subsidy to Industry Causes Deficit in Nation's Finances

No decisive action looking to an agreement respecting the Royal Coal Commission reported resulted from the conferences of mine owners and employes held in London last week. Both joint and separate sessions were held, and it was hoped that some important conclusions might follow. The points at issue, however, are being referred to the district organizations.

The operators have given the miners a detailed statement of their attitude toward the recommendations of the committee which recently suggested measures to revive the declining British coal industry.

On the vital question of wages the owners propose immediate national negotiations to settle general principles, which are to be incorporated in a new agreement to include a ratio between profits and wages, but which will leave the determination of the minimum percentage payable on basis of rates in each district to the district associations.

This means in effect that the owners refuse to consider the fixation of a national minimum wage and insist on wages being the concern of the districts themselves.

Say Operators Want Wages Cut

"This," says a statement issued by the Miners' Federation, "has constituted an almost insurmountable obstacle to an amicable settlement." The miners also contend that the operators made it evident that they intend to demand heavy reductions of wages.

"In the absence of definite proposals for a minimum percentage," they declare, "we have to assume that the position of the owners is as stated by them last July. Consequential wage reductions would vary from 1s. a day in best to over 5s. in the worst districts."

A. J. Cook, secretary of the Miners' Federation, declared in a speech April 2, that it is quite clear the owners were using the present position to declare war on the mining community and would lock out their employees to enforce their proposals.

Premier Baldwin divided his time during the Easter holidays between London and his country seat, so that he could easily be reached should the coal situation develop alarming symptoms.

Objections to continuing the coal subsidy granted last August as a temporary measure continue to be vigorously voiced. In governmental circles it is felt that the coal crises must be solved by the mine owners and miners on a strictly economic basis, without relying on further subsidy in any form whatsoever.

In this connection it is pointed out that the British coal trade has been subsidized in one way or another, during the last ten years, to the tune of about $300,000,000 out of the taxpayers' pockets.

The subsidy added £19,000,000 to Great Britain's national expenditures during the financial year ended March 31, and caused a deficit of £14,038,120. The official figures indicate that otherwise there would have been a surplus of nearly £5,000,000.

Agree to Semi-Monthly Pay; Close Mines

Although the Elm Grove Mining Co. agreed to pay its miners twice a month instead of once a month, as the company had proposed, after a strike of about 2,500 miners in the northern West Virginia panhandle and eastern Ohio, which lasted about a week, the United Mine Workers was confronted on March 31 with the startling news that the company would close down its mines for an indefinite period.

A report is current to the effect that refusal of the union miners at the plants of the Connellsville By-Product Coal Co. and at seven other mines of the Paisley interests to accept a reduction of 20 per cent from the Jacksonville scale as proposed by the company, was responsible for the shutdown. It is further stated that general manager Arkwright announced, that the company could no longer pay the present union wage scale.

The Paisley interests have been among the few in the Morgantown field that have retained an agreement with the union and made it possible in part to preserve a union organization in the Scott's Run section, the only section of northern West Virginia where any considerable number of union mines are operating.

Six other mines in this district, operated by the Lorain Coal & Dock Co., the Barton Mining Co., the United States Coal Co. and the Massillon-Belmont Coal Co., also closed down, throwing 1,730 men out of work.

Four Pursglove Mines Halt In Morgantown Field

Four mines of the Cleveland-Morgantown Coal Co., near Morgantown, W. Va., owned by the Pursglove interests, Cleveland, suspended work indefinitely April 2. This left only one operating company employing union labor continuing operations in the Morgantown field.

Expiration of existing contracts, the weak condition of the market and inability to pay the Jacksonville wage scale were assigned by company representatives as the reasons for the suspensions.

No comment on the closings was forthcoming from United Mine Workers officials. R. M. Williams, in charge of the Morgantown region, said the union was continuing its unionization activities among the men employed in open-shop mines in the district.

The only remaining union operations in Monongalia County now are the mines of the Gilbert-Davis interests.

Pittsburgh Coal Co. Ready To Open Tenth Mine

The Pittsburgh Coal Co. plans to reopen Ocean No. 5 mine, at Smithfield, Pa., within the next week. This will be the tenth mine of the company to work on the 1917 scale in the Pittsburgh district. The mine has been closed since Feb. 14, 1925. About 100 men are expected to go to work at the new operation when it opens.

There are now 15 mines working on the 1917 scale in the Pittsburgh district, a check-up of activities in the district reveals. Five mines are being operated by the Bethlehem Mines Corporation, subsidiary of the Bethlehem Steel Corp., and one by the Pittsburgh & Erie Coal Co. at Braznell.

Co-operation Necessary to Success of Mining Machines

In order to get the maximum out of a mining machine there must be close co-operation between employer and employee and an organization back of the machine, said Sam Mavor recently in the second of a series of six lectures on "Some Problems in the Mining Industry," given under the auspices of the department of mining of the University of Sheffield, England. As increasing the length of the shift was out of the question, the only solution of the problem of cutting production cost, said he, was increased application of machines in mining.

Until recently, Mr. Mavor said, mining machines had not been resorted to in British mines until all other means of making the seam pay had failed, and as a consequence such machines worked under a handicap and oftentimes failed. Increased facilities for the transportation of coal from the face were necessary, he thought.

Conveyors had fallen into disrepute because the early models had not been brought to a high degree of mechanical perfection and often worked under unfavorable conditions. Their value is now realized, however, and some of the newer mines are being laid out for the use of conveyors. Mr. Mavor stressed the importance of an unfailing supply of mine cars to handle the coal from the conveyors. In some cases haulage efficiency was raised by increasing the size of the mine cars from 10 cwt. to 20 cwt. The coal should be loaded onto the cars as soon as possible in order to eliminate expensive long conveyors.

In conclusion Mr. Mavor advised the mining students to specialize in some one line and become expert in that line. The value of the expert in the mining industry, said he, was just being realized. The mining industry was the last of the major industries to take up scientific control and management. It was very important, he said, to lay out the mine scientifically. It is in this work that the expert will be most needed.

Form New Union District In Upper West Virginia; To Fight Open-Shop Mines

District No. 17 of the United Mine Workers, in West Virginia, has been split up by the international union and a new district, embracing the twelve and one-half counties in northern West Virginia, now known as No. 31, has been formed. The change will become effective May 1. The action was taken in Indianapolis, March 26, but was not made public until April 3. The change was deemed necessary because of the geographical location of northern West Virginia, according to Van A. Bittner, international representative in charge.

In announcing the establishment of the new district representatives of the international union—Percy Tetlow, John O'Leary, A. R. Watkins, and Van A. Bittner—state that "the affairs of District 31 will be in complete charge of the international union until the organization in this field is thoroughly established."

Operators are of the opinion that while the union may wage a more determined campaign to recruit its forces in northern West Virginia, such evidently being the purpose of the establishment of a new district, the organization is confronted with a great many difficulties in view of the existing economic situation which caused nearly all the mines that had been operating under the Jacksonville agreement to suspend operations because they could no longer operate under the higher wage scale, even though friendly with the union. Under the circumstances, therefore, it is not believed that it will be possible to get producers who have been operating non-union mines to become parties to any agreement that will preclude a continuance of operation in competition with other mines in West Virginia or in other states.

Barnum on Self-Government

"Self-Government in Industry" is the theme which will be stressed at the session of the Natural Resources Division of the Chamber of Commerce of the United States when the annual meeting is held, May 11. Walter Barnum, president of the Pacific Coast Co., New York City, one of the three speakers, will discuss the question with respect to the coal industry. The other two speakers will represent the oil and the lumber industries.

Northern Pacific to Open Bids

Bids for coal for the Northern Pacific Ry. for the line extending from Mandan, N. D., to Missoula, Mont., required from May 1, 1926, to April 30, 1927, will be received until April 12 by R. J. Elliott, purchasing agent of the road, 5th and Jackson Sts., St. Paul, Minn. Not less than 1,200,000 nor more than 2,400,000 net tons will be required, to be delivered in approximately equal monthly proportions.

The Edwight mine of the Raleigh-Wyoming Coal Co., in the New River field, was closed down recently according to reports.

Pities Those Blind to Need For Conservation

"Conservation, like other vision, is not to be considered a question of morals; it is more a matter of education, of experience, of intelligent interest," said George Otis Smith, Director of the Geological Survey, in an address at the annual dinner of the American Society of Naval Engineers at Washington, D. C., March 27. "We should not condemn so much as pity the defective eyesight of our fellow citizens who can see no reason why we as a nation cannot spend as we go, regardless of the sources of our present wealth and equally thoughtless as to the wherewithal for the future. 'Please help the blind!' is the placard that should be hung on the breast of every public official who neglects any opportunity to plan for the distant future of his state or country, or tacked outside the door of the boardroom of every big corporation that fails to guard its reserves of raw material, or painted above the wide entrance to any legislative hall whose occupants can spell out that long word 'preparedness' only when martial music arouses attention and flying colors stimulate the optic nerve."

Southern Illinois coal producers are working on the details of a plan to ship coal to the Twin Cities by barge. The southern Illinois operators propose to develop a fleet for operation on the upper Mississippi River in order to regain a market for southern Illinois coal which has been practically eliminated since the freight rates went up last season.

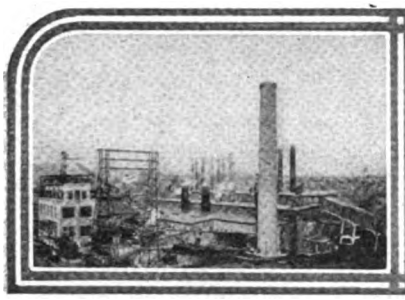
Government Needs Engineers

The U. S. Civil Service Commission announces examinations for senior mining engineer (safety service) and senior mining engineer (coal and metal), applications for which will close May 18. Vacancies are to be filled in the Bureau of Mines, Department of Commerce, for duty in Washington, D. C., or elsewhere. The entrance salary is $5,200 a year. After the probational period required by the civil service act and rules advancement in pay without material change in duties may be made up to a maximum of $6,000 a year. Promotion to higher grades may be made in accordance with the civil service rules as vacancies occur. Full information and application blanks may be obtained from the Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. civil service examiners at the post office or custom house in any city.

The Commission also announces examination for junior mechanical engineer (fuel combustion), junior mining engineer and junior engineer to fill vacancies in various branches of the government service throughout the United States. Receipt of applications will close April 17. The entrance salary is $1,860 a year. After the probationary period required by the civil service act and rules advancement in pay may be made without change in assignment up to $2,400 a year.

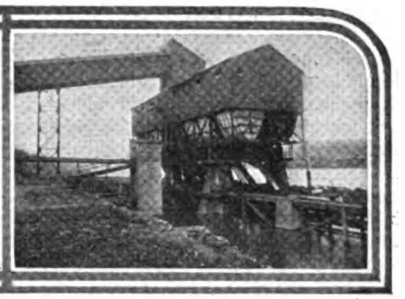
The Commission announces an examination for assistant business economist (coal), receipt of applications to close May 11. The examination is to fill a vacancy in the position of assistant economic analyst, Bureau of Mines, Washington, D. C., and vacancies occurring in positions requiring similar qualifications, for duty in Washington, D. C., or in the field. The entrance salary is $2,400 a year, with advancement to a maximum of $3,000 a year.

U. S. Chamber of Commerce Initiates Action To Abate Uneconomic Trade Practices and Abuses



The setting up of machinery for the elimination of trade abuses and uneconomic trade practices, marking a further step toward the eventual self-government of business, was announced March 18 by the Chamber of Commerce of the United States. The board of directors of the national organization authorized the appointment of a permanent committee on trade relations to serve as the focussing point for all activities in this direction.

The new committee will comprise representatives of wholesaling, retailing, manufacturing and the consuming public. It will serve in the first instance as a clearing house for information relating to the adjustment of trade disputes and the suppression of trade practices detrimental not only to the merchant and the manufacturer but to the consuming public.



It is recognized that the first task of the committee will be to promote the setting up of the necessary machinery within the various trades to facilitate the adjustment of disputes between manufacturers, wholesalers and retailers in a particular trade. It will aid in the adjustment of disputes between members of different trades and eventually, it is expected, will serve as the capstone —or lead to the organization of another committee which will serve the same purpose—in the entire structure of trade self-regulation.

"As at present contemplated," said Alvin E. Dodd, manager of the department of domestic distribution of the National Chamber, in a statement explaining the functions of the new committee, "the joint trades relations committee will be composed of one influential member of each trade. Each of the members of this committee will be the key man in developing in his particular trade a joint trade relations committee to include manufacturers, wholesalers and retailers."

News Items From Field and Trade

ALABAMA

The Pratt Fuel Corp., of Birmingham, has installed a new steam shovel, one of the largest in the state, at its mine at Hagger, Walker County. The company is making several new openings at Hagger and will erect 20 new houses for miners.

ARKANSAS

The Vilonia Coal Co., Vilonia, of which M. E. Sams is secretary, is beginning the development of 57 acres of coal land.

ILLINOIS

About five hundred men were thrown out of work April 1 with the closing of the New Baden mine of the Southern Coal, Coke & Mining Co., at Belleville. Company officials say the mine will be closed indefinitely. In a statement W. F. Davis, general superintendent, said: "Illinois must have a lower wage scale if we are to survive. It also is necessary for the officials of the United Mine Workers to accept a more liberal attitude toward mechanical loading devices and assist the operators to a day wage scale for undercutting machines used in connection therewith, if the non-union invasion of the Illinois coal markets is to be checked." Some of the miners may be taken to the Shiloh mine within a short time, Davis said.

Nokomis Mine Sold.—The Brewerton Coal Co., of New York and Chicago, it is announced, has purchased the Nokomis mine of the Nason Coal Co. The mine has not been operated since Feb. 5, and there is no immediate prospect of resumption.

Peabody mine No. 15, better known as Cora mine, at Andrew, reopened March 25, after having been closed since Feb. 11.

The Illinois Miners' Examining Board has announced its itinerary for this month as follows: West Frankfort, Miners' Hall, 8th; Duquoin, Miners' Hall, 9th; Centralia, Miners' Hall, 10th; Litchfield, Hod Carriers' Hall, 19th; Springfield, State House, 20th; Taylorville, Court House, 21st; Danville, Court House, 22d; LaSalle, City Hall, 23d; Peoria, Court House, 24th.

Franklin County produced 13,082,000 tons of coal during 1925, according to statistics compiled by Lon Fox, president of Subdistrict No. 9, United Mine Workers. The 1925 output broke the 1920 mark of 11,299,280 tons by 1,700,000 tons. Fox compiled his figures to refute the contention that union mines cannot successfully compete with the non-union fields of Kentucky and West Virginia.

INDIANA

Officials of District No. 11, United Mine Workers (Indiana) have protested against any step to appoint Walter Wills, of Linton, as a member of the Indiana industrial board. The mine officials say that because of the big percentage of accidents in mines, one member of the industrial board, which has to do with the settlement of compensation claims, should be an experienced miner.

The Indiana joint purchasing board will receive bids in April for supplying coal to state institutions for the year beginning May 1. Bidders may bid on all or part of the coal required.

KANSAS

The conference of top vein coal stripping operators of the Mulberry district with officials of the miners' union in an effort to negotiate a contract has been postponed until April 25.

Seventy-seven miners in District 14, United Mine Workers (Kansas), have completed the course of mine rescue training given by federal mine rescue car No. 6 since its arrival in the district, Oct. 19, 1925. Thirty-one miners also have completed the course in first-aid given by instructors attached to the car.

Rules for the Kansas state first-aid and mine-rescue meet to be held at Pittsburgh May 22, were drawn up March 29 by U. S. Bureau of Mines instructors and officials of the Kansas mine inspection department. The winning team will be sent to the international meet in San Francisco, Sept. 2, 3 and 4.

Fire destroyed the tipple of the Sheridan Coal Co.'s mine No. 7, near Breezy Hill, early in the night of March 30. Two shotfirers in the mine at the time escaped through an air-shaft. The mine has been operated for several months by the Eastern Coal Co. The origin of the fire is not known and representatives of both the Sheridan and Eastern companies are conducting a thorough investigation.

KENTUCKY

One of the laws enacted by the Kentucky Legislature at the session just closed, and now in effect, is Senate Bill No. 67, fixing the rights and duties of coterminous owners of mineral lands, imposing penalties for trespass underground, and giving owners of adjoining properties the right to arrange for surveys from shafts and through mines on adjoining properties to determine whether or not any trespass has been committed.

Work on the Virginia-Kentucky highway through the Lotts Creek section in eastern Kentucky, has been held up pending agreement with some of the coal companies through whose property the highway will extend. Some changes in the routing will be necessary as the line is laid out to run through miners' homes and other buildings in some instances.

Receivers of the **Himler Coal Co.** have been visiting the mine of the company at Himlerville, where portable conveyors are to be installed for transporting coal from the face of the rooms to mine cars in the heading. The mine has a capacity of 30,000 tons weekly. Fred G. Hatton, president of Hatton, Brown & Co., Inc., Columbus, Ohio, is one of the receivers.

Construction of 30 barges for the West Kentucky Coal Co. will be started this month. The new barges will be used in the company's coal transportation trade in the Mississippi and Ohio rivers.

MASSACHUSETTS

Hard-Coal Stocks Low.—Stocks of anthracite in the yards of Massachusetts retail coal dealers on March 1 totaled 53,418 net tons, according to the Special Commission on the Necessaries of Life. This compares with 725,558 tons on hand on April 1 of the preceding year. Deliveries to consumers during the eleven months ended Feb. 28 aggregated 3,887,646 tons, as against deliveries during the entire preceding coal year of 5,115,717 tons.

MICHIGAN

Will Enlarge Dock.—Work of rebuilding and remodeling property recently purchased by the Escanaba Coal & Dock Co. will be started at once. The dock will be enlarged to permit handling of 150,000 tons of coal annually and it will have an actual storage capacity of 100,000 tons. Its equipment will be capable of handling 500 tons of coal an hour.

MINNESOTA

The Zenith Furnace Co. has nearly completed extensive overhauling of its coke-oven plant at Duluth, made necessary by a fire, several weeks ago, which caused a loss of $75,000.

Digitized by Google

MISSOURI

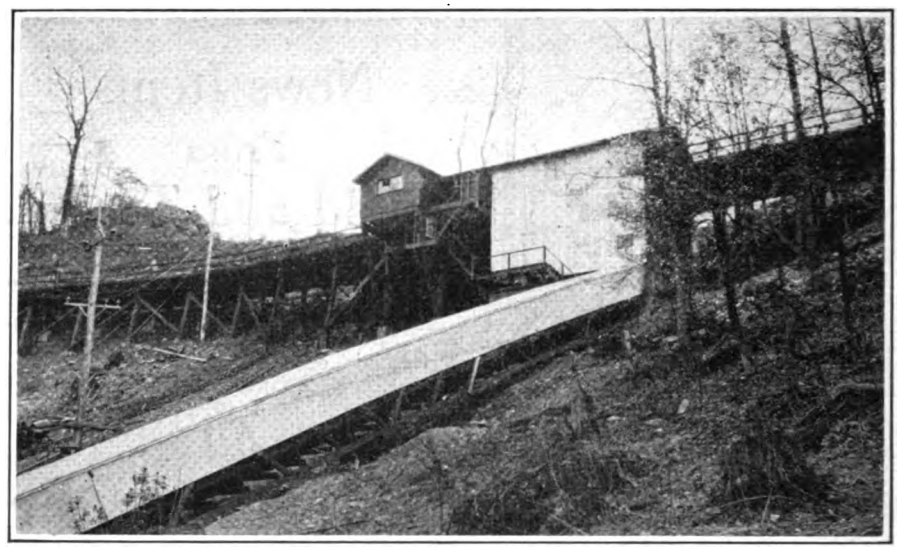
To Open $100,000 Strip Mine.—Evan Jones and A. E. Marriott, of Moberly, have closed a deal for 400 acres of coal land south of Higbee for a strip mine. The consideration was said to be close to $30,000. It is said that a switch will be laid from the Missouri, Kansas & Texas tracks to the field. The Kansas City Power & Light Co. will furnish power to operate the machines and will use all the coal produced. This will mean the expenditure of approximately $100,000 before the coal can be put on the market, it is said. The company will install a crusher at the strip pit to crush the coal before shipping.

Missouri mines in 1925, according to statistics compiled by O. L. Hengar, of the State Bureau of Mines, Jefferson City, produced 2,542,449 tons of coal valued at $7,411,162.

An injunction suit brought by the Clay Coal Mining Co., of Excelsior Springs, against local union No. 27, United Mine Workers, was refused last week by the Circuit Court in Clay County. The operators alleged that the union miners were intimidating their workers, who are non-union.

In about sixty days coal will be loaded from new strip mines to be worked near Higbee by the Howard County Mining Co. Work has begun on switch tracks by the M. K. & T. R.R. The coal company intends to remove from 30 to 70 ft. of earth off the coal by the use if the largest steam shovels built. Winson Brothers, of Minneapolis, Minn., have charge of all the operations in the production of this coal. The coal underlying the lands which were purchased, consisting of 500 acres, is 3 ft. 3 in. thick.

NEW JERSEY



Retail coal dealers at Atlantic City have joined hands in supporting an exhibition of devices for the burning of anthracite buckwheat for domestic use. They have leased a storeroom at Atlantic and Kentucky Aves., where they have set up heaters and have them in active operation. The exhibition will be continued as long as the interest of the public continues, which so far has been very satisfactory.

NEW MEXICO

An area of 720 acres of coal land in Sandoval County will be offered for lease soon by the general land offices. A royalty of 10c. a ton, an investment of $25,000 during the first three years of the lease and a minimum production of 15,000 tons yearly commencing with the fourth year of the lease are the requirements.

NEW YORK

The contract for furnishing three-quarter smokeless coal to the Erie County armory of the 106th Artillery for a year, amount not specified, was awarded on March 31 to the Dealers' Coal Co., Buffalo, on its bid of $4.83, delivered, which requires some carting. The highest bid was $5.74.

Dump-House of New Mine at Allais, Ky.

Drop-bottom cars are used at this drift mine, which was opened about one year ago in the Hazard field by the Columbus Mining Co. A rope-and-button conveyor retards the coal on its descent to the tipple located in the valley.

Bids will be opened April 10 for furnishing 35,000 tons of bituminous three-quarter slack to the Buffalo waterworks.

OHIO

The Lick Run Coal & Clay Co., of Nelsonville, has filed a petition in bankruptcy in the U. S. Court at Columbus, listing liabilities of $72,446 and assets of $132,309. This company was organized with P. J. Merz, president; Douglas McGill, vice-president, and Robert Green, secretary, to reopen a mine near Nelsonville that had been abandoned by E. A. Cole & Co. After erecting an expensive tipple operations were started, but the coal was limited. Later the tipple was destroyed by fire, but the loss was covered by insurance. Another tipple was then constructed, but the mine has been idle for several months.

PENNSYLVANIA

Mining Students Get Certificates.—Eight employees of the Bethlehem Mines Corporation, all of Wehrum, have completed a two years' course in mining sponsored by the state vocational education board in co-operation with the school of mines of Pennsylvania State College. The course was instituted three years ago by the vocational board. The instructor of the class at Wehrum is Ray Mardis, who also is employed by the Bethlehem corporation. Those who completed the course are Leonard Mulvehill, Frank Collobert, Charles Walton, Samuel A. Gromley, Thomas Madigan, Andrew Pero, Clarence Frazier and Raymond C. Mardis. Seventeen men in the class have completed one year's work.

Revenues of the Delaware, Lackawanna & Western R.R. from anthracite shipments in 1925 were $5,818,872 less than in 1924, attributable to the suspension of mining in the last four months of the year. The annual report of the company, however, reveals a decrease of only $238,673 in net income, which totaled $14,430,194. Revenues from other freight increased $2,216,186, due in large measure to special efforts made to obtain other freight traffic to fill in the gap caused by the loss of anthracite traffic.

In the week ended March 27 mines of the **Pittsburgh Coal Co.**, operating on the 1917 scale in the Pittsburgh district produced a total of 37,923 tons of coal, a new high record since operations were started last August. During the same week the mines established a new daily maximum of 6,683 tons. The number of miners working reached a new high point with 1,860.

The total net income of the Lehigh Valley Coal Co. for 1925 was $643,118, a decrease of $2,657,953 from that of 1924, the consolidated income report shows. Coal receipts for the year were $11,978,094 less than for the previous year.

Sixteen miners, arrested recently when matches were found in their clothing as they were leaving the Mollenauer Mine No. 3 of the Pittsburgh Terminal Coal Corp., were fined $50 each on charges of violating the mine safety laws at a hearing before Justice of the Peace John Popp, Jr.

Erection of a steel coal tipple, bin and trestle approach has been begun at the Mt. Hope coke plant of the Snowdon Coke Co., near Brownsville. It is expected to have the tipple in operation about the middle or latter part of April.

TEXAS

Texas Pacific Coal Income Up.—A net income of $730,430 for 1925 is reported by the Texas Pacific Coal & Oil Co., after depreciation, depletion, amortization, etc. The figure is equal to 86c. a share earned on 844,004 shares of $10 par stock, and compares with $32,665, or 3c. a share in 1924. Gross earnings for 1925 were $5,641,373, as against $5,080,915 in 1924. Other income was $536,706 in 1925 as compared with $60,554 in the preceding year. The report showed operating expenses

Digitized by Google

in 1925, $2,809,413; in 1924, $2,633,468; interest, rentals, etc., in 1925, $909,404; in 1924, $747,820; depreciation in 1925, $1,728,832; in 1924, $1,727,516.

VIRGINIA

Revive Norfolk Exchange.—Plans are on foot to revive activities of the Hampton Roads Coal Association, composed of coal agents and managers with offices in Norfolk. This will be of special interest to local shippers to the port, as the association aims for mutual friendship and co-operation for the betterment of the port and shipping facilities. Clayton M. R. Wiggs is president and Chester B. Koontz, secretary, of the association.

Safety Boosters Meet.—The seventh annual banquet of the Safety Boosters of the Clinchfield Coal Corp., held at Dante, March 27, was attended by about 200 officials. The loving cup for the unit holding the best safety record for the year was won by the Dante operation, R. S. Adams, superintendent. The 1925 fatality record was 2.5 per million tons. The addresses included "Accident-Prevention Experience," F. E. Harr, industrial claim agent; "The Mine Foreman's Duty," Frank R. Clark, superintendent Clinchco operation; "Prevention of Accidents by Falls of Slate and Coal," D. L. Rumgay, superintendent Wilder operation; "Handling the Careless Worker," R. S. Adams, superintendent Dante operation; "Psychology of a Safety Committeeman," W. R. Sparks, safety committeeman, Clinchco operation. D. H. Pape, assistant to the executive secretary of the National Coal Association, stressed the value of complete statistics on safety.

WEST VIRGINIA

A statement was issued April 3 by Robert M. Lambie, chief of the state Department of Mines, showing that one hundred safety meetings were held in West Virginia in March and that 12,000 coal miners has signed the safety pledge. "Coal, the Source of Power," the state Department of Mines film, was shown April 7 at the safety meeting held at the mines of the Mallory Coal Co. at Mallory, Logan County.

Operation of mine No. 6 of the Crab Orchard Improvement Co., at Eccles, Raleigh County, began this week. Mine No. 5, where the explosion occurred, will start in about a month. The inquest into the explosion got under way this week, starting at the mine April 7.

Foundations have been built by the Webb Coal Co. for a rope and button conveyor at its Webb mine, along the Coal River branch of the Chesapeake & Ohio Ry. at Garrison, Boone County. The Winifrede seam is worked at a height of 600 ft. above the tipple. The conveyor will be 1,200 ft. long.

Figures compiled by the Kanawha Coal Operators' Association show that in 1925 5,250,854 tons of coal was produced in the Kanawha field by 3,136 men, compared to 3,820,937 tons by 4,976 men in 1921, which the operators say was a normal year. Figures for 1925 show greatly increased activity under non-union conditions, when compared with 1921.

State mining department officials received word last week that the mine fire was completely extinguished in No. 63 of the Consolidation Coal Co., at Monongah. Recently the coal that had been burned was removed from the interior of the mine.

The Consolidation Coal Co. through the federal state employment bureau in Charleston, is advertising for coal miners at its Jenkins and McRoberts (Ky.) plants.

Strike Helped N. & W. Earnings.—Due largely to increased demand for bituminous coal because of the anthracite strike, operating revenues of the Norfolk & Western Ry. in 1925 were the largest in the history of the road. Net revenues from operations, $37,284,175, the annual report reveals, increased $9,446,594, or 33.9 per cent, over the 1924 net.

Daniel Boone Coal Corporation's Mine No. 8

Located at Heiner, Perry County, Ky., and operated and managed by the Columbus Mining Co. The mine, which produces coal from the Flag seam, formerly was the property of the Maynard Coal Co. The coal is moved from near the top of the hill by means of a steel button conveyor, to the tipple, which is equipped with shaker screens, picking tables and loading booms.

Traffic News

Lake Coal Shipments to Toledo Embargoed on Hocking Valley

M. S. Connors, general manager of the Hocking Valley Ry., has advised all lake shippers that an embargo has been placed on all shipments of coal via the Hocking Valley intended for transshipment to the Northwest until 6,700 loaded cars at the Toledo docks are cleared away. He expressed the belief that the embargo would not be of long duration, however, as the loading machines at the docks are being operated 24 hours daily. One of the causes was a freak in the current of the Maumee River, where the docks are located, which was too strong for tugs to get the lake boats in position for loading. An order was sent to Cleveland for more tugs and the larger type are being used to place the boats. The Toledo docks have a capacity of 1,000 cars daily and it will not take long to eliminate the congestion.

Advices from the Head of the Lakes show that there is still 29 in. of ice in the harbor at Duluth-Superior and less from the head of Lake Superior down to the passageways from Lake Erie. The date for opening of navigation is thus in doubt.

Rates to Black Tom Unjust, Says Tentative Report

Examiner Griffin, of the Interstate Commerce Commission, in Docket 16645, Harbor Coaling Corp. vs. Baltimore & Ohio R.R., recommends that the Commission should find the rate assailed is unreasonable and unduly prejudicial to the extent that it exceeds $2.79 per gross ton. The complainant alleged that the rate of $3.09 from mines in Clearfield, Cumberland-Piedmont and Meyersdale districts to Black Tom Pier, Jersey City, N. J., is unreasonable and unjust, discriminatory and prejudicial. The $3.09 rate applies to local track delivery, Jersey City, and the examiner agrees with the complainant that the pier rate should apply, which is $2.79. Reparation was recommended.

Suspend Hard-Coal Rates To the East

The Interstate Commerce Commission, in I. & S. 2637, has suspended from April 1 until July 30, 1926, the operation of certain schedules as published in various tariffs of the Central Railroad of New Jersey, the Delaware & Hudson, the Delaware, Lackawanna & Western, the Erie, the Lehigh & New England, Lehigh Valley, New York, Ontario & Western and the Reading, which propose changes in the rates on anthracite from Pennsylvania mines to points in New Jersey, New York and Pennsylvania. To illustrate: From the Wyoming district of Pennsylvania to Albany, N. Y., the present rate on prepared sizes is $2.65 (gross ton) via D. & H., and $3.02 via D. L. & W.-N. Y. C. The proposed schedules would make these rates $2.75 and $2.88, respectively.

Among the Coal Men

J. E. Westervelt was appointed sales manager of Castner, Curran & Bullitt, Inc., on April 1. At the same time the company announced that it had taken over the marketing of the output of additional mines with a total production of between five and six million tons.

Thomas Fraser, formerly of the U. S. Bureau of Mines, but recently assistant professor of mining at West Virginia University, has been engaged by the Pennsylvania State Geological Survey to assist in the study of fine sizes of anthracite in the anthracite region beginning in the spring. Mr. Fraser is recognized as one of the best authorities in the United States on the preparation and washing of coals. He will assume his new duties May 1 with headquarters in Wilkes-Barre. Mr. Fraser will co-operate with Dever C. Ashmead, anthracite mining engineer of the U. S. Bureau of Mines.

William T. James, superintendent of Bon Ayr Mine of the Bon Ayr Mining Co., and W. C. Barr, president of the City Coal Co., both of Jasonville, Ind., have been named members of the board of directors of a newly formed industrial bureau of that city, organized for the purpose of developing the commercial and industrial interests of Jasonville.

E. E. White, formerly president of the E. E. White Coal Co., in the Winding Gulf field, is wintering at St. Augustine, Fla.

A. G. Bailey, manager of Castner, Curran & Bullitt, Inc., at Norfolk, has taken over the management of the New England Coal & Coke Co. **H. J. Spear,** who was manager of the New England Coal & Coke Co. and the Mystic Steamship Co., a subsidiary, will give his attention to the management of the latter.

Nels R. Erickson, of Ogden, has become general sales manager of the Carbon Fuel Co. and the Blazon Coal Co., of Salt Lake City. Erickson has been general manager of the Superior Rock Spring Coal Co., of Ogden, having been connected with Utah and Wyoming coal operating companies for the past 14 years. At one time he was with the Lion Coal Co., of Ogden.

Ernest A. Bowen, formerly assistant secretary-treasurer of the Superior-Rock Springs Coal Co., Ogden, Utah, has accepted a position as traveling auditor for the J. C. Penny Co.

Edgar Blackwell, former superintendent of the New River company at Scarbro, W. Va. has been appointed safety director of that company.

Rembrandt Peale, Jr., vice-president of Peale, Peacock & Kerr, recently arrived at New York on the "Aquitania" after spending several weeks in Europe.

J. W. Bischoff has been appointed superintendent of the Bower Mine of the West Virginia Coal & Coke Co., at Bower, W. Va., succeeding B. M. Mitchell.

Major Clarence T. Starr

CLARENCE T. STARR has resigned as coal specialist for the Chamber of Commerce of the United States and on April 12 will assume the duties of assistant to the president of the Pittsburgh Terminal Coal Corporation, C. E. Tuttle, who also is chairman of the board. Major Starr was elected chairman of the Washington section of the American Institute of Mining & Metallurgical Engineers a few months ago.

Obituary

Thyssen, German Coal and Iron Magnate, Dead at 84

August Thyssen, famous Ruhr coal and iron magnate, died near Muehlheim, Germany, on April 4, aged 84. Death was due to pneumonia following an eye operation.

Thyssen began his industrial career in the '60s with a capital of $6,000, which he invested in a rolling mill at Hamborn, employing sixty men. Like John D. Rockefeller, he developed a region whose natural resources were untouched. In later years they called him the Rockefeller of the Ruhr. The first rolling mill at Hamborn is now the Deutsches Kaiser Works, employing 26,000 workers. His various enterprises engaged the service of 70,000 employees.

Beginning life as a Ruhr contemporary of the late Hugo Stinnes' father, Thyssen, unlike the Stinnes family, reinvested all his earnings in his own business until he became a veritable colossus of the coal, iron and steel industry, with holdings in India, France, Belgium, Holland and South America.

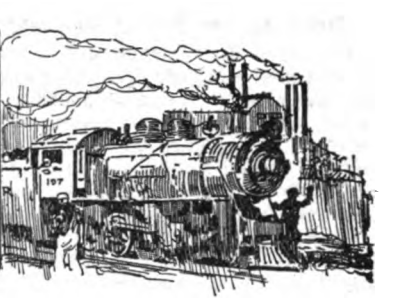
Few of the heavy industries of Germany failed to feel Thyssen's grasp. He was the biggest coal operator in the country. He owned iron mines, rolling mills, steamship lines, docks, cement factories and allied industries.

When the World War began Thyssen manufactured small arms for the Central Powers. Despite this small share of the armament industry, he went into competition for heavy armaments, and in the end he broke the Krupp monopoly in big guns.

As soon as the war ended Thyssen transformed his munition plants into electrical machinery plants and was no less successful. During the French occupation of the Ruhr the octogenarian industrialist worked fifteen hours a day while his men labored in three shifts under the eyes of French sentries. He opened every mine he had in the Ruhr and developed it to full capacity to make up to Germany the coal production she had lost when Upper Silesia and the Saar passed out of her control.

Colonel Thomas G. Price, aged 69, one of the prominent coal men of northern West Virginia, who was connected for a number of years with the Consolidation Coal Co. and before that with the Camden interests, died March 28. Mr. Price was a native of Franklin County, Virginia. Thirty-seven years ago he located in Marion County, being employed by Bennett and Talbott, railroad contractors, who built the Monongah branch of the Baltimore & Ohio R.R. from Fairmont to Clarksburg. Later he became identified with the Monongah Coal Co. and the Camden interests and for a number of years was outside superintendent of the mining plant at Monongah. He continued in that capacity after the Monongah operation had been taken over by the Consolidation Coal Co., remaining with the latter company as long as his health permitted him to do so.

Joseph Watson, pioneer Colorado resident and coal mining expert, died March 15 in Louisville, Ky., his home for the last twenty years, following an illness of a few months. Mr. Watson was 61 years old when he died, having lived in Colorado for forty-seven years. He first settled in this state in Trinidad in 1879, later lived for many years in Gunnison, and in 1907 became general superintendent of the National Fuel Co., opening the Puritan mine for that company in Weld County. In 1916 be became general inspector for the Coal Operators' Mutual Insurance Co., with headquarters in Louisville, and held that position until his death.



Ned Irish, formerly engaged prominently in the operating end of the anthracite industry and a member of the firm of Irish Bros., Philadelphia, died at his home in Norristown, Pa., on March 29. He was 72 years of age, and at his funeral on the 31st, there was a large attendance of coal men from Philadelphia and the hard-coal region.

The death is announced at Port Colborne, Ont., of **Thomas Lannan,** managing director of the Century Coal Co., at the age of 70 years. He was a prominent figure in the coal zone, having been identified with marine interprises and construction work practically all his life. He was manager of the Comion Bros. coal dock at Port Colborne, subsequently buying out the dock and merging it with the Century Coal Co., a subsidiary of the Canada Steamship Lines.

Production And the Market

Soft-Coal Trade Flounders in Aim at Stability; Distress Tonnage Sets Fictitious Values

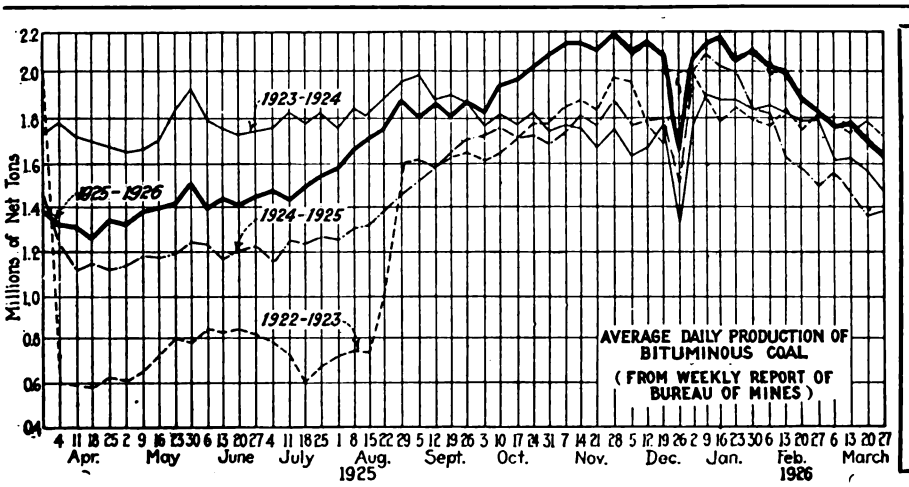
The opening of the new coal year finds the bituminous trade of the country still floundering around in its efforts to put the business upon a stable and profitable basis. In the East this process is hampered by the fact that there still is enough distress tonnage seeking a buyer to dull the interest of the consumer in offerings at fair prices and to establish a fictitious basis of values. In the West and Middle West the competition between union and non-union coals gives large industrial consumers the whiphand in discussing contract renewals.

The blizzard which swept over so many states last week added a touch of last-minute activity to the domestic trade. The flurry, when measured in tonnage, however, was inconsequential. Many retail distributors, it is true, were caught with scant stocks in their yards, but the rush orders they placed with the mines were for small lots. Only in Kansas was buying sufficiently heavy to have any real effect on the "no bill" situation.

In the drive to corral domestic business many bituminous districts established spring prices which represent substantial reductions from the schedules in effect prior to April 1. For the major domestic sizes the new circulars of the Illinois and Indiana producers show a cut of 40c. per ton. In the Far West still more drastic reductions have been made in the past fortnight, but it does not appear that these latter cuts have stimulated buying. Alabama, on the other hand, reports active contracting by retail dealers on the new spring prices.

Price Situation Unsettled

Less success has attended efforts to stabilize quotations in the Appalachian region. Low-volatiles have been particularly hard hit in the readjustment process. April circulars had hardly reached the buyer before one large West Virginia company dropped its lump price 25c. Mine-run, too, is weak in both Eastern and Western markets. Except in eastern Kentucky, high-volatile prices on prepared sizes have been wobbling badly. *Coal Age* Index of spot bituminous prices on April 5 stood at 158 and the corresponding price was $1.93. This was a decline of five points when compared with the index for March 29.



The most hopeful feature in the present situation is the steady decline in production rate. Bituminous output for the week ended March 27 was estimated at 9,609,000 net tons by the Bureau of Mines. Barring the Christmas holidays, this was the lowest weekly output reported since the beginning of last August. Holidays the end of last week held out the hope that further reductions would be registered.

Anthracite Production Climbing

Anthracite production, on the other hand, has been climbing. For the week ended March 27 the output was estimated at 1,991,000 net tons. In view of the growing disinclination of buyers to pay premium prices, the halt in this high rate last week was not unwelcome to the independent shippers. For the most part, the latter can no longer command premiums in excess of 50c. over company maximum. Steam sizes are weak.

There are signs of a slowly expanding market for No. 1 buckwheat coal in the domestic trade. This movement is slightly accelerated by the scarcity of pea. Most of the latter size now being produced is being consumed in the anthracite region. It is reported that at least one big company is planning a reduction in the No. 1 price, but there is nothing to indicate that the producers will reverse themselves on the question of prices on the larger domestic sizes.

The Connellsville coke market is featureless.

Estimates of Production

(Net Tons)

	1925	1926
BITUMINOUS		
March 13	8,641,000	10,690,000
March 20 (a)	8,283,000	10,263,000
March 27 (b)	8,353,000	9,609,000
Daily average	1,392,000	1,602,000
Coal yr. to date (c)	468,167,000	535,614,000
Daily average	1,542,000	1,760,000
ANTHRACITE		
March 13	1,656,000	1,966,000
March 20	1,513,000	1,963,000
March 27	1,640,000	1,991,000
Coal yr. to date (c)	85,627,000	50,442,000
BEEHIVE COKE		
March 20	226,000	263,000
March 27 (b)	220,000	251,000
Cal. yr. to date (c)	3,115,000	3,824,000

(a) Revised since last report. (b) Subject to revision. (c) Adjusted to equalize number of days in the two years.

Drive on for Spring Business

The drive for spring and summer business in the Middle West was opened last week with price reductions by Illinois and Indiana operators. Effective April 1, leading Franklin County shippers quoted $2.60 on lump and 6x3 egg, $2.55 on 3x2 egg, $2.50 on cook-stove egg, chestnut and mine-run, $2.40 on pea and $2 on 2-in. screenings. Central Illinois offered coal at approximately 25c. less. Fourth Vein Indiana circulars named $2.60 on lump and egg; Fifth Vein, $2.25. Advances are planned later in the season.

There also were a number of contracts signed—in most cases for screenings. Franklin County is asking $1.75 on 2-in. coal, and some business has been closed at 10@25c. higher. The prevailing contract figure on 1¼-in. screenings in southern Illinois is $1.60. Fifth Vein Indiana coal has been signed up at $1.35@$1.50. Most of the railroad bids are in, but no awards have been made. St. Louis reports that some Springfield and Mt. Olive screenings have been quoted as low as $1.25 on contract and some Standard mine-run at $1.65.

Aside from a rush demand for domestic sizes, brought about by the blizzard which swept over Illinois and neighboring states, business at the mines was sluggish. This flurry, however, resulted in many small-lot orders for immediate shipment and temporarily reduced the number of "no bills" in the southern districts. Duquoin did not fare so well and the outlook for Mt. Olive is not promising. The Belleville field is limping along.

Eastern Coals Press Middle West

Eastern shippers are still combing Chicago and other markets in the Middle West for orders. High-grade smokeless mine-run has been offered to the retail trade as low as $1.65. Quotations on high-volatile coals cover a wide range. Wholesalers have been pressed to take 4-in. Logan County block at $1.60 and 4x2 egg at $1.35. Eastern Kentucky block is $2@$2.50 and egg, $1.75@$2.25. Anthracite receipts are increasing.

Raw weather and a falling thermometer increased household demand for Kentucky coal last week. For the most part, however, retail dealers in Louisville were able to meet the demand with stocks on hand, but in some other parts of the country hurry-up orders were placed with the producers.

There is a moderate movement of Kentucky coal to Northern markets. Producers in the eastern part of the state are signing up some lake business and the western district is lining up orders north of the Ohio River in territory formerly considered the exclusive preserve of the Illinois and Indiana producers. Eastern Kentucky block is $1.75@$2.25; lump, egg and nut, $1.75 @$2; mine-run, $1.50@$1.60; screenings, 90c.@$1.10. Western Kentucky block is held at $1.75@$2; lump and egg, $1.50@$1.75; nut, $1.35@$1.60; mine-

run, $1.15@$1.50; screenings 90c. @$1.10.

Try to Unload Dock Surplus

Current movement in the dock trade at the Head of the Lakes has been erratic, in keeping with the weather fluctuations in demand. Bookings for early April delivery, however, have been substantial and industrial inquiry has improved. Sales agents have started an aggressive campaign to cut down the stocks on hand—estimated at 2,375,000 tons—before navigation opens. Irregularity in prices has been the result and quotations are off 25@50c. a ton, except upon smokeless, which slipped sharply a few weeks ago.

With orders for anthracite flowing in at an increasing rate, dock operators feel that the market will readily absorb 1,000,000 tons during the coming season of navigation. Retail yards at Superior and Duluth have been booking fill-up orders from householders who are not quibbling over what the price may be. On the industrial side the most active demand at the present time is for bituminous screenings, which are held at $4, f.o.b. docks.

Unseasonably cold weather kept the retail trade in the Twin Cities busy last week, but few orders were placed with the wholesalers. Steam buyers, too, have been holding back, influenced in their policy by the fact that they have been able to pick up distress tonnage here and there. Weather conditions also had a favorable effect upon the movement of coal in Milwaukee.

Snowstorm Cleans Up "No Bills"

The heavy snowstorms which swept over the Middle West last week cleaned up the "no bills" in the Kansas field and brought full-time operation to the mines that were open. Stripping operations were the chief beneficiaries. Shaft-mine screenings are scarce, but the demand has been met by crushed shovel mine-run. Arkansas and Oklahoma operations shared little in the rush demand. Although the retailers specified small cars of Kansas coal, they took any equipment loaded.

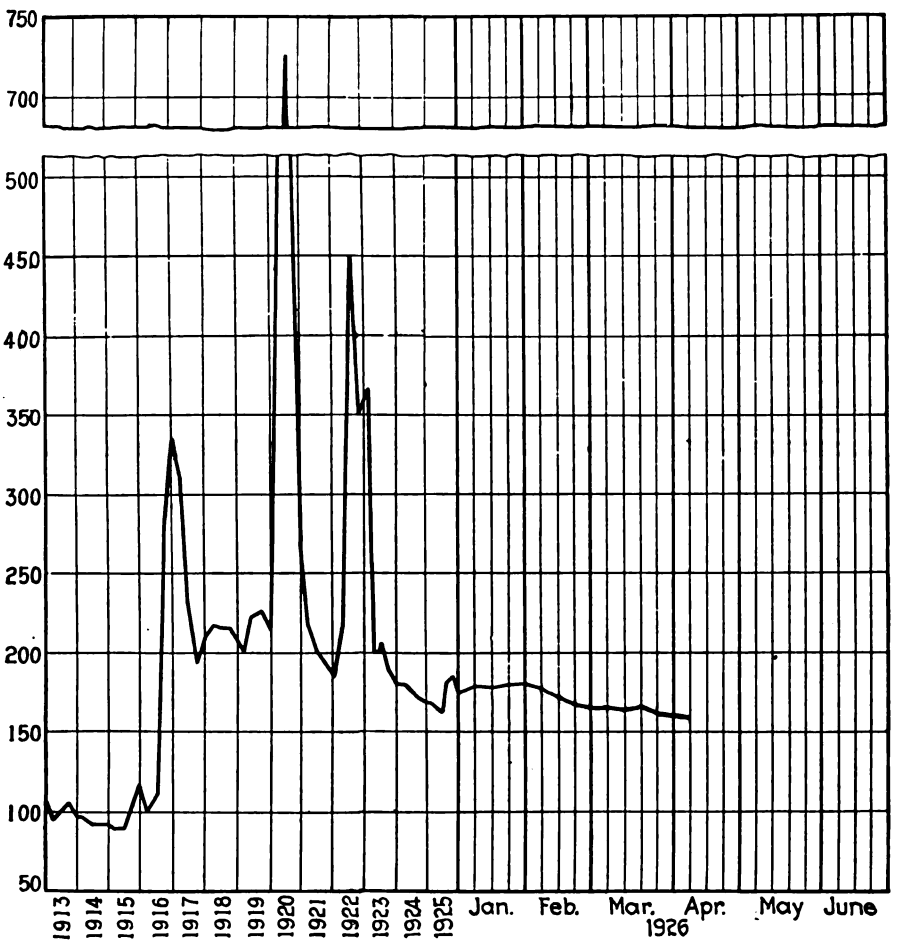
April reductions averaging $2 per ton have failed to stimulate domestic demand for Colorado coal. Retail buying, for the most part, is limited to current consumer demand. Steam-coal movement, on the other hand, is active and prices have been advanced approximately 50c. Colorado mines are running about three days a week.

A weather flurry toned up Utah retail business last week, but there was little reaction at the mines. Few operations are doing better than two days a week. Industrial demand is subnormal and "no bills" are piling up. An interesting development is the activity of companies doing business on a C. O. D. basis. Two companies, offering Carbon County coal, are now working on this plan in Salt Lake City. One has cut quotations 75c.@$1.50 and the other, $2.25 per ton.

Smokeless Prices Slumping

The price situation in smokeless coals is still unsettled. After most of the standard shippers had announced a $3 price on lump and egg for April, one of the largest in the field—the Crozer-Pocahontas Co.—quoted $2.75 and three other distributors met that figure. Nut is $2@$2.25 in the Cincinnati market; mine-run fairly steady at $2, and slack, $1.25@$1.50.

Diversion of business from the Harlan to the Elkhorn field is the outstanding development in the high-volatile market. One contract calling for approximately 700,000 tons for steel plants has been switched to the Elkhorn district on a $1.50 mine-run basis. Several Ohio and Canadian utility contracts also are going to the Elkhorn field on the same basis. The $1.50 price has been fairly well established as the ruling lake figure. Heavy contract buying on "a mine-run basis" has strengthened the market in slack. Some coal still can be had at 80c., but the better grades are $1@$1.15.



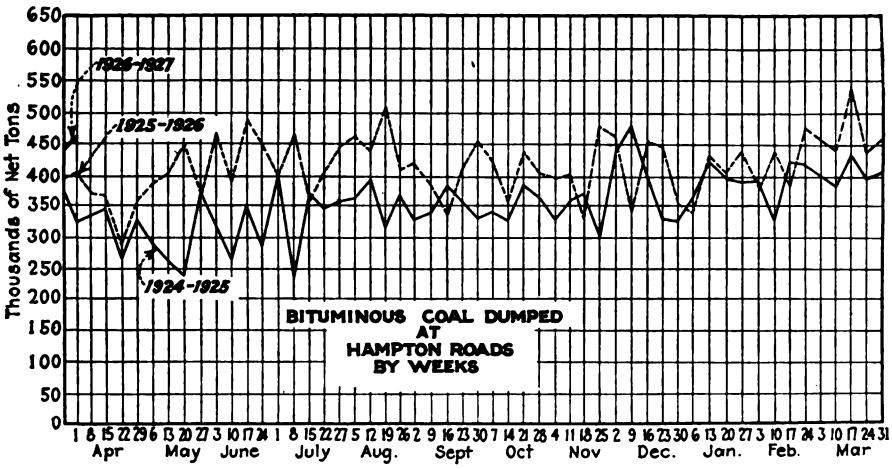
The market for prepared sizes is in a state of collapse. Southeastern Kentucky is sticking to the $2@$2.25 range on block, but 4-in. West Virginia block is freely offered at $1.75@$2 and egg is weak at $1.50@$1.75. Spot mine-run, both steam and byproduct, is draggy.

Uncertainty Rules Central Ohio

The central Ohio steam trade is still an uncertain quantity. Many of the contracts which expired April 1 have not been renewed, and there is nothing in sight to indicate that they will be. With supplies plentiful, buyers find the spot market equal to all their demands. No improvement is expected until the lake trade is in full swing. Southern Ohio, which is now producing about 18 per cent of capacity, is cherishing no hopes, however, that it will be an active participant in that business.

Except in the case of slack and nut-and-slack, it has been difficult to market eastern Ohio coal—even at a loss. Screenings, however, have again stiffened and recent quotations show an advance of 10c. Production in the No. 8 field during the week ended March 27 was estimated at 217,000 tons, or 31 per cent of potential capacity. The output was 30,000 tons less than in the week preceding and 34,000 tons under the figures for the corresponding week in 1925.

What little business is left in the Pittsburgh district appears to be drifting into the hands of a few operators. The majority of the producers seem to feel that they cannot operate on the Jacksonville scale and do not care to follow the lead of the Pittsburgh Coal Co. in its open-shop policy. That com-



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	Apr. 5	Mar. 29	Mar. 22	Mar. 15	Apr. 6	Apr. 7
Index	158	163	167	168	162	171
Weighted average price	$1.93	$1.97	$2.02	$2.03	$1.96	$2.07

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average of the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

pany during the week ended March 27 had nine mines running and produced 37,923 tons—approximately 15 per cent of its weekly output in 1923.

Slack coal is up 10c., but steam mine-run is off a dime. Screened gas coal, too, is a shade easier. Some West Virginia mines working the Pittsburgh seam have been offering three-quarter steam at $1.35, as compared with $1.90 @$2 in the Pittsburgh district. Lake season contracts have been sought by these same non-union interests at $1.45.

More Pennsylvania Mines Down

A number of the smaller operations in the central Pennsylvania field have shut down until demand shows more life. Production last month was 70,340 cars, as compared with 82,648 cars in February. Prices on the higher grades of coal are steady, but quotations on lower grades have weakened. Pool 1 is $2.50@$2.60; pool 71, $2.35@$2.45; pool 9, $2.10@$2.20; pool 10, $1.85@$1.90; pool 11, $1.65@$1.70; pool 18, $1.60.

Industrial demand for bituminous coal in the Buffalo market is as dull as has been the case for several weeks past. Nominal quotations are unchanged. Domestic demand last week reflected winter weather conditions, but there was little call for the "substitute" fuels. The only sign of interest in that section of the trade was in the low-volatiles. Consumers rebel against current coke prices despite recent reductions.

Midsummer moribundity characterizes the steam coal market in New England. Inquiry for all grades is very light. Consumers who buy in volume appear to have made a resolution to pay the lowest prices which have prevailed in recent years. They are relying upon accumulations at the southern loading piers to control the situation. Those who will not buy distress tonnage expect their regular sources of supply to modify quotations in the light of the prices at which demurrage coal has been moved.

Southern Spot Market Demoralized

The spot market at Norfolk and Newport News is demoralized. Few shippers pretend to ask more than $4.25 gross, f.o.b. vessels, for Navy Standard coal. There is a surplus available at the Northern ports for inland delivery and spot prices are wobbly. As low as $5.60 gross on cars at Boston has been heard within the past few days.

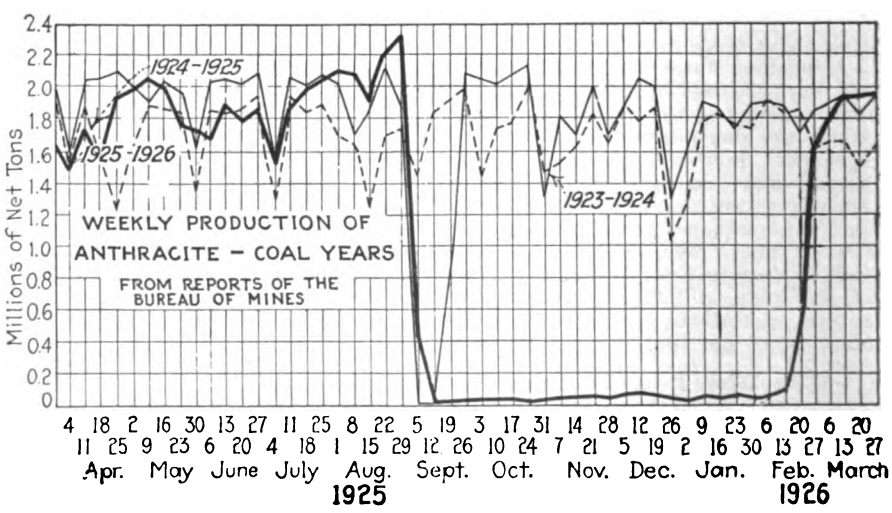
There are only occasional inquiries for Pennsylvania bituminous, either for all-rail or rail-and-water shipment. Quotations are soft. Even where the competition with the low-volatiles from southern West Virginia is not direct, the central Pennsylvania shippers know that only a minimum figure will attract any attention.

Marine freights are settling into a low season basis, especially on steamers. Only those owners with good connections are able to keep their tonnage continuously in service along the coast, and rates are correspondingly easy. Retail prices on steam coal at Boston have been reduced.

Distress Coal Still a Factor

Distress coal, which can be bought at $1@$1.25, mines, is still a depressing factor in the New York bituminous market and dulls the interest of consumers in other spot trade. Tidewater buying has been slow. There are many loaded boats in the harbor awaiting buyers. Most of these boats were loaded to relieve congestion at the piers. Small quantities of sized Connellsville coke are moving at $3.50@$3.75, ovens. A few vessels of foreign coal and coke reached the harbor last week.

At both Philadelphia and Baltimore, as at New York, there is little interest displayed by buyers in contract renewals. The only bright spot in the latter city is the export situation, which has absorbed some of the coal standing at the piers. The eagerness of Philadelphia coal men to line up contracts has resulted in many attractive price tenders, both to utilities and industrials. Spot gas slack is the weakest member of the slack family. April contracts on pool 1 coal at Hampton Roads average $1.75 net, f.o.b. mines.



Sales of domestic coals in the Birmingham market last week were largely on contract orders. At the present rate of buying the bulk of the medium and high-grade coals will be booked up through the spring and summer by the end of May. On the industrial side there has been no material decline in the demand for high-grade mine-run and washed coals. All large consumers are taking their contract quotas. Output approximates 400,000 tons per week.

New York Anthracite Demand Easier

Domestic anthracite coals were easier in the New York market last week. Independent shippers welcomed the week-end suspensions in the hope that the price situation—from their standpoint—would be improved. Current quotations cover a wide range, with the average minimum around $9.50. Stove and nut lead in demand. Pea is still scarce, much of the output being consumed in the region. There was no change in company prices on April 1, but it is reported that at least one large producer is planning a cut of 50c. on No. 1 buckwheat.

Retail dealers, however, readjusted prices to the consumer. The new schedule generally prevailing in Manhattan is as follows: Broken, $14.25; egg and nut, $14.50; stove, $14.75; pea, $10.75; No. 1 buckwheat, $6.40; rice, $5.90; barley, $5.40; bituminous, $7.25. One company announced that Welsh anthracite would be retailed at $2 per ton above the price on the Pennsylvania product.

Independent shippers at Philadelphia signalized the new coal year with reductions which brought their average quotations down to 50c. above the company range. Retail dealers, for the most part basing their prices on company coal figures, which showed no change, established the following basis: Egg and nut, $15.75; stove, $16; pea, $12; buckwheat, $8, curb delivery.

Buckwheat Demand Broadening

There is a growing demand for buckwheat as a domestic fuel and more dealers are offering this size to the household consumer. In many cases buckwheat is replacing pea, which is not being shipped in quantities equal to the demand. Summer fill-ups have started and that prevents real weakness in any domestic size. The steam trade is slow. There is considerable shading of independent prices, particularly on buckwheat.

Baltimore retailers have not deviated from their policy of placing the bulk of their orders with company shippers. With milder weather, they are hopeful that high premiums on independent tonnage will disappear. Most of the yards have some stock of each domestic size and there has been no great difficulty in supplying current needs of consumers.

Spot trade in the Connellsville coke region last week was extremely dull. There has been little call for spot furnace coke, which is quoted at $3.25, and no surplus seeking a market. Spot foundry coke is $4.50@$5, with buying light and production closely regulated. Production during the week ended March 27, according to the Connellsville *Courier* was 187,630 tons. Furnace ovens produced 104,800 tons, or 200 tons more than during the preceding week; merchant ovens produced 82,830 tons, a decrease of 2,580 tons.

New Title for Safety Director

Because Bureau of Mines officials felt that the title "Director of Safety Service" was a misnomer, a change in designation was made this week, and henceforth the official in charge of this branch of the work will be known as "Chief Engineer, Safety Service."

Total Coke Output Falls in February; Daily Rate Gains

Output of byproduct coke during February, according to the Bureau of Mines, totaled 3,500,000 net tons, a decrease of 304,000 tons, or 8 per cent, compared with the output in January, although the daily rate increased to 125,006 tons, a gain of 2,295 tons, or 1.9 per cent. The coke plants operated at about 94 per cent of capacity. There have been 80 byproduct plants in existence since November, of which 74 are active.

Total production of beehive coke in February, estimated at 1,402,000 net tons, shows a gain of 21,000 tons, or 1.5 per cent, compared with that in January.

Production of all coke amounted to 4,902,000 tons, the byproduct plants contributing 71 per cent (73 per cent in January), and the beehive plants the remainder.

Monthly Output of Byproduct and Beehive Coke in the United States(a)

(In Thousands of Net Tons)

	Byproduct Coke	Beehive Coke	Total
1923 Monthly average	3,133	1,615	4,748
1924 Monthly average	2,833	806	3,639
1925 Monthly average	3,332	893	4,225
November, 1925	3,557	1,213	4,770
December, 1925	3,760	1,307	5,067

February, 1926	3,500	1,402	4,902

a Excludes screenings and breeze.

Estimated Monthly Consumption of Coal in the Manufacture of Coke

(In Thousands of Net Tons)

	Consumed in byproduct Ovens	Consumed in beehive Ovens	Total Coal consumed
1923 Monthly average	4,523	2,507	7,030
1924 Monthly average	4,060	1,272	5,332
1925 Monthly average	4,787	1,371	6,158
Novembr, 1925	5,111	1,913	7,024
December, 1925	5,403	2,062	7,465
January, 1926	5,466	2,178	7,644
February, 1926	5,029	2,212	7,241

Of the total output of byproduct coke during February, 2,859,000 tons, or 81.7 per cent, was made in plants associated with iron furnaces, and 641,000 tons, or 18.3 per cent, was made at merchant or other plants.

Bethlehem's Output of Coal And Coke Climbs

The 21st annual report of the Bethlehem Steel Corporation shows that for the year ended Dec. 31, 1925, the mines of that concern produced 6,331,246 gross tons of coal, as compared with 5,586,200 gross tons in 1924, and that 4,446,472 gross tons of coke was manufactured as compared with 3,446,728 tons in the previous twelve months.

The coal properties of the Corporation are located in the vicinity of Ellsworth, Heilwood, Johnstown, Marianna, Slickville and Wehrum, Pensylvania; Fairmont and Morgantown, West Virginia. The properties are estimated to contain 840,395,000 tons of coal and are equipped to produce 10,000,000 tons per annum. The Corporation also owns 1,704 byproduct coke ovens.

Erie Coal Segregation Not Imminent, Is Report

No plan of segregation of the Erie R.R. coal interests is imminent or under consideration, according to a report this week. The subject of segregation of the Erie's holdings of the stock of the Pennsylvania Coal Co., it is understood, was not considered at the March 26 meeting of the railroad's directors. It has been pointed out that in addition to the fact that the Pennsylvania Coal Co.'s shares are pledged specifically as collateral security for a bond mortgage loan made to the Erie R.R., there is no interlocking of the two companies. The directors, officers and management of the Pennsylvania Coal Co. are all, it is stated, separate and distinct from those of the railroad company.

Federal Fuel Yard Asks Bids

Chief Engineer Pope, Government Fuel Yards, sent out proposals March 30 for bids on anthracite and bituminous coal for the fiscal year commencing July 1. Bids are to be opened at 10 a.m. May 12 at the office of Mr. Pope, in Washington, for 12,450 tons of anthracite and 244,500 tons of bituminous.

(a) Note that the coal statistics of the Geological Survey for a given year include only the mines that had an output in that year. Many mines that operated in 1923 produced no coal in 1924; moreover, many of the mines that did produce in 1924 worked for a short time only. The number of active mines of commercial size in Missouri was 149 in 1923 and 127 in 1924.

(b) Includes also loaders and shotfirers. (c) Johnson, Ralls and Vernon. Statistics issued by U. S. Bureau of Mines.

Foreign Market And Export News

Welsh Trade Picks Up As Boats Wait to Berth; Tyne Market Marks Time

London, England, March 23.—The Welsh steam coal trade was much more active this week, largely owing to the better arrival of shipping, and for the first time in two months ships have been waiting to berth. This factor, combined with better loading facilities at the docks, has enabled operators to clear large stocks of coal and also to put their pits into more regular operation.

There are indications that foreign buyers, in anticipation of some unusual event on May 1, are laying in heavy stocks of coal as a precautionary measure. In addition to this there is the usual accelerated activity preceding the Easter holidays. These influences have served to stiffen prices, though as yet there is little sign of operators covering the gap of around 3s. 3d. between selling prices and cost of production.

On account of this gap there is a feeling in Wales that unless the subsidy is continued or some other relief measure is introduced, many of the pits must close down. The report of the Coal Commission has been received with mixed feelings, though the general attitude is hostile.

The situation at Newcastle has fallen entirely under the influence of the Coal Commission report, and until it is known what is going to happen in the industry there is little inclination to do business of any sort. The business for March is quite good and the exports are satisfactory, but there is very little forward business on foot. The only contract worth reporting is one of 40,000 tons of Durham gas coals for the Genoa gasworks, to be delivered from May to August.

Output by British collieries during the week ended March 20, according to a special cable to *Coal Age*, totaled 5,370,000 gross tons, compared with 5,285,000 tons the preceding week.

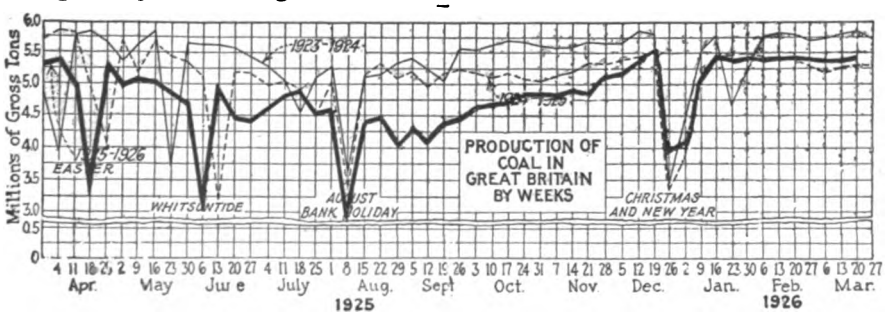
Belgian Conditions Unchanged

The Belgian market jogs on without startling change, reports Brussels under date of March 25. Domestic coals are sluggish and industrial grades maintain their position with difficulty. Foreign competition being to a certain extent eliminated by the rise of sterling, this may react favorably on the Belgian coal market, especially in the Borinage.

Coking smalls are moving at 85@87 fr. and in spite of their high prices they are in great request. Lean duffs, and especially smalls 0x8 for cement works, are scarce at 42@45 fr. per ton. In semi-bituminous, large sizes, such as 10x20 for boilers, are neglected. Small sizes, on the other hand (5x10, 6x8 and 10x15) are active, but the demand for bituminous peas and beans is restricted. The official price on lean smalls has been fixed at 70 fr.

Belgium received 269,424 tons of reparation fuels in February against 312,632 tons in January.

French Spot Demand Featureless; Agree on Summer Prices



Paris, France, March 25.—There was little change in the French coal markets the past week. Domestic demand is restricted by the weather and the merchants' yards are well stocked. Nevertheless, the mines find a fairly ready sale for their output because Belgian prices are up 6@10 fr. and British quotations are too high to appeal to French buyers. As a result there is a better movement of semi-bituminous and lean nuts. Industrial buying is well sustained.

At a meeting in Paris ten days ago French and Belgian producers reached an agreement on domestic prices in the Paris district for the summer season. The base prices on French coals at the mines range from 162 to 210 fr. on semi-bituminous, 165 to 210 fr. on quarter bituminous, 160 to 210 fr. on lean coals and 180 to 230 fr. on anthracite. A discount of 10 fr. is given for April-May orders, 6 fr. on June-July business and 4 fr. on August orders. The base price on ovoids is 136 fr. and the discounts are 15, 10 and 5 fr., respectively.

Base prices on Belgian coals range from 177 to 230 fr. on semi-bituminous 175 to 230 fr. on quarter bituminous, 175 to 235 fr. on lean and 175 to 255 fr. on anthracite. Discounts are 12 fr. on water and 10 fr. on rail shipments in April and May, 6 fr. on June-July orders and 4 fr. for August. The base price on ovoids is 116 fr. and the discounts are the same as on French patent fuel. Belgian prices are in French francs, and will be subject to correction only when exchange rates have dropped to 80 Belgian to 100 French francs.

In addition to the summer discounts, there also are discounts on large orders. These are 0.5 fr. for lots of 500 to 999 tons; 1 fr. for orders of 1,000 to 1,499 tons and 1.5 fr. for orders exceeding 1,500 tons.

French production, exclusive of the Saar, during January was as follows: Coal, 4,160,862 metric tons; lignite, 90,353 tons; coke, 293,813 tons; patent fuel, 360,319 tons. The Saar turned out 1,112,658 tons of coal and 22,249 tons of coke.

Coming Meetings

Canadian Retail Coal Association. Annual convention, King Edward Hotel, Toronto, Ont., Can., April 14 and 15. Secretary, B. A. Caspell, Brantford, Can.

American Welding Society. Annual convention, 29 West 39th St., New York City, April 21-23. Secretary, M. M. Kelly, 29 West 39th St., New York City.

California Retail Fuel Dealers Association. Thirteenth annual convention at Del Monte, Calif., April 22-24. Secretary, J. B. Muir, Oakland, Calif.

Mine Inspectors' Institute of America. Annual meeting, Seventh Avenue Hotel, Pittsburgh, Pa., May 11-13. Secretary, G. B. Butterfield, Hartford, Conn.

International Railway Fuel Association. Eighteenth annual convention, Hotel Sherman, Chicago, Ill., May 11-14. Secretary, J. B. Hutchinson, Omaha, Neb.

National Retail Coal Merchants' Association. Ninth annual convention, New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

Electric Power Club. Convention at The Homestead, Hot Springs, Va., May 24-27. Secretary, S. N. Clarkson, B. F. Keith Bldg., Cleveland, Ohio.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, in conjunction with the annual meeting of practical operating officials. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. The fourteenth congress will be held in Madrid, Spain, commencing May 24, 1926. From May 5 to 22 excursions of interest to the visiting delegates will be arranged. Information concerning the congress can be obtained from the secretary of the organizing committee, Enrique Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

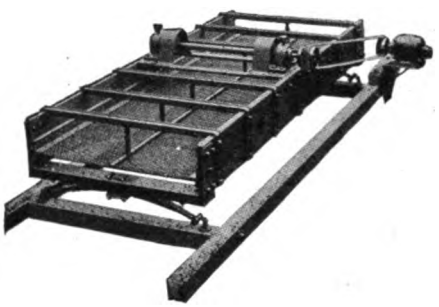
Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.



American Society for Testing Materials. Convention at Haddon Hall, Atlantic City, N. J., June 21-25. Secretary, C. L. Warwick, 1315 Spruce St., Philadelphia, Pa.

New Equipment

Light Weight and Strength Distinguish This Screen

A vibrating screen, new to the mining field, has been put on the market by the Universal Vibrating Screen Co., of Racine, Wis. This screen, the makers claim, handles efficiently either wet or dry materials, 1¼-in. in size to 30-mesh. The Type C screen is shown in the accompanying illustration.

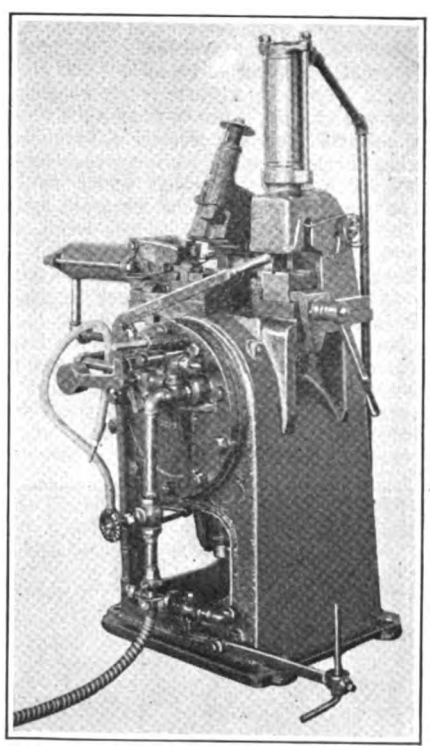
In construction the screen is strong, being built of steel and oak. The steel side members receive all the wear from material passing over the screens. The upper frame is supported on special springs at centrally located points at the end of the frame. The makers

A Slight Motion but Sudden Makes Screening Easy

A shaft with two off-center weights rotated at 1,800 r.p.m. gives this screen a vibration that makes fine material roll on its way rapidly to the holes in the wire cloth.

claim that this two-point suspension is essential, as it tends to equalize the load or feed to screen, so as to keep the vibratory action at an equal intensity over the entire screening area even though the material is fed unevenly at the upper end of screen. To eliminate all possibility of dead areas the distance between the screen cloth supports is made comparatively short. Additional vibration is transmitted directly to the center of cloth where it is most needed.

The vibrating mechanism is simple. It consists of a shaft on which two off-center weights are mounted, and which is rotated at a speed of 1,800 r.p.m. Specially designed dust-proof housings are used for the self-aligning ball bearings, and it is claimed by the makers, all parts of the assembly are 100 per cent oversize, to insure continuous and trouble-proof service. The power requirement is a little over ¾ hp.



The Type C screen, using screen cloth 3 ft. wide and 8 ft. long, is said to meet nearly all requirements. Special sizes are built, however, among which is the Type F vibrator, using either perforated plate or heavy wire cloth, 4 ft. 8 in. wide by 6 ft. long. This latter type has been designed especially for handling large quantities of fairly dry material, and is essentially a heavy-duty screen. The vibrating mechanism is mounted directly beneath the screening surface, where it is thoroughly protected by steel plates from wear of material passing through the screen, and there are no obstructions to the flow of material.

These screens can be driven from shafting in the plant or by individual motors. The weight of the Type C screen, without motor, is 735 lb., and of the special Type F is 1,050 lb.

Will Sharpen All Sizes of Hammer Drills

Rock-drill users sometimes require a drill sharpener that is sufficiently light and compact to be easily moved and that is able to make ordinary hammer-drill steel bits and shanks effectively. Among these are strip pits and coal mines, also rock tunnels in connection with the latter. To meet this need the Sullivan Machinery Co., Chicago, Ill., has developed the so-called Type C all-hammer sharpener, which weighs only 1,000 lb. and occupies a floor space of only 3½ x 2½ ft. It may be mounted on timbers or skids and is easily moved when necessary. It is capable of making and resharpening any ordinary hammer-drill steel up to 2½-in. gage, and of forging collar or lug shanks. All operations, both upsetting under the dollies and swaging or dressing out the wings, under the vertical dies, are performed by hammer action, with powerful, fast-hitting, horizontal and vertical air hammers.

The sharpener, as shown by the illustration, consists of a substantial,

Portable Type of Sharpener

Though light it has a bit-gaging device similar to that on larger machines. This accurately gages the wings and enables a true double taper to be given the bit.

Digitized by Google

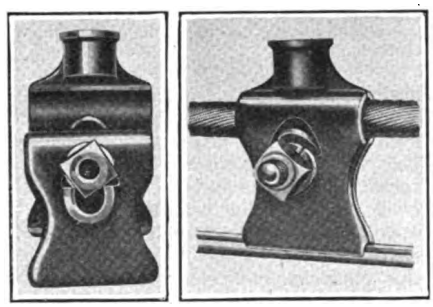
cast-steel frame on a pedestal, on which are mounted the horizontal hammer for upsetting and the vertical hammer for swaging. In the base is contained the vise or clamp for holding the steel while being dollied and the diaphragm and toggle which furnish the power to operate the clamp. The horizontal and vertical hammers are similar in type and action to those standard on older Sullivan sharpeners. Heavy springs are used to retract the dolly and to lift the upper vertical die from the steel when air is shut off. Dollying is controlled by a hand lever and swaging by a foot lever, the two interlocking, so that the vertical hammer cannot strike while the vise is closed. An adjustable bit-gaging device is provided similar to that used on the older machines, for accurately gaging the wings and for enabling a true double taper to be given the bit. This gage is mounted on a substantial hinge, which permits it to be raised out of the way when not in use, affording a clear view of all the working parts.

Small Machine Handles Much Dust

In the accompanying illustration may be seen the dust spreading machine recently developed and placed on the market by the Chas. C. Steward Machine Co., Inc., of Birmingham, Ala. This shows the machine fully guarded, and equipped with electric motor. It may be fitted with a gasoline engine with equal facility and in fact when thus equipped has been found better fitted for rock dusting the main slopes of mines, inasmuch as these passages are seldom fitted with trolley wire or other conductors from which electric current may be drawn.

This machine weighs less than 1 ton when fully equipped. The frame is all steel, electrically welded. The hopper is small, holding only about 200 lb. of dust. This is agitated by means of three disks on a shaft passing through the bottom of the hopper. This shaft also carries a small pinion which drives a gear on a valve shaft which rotates the dust valve at the desired speed. This delivers the dust to the wind pipe and also seals the air blast from the dust in the hopper.

Although this dust blower is small, it is capable of "shooting" 3,000 lb. of dust per hour without any "blow back" through the hopper. When equipped with a gasoline engine the exhaust is turned into the dust pipe and is blown off with the dust. The nozzle of the machine may be turned by a lever attached to it. An elbow which will slip over this nozzle may be employed to divert the flow of dust at right angles to the pipe if desired.



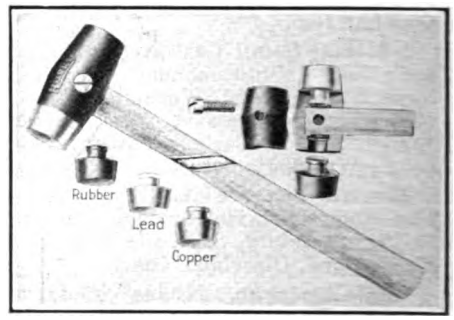
Machines of this kind have been built as low as 30 in. above the rail. They have also been used in mines where the coal ran 14 ft. in thickness, the results in both cases being excellent. In most instances where this machine is used within the mine a car filled with sacks of dust goes along with it. This serves as a source of supply, sacks of dust being taken from it as desired.

Some operators, however, are using this machine without the supply car. In such a case the dust is distributed along the entry to be treated during the day's run. The last in-going trip takes the machine into the mine and leaves it for the dust crew. This consists of two men who operate and feed the machine and also push it along the entry. This is easy as the unit is light and need only be moved a few feet at a time. The sacks of dust are picked up along the entry as they are reached. By this means the labor cost of rock dusting is small and the operation in nowise interferes with the normal working of the mine.

The builder states that these machines are being sold, fully equipped with gasoline engine, f.o.b. Birmingham, for $545 each.

Clamp Holding Trolley Wire Supports and Taps Feeder

Demand for some practical device to simplify and cut erection costs in overhead construction has led to the development of a combination feeder-trolley clamp, announced by the Ohio Brass Co., of Mansfield, Ohio. This clamp, arranged for attachment to a standard insulated hanger, supports in a single unit assembly, both the feeder wire and the trolley, the two being firmly gripped at a predetermined distance of separation, by the tightening of one center bolt.



Supports Both Feeder and Trolley Wire

This clamp supports and grips both the feeder cable and the trolley wire in a mine heading. These two conductors are thus held at a predetermined distance of separation and individual supports for each are unnecessary. Lip acts as a cable sling while feeder line is being slung.

It is estimated that the use of this combination cuts almost in half the material and the work required for the separate installation of these conductors. The clamps themselves act as feeder taps, thus eliminating all necessity for the latter. Flecto iron, a new malleable metal is used in the manufacture of this combination clamp, making, it is said, a product that is entirely free from brittleness.

Hammer Fitted with Several Interchangeable Tips

The patent and manufacturing rights to the interchangeable soft-tip hammer illustrated have been acquired by the Husky Wrench Co., 928 Sixteenth Ave., Milwaukee, Wis. The hammer is made in 2- and 4-lb. sizes.

Will Strike Cushioned Blow That Will Do No Injury

Hammer has tips of copper lead, rubber or other soft material

Hammers are supplied with interchangeable soft tips of copper, lead, rubber or other material as desired. They are marketed in sets with two of each kind of tip. The tips can be replaced after loosening the fillister-head screw and separating the housings.

New Companies

The F. P. Weaver Coal Co., Ltd., of Montreal, Que., has been incorporated to carry on the business of mining and selling coal and other fuels wholesale and retail, with a capital stock of $500,000. The incorporators are John Antliff Kent, Stewart Gordon Robertson, Hugh Canniff Willson, and others, of Toronto, Ont.

The G. & G. Coal Co., Orville, Ohio, has been incorporated with a capital of $20,000 to operate mines and deal in coal at wholesale. The incorporators are Ralph Marie, Carl Graber, Benjamin Graber, Willis Horn and H. M. Garver.

The H. D. Grace Coal Co., Coshocton, Ohio, has been incorporated with a capital of $10,000 to mine and sell coal in the Coshocton field. Incorporators are Hugh D. Grace, Edward A. Crawford, Robert H. Daugherty, Karl K. Sherrettes and Elise C. Hosick.

Electric Duster

This dust spreader is small, weighing less than a ton and is well adapted to treating mine passages where current from a trolley wire is available.

COAL AGE

The World's Accepted Authority on Coal Mining

McGraw-Hill Publishing Company, Inc. **April 15, 1926** Price Twenty Cents per Copy

West Virginia's Biggest New Pocahontas Plant

THIS new plant for Mine 261 of the Consolidation Coal Company at Juno, W. Va., is the largest and most modern operation in the Pocahontas field.

Designed for a capacity of 6,000 tons daily, it introduces the principles of large-unit capacity and higher efficiency in preparation which mean so much in successful mine operation today.

The complete plant is a product of Allen & Garcia designing and construction service. It typifies the standards and facilities of our organization which are available to coal operators *anywhere*.

A. & G. Service is built upon years of specialized experience with every phase of coal mine development and operation. Whether you are interested in developing a complete new mine, or in modernizing or merging existing properties, A. & G. Service can provide you either complete or partial service—as desired—from initial appraisal to the design, construction and equipping of every surface and underground requirement.

Consultations at your convenience.

Easy to charge— easy on charges

The mine electrician who has Exide-Ironclad Batteries in his charging barn is a lucky fellow. Exide-Ironclads charge easily and waste hardly any current.

How many tons go over the tipple or breaker in a day's time depends in large part upon the efficiency of the haulage system. When the haulage motors are driven by Exide-Ironclad Batteries the coal moves along from face to railroad car smoothly and rapidly.

Back to the charging barn at the end of the shift, yet these motors still have plenty of pep and speed left at the end of a hard day, for they are equipped with Exide-Ironclad Batteries. The voltage of this battery—and hence its pep, remains high right down to the end of the discharge period.

When miners have to wait for empties it reduces their pay and lessens your profits. At mines where the haulage motors are equipped with Exide-Ironclad Batteries, however, the empties are hustled in and the loads brought right out without delay—thanks to the never-failing speed of this battery.

Grades like this are easy for a motor, even with a heavy trip, when that motor is powered by an Exide-Ironclad Battery.

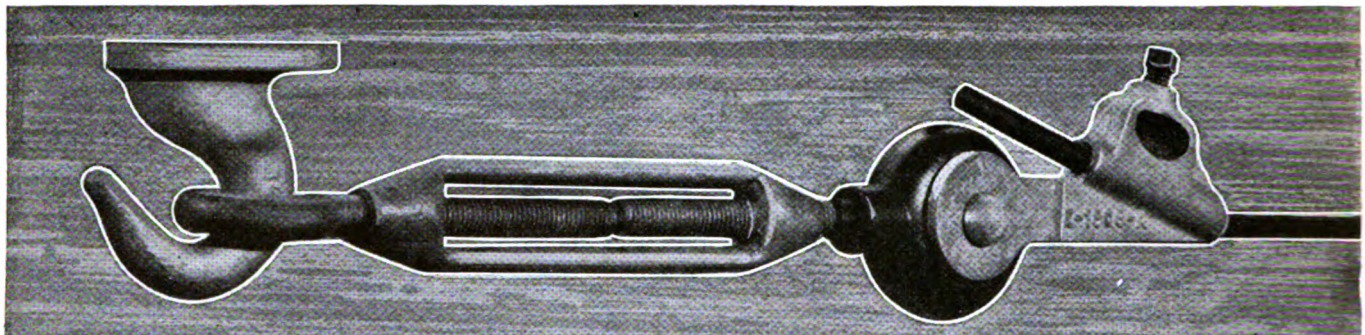
Your Under-the-Hill Problems



Coal Age has been giving diligent attention to problems close to the working face. In "Underground Management" every week will be found reference to the problems of mining's nether world. Next week we print an interesting discussion by E. O'Toole on roof action. He shows why it is so important that the roof should break clear up to the surface. His comparison of roof to a girder, though not new, brings some of the problems of roof control appreciably nearer solution. This week in the underground department is given the discussion at Pittsburgh, Pa., on turret cutting and vertical shearing. The report is well worthy of perusal.

Our Readers' Views

The Discussion page also is lively. What our friends think of the issues discussed in the editorials and articles makes interesting reading. You will remember the Huber paper on mine fans. Next week we run a critique of that article by someone who believes that our modern practice is not at fault and does not need revision in the direction of backward-running blade fans. This week, Graham Bright gives the hoist at Harworth the "once over" and after taking exception to a dozen features he remarks, in effect, that if it weren't for these it would be all right.

Temporary— or Permanent

A workmanlike job with the new O-B Dead-end Assembly

Eliminating Brittle Castings

Mine Electricians use thousands of galvanized malleable fittings for electrical overhead work. However few appreciate that the hot-dip galvanizing process takes the life out of one in five ordinary malleable castings—makes them brittle.

O-B Flecto Iron was developed to eliminate this possible brittleness. Flecto iron castings are never brittle. Hot-dip galvanizing does not decrease its ductility. This has been definitely proved by the past two years during which time all O-B galvanized malleable fittings have been made of Flecto Iron.

(B) FLECTO IRON

Too frequently there's a tendency to hang up a dead end 'most any old way. Perhaps it's only a temporary job! But plans may be changed and the extension postponed for months. Meanwhile trouble develops as the indifferent dead-end works loose.

This New O-B Dead-end Device permits a quickly-installed, neat and workmanlike job. No damage is done to the wire. There's no waste of valuable copper involved. If it's a temporary end, the device is easily removed and ready for use again at the new dead end. If permanent, it becomes a rugged, substantial and enduring terminal through which no wire slippage will occur. The turnbuckle affords a ready means of adjusting the tension.

The heavy hook is tapped to screw onto the standard expansion bolt. The powerful turnbuckle is carefully insulated from the wire clasp by means of a Dirigo molded insulator. The wire clasp itself is the new O-B cam-grip type, which merely tension tightens. The entire assembly is a perfectly simple, common-sense equipment, designed by men who are intimately acquainted with the requirements of the service.

Safety in Ventilation

ONE IMPORTANT feature in ventilation is illustrated by the Minister Stein explosion. A fall of rock in an entry entirely blocked the air. A mine amply supplied with air suddenly became deprived of all circulation. Obviously, the mine would have been safer had there been two returns. In that mine it would have been necessary to drive the headings in the rock, for they were what our metal-mining friends would call crosscuts running as they did, from the shaft to the deposit, but where there are drift mines and shafts that intersect the bed worked, two intakes and two returns can usually be constructed with relative ease. If one falls in, the other is available. Many mines have this advantage already and it is often quite helpful in recovery work. An entry of large size is not as safe as two entries of an equal cross section, because the larger the entry the more likely it is to cave and because with two entries both will not cave at the same time.

Robert M. Lambie

THE BITUMINOUS industry is proud of Chief Inspector Lambie, of the West Virginia Department of Mines. He has shown great courage and leadership in the rescue and restoration operations following mine explosions and fires, and an untiring zeal in the promotion of safety. From his close associates come several stories as to his intrepidity in the presence of great danger.

The tales of his tireless efforts during the Benwood and Barrackville explosions are now history. Last fall he acceded to a request from the state of Tennessee to lead in a search for eight bodies in a fire zone which had been sealed for three months after an explosion in the Rockwood mine. He directed and led the rescue teams during the recent Jamison explosion. Soon after, he was called to the southern part of West Virginia to fight a fire in the Paint Creek mine. During this undertaking he was exposed to carbon monoxide and as a result was for a while confined to a hospital.

In the meantime he was asked to take part in the recovery work at the Horning mine in Pennsylvania. He telephoned his willingness to do his bit in this work, but soon after suffered a breakdown which compelled him to rest. Then came the Eccles explosion and his was the responsibility for the safety of the rescuers and of those who were rescued. Though he was then in the early stages of convalescence from carbon-monoxide poisoning and had been advised to rest, he took upon himself the task of leading rescue teams to a barricade in the Eccles mine where ten men were found alive. On reaching this barricade he collapsed, and after being administered oxygen for an hour, he was carried unconscious from the mine. Now he is spending most of his time in the open air while slowly regaining his former good health.

The industry appreciates his efforts, and West Virginia is proud of him, as one of the greatest fighters of flame, smoke and gas, and as an exponent of the safety movement which under his leadership is making much progress. All join in trusting that hereafter he will curb his one dangerous tendency, to overtax his system in the pursuit of duty.

Broken Ropes

RECENTLY an electric elevator in a comparatively new hotel fell from the third floor to the basement, injuring a number of persons. An investigating committee reported that the breaks occurred in or near the sockets and that tensile tests on pieces of the broken ropes showed each to have sufficient strength to hold double the load on the elevator when it fell.

A few years ago at a certain shaft mine it became necessary to bring a 10-ton locomotive to the surface. The age of the hoisting rope was not known, but an inspection indicated little wear on the outside strands and not a broken wire in sight. The locomotive was hoisted, but a few days later the rope broke with the regular 3-ton load. The break occurred in that part of the rope which was located at the head sheave, whenever the cage was at the bottom of the shaft.

In a handbook published by one of the wire-rope manufacturers it is recommended that resocketing be done every six months, or under certain conditions, every three months. A portion of the rope should be cut off so as to get rid of any crystallized or corroded portion at the socket, and to change the rope position with regard to the headsheave when the cage is at the bottom. Other rope manufacturers advocate resocketing, according to service, at definite intervals such as once a year.

Generally speaking, mine hoisting ropes do not get the attention that they need. Inspections are superficial, records not complete, and resocketing neglected. Replacing the rope with a new one at certain intervals regardless of condition is good practice. Because of the expense, however, some users are tempted to keep the rope in service longer than the stated time and yet they do not resocket it because they expect to renew the rope in a short while. Mine ropes should be resocketed every three, six, nine or twelve months, according to service, and should be renewed at regular intervals regardless of the outside appearance of the rope. A counter should be attached to the hoist indicator to total the trips made by the cage during the life of the rope. This information would be a good guide to indicate when the rope should be resocketed and renewed.

More Than Dividends

STOCKHOLDERS of the Coal River Collieries Co., the operation financed by members of the Brotherhood of Locomotive Engineers and their friends, held their annual meeting last week. Following the precedent established a year ago, the session was preceded by an inspection trip over the company's properties near Huntington, W. Va. About two hundred of the worker-capitalists made up the inspection party. These men and women, exhibiting a pardonable pride in their partnership, acquired first-hand information upon working conditions by actual contact with the miners.

That the company in which they have invested a part of their surplus has never paid a dividend appeared to cause no great concern. They have been learning things about capital and capital's share in the products of labor in a way no polemic could teach. They are discovering, too, the unreality of the line which divides capital from labor. Such lessons are more valuable than dividends to future industrial peace and prosperity.

Unbalancing the Power Demand

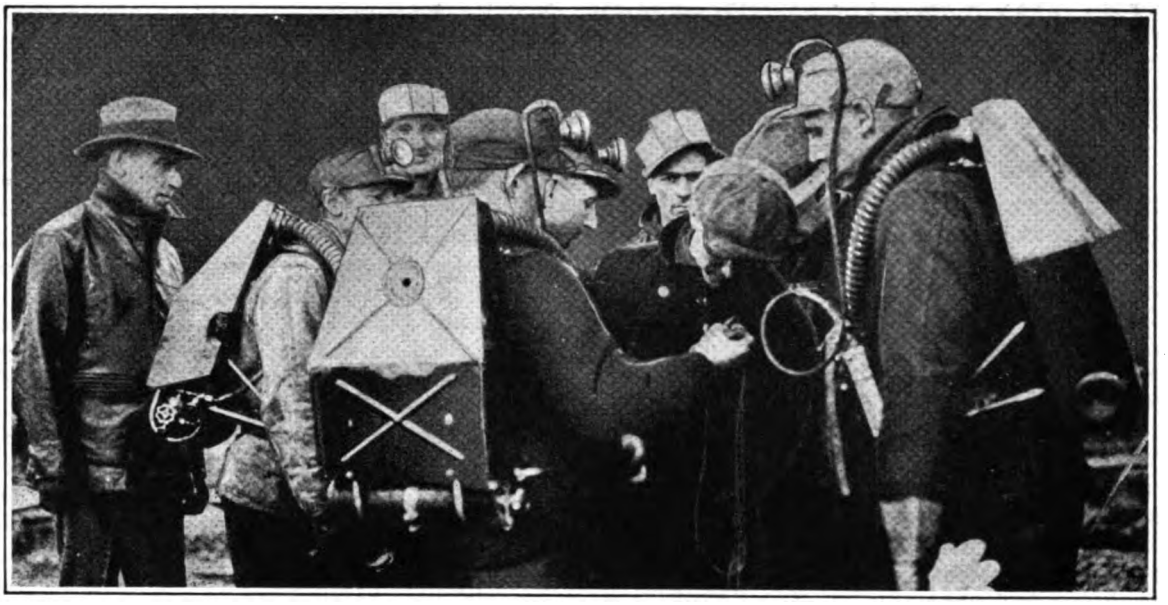
IN THESE days of severe competition for markets it behooves the coal mines to reduce their costs of production by all means possible. Although the expense entailed for power is usually one of the smallest components making up the total cost per ton f.o.b. yet where this can be lowered it is well worth while. The margin on which coal is produced is usually so small that one or two cents shaved from the cost may mean all the difference between a profit and no profit or between breaking even and sustaining a loss.

One of the ways of cheapening the cost of power, regardless of whether it be purchased or generated is to use it steadily at as nearly a uniform rate as possible throughout the entire 24-hr. day. The greatest efficiency is attained when both the power-generating and power-consuming equipment is operated to approximate capacity all the time. Unfortunately this condition can be maintained by but few industrial enterprises, and it becomes a problem as to how closely it may be approximated at any one mine. In many cases it is possible to so juggle the various power-consuming operations as to render the total load or demand approximately uniform.

The chief power consuming operations about the mines include: Hoisting, haulage, cutting, ventilation, pumping, preparation, shops, lighting and battery charging. In any particular mine one or more of these operations may be totally absent while in many if not even most cases two or more must be performed simultaneously. Thus preparation is the logical complement of hoisting, which in turn, must be prosecuted concurrently with haulage. On the other hand lighting usually attains its peak at a time when hoisting is at its minimum; the same is true also of battery charging.

It becomes possible therefore in many instances to balance the various loads one against the other with the result that fair uniformity in power consumption is attained throughout the entire day. Thus the day load might logically comprise haulage, hoisting, preparation, ventilation and shops while the night load would be made up of cutting, ventilation, pumping, lighting and battery charging. How nearly a full load factor may be maintained throughout the entire day will depend on the relative sizes of these various loads especially on the magnitude of the dewatering problem, and the flexibility with which it can be handled. Some mines afflicted with large quantities of water have such larger pumping installations that the load factor is maintained at practically 100 per cent at all times.

A disturbing influence that sometimes makes itself manifest in any scheme aiming at the preservation of unity load factor is the attitude of mine labor. Thus in the southern Illinois field the union will not countenance operation of coal cutters or mechanical loaders at night except on entry driving or other development work. Inasmuch as the pumping or dewatering load in this region is comparatively inconsequential, this throws all of the bigger operations, so far as power consumption is concerned into the day shift thus rendering its load vastly greater than that carried during the night, utterly destroying all semblance of balance between the two periods. This naturally increases the cost per ton of mine output in a direct proportion.



Where the problem of mine drainage is as light as it is in southern Illinois it would probably be difficult if not impossible to exactly balance the day and night power demands and thus obtain the much-desired 100-per cent load factor throughout the entire 24-hr. period. A transfer of the comparatively large power consumption for cutting from the day to the night shift, however, would do much to equalize these two loads especially where hoisting is done by steam as is the case at many of the mines in this region. It would thus tend to lower the cost of coal and permit the Illinois product to compete on more nearly equal terms with that from other fields.

And although it is quite true that the power bill represented by a ton of coal on car at the mine is one of the lesser components in its cost, it is nevertheless of appreciable and measurable magnitude. It could be reduced by careful balancing of loads. This would be beneficial to miner and operator alike as it is to the manifest interest of each to meet the fierce competition of other fields. By arbitrarily refusing to permit a balancing of the power demands of the day and night shifts therefore, the miners' union, figuratively if not literally, snaps the hand that feeds it.

To Make or to Mend

ECONOMY is not assured by having inadequate forces at the mines, in management, repair or accident prevention. With the force cut down too low the work is always behind. Men are busy correcting mistakes that should have been avoided, repairing wrecked equipment that should not have been damaged, explaining the shipment of inferior coal that never should have been loaded, accounting for excessive slack that should not have been produced. The forces around the mine under such a régime becomes defensive, not aggressive; they have to content themselves with the vain hope that nothing will happen, for hope takes less time and less money than prevision and prevention. Figuratively the management arrives breathless at every problem and cannot do it the justice it deserves. System goes to the wall; records are not kept; nothing can be found, and it is not long before a smoothly working organization breaks entirely down.

Procedure at Horning Mine Disaster Exemplifies Strategy to Be Adopted After Explosions

Attack on Fire Area Planned in Detail Prior to Recovery and Charge of Operations Entrusted to Leaders of the Three Shifts by Which the Work Was Conducted

By Alphonse F. Brosky
Assistant Editor, *Coal Age*
Pittsburgh, Pa.

MUCH ATTENTION has been given to the explosion in the Horning mine of the Pittsburgh Terminal Coal Corporation, among other reasons, because of its location in the industrial and bituminous coal center of the country, within a few miles of Pittsburgh. Representatives of companies which produce the bigger portion of the tonnage in the Pittsburgh district either visited the mine or tendered their assistance during the restoration and recovery proceedings. The state departments of mines and the U. S. Bureau of Mines also were well represented.

Added interest has been taken in the information furnished by a few men who escaped the explosion by a matter of minutes after having been engaged with the victims for about six hours in fighting the mine fire, of which the explosion was an aftermath. Though exact knowledge of the explosion itself is not available, the survivors brought with them to daylight information which, with that derived otherwise, has been made the basis of many theories as to just what happened. The purpose of this article is to bring out the lessons which the explosion and the subsequent recovery of the mine teach. The officials of the Pittsburgh Terminal Coal Corporation assisted in the preparation of this article by placing at my disposal the records which were kept during the recovery and restoration work.

A brief review of the events prior to the explosion is appropriate at this point: An undercutting machine, equipped with an open starting box, ignited a feeder of gas in a clay vein at the face of the Sixteenth Right butt entry of Section 4, at about 10 a.m. on the day of the explosion. The flame spread to insulating material, oil and coal dust on and about the machine. Attempts to beat out the fire and later to quench it with water failed. It was decided then to seal off this entry at *A* and also at *B* in the Fifteenth Right butt entry which runs parallel to it. Work on the construction of these stoppings began about 2 p.m. They were in a fair way of completion when the explosion occurred, at about 4 p.m. A more detailed account of these earlier events appeared in *Coal Age* of March 18.

A map of the affected workings is shown in the accompanying figure. The territory inby of Eleventh and Twelfth Right butt entries was ventilated by a split carrying about 16,000 cu.ft. of air. These two butt entries served as intakes from an air shaft which is located in the adjoining No. 3 mine close to the boundary between it and the Horning, or No. 4, mine and at a point that is about 3,000 ft. from the face of the Sixteenth Right butt entry where the fire occurred and the explosion originated. The air of this split was

Digitized by Google

conducted through the Seventh and Eighth face entries and returned through the Ninth face entry to the overcast marked *C* where it crossed over the Eighth to the Seventh face entry which from this point on was used as a return and not as an intake. Accordingly, Sixteenth Right butt entry served as an intake and Fifteenth Right butt entry as a return.

STOPPINGS HAD BEEN BLOWN OUT

About three hours after the explosion a group of men entered the mine for the purpose of exploring as much of Section 4 as possible. They found that ventilation had been crippled because the stoppings between the face entries of this section, inby of Eleventh and Twelfth Right butt entries, has been torn out by the explosion. The roof of the overcast at *C* had been lifted.

The result was that all three of the face entries inby of this point were serving as intakes, whereas before the explosion the territory was ventilated by a split in which two entries served as intakes and one as a return, as described in the preceding paragraph. Afterwards it was learned that the intake air in these entries returned to the outside, through Fifteenth and Sixteenth Left butt entries in Section 4 at point *D*. Stoppings in the latter entries had been demolished by the explosion. At the time, however, no one knew exactly what path the air followed.

AFTER the second explosion, in which no one was injured, the rescue men bravely continued their work without intermission, deciding that at no time was it safer to undertake the sealing than immediately after the flame had burned part or all the methane from the fire area. Seals were not broken till oxygen content fell below 4.2 per cent; and before recovery commenced all material had been located at convenient points, doors having been made for use wherever it had been planned to erect them. Air was reversed in the forefront of the fire area so as to take the foul air away from points where rescue squads were working. Rock dust quenched flames wherever they were encountered.

The explorers went as far as the Thirteenth and Fourteenth Right butt entries from which much carbon monoxide was being discharged. Fresh air was temporarily shut off from these entries by the erection of canvas stoppings. While this work was being executed several men with gas masks began to explore the territory further inby.

At this time, about 11:55 a.m., a second explosion occurred. It was purely an ignition of gas, which manifested sufficient force to knock down the men. Those present state that the greater force was exhibited in the middle or Eighth South face entry, probably due to the fact that the pressure followed the line of least resistance, through a chute or shoofly running from the Fifteenth Right butt to this entry. Four distinct air movements, back and forth, were felt.

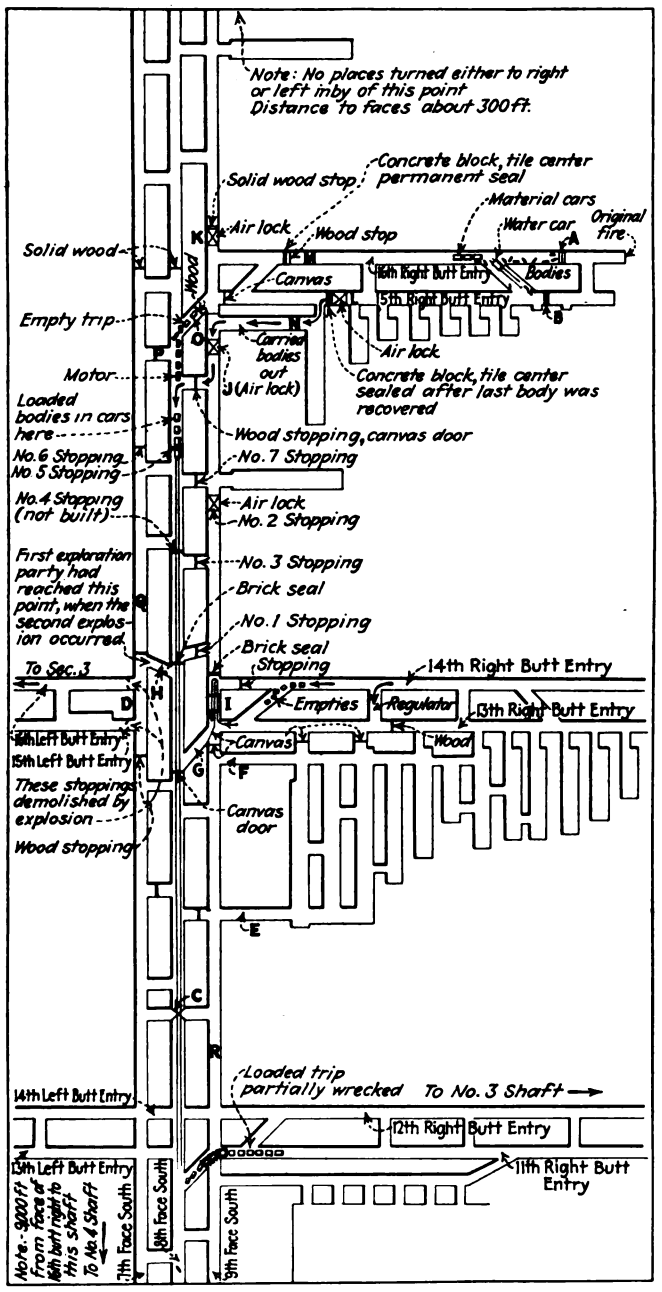
This explosion was of little consequence, no doubt, because the first explosion either ignited or carried with it much of the coal dust which had accumulated in its path. It is believed that a dearth of air at the face prevented a serious explosion. Much coked coal dust was lifted and carried by the expanding gases. No flame was observed and no heat or smoke became manifest to the men engaged in the exploration.

Though some of the men were slightly affected by carbon monoxide, none was injured. Still there were a few anxious moments for all of them which was relieved when it was found that no one had been injured to any material degree. Following this explosion the men retreated to fresh air in the Eleventh and Twelfth Right butt entries, which are, as has been stated, intakes from an auxiliary air shaft. Some of the men then decided to leave the mine.

The rest reasoned that the mine would be safer after an explosion had burned up at least some of the methane, for it might be several hours before the gas would find time to accumulate in dangerous quantity and diffuse to an explosive mixture. Therefore, preliminary steps were taken to seal the area. A brick stopping was erected in each of the three face entries inby of the Fourteenth Right and the Sixteenth Left butt entries, as indicated on the accompanying map. These were completed at about 7 p.m. on the day following the major explosion.

After these seals were erected the next logical step was to explore and restore ventilation in the workings off the Thirteenth and Fourteenth Right butt entries. As the rescue teams knew definitely that these workings were in the path followed by the flame and main force of the explosion, a careful inspection of this area was made, after which ventilation was restored by the erection of stoppings and line-brattices as shown on the map. These were so placed as to cause fresh air to enter this area at *E* and *F* and to return through the "chutes," or shooflies, *G* and *H* to the Fifteenth and Sixteenth Left butt entries and thus to the return airway in Section 3 of Horning mine. Incidentally, the latter entries served as the return for the air which was conducted by steps to the faces of the three face entries while the latter were being cleared of gas.

Having cleared the workings of the Thirteenth and Fourteenth Left butt entries the workers erected permanent stoppings which later would be needed and yet would not interfere with an already-determined plan for the restoration of ventilation. Included in this work was the erection of an air lock *I* on No. 9 face entry, between the Thirteenth and Fourteenth Right butt entries.



In the meantime a consultation was held, which was attended by representatives of the Pittsburgh Terminal Coal Corporation, the Pennsylvania Department of Mines, the U. S. Bureau of Mines, the Mine Safety Appliance Co., the H. C. Frick Coke Co., and the Bertha Consumers Co. At this consultation, over which J. J. Walsh, secretary of mines for the state of Pennsylvania presided, a plan of procedure detailing definite steps in the work of unsealing and recovery was drawn up and signed, covering, however, only the initial advances and not the complete undertaking.

These men agreed, first of all, that the seal on the Ninth face entry to Section 4 (or for that matter the seals on either of the other two face entries) should not

Digitized by Google

be disturbed until the oxygen content in the sealed area, as shown by samples analyzed by the U. S. Bureau of Mines, had fallen to approximately 4 per cent.

The steps to be taken as set forth in the agreement were as follows: Step 1—Canvas stoppings Nos. 1, 2 and 3 were to be erected at the points indicated on the map. Step 2—After these were completed fresh air was to be conducted to the crosscut in which No. 3 stopping was erected. Step 3—Matched lumber stop-

Map Illustrating Moves in Horning Rescue Work

No attempt was made to unseal the headings till the oxygen percentage fell below 4.2 per cent, but as it was feared that a little air might revive hot embers the approach was made with great caution and in accordance with a plan of campaign devised after much deliberation. In the diagram can be seen where the vicitms were found and where cars were derailed. Some men were killed at places so remote from the fire that the points where they lay do not appear in the map.

pings were to be built at points where canvas stoppings, Nos. 1, 2 and 3 had been located. Doors were to be placed in Stoppings Nos. 2 and 3, also a pipe in No. 2 stopping for the purpose of taking gas samples. An air lock was also to be provided, the door of No. 2 stopping being designated as one of its entrances.

Step 4—A matched-lumber stopping was to be constructed. This is indicated on the map as No. 4. (This stopping, however, was not erected as it was not needed.) No. 3 stopping was then to be removed and the initial seal on the Eighth face entry broken, a door being erected on that roadway. Step 5—No. 5 stopping in the Eighth face entry was to be built and then No. 6 stopping on the Seventh face entry, as indicated on the map. Next the doors in the initial stopping or seal in the Seventh face entry were to be opened.

Step 6—No. 7 stopping was to be built of 3-ply canvas in the crosscut between the Eighth and Ninth face entries, and in the Ninth Face entry an air lock was to be constructed similar to that of which No. 2 stopping is a part. The location of this was left to be decided after examination of the ground. (As matters developed, this air lock was located in accord with the specifications of Step 7 which follows.) Step 7 and last—The final air lock in the Ninth Face entry was to be erected at the point indicated by *J* on the map.

After this plan for opening up the sealed area had been decided, all materials necessary for the work were gathered and such construction jobs, as the making of doors for all locks and air locks, were completed. All these were taken into the mine in readiness for the operations in which they would be utilized. Consequently, at no time were restoration and recovery proceedings delayed for lack of material.

Oxygen Dropped to 4.2 per Cent

On Feb. 9, at 10:50 p.m. and five days after the initial seals were completed, the oxygen content of the air behind these walls had fallen to 4.2 per cent. A unanimous decision was reached to begin the recovery work in accordance with the plan of procedure already outlined. This plan was followed as far as it went, and then by common consent an additional air lock *K* was placed slightly inby of the Sixteenth Right butt entry in the Ninth face entry, another air lock *L* was erected between rooms Nos. 1 and 2 in the Fifteenth Right butt entry and a stopping *M* was constructed in the Sixteenth Right butt entry slightly inby of the first chute.

On Feb. 13, four days after the first seal was broken ventilation was restored to the last crosscut of the Sixteenth and Fifteenth Right butt entries. Fourteen bodies were recovered on the following day. The other six, which were at more accessible places, had already been found and recovered.

An important decision, reached at the consultation which preceded the main part of the restoration work, was that three men should be authorized to act as leaders, one during each of three shifts. These men were John Berry, of the Bethlehem Mines Corporation; George Riggs, of the Mine Safety Appliance Co. and George S. McCaa of the U. S. Bureau of Mines. Mr. McCaa withdrew from this capacity after several days on account of the death of his mother. His place was taken by George Grooves of the U. S. Bureau of Mines. Each of the three shifts, consisting of four rescue teams and the necessary workers, was accompanied by two state inspectors and two officials of the company or chosen volunteers of official capacity from other companies. These men served as consultants for their respective leaders.

This divergence from common practice in restoration work after an explosion is worthy of adoption where at all feasible. One man is placed in complete charge during each shift and that man leads as well as bosses.

Digitized by Google

Serious mistakes are apt to be made when supervision is conducted from the surface by a map in the hands of one or more individuals who endeavor to keep in touch with the men underground through a verbal interchange of information. Further, the scheme is of merit because a corps of consultants accompanies the leader to assist him in making decisions. Likewise, the scheme of coming to a definite agreement as to a plan of procedure before commencing operations possesses much merit.

Following is a list of the companies having teams taking part in this work: the Pittsburgh Coal Co., the Buckeye Coal Co., the Bethlehem Mines Corporation, two; the Hillman Coal & Coke Co., two; the H. C. Frick Coke Co., three; the Bertha Consumers Co.; the Vesta Coal Co. and the Inland Colleries Co. The Pittsburgh Terminal Coal Corporation had two teams and the group of companies in the coke region that maintains the Orient rescue station also supplied a team.

After all bodies were removed from the mine, concrete and tile-block stoppings were erected in the Fifteenth and Sixteenth Right butt entries as indicated on the map. These seals were kept in place until the night of March 13 when ventilation was restored in these entries. Meanwhile ventilation was conducted to the faces of the face entries of Section 4, and stoppings, doors and an overcast were erected so as to restore the ventilation in these entries to the same state as before the explosion.

In the restoration of ventilation in the Fifteenth and Sixteenth Right butt entries the air was reversed so as to carry directly into the main return what gas had accumulated in these entries, instead of taking it through other working places in the split. The intake air was conducted from No. 8 face entry through chute *G* to the face entry, thence through the air lock *J* and the passage *N* to the Fifteenth Right butt entry, thence returning through the Sixteenth Right butt entry and chute *O* to the Eighth face entry and through crosscut *P* to the Seventh Face entry which normally serves as an intake inby of overcast *C*, from which point outby it serves normally as a return. At 6:40 p.m. this reversing of the air was completed; at 10:25 ventilation in the two entries was restored. Three apparatus teams assisted by men equipped with gas masks were engaged in the work.

Not a Trace of Heat or Fire

The rescue teams made two inspections of the fire zone. This they entered through a break in the seal in the Fifteenth Right butt entry through the air lock inby of this wall. They found no trace of fire or heat and took temperature readings which indicated a normal thermal condition. Two gas samples also were taken within the zone.

After that, the seal on the Sixteenth Right butt entry was opened by apparatus men and ventilation restored in the entries in steps from one crosscut to the next. The rooms off the Fifteenth Right butt entry were swept free of gas consecutively by line brattices as ventilation was restored in steps to the face.

The Eighth face entry of Section 4 had been rock-dusted from a point within 250 ft. of its face to the hoisting shaft. Except for the 250-ft. interval which had not been rock-dusted, little evidence of flame from the explosion was observed in this entry, for here propagation of the explosion through the ignition of coal dust was absolutely checked by the rock dust. In the Seventh face entry evidence of flame was observed in an interval between its face and a point marked *Q* on the map. In the Ninth face entry similar evidence was observed in the interval between its face and the point marked *R* on the map. Evidence of coking was observed in all other places inby of the Eleventh and Twelfth Right butt entries, with the exception of the Fifteenth and Sixteenth Left butt entries which were not thus affected.

The main vent of the explosion, as manifested by flame, was in the Ninth face entry, but as seen it stopped short of the Eleventh and Twelfth butt entries, which are main intakes from an auxiliary shaft. What

Rock Dust That Stopped Flame in Horning Mine

This illustration is made from a photograph taken 24 hours before the explosion. It shows a generous application of rock dust on No. 8 face entry in Section 4. The rock dust on this entry no doubt stopped the explosion from going throughout the mine. The turnout on the right leads to the Sixteenth Right butt entry, at the face of which the fire and explosion originated. The distance from the point where the camera stood to this face was 700 ft.

was the cause of its extinction at this point? The most logical assumption is that the explosion lost its force in passing the Thirteenth and Fourteenth Right butt entries, for here it had opportunity to expand. Otherwise, in the fresh air of the Eleventh and Twelfth Right butt entries and the Ninth face entry outby of the latter, the explosion would no doubt have taken on renewed life in the direction of No. 4 shaft. Outby, in the direction of the No. 3 shaft, however, any flame that might have passed up that connecting link would have been smothered and cooled by the rock dust in a barrier 200 ft. long that had been placed between the two mines. Incidentally, the rock dust in the barrier was dislodged by the force of the explosion.

Evidence of force extended along the face entries of Section 4 from their faces to a point about 3,000 ft. outby. Evidence of great force was observed in the workings off the Thirteenth and Fourteenth Right butt entries. Force was also in evidence in the Fifteenth and Sixteenth Left butt entries which lead to the face entries in Section 3. Its manifestations were seen for a distance of about 1,100 ft. in the Eleventh and Twelfth Right butt entries which connect with the adjoining No. 3 mine of this company. No evidence of great force was seen in the Fifteenth and Sixteenth Right butt

Digitized by Google

entries at the faces of which the explosion originated. A water car and three supply cars on the latter heading were not so much as lifted from the mine track. Many of the victims who met death in this entry were found in natural positions.

The greatest manifestation of force was exhibited in the Ninth face entry. This force swept practically free of debris and dust the interval between the Fifteenth and Eleventh Right butt entries. Several loaded cars in a trip standing on the track which crosses this entry to the Eleventh Right butt entry were wrecked by the explosion, and against these cars was piled all the debris, including that from several permanent stoppings carried by the force of the blast from inby points. These materials formed what might be termed a wall crossing the entry and completely blocking it.

Rock Dust from One Entry Aids Another

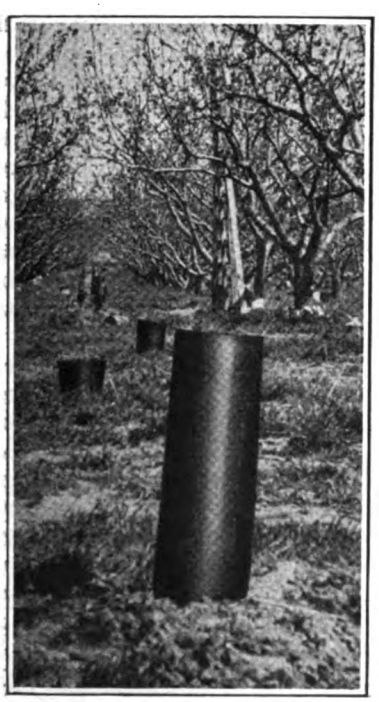
Rock dust in the Eighth face entry, coupled with room for quick expansion afforded by the Fifteenth and Sixteenth Left butt entries which join with Section 3, is believed to have confined the explosion to the limits already outlined. Open crosscuts between the Seventh and Eighth face entries inby of the overcast at *C* no doubt caused the rock dust strewn on the latter entry to be more or less effective on the former as well.

Aside from the constructive hints already drawn from the Horning explosion the following are suggested: Mines should be equipped with fire-fighting apparatus, some of which should be large and mounted on trucks and some lighter and capable of being carried. Boxes of rock dust might well be located at strategic points to assist in fighting a fire.

Fire seals should be erected with the utmost speed. Though every available agency was pressed into service to expedite the building of fire seals prior to the explosion in the Horning mine, the rate of erection did not match the speed with which an explosive mixture was developed within the zone.

Wherever possible, flame might, with advantage, be kept alive at the face or faces within the zone of a fire until the seals have neared completion. This would prevent an accumulation of gas, because whatever methane is liberated would be burned in that event as fast as it was liberated. Until the walls had been erected almost to the roof, sufficient air would have had to be introduced to the zone behind temporary brattices to support combustion.

Fire seals should be constructed of comparatively soft tile; at least the core of these structures should be thus constructed. That this would be good practice was demonstrated by the time lost and the labor expended in battering down several of the seals constructed of brick and concrete-block in this mine.



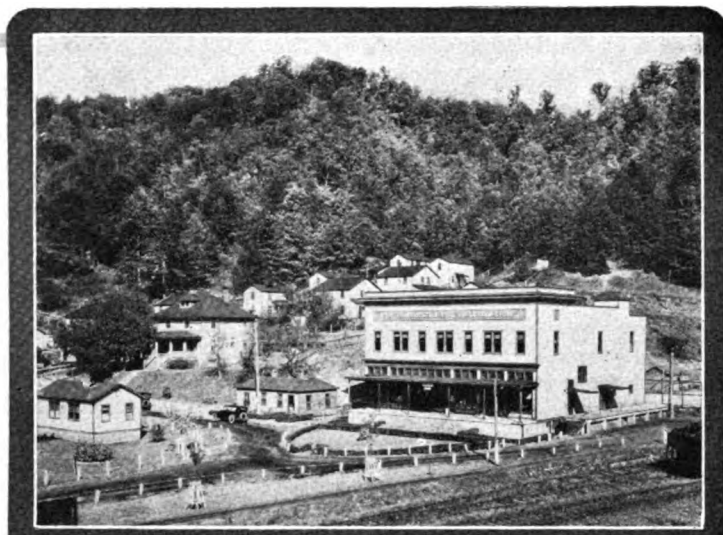
Briquets of Coal Cut into Fuel Oil's Orchard-Heating Business

By degrees coal and its byproducts are invading the realm of fuel oil. The latest invasion by coal of the sacred precincts of oil is the adoption of briquets for grove heating in the citrus belt of California.

The first heating of orchards with briquets was done successfully in the Wenatchee and Okanogan districts of eastern Washington, where apple growers of the "Inland Empire" learned that a certain amount of heating during the burgeoning of the apple trees in the spring protected them from the destructive frosts. Fuel oil was tried without success. A carload of briquets was sent to the district by the Pacific Coast Coal Co. and used with remarkable results.

Inspired by the success of briquet heating in the apple growing districts, the coal company shipped briquets to the citrus belt of Southern California. For years the oil-burning smudge-pot has been used by orange and lemon growers of California. Citrus fruits cannot stand a sudden drop in temperature and it is necessary —usually at great expense—to maintain fires in the groves during every cold spell throughout the winter. This overhead expense has been a contributing factor to the high cost of good citrus fruits.

The first use of briquets in the citrus groves was a complete success. Growers found that the clean burning, smokeless briquets did away with the main objections of fuel oil heating—complete elimination of smoke and noxious gases.



Coal Enters the Orchard

Once oil smudges exclusively were used to keep the frost from doing untold damage to budding citrus fruit crops in California and to the apple crops of Oregon and Washington. But the smudges turned whole counties black — even stopping moving picture production by hazing the atmosphere. Today Washington coal briquets are entering the orchards. In "stoves" that cost about one dollar each, briquets make clean heat and also require less attention.

West Virginia has not so completely denuded its hills as the State of Pennsylvania, where fire has removed what the axe has left and reburned the saplings seeking to establish themselves.

Shall Fire Denude or Trees Bedeck Hills Around Coal Operations?

Many mining companies have large acreages of idle land that, if not allowed to burn over, or if burned are then rewooded and watched, will give big returns on the labor expended on them.

Many Coal Companies Plant Forests to Provide Timbers for Use in Their Mines

Protection From Fire Highly Important — Natural Reseeding Adequate with Some Species—Fruit Trees Thrive on Stripped Ground—Thinning of Second Growth a Mean of Assuring Rapid Renewal of Old Forests

By Newell G. Alford
Consulting Engineer, Howard N. Eavenson & Associates, Pittsburgh, Pa.

WHAT IS BEING done to provide the mines with timber when the shortage becomes acute? Do the coal companies sense the difficulties they will face if they have made no provision for the future? In reply to these questions it may be safely said that the coal companies have been showing an unadvertised and progressively active interest in the forecasted shortage. The work of protection and reforestation is hardly broad enough as yet to be classed as general but a sufficiently serious endeavor has been manifested by both large and small operators to indicate the approach of a general and well-organized movement to meet the future timber requirements of the coal industry.

The U. S. Forest Service and the various state foresters are eager to serve the mining companies either with actual planting or helpful plans, and the coal companies will probably organize either by districts or states for the purpose of getting as much of this material assistance as they can.

The work of the coal companies differs and varies to include one or all of the following: (1) Protection by means of fire patrols, (2) Removal of dead undergrowth, (3) Proper thinning of young second growth, (4) Cutting of mature or diseased trees in the older growth, (5) Fostering of natural reforestation, (6) Artificial setting, and (7) Nursery planting and cultivation.

Of the states that are helping coal companies in their reforestation work, Pennsylvania, so far as is known, is doing much more toward providing for future supplies than any of the others. In Pennsylvania this work is by no means confined to the large producers, but most of the development so far accomplished has been done on the larger properties. Among the companies at present doing the most extensive work are: The Allegheny River Mining Co., the Berwind-White Coal Mining Co., the Bethlehem Mines Corporation, the Clearfield Bituminous Coal Corporation, the Rock Hill Coal & Iron Co. and the Wilmore Coal Co.

In the anthracite districts seven or more firms have a definite plan for retimbering their tracts of land. So far as is known, the most extensive work in this direction is being done by the Philadelphia & Reading Coal & Iron Co. In the fall of 1920 this firm organized a forestry bureau and now maintains a field force of fifteen foresters and rangers with thirty woodsmen as assistants. These men have opened and now maintain nearly 400 miles of roads and trails to make the forests more accessible for fire protection.

This company to date has planted 918,000 forest trees and expects to add about 225,000 more in the spring of 1926. The trees planted have been exclusively two-year old seedlings and largely of the pitch, jack, red and Scotch pine species. Though the planting has been extensive, the principal work of this forest bureau has been and is fire protection. An idea of the necessity of such protection may be gathered from the fact that 831 fires were fought on this company's property within the last four years, the area burned over by them aggregating nearly 50,000 acres.

This forestry bureau is self-supporting, in that it

From a paper entitled "Reforestation Progress by Coal Mining Companies" presented before the Coal Mining Institute of America, Pittsburgh, Pa., Dec. 9, 1925.

Digitized by Google

supplies to the company an average of about 1,500 carloads of timber per annum. The trees cut are largely matured, the dead and defective timber being used mostly for mine lagging and props. Experience in this district shows that the cost for protection and development in a case like this is from 30 to 40c. per acre per year. This company employs a forester with unusual training and experience, and it is his thought that, where more than 25,000 acres of land are involved, the practice and technical nature of such work thoroughly justifies the services of a specialist.

On the authority of the U. S. Bureau of Mines, it may be stated that about nine board feet of timber is used in the anthracite districts per ton of coal mined. Furthermore, this consumption has practically doubled within the past eighteen years, and the unit price has quadrupled.

Over one million trees were planted with state aid in the spring of 1925. Probably the Wilmore Coal Co. is the leading firm in the scale of its reforestation. It has so far planted over 400,000 seedlings. These have shown excellent progress. For the last two years it has obtained two-year old seedlings from the State Forestry Department. These were mostly short-leaf, Scotch, pitch and red pine, Japanese and European larch. Next year this company expects to continue with white pine and as much white ash as it can obtain.

HAS ITS OWN NURSERY

Because it is believed that the ability of the state to distribute young trees will be taxed by heavy demands next year, this company is now preparing its own nursery so that eventually its forestry organization will supply all the seedlings it needs. It is expected that, in possibly fifteen or twenty-five years, mine props will be cut from present plantings.

So far the Wilmore Coal Co. has not attempted the planting of hardwoods as it believes that these varieties come from seed latent in the soil. It found in one case that a fine stand of white oak sprang up after pine had been cut off, indicating that the seed had been dormant in the soil for years.

The Bethlehem Mines Corporation began planting seedlings from the State Forestry Department in 1919, and to date has set out nearly 300,000 trees of this type. The experience of this company has been confined to the red, pitch and jack pines, which have proved to be rapid growers with ability to make a good growth on very indifferent soil. Pitch pine planted on one tract in 1919 has now attained a height of 15 ft. and a diameter of 5 in. at a point one foot from the ground. The other species have done almost equally well. Another phase of the work provides for the cutting out of dead chestnut and timber damaged by fire or disease. This cutting is under the supervision of a graduate forester who marks the trees which should be cut down and removed.

FAVORS CONSERVATION

During the last three years the Rochester & Pittsburgh Coal & Iron Co. has planted 500,000 trees in barren places. This organization believes in the conservation rather than in the planting of hardwoods. It utilizes hardwood trees down to the small limbs which are turned into sprags, with a consequent minimum of waste. Cut-over areas are allowed to develop a second growth of hardwood. The experience of this company so far has been highly gratifying.

Fig. 1—Fruit Trees Will Grow in Strippings Waste

Several thousand fruit trees have been planted in Indiana on such overturned areas as this, with results which surpassed those derived from orchards on solid ground. Here is a constructive measure which should not be overlooked.

In Ohio, the Carbondale Coal Co. began reforestation of waste land in 1906, and each year since has planted an average of 10,000 seedlings of the pine species. It has lately transplanted trees having a diameter of as much as 12 in., one foot from the ground, and over 30 ft. in height. Based on the density of tree growth in that section, this company has found that in general it takes three acres of timber for the mining of one acre of coal.

Three other concerns in the Ohio coal fields have been following a definite plan of reforestation under the guidance of the state forester at Wooster. Though these coal companies are not doing work comparable in scale with those in Pennsylvania, there are now ten reasonably large producers in Ohio who contemplate the starting of a definite program in timber work in 1926.

There is still a large quantity of timber suitable for mine props in the southern portions of Illinois and Indiana with a large available supply coming from Missouri and Kentucky. With the curtailment of this supply in sight, several of the larger coal companies in Illinois have begun conservation work. This consists of protecting standing timber against fire by means of guards and patrols, also stimulating natural production of standing trees by thinning stands of young second growth that are too thick. This constitutes a

Fig. 2—Wooded Hills in Central Pennsylvania

Here is a mine, as indicated by the tracks on the clearing in the lower right-hand corner—and here also are newly grown trees. At present the mine at this place supplies itself with low-cost timber from nearby hills but in the future it will have to import timbers from distant points at a high cost unless it has foresight enough to conserve its timber resources.

Digitized by Google

large part of the present standing timber. They are also cutting such trees as have reached maturity in the older stands.

One of the three largest coal producers in Illinois has outlined a plan for reforesting land that involves the replanting of a definite acreage as wooded areas are cut off. This company has cleared land unsuited for farming use, and says that the success of its program depends largely on its ability to protect its present standing trees.

In southern Illinois large quantities of timber could be grown on worthless vacant land that is good for nothing else. If the state had a more liberal taxation policy for reforested areas, retimbering doubtless would be promptly and actively started in the southern portion of the state. Seventy-six per cent of the total area of Illinois is farm land, the rest of the land being occupied by cities, wastes, forests and unimproved pasture. Much the larger portion of the cultivated land lies in the central and northern part of the state. The Illinois Division of Natural History Survey estimates that the maximum area that could be used for forest production is probably not over 5,000,000 acres, and that it would take the state 100 years or more to produce enough timber to take care of its needs.

THIS COMPANY USES SEEDLINGS

One of the earliest pioneers in forest protection and the cultivation of timber was the St. Bernard Mining Co. in western Kentucky. This company was recently sold to the West Kentucky Coal Co. In 1890 it began the planting of seedlings on waste and vacant land from its own arboretum, and in 1920 it had the following quantity of timber from artificial reforestation on several tracts embracing 550 acres in all:

Table I—Reforestation Timber on Property of West Kentucky Coal Co.

Number of Trees	Kind of Timber	Range in Diameter One Ft. above Ground
1,310,000	Black walnut	4 to 16 in.
230,000	Catalpa	5 to 10 in.
400,000	Black locust	3 to 10 in.
30,000	Tulip (poplar)	5 to 15 in.
1,970,000 trees		3 to 16 in.

In addition the St. Bernard Mining Co. in 1920 had approximately 30,000,000 board feet of natural growth on the stump on 10,000 acres of land of 12 in. diameter and over, made up as follows: 20,000,000 ft. of oak, 1,000,000 ft. of hickory, 4,000,000 ft. of gum and 5,000,000 ft. of poplar.

Fig. 4—A View Typical of the Pennsylvania Terrain

No attempt has been made apparently to thin out the second growth, nor has any effort been made to replant the land where no trees are growing. Future generations will be lamenting the fact that the present operators failed to note the marvelous possibilities of the idle land lying above their coal mines.

A few other concerns in western Kentucky have been interested in this work. The W. G. Duncan Coal Co. has planted about 10,000 catalpa trees with satisfactory results, and has found that a natural growth of walnut trees can be started by scattering the seeds through old fields. In this section one of the greatest factors in reforestation has been the recent passing of a stock law covering Muhlenberg County, which it is expected will have a notable effect on young growth.

In this part of Kentucky old fields are showing a satisfactory second growth, although this is not usually of the most desirable species. Sweet gum, hickory and sycamore are predominating in these areas. In West Virginia, where the largest coal producers are interested in forestry, activities have been confined largely to systematic fire protection.

PROTECTION AGAINST FIRE ONLY

In Virginia, the Clinchfield Coal Corporation and the Virginia Coal & Iron Co. are likewise engaged in protective work. In the Alabama coal fields where mine timber is now none too plentiful, several of the large producers are similarly following a systematic plan for

Fig. 3—An Area Greatly in Need of Thinning and Protection Against Fire

A fire started in this growth would annul years of patient effort of Nature to restore the destructive work of the lumberman. The danger could be largely avoided by removing the underbrush, thinning out the trees and maintaining fire patrols. Hilly ground, though frequently farmed, would be better reserved for the growth of timber. A farm on rough ground rarely affords the farmer any more than a bare subsistence. Plowing rapidly denudes the humus that the old tree growth has created.

Digitized by Google

protecting the timber from fire. In certain sections fire guards are cleared of all growth and burned over annually.

It is interesting that in Colorado an investigation has shown that to a large extent natural reforesting will

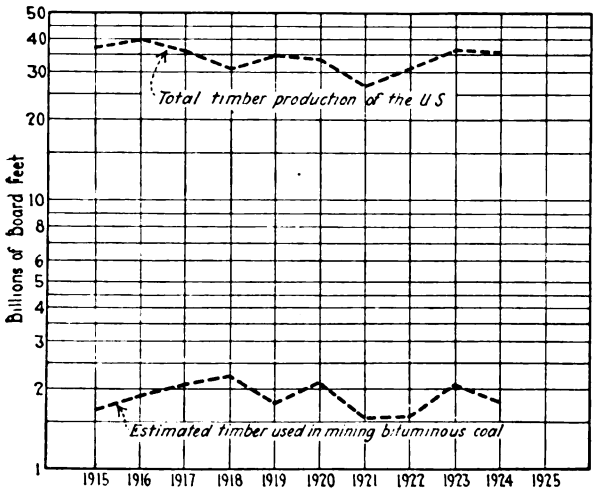

Fig. 5—Timber Used by Mines and for All Purposes

Fortunately for our future, the timber use in the United States is stationary year by year. Economies are preventing the upward swing in the curve of production as they have in coal, but fortunately for the timber industry the price changes leave the industry quite serene.

take care of itself. The Colorado Fuel & Iron Co. has found that by not cutting trees on the ridges and leaving a sufficient number below, second growth is coming on in sufficient quantity to provide for future needs.

Contrary to the common belief when coal stripping

Table II—Timber Cut in the United States for All Purposes
1915–1924

	Board Feet		Board Feet
1915	37,011,656,000	1920	33,798,800,000
1916	39,807,251,000	1921	26,960,864,000
1917	35,831,239,000	1922	31,568,688,000
1918	31,890,494,000	1923	37,165,505,000
1919	34,552,076,000	1924	35,930,986,000

Supplied by the "American Lumberman"

Table III—Consumption in 1924 and Expected Requirements of Timber Used in Bituminous-Coal Mining

Year	Board Feet	Year	Board Feet
1924	1,788,200,000	1929	2,312,000,000
1925	2,146,000,000	1930	2,405,000,000
1926	2,176,000,000	1931	2,479,000,000
1927	2,213,000,000	1932	2,553,000,000
1928	2,264,000,000	1933	2,627,000,000

became prevalent, the waste lands from this method of mining are found to be excellently adapted to the growing of trees. This has been demonstrated in Penn-

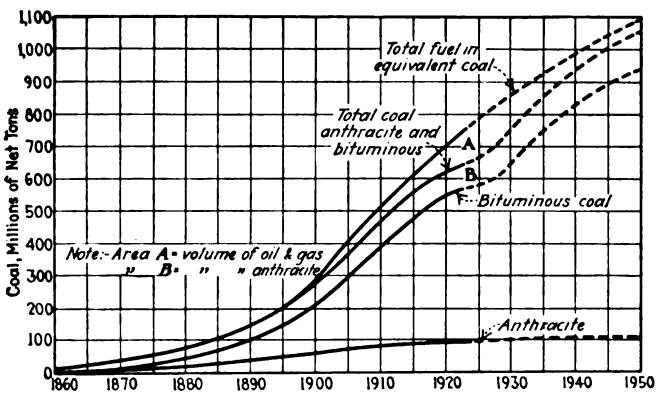

Fig. 6—Past and Future Fuel Production in the United States

The fuel requirements are expected, despite economies, to advance steadily but the part of coal in this fuel output has temporarily been reduced by oil. In time, however, coal will probably recover the business lost to oil as is shown in the chart by the upward bend of the coal curves.

sylvania. On certain overturned areas in Indiana several thousand fruit trees have been planted, with the highly surprising result that these trees are showing a much better performance than any neighboring orchards.

Generally, "the fundamental problem is to increase the production of timber by stopping forest devastation. About one-half of the timber left is in three Pacific coast states and over 61 per cent is west of the Great Plains. The annual new growth of timber is only one-fourth of the yearly consumption. The present cut of lumber in Pennsylvania is less than the City of Pittsburgh alone demands. The production of yellow pine is declining and within ten years will probably not exceed the requirements of the southern states themselves. Practically as much timber is destroyed annually in the United States as is produced for all uses."*

MINING USES THREE BILLION FEET

If the coal industry as a unit will actively join the growing movement for conserving our wood resources, the taxing of embryo forests by states can be supplanted with legislation that in time will rewood much of the vacant space suitable only to the growth of trees. Practically 3,046,000,000 board feet of timber

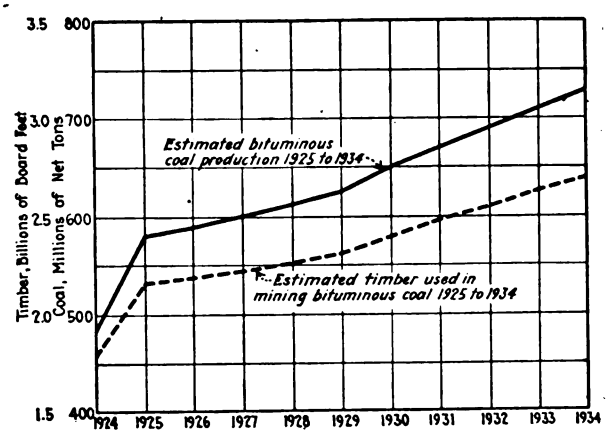

Fig. 7—Bituminous Coal Production and the Timber That Will Be Needed

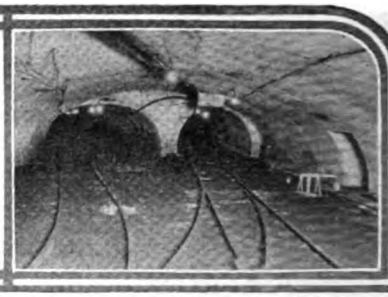
Evidently the assumption is made that the need for timber will not be reduced by the introduction of steel, concrete or other substitutes or by economy in the use and reuse of lumber or by its extension in life by preservation.

are used annually in American mining, and approximately 60 per cent of this quantity is consumed in producing bituminous coal.

Fig. 5 shows that the quantity of timber cut yearly in the United States from 1915 to 1924 for all purposes has been nearly uniform and that the demands of the bituminous coal mines during the same period were also fairly constant. The reported total annual timber production for this period is given in Table II.

Fig. 6 shows the past and expected future production of bituminous coal. This is not submitted as a prophecy, but is based on the best data obtainable at this time.



Based on the expected future bituminous coal production shown in Fig. 6 and using the estimated unit of 3.71 board feet of timber per ton of bituminous coal mined, Fig. 7 shows the expected increase in the use of timber for soft-coal mining. It is expected that the true average timber consumption per ton of coal will be slightly higher rather than under this weighted average. The values as determined in Fig. 7 are shown in Table III. All of these figures are based on data obtained from the best sources now available.

Underground Operation

Discuss Turret Cuts and Vertical Shears At Pittsburgh Meeting

In Thick Coal Longwall Fails and Why?—Cutting Wide Face with Arc Kerfs—Shearing Without Horizontal Cuts — Are Better Bits Needed?

At the bimonthly meeting of the mining section of the Engineers' Society of Western Pennsylvania, held in Pittsburgh on March 30, a paper on "Various Methods of Cutting Coal" was presented by W. R. Jarvis, Pittsburgh district manager of the Sullivan Machinery Co. As this paper dealt largely with methods of cutting as applied to new systems of mining, longwall was a topic in the discussion which followed. As one of the men expressed his impression of the meeting: "It gave the members an opportunity of kicking the old dog, *longwall*, around again."

Henry J. Lewis, consulting engineer of Pittsburgh, opened a discussion on longwall mining. Successful longwall operations, by and large, have always been in thin coal. People who try longwall in thick coal generally go back to room-and-pillar mining. Longwall in thick seams fails because the roof is too completely destroyed. Instead of bending, as it would in the mining of thin coal, it shears.

FAILS FOR LACK OF PACKING

L. D. Tracy, mining engineer, U. S. Bureau of Mines, Urbana, Ill., attributed failures of longwall in thick seams to a dearth of waste material for the building of pack walls. He knew of a longwall failure in thick coal at an English mine, though it is in Great Britain that longwall is best understood. This failure was caused by the lack of materials for the building of pack walls. He did not see how longwall could be worked successfully without pack walls.

E. H. Coxe asked Mr. Jarvis how a 30-ft. room could be cut with a machine which operates from a position on the mine track. Mr. Jarvis said that to undermine a place of that width two separate cuts must be made. In reply to further questioning, Mr. Jarvis added that a pivotal, curved cut, 20-ft. wide, will not shoot as well as one which is 15 ft. wide because the depth of the kerf diminishes from the center toward either rib. Mr. Jarvis denied that he had in his paper advocated the use of 16-lb. rails for track-mounted cutting machines. He emphasized the need for heavy rails securely anchored, for this purpose and placed the minimum limit of rail weight at 16 lb. A heavier rail than this he declared would give much better results.

ANGULAR FACE SUGGESTED

Graham Bright asked if a wide place could be cut by a track-mounted machine by swinging a track parallel to an angular face. Mr. Jarvis said that this is being done with some degree of satisfaction in several West Virginia mines. Mr. Coxe believes that even though advantage be taken of cleavage planes in driving these rooms much difficulty would be experienced in breaking out the coal in the acute-angled corner. Mr. Jarvis said that both the obtuse and the acute corners would have to be more or less rounded.

Edward Steidle asked if anyone by shearing had managed to eliminate the use of shots, to which question Mr. Jarvis replied by saying that though shearing had not totally eliminated shooting it had reduced the use of explosives and had made it possible to produce better coal. As to its applicability to the mining of coal on a long face, Mr. Jarvis said that no long-face shearing machine has yet been developed and doubted whether if it were it would be of any advantage. W. W. MacFarren said that a shearing bar might be mounted on a loading machine which would operate in a position parallel to the face. If the shearing cuts were shallow enough a hydraulic jack might be utilized for breaking out the coal, thus eliminating shooting. The face would have to be undercut first.

HORIZONTAL CUT OBLIGATORY

Mr. MacFarren inquired whether shearing without horizontal cutting had been tried and with what success, but Mr. Jarvis questioned whether it would give satisfaction under any condition. The scheme was tried in narrow work in a mine of the Vesta Coal Co., at California, Pa., working the Pittsburgh seam, but the attempt failed. Mr. Lewis remarked that shearing does not relieve weight and so free the coal, which is the main object of undercutting.

"Have cutter bits of alloy steel met with much success?" asked Mr. MacFarren. Mr. Jarvis sees no advantage at present in the use of higher grades of steel for cutter bits chiefly because they are handled with so little care that many are lost, but also because of the manner in which they are forged. No doubt a high-grade bit steel would be of great advantage providing means were made available at the mines for forging the steel in a more scientific manner.

BETTER BITS AND BATTERIES

Graham Bright declared that in his belief the storage-battery cutting machine will demonstrate the advantage of better steel bits. The Consolidation Coal Co. has discovered in the operation of storage-battery cutters that in cutting a place a dull bit will consume about twice as much power as one that is sharp. Machines of this type in the Consolidation mines are cutting regularly 18 to 30 places per shift, a record that could not be achieved if dull and inferior bits were employed in the cutter chains.

Why Not Make More Lump?

It is indeed surprising that such a small proportion of the coal operators of the United States give little or no effective attention to an essential phase of the coal business, namely, increased lump-coal production. If a company employs a competent man to supervise the shooting of coal, the output of lump can be increased from 5 to 10 per cent. If, for illustration, a mine has a capacity of 2,500 tons per day, and the lump coal is increased 7 per cent, that would mean 175 tons increased lump coal for the market. Let us suppose the market price is $1.25 per ton more for lump than for slack. This would mean a net gain for the operator of $218.75 per day or $4,375 for each month of 20 working days.

If the company has six mines situated so that a supervisor could manage them all, figuring on the same basis as before, it will be clear that the operator would make $26,250 per month. The cost of haulage would be decreased as the loader could crib his cars and thereby load more coal for any given quantity of haulage equipment.

SHOOTING AND CLEAN COAL

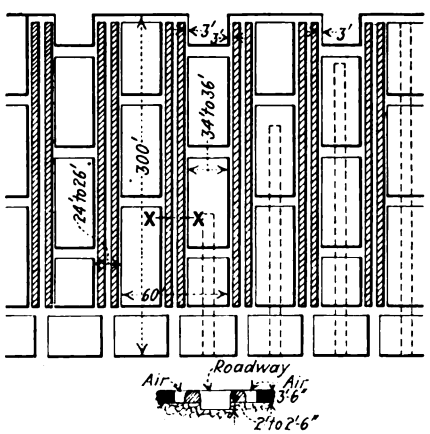
A cleaner grade of coal can be loaded if the coal is properly shot as the bone or other impurities will not be shattered and mixed with the coal. If the company does the shooting, the powder expense will be decreased. Last but by no means least the safety of the men and property is enhanced materially and the danger of explosions is greatly diminished by the proper placing, charging, and tamping of holes. No doubt the reason so little interest is taken in this phase of the business is due to mistakes of the foreman or superintendent in selecting men to supervise this part of the work.

Frequently, in my observation, superintendents have selected men to supervise the shooting of coal simply because they had given good results in the physical performance of that particular class of work. However, a good coal shooter may be a failure at supervising and demonstrating. To give results as a supervisor, it is absolutely essential that the man have knowledge of explosives, practical experience in shooting coal, executive ability and the power to handle and control men. A man who has had experience managing mines would make an ideal man as supervisor of shooting, provided he has given explosives and increased lump-coal production study and thought.

No doubt Congress will in the near future enact laws relative to the conservation of lump coal, thereby eliminating much needless waste.

THOS. F. HOYE.

Huntington, W. Va.



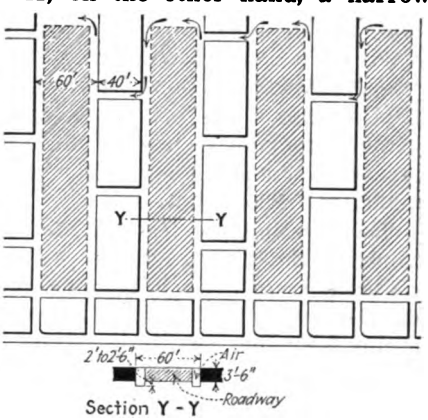
Double Chambers Best Suit Thin Anthracite

Now that the thick beds in some parts of the anthracite fields have been mined, it behooves the engineers to study the problem of mining the thinner seams, which in places have not as yet been touched.

In mining beds of 3 ft. 6 in. and over, the chamber-and-pillar method of mining has been adopted and proved successful, both in first mining and later in the second mining by means of which the pillars were recovered, but in the mining of the smaller beds this method, although applicable to first mining, is apt to prove too costly during second mining.

At present, where the smaller beds are being mined by the chamber-and-pillar method, the general practice is to drive the chambers on 60-ft. centers with a working face 24 to 26 ft. wide, leaving a 34- to 36-ft. pillar between each chamber.

In a bed 3½ ft. thick a miner removes from 24 to 30 in. of rock, 10 ft. wide, in order to make height for his roadway and for the laying of the car tracks. With this rock he fills the gob. The wall of rock formed between the gob and pillar on one side of his chamber creates an air-course 3 ft. wide for ventilating the working face. Sometimes the miner has more rock than he can pack into the gobs, and he has to load some of it into cars, which are sent to the rock dump to be unloaded.



Putting Road on Room Center

The rock is gobbed on both right and left and therefore with minimum labor but, when an attempt is made to recover the pillar, it must be split or slabbed. But pressure may have rendered these methods impossible. If the room is reopened half the stowed rock must be hauled away—an impossible proposition.

When the time comes to recover the pillars in these small beds, the track will be laid either in the old roadway, or in a narrow heading bisecting the pillar.

If the track is laid in the old roadway it means that 50 per cent of the rock which was packed in these chambers during first mining must be moved to enable the miners to get at the coal. This will prove an expensive item.

If, on the other hand, a narrow heading is driven through the length of the pillar, all the rock which will be cut for the roadway must be loaded into cars and sent out to be unloaded.

Use Wide Room with Two Roads

With this method, if the room will stand driving at such great width, it is easy to get at the pillars to draw them. If they are to stand long they should be packed tight.

To eliminate this expense during the recoving of pillars, why not adopt the double-chamber method of mining in these small beds, as follows: The working faces of each double chamber to be 60 ft. wide, pillars between each double chamber to be 40 ft. wide; chamber lines to be set on 50-ft. centers, sights being kept 5 ft. from one rib; the roadways to be carried alongside the pillar, and all rock to be packed in the space between the two roadways.

The advantages of this method applied to the mining of the smaller beds would be: (1) All rock produced in the chambers during the first mining could be stowed away between the two roadways, forming a substantial pillar for supporting the roof. (2) When recovering the pillars in second mining, the tracks being laid on both sides of the pillar, there would be no rock gobs to handle, thereby reducing the cost of production.

Harworth Hoist Well Designed to Meet Abnormal Depth of Shaft

With Skips or Large Cars Size of Equipment Could Be Reduced—Far Superior to Old Steam Hoist—Might Accelerate More Rapidly, Thus Decreasing Second Peak

By Graham Bright
Consulting Engineer, Howard N. Eavenson & Associates, Pittsburgh, Pa.

The two large hoists, illustrated and described in the April 1 issue of *Coal Age* and now being installed at the Harworth Colliery, near Sheffield, England, are splendid examples of the progress in design and construction of mining equipment being made by British engineers.

The hoisting problems in the coal mines of the United States are quite different from those in England and on the Continent, in that our coal seams lie much nearer the surface, and that depths of 3,000 ft. are found only at metal mines.

The first impression that an American engineer receives upon reading the description of the Harworth hoists is that there is a large amount of hoist for the output. This is, no doubt, due to the fact that skip hoisting is not allowed in the coal mines of England, and British conservatism will not permit the use of a mine car of sufficient size to afford maximum economy in the operation of a coal plant.

Could Save a Hoist

With skip hoisting, the same quantity of coal could be hoisted with a much smaller drum and cable, or with the same drum and the same cable the entire output of both shafts could be hoisted from either one of them. The power equipment necessary to drive the hoist would, of course, be roughly in proportion to the quantity of coal raised in a given time. By the use of larger cars, the cage and empty-car weight would be less, which would reduce the drum and rope size and, at the same time, simplify the decking arrangements.

The steam-turbine driven flywheel set is cleverly planned and is certainly a great improvement over the usual steam hoist with its great fluctuation in steam demand and with its unfortunate inability to use modern high pressures and superheated steam.

The use of a steam turbine for each flywheel set and a third turbine to drive a generator for the other mine load is an economical arrangement both from a first-cost and operating standpoint. From a standpoint of continuity of operation, the alternate scheme of installing two or more turbo-generators all alike and driving the flywheel sets by induction motors would receive, and no doubt did receive, careful consideration.

All-Electric Better

With the scheme as installed, a breakdown of either flywheel turbine would close down one hoisting shaft, whereas a breakdown of the turbo-generator would shut down all productive operation. With all developed power electric, a breakdown of any turbine would not affect operations, for one spare turbine would be available. With the all-electric scheme, an emergency connection could be put in from a central-station system, in which case a spare turbo-generator would not be necessary. Central-station power could be relied upon not to fail at the same moment as the power generated at the station.

The use of two hoist motors and two generators instead of one motor and one generator is largely a matter of available equipment. In general, single machines from an economical and operating standpoint prove better suited to hoist motor capacities up to 2,000 hp.

Eddy-Current Brake

The eddy-current brake necessary with the turbine-driven flywheel set is not necessary with the motor-driven flywheel as the induction motor will act as a generator and will pass the excess power on to the power system when lowering unbalanced loads.

From the hoist duty cycle shown, a reduction in rope speed of about 12 per cent could be obtained by shortening the accelerating and retarding periods from 16 sec. to about 10 sec. This would, of course, increase the accelerating peak and reduce the secondary peak, which, in many cases, is desirable. The reduction in rope speed would increase the safety of operation and would slightly decrease the heating of the equipment.

Flywheel Inadequate

The flywheel seems to be a little light for complete equalization of the load with the reduction in speed as shown on the duty-cycle curve. Complete equalization is not necessary, of course, in many cases, but the prime mover must be able to take care of peak loads greater than the average if the flywheel is not heavy enough for complete equalization.

For many years cams, shafts and safety links have been used on control systems in England and on the Continent, but this practice has largely been discontinued in this country in favor of accelerating and retarding relays, geared limit and hatchway limit switches.

This latter control system will give full safety under all conditions, will allow the operative much more latitude and ease in handling the control lever and will more completely safeguard the motors and generating equipment against overloads caused by the careless handling of the control lever.

Protection at Landings Only

With the cam-and-lever system, only at the end of the cage travel is there protection of the equipment against a careless movement of the control handle that would give excessive rates of acceleration or retardation. The large hoist of the Chicago, Wilmington & Franklin Coal Co., at West Frankfort, Ill., is an exhibit of the manner in which full automatic control can be attained with full safety features without the use of the cam system.

British engineers are to be congratulated on the splendid hoisting system being installed at Harworth. After all is said, only the failure to use skips differentiates this hoist, except in detail, from those commonly installed at American mines.

Splint Resultants Drive Out Mine Run of Softer Coals

Perhaps there are few who realize the changes in the market which are modifying conditions in the southern West Virginia field. For more than a year the gas-coal mines have seen their market almost ruined by the splint-coal mines which sell, in competition with gas mine run, the product left after abstracting the lump. The gas coal is a little better for steaming than this splint "resultant," but the price which the former commands is not enough to pay for mining it. All around the region the "soft-coal" mines have been closed down, and the splint-coal mines have been developed. As these latter are becoming capable of meeting the demand, it seems likely that the gas-coal mines will not be reopened.

SPLINTS AND GAS BEDS

It should, perhaps, be said here that the high-volatile coal in southern West Virginia may be divided into splints and gas, or "hard" and "soft" coals, as they are termed locally. The splints come from the following beds: Coalburg, Winifrede, Block Five, and Lewiston. The gas-coal beds are: Eagle, Powellton, No. 2 Gas, and Cedar Grove. The last of these is sometimes classified as a splint, and in the western part of the Kanawha field and over on Island Creek the No. 2 Gas is so hard that it also is thus classified.

All the hard coals are screened, and the lump sold for domestic fuel; what remains goes as nut and slack. Island Creek has built up a large business by passing the coal over 6- or 8-in. screens, getting a fancy price for the block and a price for the coarse resultant somewhat lower than the regular mine-run price.

One company has confined its output to six splint mines and three gas mines, shutting down ten that were mining gas coal. Two more may have to be shut down. The tonnage, however, at the few mines still working has been maintained, and the company mentioned produced more coal last year from the nine mines than in any year since 1915.

Railroads that used to buy gas mine run have gone to splint mine run and resultants, so that over half of the rich steam coal acreage in the high-volatile districts is worthless as an investment.

Twenty odd years ago, when an anthracite strike of any duration occurred, there was a corresponding coal boom in West Virginia, but the recent strike had no effect that could be noticed, certainly not enough to afford a profitable business. If West Virginia, with the 1917 scale, with the anthracite strike in full swing and with the mines in other states trying to work on the Jacksonville scale, cannot make a decent profit, what will happen now that the strike is settled if the Jacksonville scale should be annulled?

WEST VIRGINIAN.

Defends Cast-Iron Wheels For Mine Cars

I read with interest an editorial on page 254 of Feb. 18 issue of *Coal Age*, under the heading: "Lighter Wheels and Heavier Loads." It seems to me some one has given you some wrong information concerning car wheels for mine car use.

My company has been manufacturing mine car wheels as a specialty for over forty-five years and we have watched carefully the development of the mine car wheel business in the United States. We have investigated personally the mine car wheels used in foreign countries—England, France, Germany and also Canada — which use some steel wheels on account of the high duty of importing American material.

The foreign countries generally have cars that carry maximum loads of from one to one and one-half tons while American cars today average a minimum of two and one-half tons and we are now building a large percentage of our cars to hold four to five tons and designing cars that will carry from five to ten tons.

HAVE SOFT TREADS

You mention some of the steel wheel difficulties. We believe that a steel casting is usually so soft in the tread that it will not last more than a few weeks in modern mine service where the trips are hauled long distances at high speeds, and when braking or spragging is necessary a steel wheel will not last more than one round trip. If they are made heavy enough to give much wear on the tread they cost two to three times the price of cast iron, and if they are made light enough to compare in first cost with cast iron they flatten between the spokes and you have a wheel with as many sides as you have spokes within a short time.

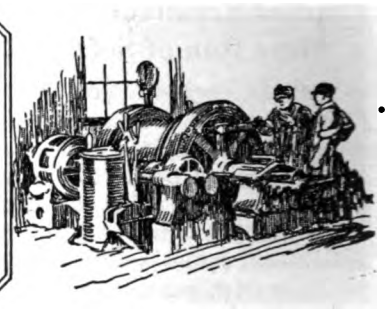
We believe the mining company to which you refer has made strong efforts to secure a steel wheel and has tried to forge or roll these with little success and at high cost.

Steel wheels are largely used on railroad cars today on account of their flange strength, the steel flange being stronger than cast iron, but as to actual economy cast iron wheels are being used today in quantities that show them to be on the increase instead of the decrease, and only on their heaviest cars where the flange-strength limit has been reached are they using steel wheels. Large steel wheels can easily be rolled but this is a serious problem in manufacturing small wheels.

LOST POWER AT CURVES

You overlooked one important point in reference to the steel wheels and mine car wheels in general. At least 99½ per cent of all mines now in use have wheels that rotate on the axle. The particular mine to which you refer is equipped with cars that have the wheels pressed on the axles and the bearings are in boxings. This makes a car consume considerable power in rounding curves for wheels pressed on axles on sharp curves makes it necessary for one or the other wheels on the axles to slip. The trackage in most mines contains curves that are rather sharp, especially at room necks.

You will find upon investigation that the reduction which you give in weight of steel under cast iron wheels is somewhat overestimated and we doubt if there is such a difference, especially if the steel wheel has sufficient tread for any reasonable amount of wear.



Chilled cast iron is one of the hardest substances known and, when polished, gives a very smooth running wheel on a rail. Cast steel or rolled steel wheels cannot be made satisfactorily when they must be machined in the hub for the fitting of roller bearings or, in a number of instances, arranged for lubrication in the wheel itself. As stated above, most of the wheels run loose on the axle, so there must be some bearing provided in the wheel itself and this practically eliminates steel wheel construction—either the rolled or cast type.

Some English steel wheels were shipped to this district about two years ago and they lasted about 60 days in service. Ten miles an hour speed, common in the United States, is different from hand pushed service in England. WHEELMAN.

Practical Pointers For Electrical And Mechanical Men

Oil Circuit Breaker Should Receive More Frequent Attention

Test Breaker by Hand First, Then Electrically, But Not Connected with Line—Inadequate Connections May Heat Equipment—Set Breaker Plumb

By H. J. Pfandhoefer
General Electric Co.

An oil circuit breaker is the valve for the outlet or intake of generated electrical energy, and if not properly installed or maintained, stops the production or reception of power. It is, therefore, extremely essential that it be properly installed, and after installation that it receive as much care as a main steam valve or water valve.

Oil circuit breakers when operating under short circuit must open many times the normal generating capacity of a system, for, when a short circuit occurs, the current rises greatly and this higher current must be broken at the time of trouble. For this reason some points to be borne in mind when installing a circuit breaker may well be enumerated:

INSTALLATION SUGGESTIONS

Installation—(1) All manufacturers in shipping oil circuit breakers provide complete instructions for the installation of the breaker. Follow these instructions carefully and to the letter.

(2) After installation carefully check all moving parts to see that they function properly and freely, and that all bearings run free.

(3) Check studs and be sure that they are properly tightened in place.

(4) Inspect contacts for alignment to make sure that they all seat properly, that they do not bind, and that all contacts make and break at the same instant.

(5) Be sure that the tanks are provided with the right kind of oil and are filled to the proper level, and that the oil is clean and dry.

(6) Oil all moving parts on the mechanism thoroughly before attempting to put it into service.

(7) The breaker should now be ready for trial. Always try the breaker by hand first whether manual or electrical, and be sure that the breaker is dead before this trial is made.

BEFORE PUTTING ON LINE

(8) If the breaker is electrically operated and all the foregoing tests show its correct functioning and if further the breaker operates satisfactorily by hand, then try electrical operation with the breaker still disconnected from the line. Do not try to operate it electrically with the tanks off. The tanks should be in place so that the additional effect of the contacts traveling through the oil is obtained. If trial is made without the tanks, there is also some danger of injury to the breaker because the contacts lack cushion when they do not travel in oil.

(9) Connections can now be made to the breaker, and when made they should be tight and of ample size, otherwise heating may develop in the breaker. The equipment may be held responsible for this heating, when as a matter of fact, the trouble is in the heating of the connections and the transfer of this heat from them to the breaker.

(10) Be sure the breaker frame is thoroughly grounded.

GIVE BREAKER AIR

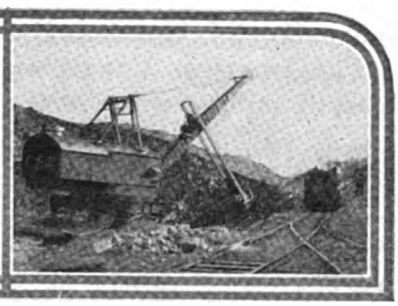
A Few Don'ts: (1) Don't install a breaker in a dead air pocket. All electrical apparatus must have changing air. I have seen many cases where breakers installed in dead air pockets have unduly heated simply because the air was never changed. As a result the heat continually pyramided, and the breaker was held at fault when the circulation of a small quantity of air was all that was needed.

(2) Don't guess. Your guess may be wrong and cause a shutdown which, of course, means a loss of revenue. If you do not know, find someone that does or look up your instructions on that particular breaker and find out.

(3) Don't expect an indoor breaker to withstand the elements. It is not expedient to install one of this type in a wet room or by a window left open during a storm.

(4) Don't install the circuit breaker so that it is out of alignment. If it is not properly aligned at the time of the installation some parts may bind just when you want it to open automatically.

(5) Don't install a breaker too small in ampere-carrying or in interrupting capacity and expect it to function properly on your system. In the first case the breaker will heat; in the second trouble will develop if the breaker has to operate under a short circuit.



INSPECT YOUR BREAKERS

An oil circuit breaker is liable to be regarded as a piece of apparatus to be installed and forgotten. There are no rotating parts to call the operator's attention to the fact that it is a piece of electrical apparatus and consequently he neglects it. An oil circuit breaker, like any other piece of electrical apparatus should receive ordinary care, or the best results will not be obtained from it. One would not think of allowing a turbine to run year in and year out without periodical inspection, or at least without putting some oil in the bearings. An ounce of care in installation and maintenance, as with all electrical equipment, may save many pounds of regret. Equipment other than electrical needs care throughout its period of use, but electrical apparatus is unfortunate in that it often falls into the hand of those who do not properly understand it.

News Of the Industry

Coal Hearings in Congress Elicit Many Remedies for Emergencies; Constitutionality Imperils Legislation

By Paul Wooton

Washington Correspondent of *Coal Age*

Constitutionality is the big obstacle in the path of coal legislation. This was brought out clearly during the second week of the coal hearings before the interstate and foreign commerce committee of the House of Representatives.

The committee is earnest and conservative. It has no desire to attempt to exceed the powers of Congress. Chairman Parker evidenced marked impatience when Representative Black, of New York, suggested that the Supreme Court should be allowed to pass on the question if there is doubt as to the constitutionality of proposed coal legislation. Chairman Parker made it very clear that the committee will recommend no legislation which fails to square in all particulars with the Constitution.

The chances of any legislation have been hurt by differences of opinion among the members of the House as to what form the legislation should take. Each witness has a different plan and most of them are hostile to the other proposals. There is marked opposition to the creation of another "extravagant" government agency to deal with coal. There has been considerable crystallization of opinion against lodging emergency powers with the President.

Operators Invited to Appear

In line with the plans of Chairman Parker fourteen prominent bituminous operators have been invited to appear before the committee. They are to be asked what they have to suggest to prevent an interruption of coal supply. The position that they will take already is indicated. A spokesman for the operators declares that there is no problem in bituminous coal. The demand expressed at these hearings is for protection in the matter of anthracite supply. Anthracite and bituminous coal are very different commodities, he points out. If anthracite were another color and if it were not known by the name "coal," the bituminous product would not be dragged into this hearing, it was said. The demand for legislation is coming from the anthracite-consuming territory.

The point is made that under present conditions a strike among the soft-coal workers would not interfere particularly with supply. Non-union operations have increased to the point where they can meet the country's requirements. All western Kentucky is now non-union. Only 5 per cent of West Virginia's production now comes from union mines. Indiana and the Pittsburgh district are developing production which is not under union control.

No Assurance Against Strikes

The position of the operators seems to be that the public is amply protected in the matter of bituminous coal supply, except possibly against strikes. The producing area is scattered widely. There is no semblance of monopoly or centralized control of production. As there now is no great probability that a coal strike could stop enough bituminous production to cause much trouble the greater danger lies in the possibility of a railroad strike. Even that is becoming more remote, but the hearings before this same committee developed the fact clearly that no absolute assurance against strikes can be established. The feeling is that that situation can be controlled only by public opinion. The conduct of the public during the last strike, it will be pointed out to the committee, has done more to discourage another anthracite strike than any legislation that could have been enacted.

All Witnesses Have Cures

During the week the committee heard as many remedies as witnesses. Representative Black, of New York, wants to set up a government corporation empowered to operate coal mines during emergencies. He also thinks the coal industry should have a czar—a man the public could picture and who could be held responsible in the public mind. He has in mind for the coal industry a position comparable to that held by Judge Landis in baseball; by Will Hays in the motion-picture business, and by L. S. Storrs in the electric-railway industry.

Representative Mead, of Buffalo, would set up a council composed of a representative of the Federal Trade Commission, of the Interstate Commerce Commission and of the Department of Labor.

Representative Boylan, of New York City, urged that the President be empowered to take over the mines in an emergency operating through the departments of Commerce and Labor. He also condemned the Pennsylvania anthracite tax.

Urges "Pitiless Publicity"

"Pitiless publicity" was recommended by Representative Fish, also from New York, as the best way of controlling the coal industry. He told the committee that the coal situation is the greatest issue before Congress and that the public should have the whole truth of current developments in the coal situation. He recommends fact-finding by the Interstate Commerce Commission. He also asserted that a powerful lobby has been working for years to prevent this legislation and that a large majority of coal operators are unscrupulous in their relationships with the public.

Plan to Assure Consumer Of Coal Quality

In line with announced plans of Joseph Buchanan, Indianapolis (Ind.) smoke inspector, for the regulation of coal sales so that the consumer may be assured of the quality of the product he buys, the Better Business Bureau has drafted for presentation to the City Council an ordinance providing that when coal is delivered a duplicate ticket, designating "either the true, usual and customary name of such fuel, or the name of the state from which it comes, together with the name or number of the district, mine or seam from which it was mined," be given to the purchaser with a description of the size and character of the fuel.

Substitutions or mixtures of fuel would not be permitted under the ordinance, except by understanding with and consent of the purchaser. Penalties for violation of any of the provisions include fines ranging from $25 to $100 for the first offense and from $50 to $200 and revocation of the license of the offenders for the second offense. The inspector said he would include a proposal to have all coal sold according to government specifications and arrangements for tests to be made of questionable fuel by the city chemist.

Journalists of Americas Hold Pan-American Congress

With the capital decorated as for an inaugural, publishers and editors from Central and South America, Mexico and the West Indies arrived in Washington on April 7 and met a similar group of representatives of the press from all parts of the United States at the First Pan-American Congress of Journalists.

The gathering is considered the most important journalistic conference ever held in the New World. Twenty-one republics are represented. Dr. Walter Williams, director of the School of Journalism, University of Missouri, was elected permanent chairman and Willis J. Abbott, editor, the *Christian Science Monitor*, Boston, vice-chairman.

Welcomed by President Coolidge and addressed, among others, by Herbert Hoover, the congress organized the Pan-American Association of Journalists to perpetuate the movement toward international understanding through the press initiated at the present gathering.

Among the prominent journalists taking part in the discussions at the Washington sessions were Señor Dr. Jorge Mitre, of *La Nacion*, Buenos Aires; Arthur Capper, Senator from Kansas; Rollo Ogden, editor, the New York *Times;* Frank B. Noyes, president of the Associated Press; Dr. James Melvin Lee, director of the School of Journalism, New York University; Señor Don Ernesto Montenegro, of *El Mercurio*, Santiago, Chile, and Dr. Benjamin Silva Herrera, of the *Diario Nacional*, Bogota, Colombia. These men discussed the part of the press in maintaining understanding among the American nations, as well as the various problems of news gathering, advertising and editorial policy common to all journalistic enterprises.

Following the Washington sessions of the congress, which terminated April 13, the 100 or more Latin-American editors started by motor bus on a tour of the eastern and central parts of the United States which will last approximately one month. On this tour many of the great industrial plants of the country will be visited and an inspection made of the highway development.

Kansas Shovel Operators to Consider Union Agreement

Five operators of the top vein of coal in the northern part of the Pittsburg (Kan.) field held a conference in Mulberry, April 7, with President Matt L. Walters and other officials of District 14, United Mine Workers, when it was decided that the miners should draw up an agreement for formal submission to the operators at once. Operators say they are paying the union scale for all work in the steam-shovel mines except what they class as common labor.

Refusal of the operators to sign a contract with the union including the scale for these employees was the occasion for the union miners "marching" on these mines a few weeks ago. That form of organization promotion eased after President Walters, other district officials and Alexander Howat, former president, were arrested. Their trials on charges of unlawful assembly and disturbing the peace have not yet been held. All are out on bond.

In a referendum on March 30 miners of the district decisively voted down a levy of 2 per cent of the earnings of working miners for the relief of unemployed members and a defense fund for the arrested men.

Unskilled Workers' Wages Rise Rapidly Since War

The findings of a recent report on wage changes in 29 countries by the International Labor Office are to the effect that international commercial competition has depressed wages in the export and import industries out of proportion to changes in wage levels which have taken place in strictly domestic lines of production.

The Scandinavian countries are the outstanding examples of those in which real wages are much higher than the 1914 index. The United States, Canada, Australia, Spain, Italy and Switzerland have in the past two years moved up into a similar position.

Another interesting fact brought out by the study is the position of unskilled as compared with skilled labor. In 1914 unskilled workers' wages were about 50 to 70 per cent of skilled workers' wages; in 1920 they were 80 to 90 per cent. This ratio has declined slightly but still remains much higher than in 1914.

War Department Wants Coal

The New York General Intermediate Depot, Quartermaster Supply Office, U. S. Army, Brooklyn, is receiving bids for the various camps, depots and buildings under its jurisdiction in the states along the Atlantic sea coast as far south as Delaware for nearly a quarter million tons of anthracite and bituminous coal, besides small tonnages of coke and briquets.

The first opening took place April 14, when bids were received for 71,445 gross tons of the various sizes of anthracite, 34 net tons smithing coal, 6 tons bituminous mine-run and 175 tons of briquets.

On April 19 bids will be opened for 10,851 net tons of bituminous mine-run and 7,038 net tons bituminous lump. On April 23 tenders will be received for 48,763 net tons of bituminous mine-run, 7,250 tons of bituminous lump and 30 net tons of coke. On April 27 bids will be opened for 58,517 net tons of bituminous mine-run, 26,971 tons of bituminous lump and 205 net tons of coke.

Indiana State Bids Rejected

All coal bids for state institutions of Indiana submitted recently have been rejected. The state joint purchasing committee said bids were received from forty-two firms. All the bids were considered too high. New specifications will be sent out and a new contract is expected to be let about May 20. The contract will call for thousands of tons of coal for the coming fiscal year.

I. C. C. Denies Plea to Make Emergency Rates Permanent

The Interstate Commerce Commission on April 12 denied petitions that emergency rates prescribed on coal from Southern fields to New England points during the anthracite suspension be made permanent or continued in effect pending establishment of permanent rates. The emergency schedules became effective Dec. 31 last and will expire April 30.

The Commission said its action was not to be construed as prohibiting the carriers from voluntarily continuing the present rates for such additional time beyond April 30 as in their judgment necessity might require.

The Commission reopened the proceedings for further hearings at a date to be fixed later, to determine the reasonableness of rates on bituminous and semi-bituminous coal and coke from mines in Pennsylvania, Ohio, Maryland, Virginia, West Virginia and eastern Kentucky to all points in the Middle Atlantic and New England States. The hearing also will consider rates on semi-anthracite from mines in Virginia to points in the Middle Atlantic and New England States.

The petitions to make the emergency rates permanent were filed by the New England Governors' Fuel Committee and others.

Ewen Miners Sign Contract For Pay by Ton

A new wage agreement, based on pay by the ton, has been accepted by the miners of the Schooley and Ewen shafts of the Ewen Colliery of the Pennsylvania Coal Co., at Pittston, Pa. Heretofore the men have worked on consideration, $8.80 for miners and $7.70 for laborers.

The new working agreement was framed last week at a meeting of representatives of the union and officials of the Pennsylvania Coal Co., following an inspection of the chambers in both shafts. The belief is that the new wage scale at the Ewen will be a benefit to the miners and company alike. International Organizer Frank Agati, who served as a member of the negotiating committee during the suspension, addressed the miners and urged acceptance of the new agreement.

Receiver for Southern Coal

Harry A. Mackey, City Treasurer of Philadelphia, was appointed receiver in equity for the Southern Coal & Iron Corp. on April 8 by U. S. District Judge Dickinson at Philadelphia under a bill in equity filed by William A. Behan, secretary and treasurer of the concern. The company is a Virginia corporation, capitalized at $3,000,000, and has offices in Philadelphia. Its home office is in Roanoke, Va. Its business is mining and selling iron, iron ores, coal and sand, and it has plants at Rittenhouse Gap. It owns leaseholds and mineral rights and also the capital stock of the Roanoke & Botetourt R.R., which represents a graded railroad right of way in Virginia.

British Miners Reject Lower Wages, Longer Hours and District Pacts; Invite Owners to Continue Parleys

Miners' delegates from all British coal fields, at a conference in London April 9, adopted a resolution against the acceptance of wage reductions, the lengthening of hours and the substitution of district for national agreements regarding minimum wages. As a result of this action another serious deadlock looms between the operators and miners.

Acceptance of some of the proposals was suggested as part of a panacea for Britain's crisis in the recent report of the Royal Coal Commission, but since the publication of this report the miners have been careful to state that they have not refused to follow it as a whole in seeking to put an end to the crisis. Their opposition to the suggestions of the Coal Commission in such vital matters as those stated above, however, has created pessimism as to the feasibility of general settlement of the crisis along the lines laid down in the report.

Public concern is intensified by the fact that on May 1 the coal subsidy will be withdrawn and some new way must be found of adjusting the serious differences between the mine owners and the miners.

A ray of hope was seen when it was stated after the conference of the miners' delegates that the miners' executives had extended an invitation to the mine owners to meet them again immediately for the purpose of continuing negotiations. It is felt that last Friday's conference did not decide anything definite, but simply gave a hint to the miners' leaders in various districts as to what the delegates at the general conference thought the best line to be adopted.

After the districts have been heard from there will be another meeting of the miners' delegates, following which something definite doubtless will be decided.

It is not likely that the Premier, Stanley Baldwin, or any members of his Cabinet will meet either the mine owners or the miners for the present. Governmental pressure, however, will be brought to bear in an endeavor to bring the warring factions to an agreement. It will be pointed out that a stoppage in the mining industry will result in serious financial losses not only in the coal industry but in affiliated industries.

The government is ready to give all possible assistance to both sides in the controversy and in the negotiations which, it is believed, will be resumed in the near future.

Bittner Asks Rehearing

Petition for a rehearing was filed with the West Virginia Supreme Court of Appeals at Charleston on April 6 for Van A. Bittner, chief international representative of the United Mine Workers in northern West Virginia. By this procedure the sentence of six months' imprisonment for contempt imposed by Judge I. Grant Lazelle in Morgantown will be stayed again. A month ago a writ of error was refused by the Supreme Court of Appeals. In the meantime Bittner is at liberty on the strength of the bond which he originally furnished for the writ of error.

Miners' Representatives Keep a Date with British Premier

Officials of the Miners' Federation of Great Britain in front of 10 Downing St., London, where they discussed the findings of the Royal Coal Commission with Stanley Baldwin, the Prime Minister. Left to right: Tom Richards, Herbert Smith, president of the Federation; A. J. Cook, secretary, and W. Richardson.

Supreme Court Sustains Commerce Commission on Emergency Priority Orders

In two decisions by Chief Justice Taft the U. S. Supreme Court on April 12 further sustained the authority of the Interstate Commerce Commission to issue priority orders for shipment of coal in periods of emergency, clarifying both the Elkins act and the Transportation act. Many points were covered by the Court last year in the Avent case; the decisions April 12 amplify these views and cover issues not raised in the previous case.

The two decisions reversed the actions of the U. S. District Court for Eastern Michigan, which had sustained demurrers to indictments returned against defendants under the Elkins act on charges of having violated provisions of Service Order No. 23 of the Interstate Commerce Commission, issued in July, 1922, establishing priority in coal shipments. The federal government appealed from the lower court's decisions. The action of the Supreme Court reinstates the indictments for trial on the merits of the cases.

The P. Koenig Coal Co., of Detroit, was indicted on charges of knowingly receiving as a shipper concessions from a carrier obtained by false representations to the carrier. In one count it was charged the Koenig company obtained shipment of coal from a West Virginia mine to Detroit on representations that the coal was destined for the Samaritan Hospital, when, in fact, it was intended for, and was delivered to, the Dodge automobile factory. Other counts were of a similar nature. The District Court sustained a demurrer on the ground that there could be no indictment under the Elkins act as no offense could be committed without the guilty knowledge and collusion of both shipper and carrier.

Shipper's Plea Denied

In its decision reversing this opinion, the Supreme Court holds there is nothing in the statute which releases a shipper from guilt because the carrier which granted the concession thought it was lawful.

An indictment against the Michigan Portland Cement Co. was returned on the charge that, in connection with the Bewley Darst Coal Co., the company obtained shipment of coal from a Kentucky mine to the Municipal Light & Power Co. at Four Mile Run Lake, and appropriated the coal to its own use. A demurrer on grounds similar to that in the Koenig company case was sustained by the District Court.

In the arguments before the Supreme Court, counsel for the cement company raised the points that violations of the Elkins act must be limited to concessions or discriminations violating a published tariff of a carrier and that the Transportation act does not give the Interstate Commerce Commission authority to fix preferences and priorities in transportation in that car service does not include transportation. Both of these contentions are swept aside by the Supreme Court decision.

New England Retailers' Meeting Stresses Better Coal Quality and Service

Regret that the anthracite operators had seen fit to abandon the practice of reducing prices on domestic sizes on April 1 was voiced by members of the New England Coal Dealers' Association in a resolution unanimously adopted at the twenty-fourth annual convention of the organization, held at the State Armory, Worcester, Mass., April 7-8. This departure from tradition, they explained, had created more or less resentment in the minds of some of the household consumers.

In discussing the action to be taken when the resolution was offered for discussion, one retailer wanted to know how he was to placate the irate consumer when the latter objected to paying winter prices for summer deliveries. Another dealer stated that the failure to reduce prices had sacrificed the favorable opinion some of his customers had for the industry during the late strike. A third speaker said that his retail company had made a cut of 50c. per ton in order to hold the good will of the householders.

A second resolution offered at the same time and adopted without discussion urged the producers to maintain a strict inspection service so that all shipments made should be up to the uniform standards approved by the Anthracite Operators Conference last year.

Urges Solid Front Against Oil

Harry L. Gandy, executive secretary, National Coal Association, was the principal speaker at the first day's session of the convention. Mr. Gandy urged organized opposition to fuel-oil competition and suggested further that the coal trade devote more attention to quality and service and less to price in its salesmanship efforts. Turning to the question of bituminous coal for domestic consumption in New England, he cited the experiences of the recent hard-coal strike and the limits on anthracite production as reasons why the dealer should consider soft coal.

Mr. Gandy closed his address with a brief discussion of the legislative proposals now being considered by Congress. Suggestions for emergency seizure and operation of the mines, he asserted, lacked a Constitutional basis. Moreover, the taking over of the mines would only add to the public burdens, compelling the consumer to pay more for his coal. Nor is there any warrant for the fact-finding legislation, which must rest upon a breaking down of the safeguards against federal encroachment in the domain of private business. Harry E. Davis, counsellor to the Chamber of Commerce of the United States, also touched upon the legislative situation in his annual report.

At the Thursday morning session C. Willing Hare, vice-president and general manager of the Anthracite Coal Service, outlined the plans of the hard-coal producers to meet competition and to help the retail distributor meet competition. The Anthracite Coal Service had been launched, he said, because the competitive situation demanded that the industry meet its sales problems with trained engineering skill. The gains since made in recovering business that had been lost or was about to go to other fuels had fully justified the service.

Col. A. N. Payne, assistant to the vice-president in charge of traffic, Boston & Maine R.R., outlined the different classes of loss and damage claims presented to railroads and the steps which should be taken by claimants, first, to establish clear records on cars and, second, to support their claim papers with evidence which will lead to prompt payment.

Clear thinking, asserted Richard F. Grant, president, Susquehanna Collieries Co., will cure many of the ills and expose many of the fallacies of the day. There is too much loose thinking, too great a willingness to let others do our thinking. Thinking based upon knowledge of the facts of a situation will end much of the unfair charges now hurled against business and American institutions. It will lessen and curb the cry for government in business because it will bring the realization that managerial ability is a personal, not a bureaucratic, possession and that any system which gives men leadership except upon demonstrated merit invites destruction.

W. A. Clark was again the unopposed choice for president of the association.

Soft Coal an Aid to Art, Says British Painter

Sir John Lavery, British artist, on arriving in London last week, had some interesting comments to make on his recent five-month stay in the United States. Speaking of the effects of the temporary use of soft coal on New York, the artist said: "The effect of this temporary eclipse on great blocks of masonry is beautiful in the extreme, and I thought if Turner had been alive how it would have appealed to him. The softened effect on huge skyscrapers is wonderful."

Mines of Pursglove and Paisley Interests Resume With Reduced Wage Scale

The Pursglove interests, of Cleveland, last week posted notices at their mines announcing that beginning April 12 the plants of the Cleveland-Morgantown Coal Co., controlled by them, would be operated on what amounts to the 1917 wage scale. The notices were placed at the four mines of the company on Scotts Run, in the Monongalia field of West Virginia, on April 7. Following closely after the formation of the new union district, No. 31, this action is regarded as significant, especially as the Cleveland-Morgantown Co. has been one of the few companies in the Morgantown district which has continued to operate in agreement with the union at a time when other companies were operating on an open-shop basis.

Mines of the Pursglove interests were closed down on April 1, the explanation being given that the company could no longer operate under the terms of the Jacksonville agreement. The new wage scale represents a 30 per cent reduction from the Jacksonville scale, with pay at the rate of 60c. a ton for picking mining in entries, rooms and pillars, with 62½c. an hour for drivers, motormen, gathering locomotive men, trackmen, timbermen, bratticemen and 75c. an hour for carpenters.

Steps also have been taken by the Paisley interests, who control mines in the northern Panhandle of West Virginia, in eastern Ohio and southern West Virginia, to operate the Murray mine of the Morgantown Gas Coal Co. on a lower wage scale, several cars having been loaded last week. The understanding is that an agreement has been entered into with the men employed at the mine to pay at a rate about 20 per cent lower than the Jacksonville scale.

With the Pursglove and Paisley interests operating independent of a union agreement the Gilbert-Davis Coal Co. is about the only firm of any size in northern West Virginia that continues to work under the Jacksonville scale.

Witnesses Say Runner of Open-Type Cutter Ignited Gas at Eccles Mine; Jury Declares Cause Undetermined

Failure of a machine runner to test for gas before taking his machine to the face of a place in the Eccles mine of the Crab Orchard Improvement Co., at Eccles, Raleigh County, W. Va., was declared by witnesses as probably the most vital factor in the explosion which occurred in that mine on March 8. Testimony set forth as possible contributing factors an accumulation of gas in the place resulting from the collapse of a three-day old canvas stopping in the next to the last crosscut, probably due to a fall of roof, and an arc from an open cutting machine. This theory was many times repeated by witnesses at the inquest of this explosion, which was held at the mine on April 7.

On the other hand, the jurymen with due caution expressed their view in a verdict that the nineteen victims of the explosion "came to their death by a gas and coal-dust explosion and afterdamp. We are unable to find, from the evidence produced, how the gas was ignited."

Best Runner on Job

William Dickey, the machine runner in question, was the best runner on the job, according to J. P. Horn, acting general superintendent. In the opinion of other witnesses who were more closely associated with him, however, he was the best only as a "coal-getter." Each witness when asked whether he believed this cutter had examined the place carefully before allowing the machine to approach the face answered in the negative.

Harry Nisbet, fireboss, remarked on the stand that complaints came to him that this man frequently omitted the preliminary inspection of his places. Mr. Nisbet said he warned Mr. Dickey repeatedly not to omit this precaution. This fireboss added, when questioned, that he had no authority to discharge this alleged careless man. He admitted that he had not at any time reported this alleged willful violation of the mine law to anyone in authority.

Four years ago Mr. Dickey and his son ignited gas at the face of a place in the Eccles mine, as a result of which the latter was burned. The mine at that time belonged to another company. On this occasion Mr. Dickey did not carry a safety lamp with him.

Marshall Loving, section boss, said that shortly before the occurrence of the explosion he met Mr. Dickey with his machine near the place where the explosion is believed to have originated. The cutter's safety lamp was not lit. A tracklayer later told Mr. Loving that he saw the cutter light his lamp.

On the day of the explosion he found a trace of gas at the faces of Third Left off the aircourse in Section A-1, where the explosion seemingly originated. In addition to bossing, his duties consisted of bratticing and shotfiring. The canvas in the places inspected that day was in fair condition, but in spots it was more or less worn.

Fireboss Nisbet asserted that the place where Dickey was cutting in Section A-1 gave off much gas. A line brattice had been hung in this place to a point within about 12 ft. of the face. In his run on the day of the explosion, he found the ventilation good and the places visited clear of gas. Although the last crosscut in the place had been completed three days, the crosscut next to the last had not yet been sealed with a permanent stopping. A canvas brattice hung in this crosscut.

Section Boss Loving remarked that the top in this vicinity was none too good. He thinks the temporary canvas stopping in the next to the last crosscut may have been torn down by a slate fall. An accumulation of gas also might have followed a disarrangement of the line brattice already mentioned. He made his last inspection of this place three and one-half hours before the explosion and found no gas. Several falls had occurred in the vicinity, but these were not sufficient, in his opinion, to interfere with ventilation to any great extent.

About 70 per cent of the coal was mined by pick from pillars. Narrow places were cut by three machines—a permissible undercutter, an open-type arcwall and an open-type turret or center-cutting machine. The last-mentioned machine was believed to have been responsible for the ignition of gas. It had reached the face, but none of the tools had been removed from it, and the controller was shut off. A safety lamp hung from the rear headlight of the machine. The bodies of the two runners were found about 40 ft. from the machine. It is believed that after the gas was ignited they ran outby until they were overcome.

Wanted Dust Removed

Robert Lilly, state mine inspector of the district, made with W. L. McGinnis, state inspector of an adjoining district, a joint inspection of the Eccles mine on Jan. 25, 26 and 27. As a result of this inspection they recommended that a large quantity of dry coal dust in Section A-1 be removed and that timbers be set. Otherwise the mine was in excellent condition.

C. A. Sine, superintendent, did not believe that much of the dust that accumulated was dangerous inasmuch as it was mixed with a large quantity of sand that had been ground fine under the wheels of the locomotives. Chief R. M. Lambie, of the West Virginia Department of Mines, said that when such a mixture is suspended in the air most of the sand would fall away from the coal dust to the ground. He drew from Mr. Sine an opinion that an inert, pulverized material, preferably limestone dust, would have stopped the propagation of the flame.

The changes recommended by State Inspectors Lilly and McGinnis after their last inspection were being made according to J. P. Horn, acting general superintendent. The Eccles mines were taken over by the Stonega Coke & Coal Co. on Sept. 15, 1923. Since that time, to the best of his knowledge, no other gas ignition had occurred in this mine. Sixty cars of refuse had been removed from the haulway of Section A-1.

Much Brake Sand

The grades of the track in this section are heavy—as much as 10 per cent—and on these the locomotives used an average of two-thirds of a carload of sand per day. In contradiction to hints made by several witnesses to the effect that brattice cloth was not always available when needed, Mr. Horn testified that more than sufficient canvas always was on hand. The company expected its men to tear down canvas where it was not needed and to use it over again so long as it was serviceable. Some men were reluctant to do this.

All machine runners and their assistants had been examined for competency—a step in advance of the mine law, which requires examination of runners only. Gas samples were taken and analyzed each week. The mine was sprinkled at regular intervals by water boxes. Section A-1 was thoroughly sprinkled the day before the explosion.

All evidence as to the origin of the explosion indicated that the place mentioned and the facts stated were the cause of the disaster. The fact that coal dust played the biggest part in the explosion was definitely established—first by the distance traveled and second by the evidence of coking. Inspector Lilly believes that the main force of the explosion in Section A-1 traveled outby through the aircourse. Less force was exerted in the haulway because here the pressure was relieved by expansion into the many rooms that connected with it. He believed that the two split paths of the explosion met at the junction of the two headings of Section A-1 with No. 1 West headings. The blast was boosted and receded in intervals until it finally spent itself through a relief of pressure. Manifestations of force were noted as much as 2¼ miles from the seat of the explosion. Where the suspected cutting machine was in operation little evidence of violence was seen.

Miners Sign Scale and Give Employer Scarfpin

James Moore, owner and operator of the Sunnyside mine, at Evansville, Ind., is wearing a diamond stickpin, presented him by his employees when they renewed their wage contract last week.

Loyalty of Moore's miners to their employer was one of the chief obstacles in the way of southern Indiana union miners in their recent attempt to unionize that field. The Sunnyside miners refused to quit work despite the appeal of the union men when Moore asked them to remain.

Moore's contract with his men calls for 90c. a ton or $6 a day for mining this year. This is the same wage paid them last year.

Mine Accidents Claim 164 Lives in February; Fatality Rate Recedes

Accidents at coal mines in the United States in February, 1926, caused the death of 164 men compared with 318 in the preceding month, according to information received from state mine inspectors by the U. S. Bureau of Mines. The total fatality rate for the month, based on a production of 48,660,000 tons of coal, was 3.37 per million tons, as compared with 4.25 for February, 1925. Of the 164 lives lost in February, 157 were at bituminous coal mines, only 7 fatalities occurring in the anthracite field, the anthracite mines being closed until operations were resumed Feb. 18. The fatality rate for bituminous mines in February was 3.37 per million tons based on an output of 46,577,000 tons of coal, and the rate for anthracite was 3.36, based on a production of 2,083,000 tons. In February, 1925, the rates were 3.77 and 6.83 respectively.

Two major disasters—that is, accidents causing the loss of five or more lives—occurred during the month. On Feb. 3 a mine explosion at Horning, Pa., caused the death of 21 men. On Feb. 16 an explosion, caused by shot-firing, killed 8 men at the Nelson mine, at Nelson Creek, Ky.

Accident records covering the first two months of the year show a loss of 482 lives, which is 51 more than for the same period in 1925. The rate per million tons for the period was 4.70 as compared with 4.08 last year. The rates for major disasters alone for these periods were 1.67 in 1926 and 0.55 in 1925.

An analysis of the principal causes of the 482 fatalities in 1926 shows a reduction in the per-million-ton death rates for all of the principal causes except explosions of gas and coal dust. A comparison of the rates for the first two months of the two years is shown by the following figures:

	Jan.-Feb., 1925	Jan.-Feb., 1926
All causes	4.085	4.703
Falls of roof and coal	1.810	1.756
Haulage	0.749	0.663
Gas or dust explosions	0.701	1.785
Explosives	0.274	0.098
Electricity	0.142	0.127

Shaw Invests in Project To House Miners

George Bernard Shaw, Irish playwright and socialist, has lent £30,000 at 5½ per cent interest to the rural District Council of Easington, near Durham, England, which is to be used to help finance a big housing project, according to a London dispatch to the New York *World*, dated April 2. When questioned by newspaper men Britain's most prolific commentator refused to comment on the loan other than to state that it was "a purely private investment." Easington is a populous coal-mining district.

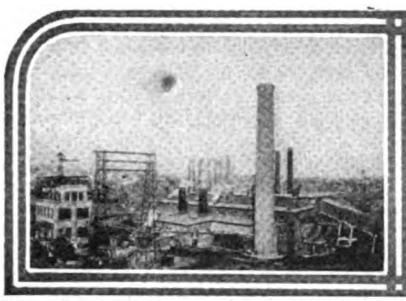
Glen Rogers Plant Passes to Old Ben for $3,000,000

Since the recent announcement by the Old Ben Coal Corp., of Chicago, that it had acquired some coal properties and connections in the non-union fields of West Virginia and Kentucky confirmation has been forthcoming that the company purchased the Glen Rogers (W. Va.) plant of the Raleigh-Wyoming Coal Co. on April 1, although Carl Scholz, vice-president and general manager of the latter company, had denied the first report of the sale.

Approximately $3,000,000 is said to have been involved in the deal, which includes 9,000 acres in Wyoming County. The Glen Rogers plant is said to be one of the best equipped in southern West Virginia, output in 1925 totaling 250,095 tons.

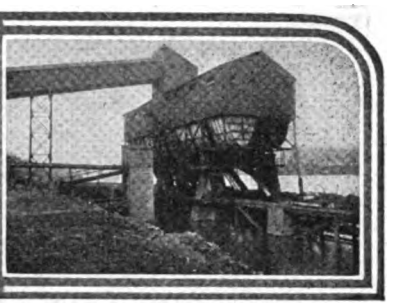
Preparing Safety Statement

A comprehensive statement of the attitude of the Bureau of Mines on matters pertaining to safety and health in coal mines is being prepared by George S. Rice, the Bureau's chief engineer. This statement will contain 10,000 words and will be published in the form of a bulletin. It will be fully annotated and will be used as a text book for the safety extension service.



Sealed Proposals Will Be Opened by the Supt. of Lighthouses, Philadelphia, Pa., 2 P. M., May 18, 1926, for anthracite and bituminous coal, acetylene and acetone, and fuel oil for fiscal year 1927. Information upon application.

Coal-Mine Fatalities During February, 1926, by Causes and States



(Compiled by Bureau of Mines and Published by *Coal Age*)

State	Underground												Shaft					Surface							Total by States

News Items From Field and Trade

ALABAMA

Fire of unknown origin broke out in abandoned workings in the Flat Top mines of the Sloss-Sheffield Steel & Iron Co. on March 26. The blaze was confined to a restricted area a mile or more from the portion of the mine being worked and was extinguished without injury to workers and caused only a nominal property damage. This mine is operated by the State of Alabama under lease and is worked with convict labor, the coal being delivered to the owners at a stipulated price per ton.

Work-Train Collision Kills Seven.—A passenger train operated on the Birmingham Southern R.R., a subsidiary of the Tennessee Coal, Iron & Railroad Co., transporting employees of the latter to and from Birmingham and other points to the Bayview and Edgewater coal mines, collided head-on with a work train of the same line March 30, resulting in the death of seven employees and the injury of twenty-one others. Those killed were all negroes. Only two of the others were injured seriously.

The Birmingham Southern R.R. has ordered 100 gondolas from the Tennessee Coal, Iron & Railroad Co.

ILLINOIS

The Republic Coal & Coke Co., Chicago, will henceforth exclusively distribute Roxana Petroleum Corporation's entire production of petroleum coke from its Kansas, Illinois and Indiana refineries.

Magnetically locked safety lamps have been introduced into thirteen mines in southern Illinois. The move was the result of the explosion several months ago at West Frankfort which was caused by a miner tampering with a lamp in one of the passages.

Claim Illinois Record.—A record for two-man coal mining in southern Illinois is being claimed for Jack Pierson and Albert Kun at Ledford, southeast of Duquoin. From March 1 to 15 they loaded 461 tons of coal. Pierson was then taken ill, and during the next ten days Kun working alone loaded 240 tons.

INDIANA

Panhandle Mine No. 5, at Bicknell, which closed its general workings Feb. 25 to work new entries, has resumed hoisting with a full force. A shortage of rooms was caused a few months ago by the squeezing and caving of a number of working places on the east side of the mine. A night and day struggle for new rooms to replace the loss was maintained. All the mines in the Bicknell field have been working for the past month, which is considered rather exceptional for this season of the year.

The Standard mine, at Wheatland, which has been working steadily for the last few months, is increasing its daily tonnage by the addition of much new loading machinery.

The Warren Coal Co., of Terre Haute, has filed a certificate of dissolution with the Secretary of State.

KENTUCKY

Representative Kirk (Rep., Ky.) has introduced H. R. 10769, to establish a mine rescue station at Hazard. The bill was referred to the mines and mining committee.

NEVADA

Developing Nevada Coal Mine.—While Nevada produces nearly every known metal and many of the nonmetallics, no commercial body of coal has yet been developed. Herman A. Darms, who for several years has persisted in his efforts, although handicapped by lack of funds, to open up a coal prospect at Coaldale, about seventy-five miles west of Tonopah announces, however, that he is now financed to complete his development plans. He has already ordered a carload of timbers to be used in framing the old shaft to a depth of 280 ft. on top of the first coal structure, which was opened up three years ago. When work of timbering the shaft has been completed, it is his plan to extract 150 tons of the coal for use in the boilers of the diamond drills. The drills are good for 2,500 ft. and the ground will be thoroughly explored.

NEW YORK

The contract for furnishing 85,000 tons of fuel to the Great Lakes Transit Corp. (Conners Line) was let last week to Consolidation Coal Co. for 55,000 tons, to be delivered at Buffalo, and to the N. A. Hanna Co. for 30,000 to be delivered at Erie, Pa. Prices are withheld.

OHIO

The Johnson mine of the Cleveland & Western Coal Co., Dilles Bottom, employing 250 men was closed down indefinitely April 6 on orders received from Cleveland headquarters. The Franklin mine of the same company, at Stewartsville, idle since March 31, resumed operations the same day, and the Pipe Creek mine, largest in eastern Ohio, employing 700 men, is working.

Nearly 50 per cent of eastern Ohio mines are in operation at present, according to an official report issued by C. J. Alberson, commissioner for the Pittsburgh Vein Operators' Association. The report shows daily production of 33,800 tons, which is 29 per cent of the maximum capacity of 113,100 tons. Forty-six of the 108 mines in the field are working.

Resume Strip Mining.—Strip mining has begun in eastern Ohio due to an increased demand attributed to the opening of the lake season. The Central Mining Co. has put two steam shovels to work on its properties along the Lincoln highway in Columbiana County. Other mines in the district report good prospects for steady work.

Papers have been filed increasing the authorized capital of the Byesville Coal Co. from $12,500 to $25,000. Alex Ramage is president and H. P. Muhlbach, secretary.

Bids will be received by the Board of Public Affairs of Barnesville on April 27 for about 1,500 tons of three-quarter screened or forked coal, Pittsburgh No. 8 vein, for the Water Works Department, to cover the period from May 15, 1926, to May 15, 1927.

At the annual stockholders' meeting of the Hocking Valley Railway Co., held April 6, W. J. Harahan, Richmond, Va., K. D. Steere, Cleveland, and Willis D. Wood, New York, were elected directors to serve until April, 1929. Other directors continued in office. Routine business only was transacted.

PENNSYLVANIA

Reading Revenues Unhurt by Strike.—In his annual report as president of the Reading Company, A. T. Dice stated that the recent anthracite strike did not curtail the revenues of the company. On the contrary, due to the diversified business the company actually enjoyed an increase in traffic, much of the loss from anthracite movement being offset by the movement of bituminous coal and coke. Prior to 1897 about half of the road's entire tonnage consisted of hard coal, and a strike in those days almost meant disaster. Now this is all changed, for whereas in 1895 anthracite constituted 55 per cent of the tonnage, fifteen years later it was only 38 per cent of the total, and two years ago it was 21 per cent. During the past year it was only 18 per cent.

Ship to Test Pulverized Fuel.—Under the auspices of the Navy Department tests are being arranged for at the Philadelphia Navy Yard, at League Island, of the use of pulverized fuel on merchant ships. A plant already has been set up at the yard and devices which have been developed by several manufacturers are to be tried out. It

Digitized by Google

Mine No. 261, Consolidation Coal Co., Caretta, McDowell County, W. Va.

A group of company houses with the mine plant in the background. To date the coal is still being hoisted through the auxiliary shaft. The permanent tipple and screening plant is now being completed. In the foreground of the photograph is concrete-surfaced state road No. 66.

is asserted that, if necessary, a crusher can be erected on board ship to pulverize low-grade coals, and this powdered fuel can be utilized in oil-burner installations.

Seven employees of the Bethlehem Mines Corp. at Heilwood, have been granted certificates upon graduating from the two-year course of mine instruction sponsored by the Vocational Education Board in co-operation with the School of Mines of Pennsylvania State College. The successful students, all of Heilwood, are Charles Covalesky, Eugene Croyle, Fred Haas, Ralph Muffley, Michael W. Thomas, W. T. Trinkley, and Blair Muffley. The certificates were presented by W. G. Duncan, associate professor of industrial education of Pennsylvania State College. Blair Muffley was the instructor of the class.

At the Royal Mine of W. J. Rainey, Inc., at Royal, Fayette County, which closed down three weeks ago for electrification, the installation of the electric hoist and haulage system has been finished and operation resumed. Some electric pumps are still being installed.

More than 400 acres of coal land in Hamilton County Ohio, owned by the Harmon Creek Coal Co., in which John A. Bell was a heavy stockholder, were held to be within the terms of a mortgage issued to the Colonial Trust Co. in an opinion filed last week in common pleas court at Pittsburgh by Judge John D. Shafer. The trust company brought suit against the coal company, asking the court to order the directors of the latter company to make a deed for the Ohio coal land so as to include it within a mortgage executed on June 18, 1917, when $1,500,000 of bonds were issued.

Pittsburgh Terminal Profits — First-quarter earnings of the Pittsburgh Terminal Coal Corp. were between $125,000 and $150,000 after all charges, but before federal income taxes. Last year there was a net loss of $97,000. Production of 379,000 tons in March of this year compares with 223,000 last year. The company is well sold ahead, practically all of its contracts expiring April 1 having been renewed for another year.

Bituminous coal (revenue) transported by the Reading Co. during February, 1926, totaled 2,489,400 gross tons, compared with 1,659,753 tons in the corresponding month of 1925.

Open-shop miners of the Pittsburgh Coal Co., loaded a higher coal tonnage at 10 mines in the Pittsburgh district April 7, than in any single day since operations were resumed last August, independent of the United Mine Workers, the company reported. The total was 7,084 tons, The company passed the 2,000 mark in the number of men working under the November, 1917, wage scale, for the first time when 2,106 men reported for work.

Many Mines Idle.—Of the 643 coal mines on the Pennsylvania R.R. in the central Pennsylvania field 370 were idle last week, 49 working one day a week; 63 two days; 58 three days; 33 four days; 27 five days; 42 six days. Loadings for the week ending April 3, totaled 11,723 cars, as against 14,631 for the preceding week. March loadings were 70,245 cars, as against 82,648 in February.

The Century Coke Co., near Brownsville, has closed down, as has the Mt. Sterling plant of the Consolidated Coke Co. The Gray's Landing plants of the Consolidated Coke Co. and the plants of the Husted-Semans Coal & Coke Co. at East Middlesboro, both in Fayette County, are running very short time.

The Jones & Laughlin Steel Co., Pittsburgh, will start work at once on the construction of ten gondola type barges for the Vesta Coal Co., one of its subsidiaries. They will be used in carrying coal from the mines to the mills and to ship steel to Southern ports.

John A. Bell, Carnegie banker and coal operator, under sentence for embezzlement, who suffered a stroke March 26, was reported little improved last week. This is the second stroke Bell has suffered since his business affairs got him into difficulties. Last summer a stroke paralyzed his left side. Bell, who is 72 years old, was sentenced Feb. 1 to six and one-half years in the county jail for embezzlement in connection with the conduct of the Carnegie bank. He is out on bond while his appeal to the state Superior Court is being considered.

Cosgrove-Meehan Earns $162,839

Net earnings of the Cosgrove-Meehan Coal Co., of Johnstown, Pa., reported for 1925, were $162,839.27, after all charges, including preferred dividends, but before federal taxes, or 68c. per share on 239,467 shares of no par common stock. Total assets were $12,727,065.45, including current assets of $1,947,462.02, and fixed assets of $10,375,406.70. Deferred charges and prepaid expenses totaled $404,196.73.

The suit of the Hercules Cement Co., of Philadelphia, against Hall Bros. & Co., Inc., of Baltimore, was tried in the Court of Common Pleas at Philadelphia, April 5. The plaintiff claimed about $3,700 damages for non-shipment on an order for Fairmont coal to be supplied in April, 1922, during the strike of the United Mine Workers. The jury rendered a verdict in favor of the defendant.

UTAH

New Spur to Coal Region.—The Interstate Commerce Commission has authorized the Denver & Rio Grande Western R. R. to abandon the Kenilworth & Helper R. R., 3.75 miles long, in Carbon County, chief coal producing section of the state, and at the same time gave permission to construct a spur of 6.25 miles from Spring Canyon Junction eastward into a rich coal field now in part served by the road to be abandoned. It was stated that the old road was expensive because its grades are 6 per cent and more, while the new spur will have a maximum grade of but 3 per cent westward and 1.5 per cent eastward. Construction will start at once and it is expected that the new line will be ready for use Oct. 1. It will serve a new mine to be opened soon by the Independent Coal & Coke Co. and at the same time will continue to serve that company's present mine. It is said the new spur will take care of 600,000 tons of coal the first year of its operation, increasing within five years to a million tons. The construction of the spur will involve an outlay of $469,000.

VIRGINIA

The name of the Blue Diamond Coal Co. has been changed to the Bonnie Blue Coal Co., with headquarters at Diamond. James Dupup is the general manager. This company is owned by H. C. Williams and associates of Middlesboro.

The average weekly production of coal in the Virginia field for eleven weeks of the calendar year 1926, end on March 13, was 233,800 tons, representing about 90 per cent of the producing capacity of the field. Out of a total of 156 mines in the field 75 were idle and 81 active. Production to the

Digitized by Google

end of the second week of March this year was 2,572,400 tons, against 2,157,000 tons in 1925 and 1,934,000 tons in 1924.

WEST VIRGINIA

The Talbot-Chambers Coal Co., 1708 Union Trust Building, Cleveland, recently filed a certificate at the office of the Secretary of State, in Charleston, which shows that the name of the corporation has been changed to the Dragon Coal Co.

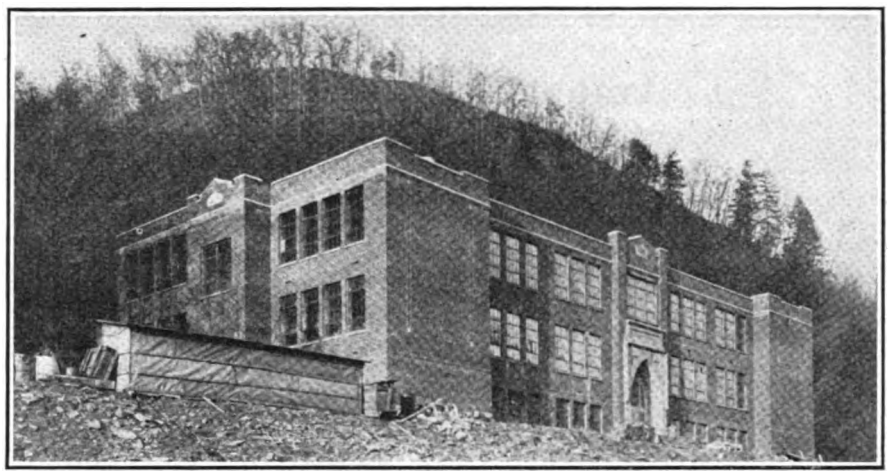
In order to make improvements the Fordson Coal Co. has suspended operations at Nuttallburg for a few weeks. The company is engaged in installing a new retarding conveyor which will reduce breakage in loading coal into the cars.

Col. T. E. Houston, with interests along the Norfolk & Western, and Capt. R. R. Smith, of the R. R. Smith Coal Co., of Huntington, operating mines in the Logan and Pocahontas fields and the Elkhorn field of Kentucky, have become interested in the transportation of coal by water down the Ohio River and have acquired a frontage on the river at Kenova for the purpose of installing river loading equipment.

The Whiteley Creek Coal Co., of Monongalia County has surrendered its charter at the office of the Secretary of State in Charleston.

The Farley Coal Co. has changed its plan of capitalization from 3,000 shares of common stock to 2,000 shares of preferred stock at $100 and 4,000 shares of common stock at $1 a share, reducing its total capitalization from $300,000 to $204,000.

The Meadow Creek Coal Co. has increased its total capitalization from $200,000 to $400,000.



A petition in voluntary bankruptcy was filed last week in the office of the U. S. deputy court clerk at Huntington by the Kentucky Elkhorn By-Products Coal Co., of Huntington. Thomas F. Bailey, vice-president of the company, appeared as the petitioner. Assets are listed at $124,106.25 and liabilities at $144,649.17.

The Buckeye Coal Mining Co., Warren, Ohio, a West Virginia corporation, was dissolved and surrendered its charter at the office of the Secretary of State in Charleston April 1.

The United States Coal & Coke Co., operating in the McDowell County field, has announced in a safety bulletin that there has not been a single fatal accident at Gary within the last four months and that during those four months the company mined 1,300,531 tons of coal.

The Wentz Corporation, Philadelphia, Pa., a West Virginia corporation, recently filed amendments to its charter at the office of the Secretary of State in Charleston.

The state Department of Mines last week issued certificates for mine rescue and first aid work to 10 seniors in the mining engineering school of West Virginia University, at Morgantown. Those who received certificates were Harry G. Kennedy, Percy H. Gillie, C. A. Ray, Russell W. King and Patrick D. McMurrer, all of Charleston; Iva A. Given, Sutton; R. W. Wotring, Morgantown; G. E. Fish, Buckhannon; N. R. McGinnis, Fairmont, and C. H. Farmer, Bolt. The training was given recently at the University by state mine department officials.

New High School at Coalwood, W. Va.

Approximately $100,000 is being expended on this building, erected on property of the Consolidation Coal Co., in McDowell County. Besides the usual complement of recitation rooms there is included a combination gymnasium and auditorium seating 550, a chemical laboratory, physical laboratory, study hall, library, teachers' rest room, and so forth. Nothing is lacking to make the high school all that is to be desired. Among the special courses are domestic art, domestic science, and manual training.

Information has been received by the state Department of Mines, in Charleston, that the seals over mine No. 63 of the Consolidation Coal Co., at Monongah, which has been afire, were removed last week. There is considerable fire apparent, but this will be fought direct, according to reports.

The estate of the late W. M. Puckett, president of the Cabin Creek Consolidated Coal Co., is valued at $114,628.80, according to a report filed in Charleston March 23 by appraisers. He owned 952 shares of Cabin Creek Consolidated Coal Co., which is valued at $95,200.

Because of the large number of bidders and inability to inspect all of the mines, the Chesapeake & Ohio Ry. has deferred letting coal contracts until May 1.

The Stover Coal Co., located at South Nuttall, Fayette County, has closed down its mine temporarily.

The Consolidation Coal Co. has rock-dusted its Carolina mine, on the Western Maryland Ry. in Marion County, according to reports received by the state Department of Mines.

Recently on Keeney's Creek in the Lookout section, oil drillers reached a new coal seam 500 ft. below the measure now being worked there. It means a new development in these coal fields, it is reported.

Pocahontas Has Big Year.—Earnings of the Pocahontas Coal & Coke Co. in 1925, according to the annual report, were the largest in the company's history. Royalties on coal mined and coke manufactured were $1,546,451.10 and other income was $84,566.04, or total earnings of $1,631,017.14, compared with $1,410,581.45 in 1924. Operating expenses were $158,357.06 and taxes $185,837.65, leaving net earnings of $1,286,822.43. The company neither mines nor sells coal itself, being a land-owning company, all of whose capital stock is owned by the Norfolk & Western Ry.

Grant Town No. 1 and Lowesville No. 3 mines of the New England Fuel & Transportation Co., produced 132,000 tons of coal in March and established a new daily record on April 1 with an output of 5,100 tons.

In order to reduce the danger of explosions to a minimum, the Landstreet-Downey Coal Co., operating on the Rockhouse Fork of Pigeon Creek, in Mingo County, is having its mines rock-dusted. The Leckie Colliery Co., operating near Williamson, also expects to rock-dust its mine, a spraying machine having been received.

The Marion Division of the Bethlehem Mines Corporation smashed all production records in March, when the mines at Dakota and Barrackville exceeded the former peak daily, weekly and monthly loadings. During March the Dakota mine loaded 114,032 tons in 27 working days, an average of 4,223 tons daily.

Engineers have begun the installation of a device in the Dakota mine of the Bethlehem Mines Corporation which is expected to prevent short-circuits in the air currents. The idea is said to be revoluntionary, but as it has been worked out only theoretically, its success will not be known until it has been in actual use for some time. Company officials will not reveal details of the plan until it has been thoroughly tested.

CANADA

A new field of high-grade lignite has been found by William Woodend, who for the last few years has been slowly developing the Copsey mine, some forty-five miles south of Moose Jaw in the Ardill district, on the west bank of the Lake of the Rivers. It is estimated that the deposit will yield approximately 4,000 tons of fuel per acre, and the area of the coal, while yet undetermined, will be several square miles at least. The main seam is over 4 ft. thick and only 80 ft. below the surface.

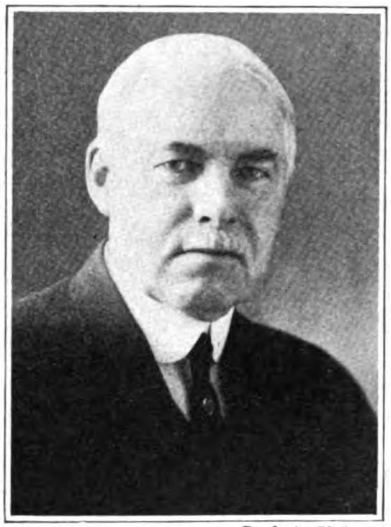
Among the Coal Men

Joseph D. Zook, who for the last eight years has been vice-president of the Nason Coal Co. and has taken an active part in its management as well as of the Illinois Coal Corp., has joined the forces of the O'Gara Coal Co., Chicago, as vice-president, effective April 1. He also is a director of the Illinois Coal Operators' Association and has an enviable reputation in the industry.

L. E. Young, general manager of the Union Colliery Co., St. Louis, Mo., is kept pretty well on the jump between attending meetings of the scale committee of the Illinois operators, besides investigating recent developments in mine production costs, which take him all the way from St. Louis to Pittsburgh.



J. B. Marks, vice-president and assistant to President J. F. Welborn, was made a new Colorado Fuel & Iron Co. director at the annual meeting. Other directors, re-elected, are George B. Berger, Thomas M. Debevoise, Fred Farrar, William V. Hodges, S. G. Pierson, Albert A. Reed, M. D. Thatcher, E. H. Weitzel, J. F. Welborn, E. T. Wilson and Arthur Woods. Members of the executive committee who also were appointed are J. F. Welborn, Thomas M. Debevoise and Arthur Woods. The officers are J. F. Welborn, president; Arthur Woods, vice-president; J. B. Marks, vice-president and assistant to president, in charge of sales, traffic and purchases; E. H. Weitzel, vice-president and general manager; S. G. Pierson, vice-president and treasurer.

M. B. Mitchell has resigned as superintendent of the Bower mines of the West Virginia Coal & Coke Co. to become general superintendent of construction for the Fairmont Mining Machinery Co. Before going with the West Virginia Coal & Coke Co. Mr. Mitchell was for several years general superintendent of the Marion division of the Bethlehem Mines Corporation.

Stephen Downs, Lansford, Pa., fuel engineer for the Lehigh Coal & Navigation Co., delivered an address in the Chamber of Commerce Building, Philadelphia, on April 7 in the lecture course on "Combustion" being conducted by the Anthracite Economy Service. Mr. Downs detailed the methods of the campaign entered into by his company in Lansford, Allentown and Easton in its direct to the consumer plan of inducing the burning of anthracite buckwheat in household heating plants, with the results obtained. He also displayed types of grates used in the heaters of the consumers who gave the scheme a trial.

U. S. Senator Fred M. Sackett, one of Louisville's leading coal men, has returned to Louisville for three or four weeks, after some time spent in Washington. Mr. Sackett is an operator, jobber and retailer.

H. A. McAllister, who had been manager of mines of the Logan division of the West Virginia Coal & Coke Co., has been made manager of mines of the Thurmond Consolidated Coal Co.

P. & A. Photos.

Samuel W. Parr

In recognition of his distinguished achievements in chemical science, Samuel W. Parr, professor of applied science in the University of Illinois and one of America's greatest experts in the chemistry of coal, is the winner of the Chandler gold medal for 1926, it has been announced at Columbia University, New York City. Dr. Parr, known chiefly to Illinois people as the inventor of the Parr low-temperature coking process for coking Illinois coal, is well known nationally for other reasons. He perfected a new alloy, ilium, used in many ways as a substitute for platinum, although costing only a fraction as much. He has also presented the scientific world with many valuable instruments.

E. M. Showalter, of the Continental Coal Co., is ill with influenza at his home in Fairmont, W. Va.

Charles M. Paisley, treasurer of the Kelly's Creek Collieries Co., Charleston, W. Va., and Carl Scholz, vice-president and general manager of the Raleigh-Wyoming Coal Co., Charleston, are among the active spirits in the recently organized and chartered Charleston Business Men's Club.

Charles Whiting Baker, formerly editor of *Engineering News*, has become associated with Baker, Simonds & Co., Inc., investment bankers, 115 Broadway, New York.

Obituary

James A. Abraham of Sonterfield, Pa., died March 27 from a complication of diseases, aged 50. He formerly was employed by the Whyel Coke Co., of Uuniontown, as a superintendent for one of the Whyel plants for a number of years.

W. L. Malone, of Philippi, W. Va., World War veteran and coal operator, passed away April 2 at a hospital in Clarksburg, W. Va., following a five weeks' illness. Mr. Malone was well known in the Barbour County coal field and in adjacent coal territory, having been engaged in the coal business for several years.

William Henry Brasfield, a pioneer developer and owner of coal properties in Walker and Jefferson counties, Alabama, died at his home near Burnwell, Walker County, March 26, at the age of 82 years. Mr. Brasfield was widely known in industrial circles in the Birmingham district. He is reported to have left a valuable estate.

Phillips W. Hoskins, an old resident of Birmingham, Ala., who claimed to have been the pioneer coal miner of the district, died in Nashville, Tenn., March 27 at the age of 91 years. Mr. Hoskins assisted in opening the McIllwain mines, near Birmingham, prior to the Civil War. He is survived by seven sons and one daughter.

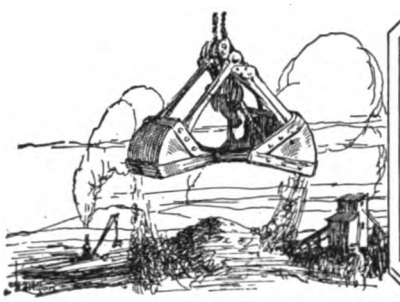
Traffic News

New N. Y. Coke Rates Approved

The New York Public Service Commission has approved rates of the New York Central (East) on coke, coke breeze and coke dust from Geneva to Boston & Albany stations as follows: Brookview to Ghent, inclusive, $3.02 (reduction 26c.); Pulvers, Mellenville, Claverack, East Chatham and Canaan, $3.16 (reduction 15c.); Hudson Upper, $3.15 (increase 25c.). Also rates from Solvay and Syracuse to these Boston & Albany stations: Canaan, Claverack, East Chatham, Ghent, Hudson Upper, Mellenville, Pulvers, $2.90 per net ton (increase to Hudson Upper 38c. and to other points 13c. per net ton)—Effective April 20, 1926.

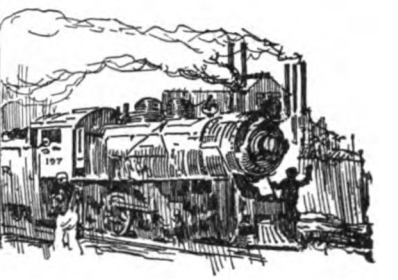
Hard-Coal Rates Attacked

The Erie R.R. has filed a complaint with the Interstate Commerce Commission contending that the present division of rates on anthracite to points in Illinois beyond the Chicago switching district is unreasonable.



The Big Vein Anthracite Collieries, Inc., of McCoy, Va., has attacked rates on coal from McCoy to points in Pennsylvania, New York, Indiana, Illinois, Michigan, Missouri, Iowa, Wisconsin and Minnesota. Existing rates, it is declared, are unduly preferential to other mines located on the Virginian Ry.

The Brackett Coal Co. has filed a complaint with the Interstate Commerce Commission against rates of $4.54 per gross ton on anthracite and $4.66 on prepared sizes from the anthracite region in Pennsylvania to Newton, Mass.



The Electric Service Co., of Dodge City, Kan., complains against rates of $2.68 from Irma and $4.41 from Dawson on carload shipments of coal to Dodge City.

The Illinois Coal Traffic Bureau has attacked the rates on coal from Illinois mines to points in the St. Louis switching district and has asked the Interstate Commerce Commission to consolidate its complaint with that of the Perry Coal Co.

Production And the Market

Coal Trade's Quest for Firm Basis Marked by Striking Territorial Contrasts

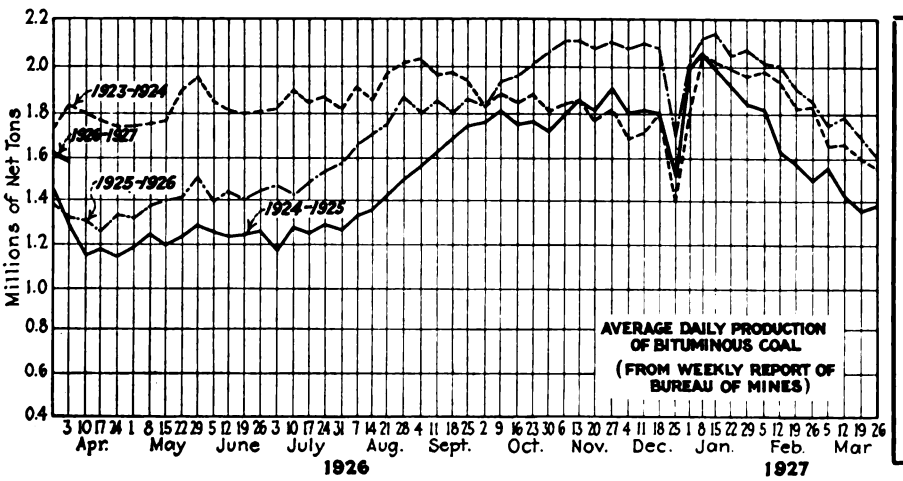
Efforts of the bituminous trade to reach solid ground for business in the new coal year are marked by sharp territorial differences in conditions. These are particularly noticeable in the steam-coal contract situation. In Illinois and Indiana, for example, industrial consumers have abandoned their attitude of indifference. Many of the agreements now being signed give the shipper the option of supplying non-union coal if union mines are closed down. The Birmingham district also reports activity in contract renewals at higher prices.

Along the Atlantic seaboard, on the other hand, contracting is backward. What business is closed is closed so quietly that it has no effect upon the market. Distress tonnage still blocks the attempts of Eastern producers to persuade buyers to sign up agreements at prices that will not mean a loss to the shipper. The record in the Southwest and in Rocky Mountain territory is no more encouraging. And railroad renewals are an uncertain quantity in all districts.

The situation in the Eastern fields is further complicated by the backwardness in the lake season. Some tonnage has been loaded at the lower ports, but no vessels have cleared. Congestion between the mines and the docks at Sandusky and Toledo has forced the railroads to embargo further shipments until the blockade has been broken. This means that the great safety valve for the Appalachian Region at this season of the year is somewhat choked.

Downward Movement of Prices Continues

Under such conditions, and with production still above the seasonal averages for the two preceding years, it is hardly surprising that the downward trend in spot prices continues unchecked. *Coal Age* Index on April 12 stood at 158 and the corresponding price was $1.91. Losses were registered by Eastern coals generally; even slack, which was stronger in some markets, did not wholly escape. The greatest stability in prices was shown in the Middle West.



Notwithstanding the holidays, bituminous production the week ended April 3 was estimated at 9,034,000 net tons by the Bureau of Mines. This was 592,000 tons less than in the preceding week. Most of this decline was due to the observance of Mitchell Day in the union fields. Contrary to past performance, output on Good Friday and Easter Saturday was ahead of the preceding week. Loadings on Easter Monday were less than 12 per cent under those for March 29.

Criticize Anthracite Price Policy

The larger anthracite producers are meeting no difficulty in effecting a prompt disposition of their output of domestic sizes. Retail distributors, however, do not try to conceal their disappointment over the failure of the operators to make the old-time spring reductions. They also find that this failure is bitterly resented by some householders who are now withholding fill-up orders. In some cases the retailers themselves have cut their prices to induce consumer storing.

Independent tonnage at high premiums is finding hard sledding. Not only does the retailer refuse to pay over 50 or 75c. premium, but he is becoming more discriminating in the sizes he will accept. Chestnut still leads in demand. Egg and stove are struggling for second place in New York, but egg is less popular in Philadelphia. Complaint continues that pea is scarce. The steam sizes are easy and prices are being shaded to move tonnage which cannot be put in storage.

The spot market in Connellsville coke is close to stagnation, but production is being closely regulated.

Estimates of Production

(Net Tons)

	1926	1925
BITUMINOUS		
March 20	10,263,000	8,283,000
March 27 (a)	9,626,000	8,353,000
April 3 (b)	9,034,000	7,547,000

Interest in Contracts Revives

Renewed interest on the part of purchasing agents for big industrial consumers is leading to more contract renewals in the Middle West. The uncertain outlook for the last year of the Jacksonville agreement in the union fields has made buyers less cocksure of the open market. Many Illinois and Indiana operators are writing contracts which give them the option of shipping western Kentucky coal if their own output is shut off. Railroad fuel agents, however, still pursue a policy of watchful waiting.

Broken running time is the rule in the mining fields. Steam coal is the backbone of the present movement. The rush-order business in domestic sizes, due to the blizzards, has subsided. Two to three days a week is the average for southern Illinois proper. Mt. Olive and Belleville are in worse shape and Indiana and central Illinois also find it difficult to keep up production. The ubiquitous "no bill" is no snob.

The end of the storm flurry hit Eastern coals as hard as the Illinois and Indiana sizes. Chicago territory has been absorbing much less West Virginia and eastern Kentucky offerings. Anthracite, on the other hand, has been freely accepted. In St. Louis the prospects of early consumer buying of either anthracite or smokeless coals are slight. The principal demand in that market has been for Mt. Olive and Standard district coals.

Kentucky Movement Slowing Down

Prepared sizes of Kentucky coals were easier last week. Weather demand had lightened and, in the eastern part of the state, the lake movement had not begun to have any effect upon the market. At the same time, commitments on fine coal forced screening. All of these factors worked toward a weakening in the prices on the prepared sizes—particularly in the western district. Screenings were stronger. Western Kentucky block was $1.65@$1.85; lump and egg, $1.40@$1.65; nut, $1.35@$1.60; mine-run, $1.15@$1.35; screenings, 90c.@$1.15. Eastern Kentucky block was held at $1.85@$2.25; lump, egg and nut, $1.75@$2; mine-run, $1.50@$1.60; slack, $1@$1.10.

Considering the season of the year, however, the Kentucky situation is unusually good. Operators in the eastern part of the state expect to participate heavily in the lake movement. The recent sales agreements with Illinois operators lead western Kentucky producers to look forward to a substantial movement of their coal to the Middle West and Northwest. Some railroad business has been closed, it is reported, around $1.50, mine-run basis.

Operations at some of the docks at the Head of the Lakes again are on a part-time basis. March loadings were 14,836 cars, as compared with 16,388 cars a year ago. A reduction of stocks to 2,000,000 tons by the opening of navigation is the goal set by the dock men at Superior and Duluth. The first

arrivals of coal from the East are not expected much before May 1. Current retail buying is on a hand-to-mouth basis. Industrial buying is well sustained.

Domestic Call for Dock Coal Softer

Demand for fuel for domestic use at Milwaukee has fallen off sharply with the return of milder weather. Industrial requirements, however, are normal for this season of the year and little out of the ordinary is promised in steam buying for some time to come. Prices are unchanged. Aside from a tag-end business in the retail division of the trade, the market at the Twin Cities has been featureless. In the steam section, buyers again are dictating the terms of sale, although price levels have shown no violent reactions in the past few weeks.

The accumulation of orders brought about by the reappearance of winter conditions in the Southwest late in March kept most of the Kansas mines still working fairly busy last week. These orders, however, were not an unmixed blessing. Although they cleaned up the "no bills" of prepared sizes, they also resulted in a slight surplus of screenings. Prices on fine coal, however, were nominally unchanged. In Arkansas and Oklahoma there was little activity. April storage prices of $5 on Paris (Ark.) lump, $5.25 on McAlester and $4.50 on Wilburton lump were announced last Friday.

Colorado, too, benefited by the weather demand, which quickly absorbed the unbilled loads. These latter, estimated at between 500 and 600 cars, were proving a serious menace to continued operations. In some cases, the mines were compelled to work extra shifts to catch up with rush orders. Utah also reported a better demand for lump and stove than for several weeks past. Steam coals, however, were draggy. Prices at Salt Lake City were firm, despite the recent reductions by the C.O.D. distributors of fuel.

Smokeless Prices Slump Unchecked

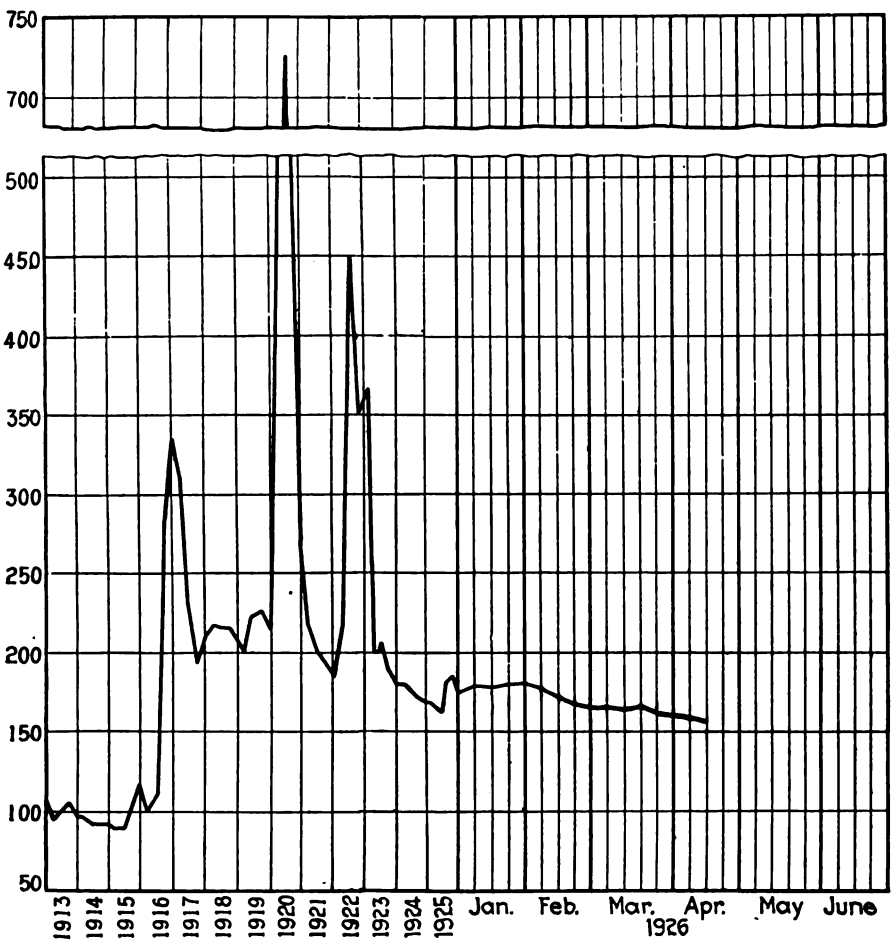
Attempts to check the downward movement in prices in the Cincinnati market are meeting with scant success. Prepared sizes of smokeless were pounded again last week, forcing some lump down to $2.50, although one producer is sold up for the month at $3. Egg also weakened and nut dropped to $2. Some sales of mine-run were shaded 15c. under the $2 base. Slack he'd firmly at $1.25@$1.50.

The high-volatile coals withstood the onslaught against prices better than the smokeless grades. Quotations already are on such low levels that few producers are willing to make further reductions. This policy has actually increased spot prices on slack 10c. Coal movement through the Cincinnati gateways last week was 8,893 cars, or 2,543 cars less than in the preceding week, but 1,971 cars more than a year ago.

Even these figures indicate that production still is too far ahead of demand to support profitable prices. The late opening of the lake season also is having a depressing effect upon spot quotations and contributes materially to the underlying weakness. Local retail business at Cincinnati jogs along unchanged. High waters have hampered river movement.

Contract Situation Still Unsettled

The steam-coal contract situation in central Ohio is still very much unsettled. Most of the larger consumers are buying in the open market. No decision has been announced on railroad business and some of the carriers are taking in supplies on a 30-day basis. The spot market is fairly active, with screenings stronger because of reduced lump output. Retailers are buying only for immediate requirements.



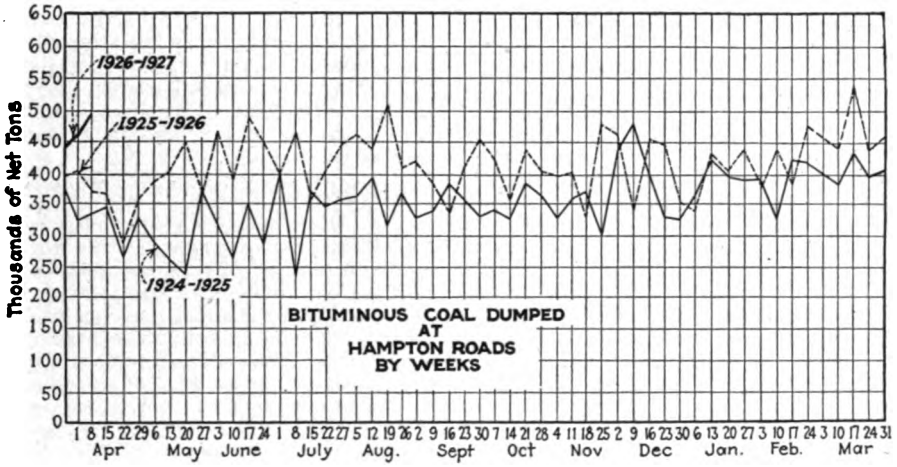
Embargoes on shipments to Sandusky and Toledo have blocked lake movement. There are several thousand loads between Toledo and the mines and the yards have been badly congested. It is not expected that boats will begin to clear the lower ports much before May 1. Some lake business has been closed around $1.50, mine-run. Southern Ohio, which will share little in lake business this year, is producing about 17 per cent of capacity.

Eastern Ohio output during the week ended April 3 approximated 191,000 tons, or 32.7 per cent of capacity, as compared with 217,000 tons the preceding week and 200,000 tons a year ago. The outstanding feature of the Cleveland market is the growing strength in nut-and-slack and slack quotations, which have increased 5 to 10c. per ton in the past week. Other sizes are dull. New additions are being made to the list of idle mines.

Union Blight on Pittsburgh District

The pessimism which descended upon the Pittsburgh district several weeks ago is unrelieved. Prices are unchanged because the volume of spot trading is so small. Less than 25 per cent of the normal commercial output of the district is being produced and a great part of that tonnage is credited to operations which have broken away from the union scale carried in the Jacksonville agreement.

Central Pennsylvania has settled down for a period of idleness. By far the greater number of the mines in the district are either down completely or working only a few days a week. Pool 1 coal is quoted at $2.75@$2.85; pool 71, $2.60@$2.75; pool 9, $2.40@$2.50; pool 10, $1.85@$2; pool 11, $1.70@$1.85; pool 18, $1.60@$1.65. These quotations are 25 to 40c. higher than those of the preceding week on pools 1, 9 and 71 and 5 to 15c. higher on the other pools.



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	Apr. 12	Apr. 5	Mar. 29	Mar. 22	Apr. 13	Apr. 14
Index	158	160	163	167	161	172
Weighted average price	$1.91	$1.93	$1.97	$2.02	$1.95	$2.08

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average of the twelve months ended June 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

The industrial market at Buffalo shows no improvement. Slack is somewhat scarce because there is little screening at the mines. Nominal quotations are: Fairmont lump, $1.60@$1.75; mine-run, $1.40@$1.50; slack, $1.25@$1.40; Youghiogheny gas lump, $2.15@$2.40; Pittsburgh and No. 8 steam lump, $1.85@$2.10; slack, $1.20@$1.50; Allegheny Valley mine-run, $1.60@$1.85. In the domestic market the only serious contender against anthracite is coke. The weather has kept Toronto retailers busy. Stove is retailing at $15.75; egg and nut, $15.25, and pea, $12.50.

New England Steam Horizon Dark

The New England steam-coal market is without favorable development. Prices are more or less nominal because spot buying is so scattered. In many cases large consumers are protected by unexpired contracts and have no interest in the spot market. Others are waiting for breaks before adding to their reserves. Salesmen are combing the territory for stray orders and are making many inducements to wean away buyers from accustomed sources of supply.

There is too much coal standing at the southern loading piers to make prices stable. The situation is further complicated by the small volume of tonnage sold in the spot market and by occasional offers of distress coal. Nominally the range on Navy Standard per gross ton f.o.b. vessel at Norfolk and Newport News is $4.10@$4.35. Some No. 2 coal is to be had at less than $4.

Inland Prices Weak

For inland delivery coal on cars at Boston and Providence is around $5.50. The market is so uncertain that there is little attempt to force coal upon reluctant buyers. Central Pensylvania coals show no appreciable change from conditions which have prevailed for over a month.

Improvement in the New York bituminous market is still held back by sales of distress tonnage. Last week it was reported that there were more than 250 boats anchored in the East River waiting for buyers. Enough distress tonnage has been cleaned up, however, to stiffin the resistance of shippers when buyers try to name their own prices. Contracting is not keeping pace with other years. During the past week another cargo of foreign coke arrived. Domestic coke is slow at $3.25@$3.75, ovens.

Philadelphia Market Dull

The Philadelphia spot market is as dull as that of New York. Sellers appear to have abandoned their efforts to force contracts on buyers and are letting the trade drift along on a day-to-day basis. With more mines closing down, the pressure of spot tonnage is lessening. Slack, in particular, is less freely offered and some large consumers are turning to mine-run.

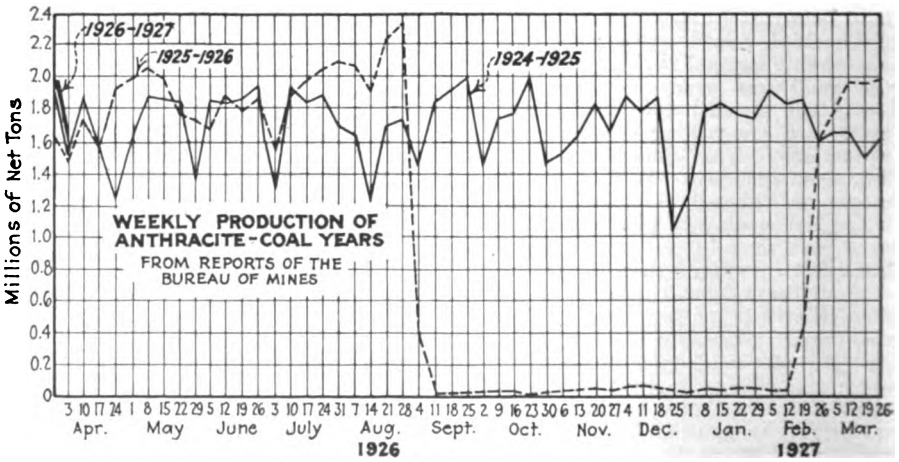
Privately the policy of the railroads is being sharply criticized by the coal men. Some carriers have been endeavoring to establish a going price to be paid for coal on the basis at which they picked up distress tonnage after the end of the anthracite strike. These figures, say the producers, are so far below the cost of production that they are absurd. The Philadelphia tide trade is quiet.

Baltimore Situation Unchanged

The new coal year has brought none of the active contracting for steam and gas coals that once marked the advent of spring in the Baltimore bituminous market. The spot price range is so low that it discourages long-term orders and daily receipts negative any fear of a shortage in supply. On the export side there are faint signs of betterment. March exports were the largest in two years. During the first week of April 14,869 tons was loaded for foreign shipment.

Spot demand in the Birmingham field is less active, but continues to absorb all the free coal of medium and high grade offered. It is the lower grades that suffer, although accumulations have been kept down to a minimum. Little difficulty is being experienced in renewing steam coal contracts and, in most cases the prices show advances over those carried in the 1925-26 agreements. Contract movement, as a matter of fact, is taking care of the bulk of the current production.

There is very little demand for spot domestic coal because weather conditions do not encourage heavy consumption of fuel. Most of the high-grade coal, however, is sold ahead on contracts which will take the greater part of the output off the market for the next three or four months. White-ash coals are in disfavor with buyers. Movement of domestic coke also is slow, with egg and nut quoted at $4.50@$5. Spot and contract foundry coke is firm at $5.50@$6.50, ovens.



Company Anthracite Readily Absorbed

The New York trade is buying domestic company anthracite freely, but independent shippers are seldom able to book orders at premiums exceeding 75c. Consumer buying has dropped off and some of the tonnage now being received is going into storage at the dealers' yards. Chestnut still holds first place in demand, but stove and egg are running it a close race. Pea continues scarce. Steam sizes are slow. Some of the large shippers are contracting No. 1 buckwheat at $2.50. Rice is holding its own, but some barley is going into mine storage.

On the whole, the anthracite situation in Philadelphia is a counterpart of that in New York. If there is any reluctance on the part of the retailers to take in domestic coal from company shippers it is shown in egg and, occasionally, in stove. Current movement to the householder is good, but not heavy enough to create a premium wholesale market except in pea. All steam sizes are soft and some independent contracts on No. 1 buckwheat have been closed at $2.35.

Householders Hold Back

The retail trade is much disturbed because householders in many cases have refused to place their usual fill-up orders at the present prices. These prices are generally about $1 above the

prices in effect last April. Some price-cutting has been resorted to on desirable business, but for the most part the householder announces that he will postpone his buying indefinitely.

Cut Retail Prices at Baltimore

Baltimore retailers are offering hard coal to the householder at a cash discount of 50c. per ton. The new cash prices are: Broken coal, $15; egg, $15.50; stove, $16; nut, $15.50; pea, $12. These prices represent reductions of 50c. to $1 per ton from the winter basis. The experiment is frankly announced as a move to reduce the number of slow accounts on the dealers' books.

Stagnation threatens the Connellsville market in spot coke. Contract deliveries are taking care of the furnace demand and most of the foundries are protected until June 30. Demand from miscellaneous consumers is small. Spot furnace coke last week was $3@$3.25, with the top price ruling only on small lots. Spot foundry coke has dropped to $4.25@$4.75.

Production is closely regulated to orders and there is little surplus at the ovens. Output for the week ended April 3, according to the Connellsville *Courier* totaled 180,850 tons. Furnace oven production was 102,000 tons, a decrease of 2,800 tons when compared with the preceding week; merchant oven output was 78,850 tons, a decrease of 3,980 tons.

Self-Regulation in Business To Engage U. S. Chamber

Representatives of more than 1,400 business organizations located in every state in the Union have been invited to attend the three-days' annual meeting of the Chamber of Commerce of the United States to be held in Washington May 11 to 13.

The major subject, around which all the discussions of the meeting will center, will be "Self-Regulation in Business." Prominently featured on the program are two additional subjects, namely, "Local and State Taxation and Budgeting," and "Relations of the States to the Federal Government."

High government and state officials and business men of national prominence will take part in the discussions. Among the speakers will be Governor Albert C. Ritchie, of Maryland; John W. O'Leary, president of the Chamber of Commerce of the United States; Fred I. Kent, vice-president, Bankers Trust Company, New York; Julius H. Barnes, formerly head of the United States Grain Corporation, New York; Dr. Julius Kline, director of the Bureau of Foreign and Domestic Commerce; S. W. Wade, Superintendent of Insurance, Raleigh, N. C.; A. L. Humphrey, president, Westinghouse Air Brake Co., Pittsburgh; Milton E. Marcuse, president, Bedford Pulp & Paper Co., Richmond, Va.; John B. Miller, president, Southern California Edison Co., Los Angeles; E. T. Meredith, former Secretary of Agriculture, Des Moines, Iowa; A. J. Brosseau, president, Mack Truck Co., Inc., New York, and R. Goodwyn Rhett, president, Peoples National Bank, Charleston, S. C.

With a view to facilitating the discussions, the conference will be divided into nine group meetings, each representing a particular branch of American business. These groups are as follows: Agriculture, civic development, domestic distribution, finance, foreign commerce, insurance, manufacture, natural resources production and transportation and communication. The natural resources production group will discuss "Hydro-electric Power"; "Coal, Lumber and Oil"; "Desirability of Self Government in Industry—How to Accomplish it in These Industries."

World's Coal Production During 1925 Exceeds That of Two Preceding Years

World's total production of all coal in 1925 is estimated by the U. S. Bureau of Mines at approximately 1,368,000,000 metric tons. This output, when compared with the revised figures of production for 1924 is an increase of 13,400,000 metric tons. There were some notable increases in certain of the coal-producing countries, and rather pronounced decreases in others. In the United States, while there was a great decline in the anthracite output for the year, amounting to 23,400,000 tons, when compared with 1924, this was more than offset by the production of bituminous coal, which amounted to nearly 36,000,000 more than a year ago. Countries, other than the United States, which showed greatly increased production in 1925 over 1924 were France, Germany and Russia, while Canada, Czechoslovakia, Hungary, Poland and the United Kingdom showed decreases. The following table summarizes information received by the Bureau of Mines up to March 13, 1926:

Coal Produced in Principal Countries of the World, Calendar Years 1923, 1924 and 1925

(In metric tons of 2,204.6 lb.)

Encouraging Fuel Research

Walter Barnum, of New York City, president of the Pacific Coast Co., operating large bituminous coal mines in the State of Washington, has been appointed to represent the National Coal Association on the advisory committee of the Massachusetts Institute of Technology in respect to a graduate course in gas and fuel engineering. The growing realization of the bituminous coal industry that fuel research activities should be encouraged is reflected not only in this appointment but in the financing by the National Coal Association of a graduate research fellowship in low-temperature distillation at Carnegie Institute of Technology for the academic year 1925-26.

The experimental investigations in gas and fuel engineering which will be made in connection with the graduate course at Massachusetts Tech embrace a list of twelve major subjects.

Foreign Market And Export News

Welsh Loadings Heavier; Future of Industry Hurts Sales for May Deliveries

London, England, March 30.—Shipments of coal from the Welsh ports have been on a heavier scale during the past few days on account of the Easter holidays, and the improved weather conditions have enabled ships to arrive at the docks on schedule. At most of the docks better working has enabled the large standing stocks of coal to be cleared, with the result that nearly all of the collieries are again operating on full time. Deliveries for the most part have been in the nature of clearing off arrears, and new business has been only moderate.

For shipment after Easter the trade has fallen off a little, though this may be put down largely to the uncertainty existing as to what will happen in the industry at the end of April. Because of this uncertainty, operators are showing little tendency to enter into fresh obligations except at greatly advanced prices.

There is a popular feeling, however, that the difficulties expected at the end of April will be satisfactorily tided over and that there will be no national stoppage. How these difficulties will be dispensed with without the aid of a subsidy or "temporary assistance," as the current phrase has it, is not explained.

Contract inquiries on the market include one for 150,000 metric tons for the Egyptian State Rys. and the Uruguayan Electricity Department is inviting tenders for supply until June, 1927. Prices generally are stronger.

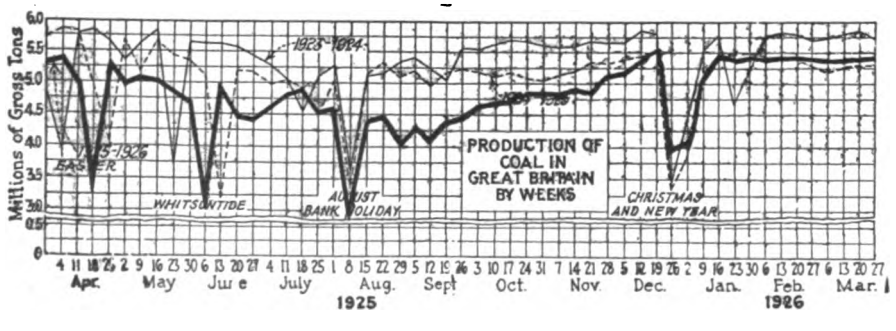
The Newcastle market is uncertain on account of the difficulties which are expected on a national scale on May 1. There is plenty of inquiry for April shipment, though little business is being done. Prices are steady. Orders include 40,000 tons of gas coals for Genoa, 12,000 tons of gas coals for Malmo and 10,000 tons of gas coals for Gothenburg.

Output by British collieries during the week ended March 27, according to a special cable to *Coal Age*, totaled 5,415,000 gross tons, compared with 5,370,000 tons the preceding week.

British Coal Exports Decline

British coal exports in February totaled 4,349,000 tons, which is 4,000 tons less than in February, 1925. The decrease of 176,000 tons in shipments to France was the largest decline. The increase of 195,000 tons in sales to the United States was the principal gain. Sweden, Spain, Algeria and Gibraltar bought in substantially reduced volume.

Argentine Coal Imports High In February



During the four weeks ending Feb. 19 Argentine coal imports reached 220,195 metric tons as compared with 342,047 received during the thirty-one days preceding, cables Commercial Attaché Edward F. Feely, Buenos Aires, to the Department of Commerce. Although not so large during the period just ended as in the foregoing four weeks, the weekly average is higher than it has been for several months.

Of the quantity received during the period covered by the cabled report, 189,484 tons came from Great Britain, 26,719 from Germany and 3,992 from the United States. Quotations c.i.f. Buenos Aires are as follows: British, 36s. ($8.75); German, 38s. ($9.24) and American—no quotations.

Austrian Consumption Declines

The 1925 consumption of coal in Austria declined more than 250,000 metric tons from the 1924 total, according to provisional figures recently issued by the Austrian Ministry of Commerce. These figures show a 1925 total of 8,429,416 tons, of which 3,157,736 tons, including 3,012,558 tons of lignite, was produced within the country. Consumption of domestic coal, however, was more than 235,000 tons in excess of that for 1924.

Austrian coal and coke imports totaled 5,271,680 metric tons in 1925. Of this quantity, 4,252,789 tons was bituminous, 505,483 tons, lignite and 513,408 tons, coke. This represented a decrease of 493,175 tons from the 1924 importation. Bituminous and lignite imports decreased 285,130 tons and 242,050 tons respectively. Imports of coke increased 134,005 tons.

Soviet Coal Output Gaining

Figures received by the Russian Information Bureau from the State Planning Commission show heavy gains in coal output by the Soviet Union during January, 1926, as compared with the corresponding month a year ago. Coal production was 45 per cent greater than in January, 1925, standing at 2,007,000 tons in January, 1926, as against 2,093,000 tons in December. Petroleum output of 636,000 tons was 10,000 tons less than in December, but 21 per cent heavier than in January, 1925.

Coming Meetings

Virginia Coal Operators' Association. Annual meeting, April 17, Norton, Va. Secretary, C. B. Neel, Norton, Va.

American Welding Society. Annual convention, 29 West 39th St., New York City, April 21-23. Secretary, M. M. Kelly, 29 West 39th St., New York City.

California Retail Fuel Dealers Association. Thirteenth annual convention at Del Monte, Calif., April 22-24. Secretary, J. B. Muir, Oakland, Calif.

Mine Inspectors' Institute of America. Annual meeting, Seventh Avenue Hotel, Pittsburgh, Pa., May 11-13. Secretary, G. B. Butterfield, Hartford, Conn.

International Railway Fuel Association. Eighteenth annual convention, Hotel Sherman, Chicago, Ill., May 11-14. Secretary, J. B. Hutchinson, Omaha, Neb.

National Retail Coal Merchants' Association. Ninth annual convention, New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

Electric Power Club. Convention at The Homestead, Hot Springs, Va., May 24-27. Secretary, S. N. Clarkson, B. F. Keith Bldg., Cleveland, Ohio.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, in conjunction with the annual meeting of practical operating officials. Assistant secretary, E. R. Coombes, Washington, D. C.

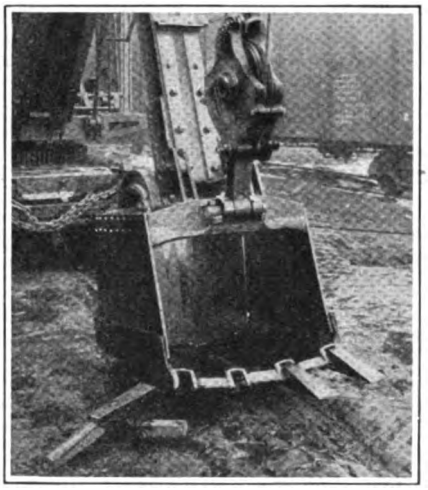
International Geological Congress. The fourteenth congress will be held in Madrid, Spain, commencing May 24, 1926. From May 5 to 22 excursions of interest to the visiting delegates will be arranged. Information concerning the congress can be obtained from the secretary of the organizing committee, Enrique Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.



National Coal Association. Ninth annual meeting, June 9-11, at Drake Hotel, Chicago, Ill. Executive secretary, Harry L. Gandy, Southern Bldg., Washington, D. C.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

New Equipment

Wedge-Shaped Tooth Sockets Part of Dipper Front

The new ¾-yd. dipper of the Erie Steam Shovel Co., Erie, Pa., features four tapered sockets for the teeth cast as integral parts of the manganese steel lip, which is 1 in. thick and extends 9 in. up on both sides. The placing of the outside teeth at the extreme corners is claimed to be a considerable advantage when side cutting on heavy banks. The teeth are reversible and made of chrome manganese steel. No bolts or rivets are necessary to hold the teeth, which are fastened by firmly wedging them against soft steel shims. The teeth are easily removed by driving a small drift wedge under them through a hole provided in the back of the socket for this purpose.

Flush Outer Teeth Clear Wider Path For Edge of Bucket

Tapered sockets cast as integral parts of the manganese steel lip permit teeth to be set in bucket and removed with ease.

Synchronous Motors with High Starting Torque

Heretofore, synchronous motors have had a low starting torque. The General Electric Co. of Schenectady, N. Y., has, however, designed and is now marketing a line of these machines for general-purpose application. These motors are recommended to drive loads, the torque requirements of which have been heretofore met by standard squirrel-cage induction motors. The new machines known as types TS and QS of the 7,500 series, range from 20 to 150 hp. at speeds of 1,200, 900, 720, and 600 r.p.m. at 60 cycles.

These motors meet all the Electric Power Club requirements for general-purpose machines and give satisfactory starting characteristics. They are of strong construction and with minor changes will operate at either unity, 90-per cent or 80-per cent power factor. They are rated at 40 deg. continuous load at unity power factor and at 90- and 80-per cent power factor, the temperature of the stator will not exceed 40 deg., with 50 deg. on the rotor.

Adequate starting torque is the most important factor in the design of the new motors, each machine being guaranteed to deliver the same starting torque with the same inrush current as will a standard squirrel-cage induction motor of similar rating. At full-line voltage the motor will accelerate and synchronize a load whose torque is 100 per cent of the rated full-load torque of the machine.

Revolving fields are employed on these motors. These are of the salient-pole type and are separately excited, ordinarily by means of direct-connected exciters. One of the principal advantages inherent in these machines lies in the fact that the amortisseur windings are not limiting factors upon the temperature rating. These starting windings will not become dangerously hot before the primary motor coils are overheated. Thus adequate overload protection in the alternating current lines will also protect the amortisseur windings from overheating whether as a result of failure to start or because of operation without excitation.

Semi-automatic control is recommended for these motors. In this control field excitation is automatically applied. The motor is started by means of a manually operated, self-contained compensator. The manipulation necessary to start one of these machines is, therefore, identical with that entailed in starting a squirrel-cage induction motor.

Powder in Pellets Safer and Better Than in Grains

A new form of explosive, known as pellet powder, which tends to make coal mining safer, has been developed by E. I. du Pont de Nemours & Co., Inc., of Wilmington, Del. In substance it is the same product as black blasting powder but instead of being in granular form, is made up in pellets which are wrapped in a thin paraffined paper shell similar to a dynamite cartridge which is then packed in a wooden box. It has been extensively tested in the field and when used the danger of the steel keg in which black blasting powder is packed is eliminated. Steel is a good conductor of electricity. In the past many fatal accidents have occurred because such kegs came in contact with electric wires or cables causing the contents to explode.

Many miners are in too big a hurry to open a metal keg by turning back the lugs and removing the bung as designed by the manufacturers. To save time they drive a pick through the top and pour the powder out through the opening thus made. Occasionally enough heat is developed by the pick to ignite the powder and an explosion results. Ignitions have also taken place from

Digitized by Google

driving a wooden point through the top of the keg.

Ordinary black blasting powder is granular, and in the small sizes, especially, is quite free running. Thus there is always danger of a charge leaking down the borehole and becoming ignited at the collar by the spit of the fuse or from the miner's squib.

Transferring powder from keg to jack or from jack to cartridge if an open light is present is dangerous because an air current may carry the dust from the powder to the light thus causing an explosion. Sparks dropping into a keg or jack of blasting powder have caused similar accidents.

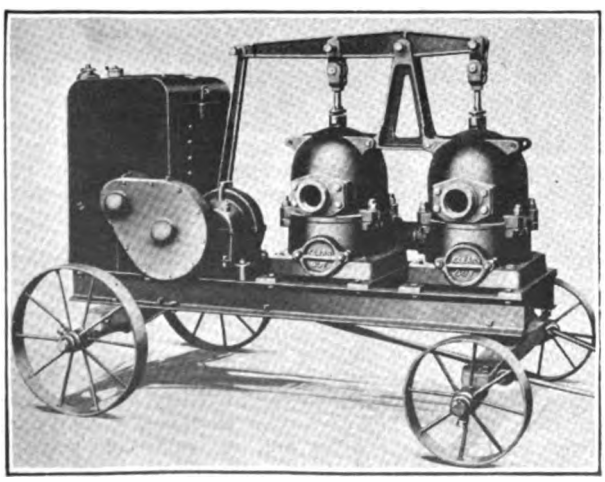
NEW POWDER NON-RUNNING

Pellet powder is said to have practically none of these disadvantages. While it is not a permissible explosive, and consequently is not safe for use in gaseous mines, its being packed in wooden boxes renders it free from the hazard of firing from accidental contact with charged wires. There is no temptation to drive a pick through a box of pellet powder as the lid can be pried off quickly and safely. The pellets are wrapped in paper and, being used in this condition do not tend to run down the bore hole to the collar, thus laying a train along which fire may run back to the main charge. They are not dusty and do not require to be transferred into a powder jack as they are already made up into cartridge form. Moreover, being of a uniform size, it is possible to gage the quantity of explosive needed to bring down the coal much more accurately than is possible with a granular explosive that is poured into a cartridge made by rolling paper over a pin which, in size, may be anything from a tamping stick to a pick handle. It is said that much explosive can be saved because a charge of pellet powder is easier to gage than is one composed of granular powder.

Experiments indicate that much less smoke is evolved from pellet than from granular powder. No explanation can now be given to account for this phenomenon.

It is said that the production of lump coal when pellet powder is used has been highly satisfactory. Although in some beds of coal its action was little or no better than that of granular powder, these were much in the minority. By far the greater number of reports show a readily noticeable increase in the quantity of lump produced by the use of pellet powder.

This new explosive can be fired by means of either fuse or electric squib, the latter being the ideal method as it permits of closer confinement. The electric squib also has the advantage in that the loader has control of the exact time when the shot is to be fired and there is much more freedom from smoke than when fuse is employed. The holes through the middle of the pellets are so made that when used with fuse, this can be inserted in one end of the hole, turned over upon itself and jammed into the other end of the hole, making a hitch that holds fast so that the fuse will not pull out. Pellet powder can be fired by means of miners' squibs but this method is not recommended.



Pellet powder heretofore never has been made in the United States except experimentally, although it is extensively used in France and Great Britain. In 1912 some experimental lots were tried in some of the coal fields of West Virginia. Though the results were promising, the necessity for concentrating every effort during the war on standard explosives put an end to these experiments. Last fall, however, further experimental work was done with this explosive and as a result two mills have been equipped for its manufacture. At the present time it is made in pellets of 1⅛, 1¼ and 2 in. diameter.

It is claimed that no combination gives greater safety than pellet powder and an electric squib except as regards the liability to ignite gas or coal dust.

A Portable Diaphragm Pump For Construction Work

Portable pumping outfits, such as the one shown in the accompanying illustration, can be used to advantage on construction jobs, where it is necessary to keep an excavation free from water. The illustration shows a double 4-in. closed-top diaphragm force pump having a capacity of 16,000 to 20,000 gal. per hour against a head of 60 to 70 ft. The pump is made by the Novo Engine Co., of Lansing, Mich., and is operated by a Novo UF two-cylinder 3- to 6-hp. gas engine. This engine has a 180-deg. opposed-throw counterbalanced crankshaft running in tapered roller bearings.

Diaphragm pumps usually work under conditions not conducive to long life of wearing parts. The self-oiling speed-reducing unit used on the pumps shown completely incloses and protects all gearing, eliminating many disadvantages of the open-geared type pumps. These pumps are surplus-powered and smooth running, thus minimizing the strain upon the engine and pump, and lengthening the life of the outfit.

Diaphragm Pump

Truck carries its own gas engine of 3 to 6 hp. The pumps have a capacity of 16,000 to 20,000 gal. per hour against a head of 60 to 70 ft. Said to have unusually long life.

Industrial Notes

The Chicago Pneumatic Tool Co. recently acquired **George Oldham & Sons Co.** of Baltimore. The manufacture of the Oldham products which are continued will be conducted at the Detroit plant, 6201 Second Boulevard. The sales will be combined and handled from the Chicago Pneumatic Tool Co.'s branches as well as through their domestic and foreign agency connections.

R. J. Quinlan is now a sales engineer for Street Bros. Machine Works, Chattanooga, Tenn., makers of hoists, cableways, derricks, draglines, skidders, etc. Mr. Quinlan was previously with the Bluefield Supply Co. for four years as manager of the electrical supply department. Before this, he was for a number of years with Fairbanks, Morse Co. in the sales department. Mr. Quinlan has a wide knowledge of the coal fields.

The Trico Fuse Mfg. Co., Milwaukee, Wis., has rebuilt and enlarged its electrical testing laboratory, with latest and best equipment installed. The offices also have been enlarged and in the factory new lighting equipment has been installed and production facilities considerably increased. The sales organization has been increased by the appointment of Herbert E. Hartstein as eastern sales manager; Philip Rypinski as central sales manager, and Fred C. Geiler as western sales manager.

The Hazard Manufacturing Co., Wilkes-Barre, Pa., announces the appointment of **Laurence W. Bevan** as general manager; **William S. Hart** as special representative in the oil fields of the United States, with headquarters at Wilkes-Barre, and of **Thomas A. Keefe** as district manager at Chicago.

Headquarters of the Western district of the **Graybar Electric Co.** has been transferred from St. Louis to Kansas City, and **H. N. Goodell** has been appointed as district manager and manager at Kansas City.

Lawrence E. Buzard has been appointed general sales manager of the **Fate-Root-Heath Co.**, manufacturers of Plymouth gasoline locomotives, Plymouth, Ohio, succeeding H. R. Sykes, who recently resigned. Mr. Buzard, who was formerly assistant sales manager, has been with the company a number of years. He will have direct charge of locomotive sales and thirty-four district sales representatives.

H. C. Osman, sales manager of the Nugent Steel Castings Co., Chicago, has been elected secretary of the company. He will continue to have charge of the sales for the company. **C. A. MacDonald**, formerly secretary, has been elected treasurer.

TRUSCON *COPPER STEEL BUILDINGS

Permanent Types of Standardized Construction

Truscon Service *Includes* Planning-Manufacture-Erection-*One Contract* *No Extras*

Standardized for the Mining Industry!

You obtain from Truscon a better steel building design to meet your special requirements. The right building at the right time and at the right place.

You obtain at no extra charge, Truscon Service, which involves problems of construction from preliminary studies, layouts, simplification of ideas, refining of cost, to the complete erection of the structure.

You obtain a permanent, non-burning building made from rust-resisting copper alloy steel. You obtain Truscon Steel Windows, Doors, and Roof, all quality products. There is something superior about a Truscon Building. It is built to last indefinitely.

Storage Batteries

This week *Coal Age* describes an installation of storage batteries to cut down peaks. Incidentally it makes it possible to keep things moving when power fails or the generator is not working.

That ability to run, night and day, Sundays and holidays, regardless of trouble anywhere along the line or of circuit breakers kicking out is what we want if, in gaseous workings, we are going to drive such single entries as C. H. Trik will advocate in next week's issue. The battery will assure us that the auxiliary fan will not stop even if the line is severed between the battery and the substation. Breakers may go out, power may fail; but the fan will take care of the gas. The equipment should be such as will be safe in an explosive mixture.

Mr. Trik's suggestions are all worthy of careful consideration. We must have safe conditions in mines, but it is not certain that we cannot have just such conditions with auxiliary fans which give much more positive air circulation than we have too often today.

Purchased Power

Another article will show what central-station power has done for Illinois operators. Because most Illinois mines are shafts up which the coal must be raised, their power consumption per ton of product may be high, but practically all of the load comes on in the daytime. The load factor of the mine is therefore low, whereas that of the central station, because of the diversified load served is much higher. The central station also relieves the mine of the water problem which in Illinois may be serious.

Type AW-13 O-B Rail Bond

New Armored Terminal Arc Weld Bond with clamping hook for base of rail

By enabling the bond to be clamped firmly to the rail base before welding is started, the hook feature illustrated above insures a more solid weld in less time. It is just flexible enough to conform to the shape of the base, and stiff enough to grip tightly. A tap of a hammer sets it in place.

In this Type AW-13 Rail Bond the terminal is steel. The copper strands of the bond are embedded by electric welding in the heavy steel terminal, which protects them from the direct heat of the arc while the bond is being welded to the rail.

A copper sleeve around the strands where they enter the terminal absorbs vibration and practically eliminates all chance of breakage at this vital point.

O-B Equipment includes:
Rail Bonds
Arc Welding Machines
Welding Rods
Welding Accessories

Problems of the Coal-Mining Industry

R. DAWSON HALL
Engineering Editor

Volume 29 NEW YORK, APRIL 22, 1926 Number 16

Rock Handling

ONE OF THE MOST important of mine problems is rock disposal. We have no difficulty in dumping coal, because as fast as it is dumped the railroad hauls it away, but rock when dumped into a pile grows in bulk, and the dump has to be moved forward repeatedly, the rock being laboriously prepared for the reception of the track extension by hand. There have been many ways provided of disposing of rock to better advantage, by the use of a bin for transference to slate lorries, cableways, conveyors and other means of transportation; but many think the cheapest installation good enough.

If they would calculate the cost of thus placing rock, duly considering the time lost in mine operation, they would find that a good rock-disposal plant would pay good interest on the investment and make it profitable to remove the rock cluttering airways. In many cases the wedging or shooting of drawrock would not only reduce air resistance, but would make the maintenance of roadways and airways less costly. In any thin seam the same care should be taken of the problems of rock disposal as is given to the dumping of coal and in some mines more care should be given to rock than to coal handling. Because rock is waste and coal is the profitable product it is difficult to induce the management to see that both are engineering problems to be solved in the most economical manner. For this reason, the rock problem is usually attacked by strong-arm methods with their accompanying waste of effort. In some mines this rock-handling is a bigger problem than coal handling, and far more costly, because of the lack of railroad co-operation.

Bigger Cars, Larger Profits

IN FOUR YEARS the railroads have increased the average capacity of their cars from 42.5 to 44.7 tons. This is one of the important sources of railroad economy. This fact should not be forgotten by the coal industry. Nothing holds back mine operation more than its pigmy equipment, especially as coal is now being loaded mechanically and without the meticulous care that used to be shown in building up the car by the use of lumps.

As cars are now moved by power over heavy rails and long distances they can and should be made bigger than they were when they were propelled by hand or animal power over wood rails and for short distances. Heavier equipment will inevitably replace light, and until it does mechanical loading will be placed at a disadvantage. Only those who recognize that a new era in loading methods means a new era in the transportation equipment will prosper. We are prevented from developing by the narrower standards of earlier years, which we find difficult to outgrow.

A pension list for antiquated cars is much needed. "The class 1 railroads in 1925 retired 117,021 freight cars, having an average capacity of 38.77 tons or an aggregate of 4,537,287 tons, and installed 125,760 cars, having an average capacity of 47.37 tons or an aggregate capacity of 5,956,930 tons. The net gain in car units," says the Bureau of Railroad Economics, "was only 8,739 cars, but the net gain in aggregate capacity was 1,419,643 tons." This is an increase in the size of the new cars as compared with those they replaced of 22.2 per cent. The older cars at the mines are not only deficient in capacity but in type of construction, and many even if not worn out, should be relegated to the scrap heap.

Will Use Coal to Generate Gas in California

IN RECENT YEARS petroleum has been the sole source of the commercial gas production in California although before the intensive development of petroleum deposits coal was used for gas manufacture, as it is now used in those regions where petroleum is at a disadvantage on account of cost. Gas plants in which petroleum and its products are used admit of a relatively simple and economically operated unit, and the gas produced is low in cost where "cheap" petroleum can be obtained. The fluctuating price of petroleum and the prospect of a gradually increasing price are now definitely turning the attention of the important gas-producing companies in California to a consideration of the future and the probability of having to rely upon coal as a source of gas.

Although no official announcement has been made it is understood that one of the large gas companies supplying many of the communities in California is experimenting with California coals in an endeavor to use them in gas manufacture. Two new gas generators that will produce 3,000,000 cu.ft. of gas per day are to be erected in one of the interior towns. They are to be designed for the utilization of coal. Certain coal deposits in Shasta County are now supplying the fuel for experimental purposes.

The return to coal as a more stable commodity is especially significant in a state like California, for petroleum has displaced coal for most purposes and has reduced the demand for this fuel to relatively small dimensions. It means no doubt that in California and other Western States is being seen the beginning of the end of the dominance of petroleum for gas and fuel purposes. In time a greater utilization of coal is to be expected.

Dangers of Negation

THE COAL INDUSTRY has been in the shadow of government regulation more than a decade. During the Frelinghuysen and the Calder investigations and in the days immediately preceding the creation of the United States Coal Commission the shadow bulked so large that to many it seemed the herald of impending reality. Whether the hearings now going on before the House committee on interstate and foreign commerce at Washington will again give the shadow the touch of immediacy appears doubtful. The desire for an early adjournment and a Congressional program which leaves little time for extended consideration of new legislative proposals are working for the coal industry.

It would be poor policy, however, to treat the situation lightly merely because the danger is a future rather than a present peril. The agitation of the past ten years cannot be put out of mind. That agitation has been symptomatic of conditions which the industry must face squarely if it is to find the remedy that will end the demand to broaden the field of federal activity. Political ambitions, false theories of the function of government, unsound economics and out-and-out demagogism have contributed to this agitation and have helped to keep it alive. But there also has been an intermittent public insistence that some action be taken.

To protect itself from the threatened assaults upon its business independence the industry has relied largely upon a program of negation. It has, for the most part, devoted its energies to laying bare the constitutional weaknesses of the various legislative schemes offered. Some attention, it is true, has been given to demonstrating the impracticability of the legislative remedies. By and large, however, the spokesmen for the coal trade have contented themselves with arguing that suggested governmental activities would be an invasion of the rights of the industry and would contravene the organic law of the land.

The Constitution of the United States is an instrument which should command universal respect. Representatives of the industry would be failing in their duty if they did not point out the constitutional pitfalls in the path of federal regulation of the coal trade. And yet an appeal to constitutional guarantees is at best an uncertain defense. Eminent counsel disagree. The scorned *obiter dicta* of yesterday are frequently the fixed precedents of today. Where the public is determined to take control, the skill of the lawyer in explaining how the statutes conflict with the Constitution only leads to a reframing of the laws to cure the defects disclosed. That was the history of the development of the Act to regulate commerce. There is no reason to believe that history cannot be repeated.

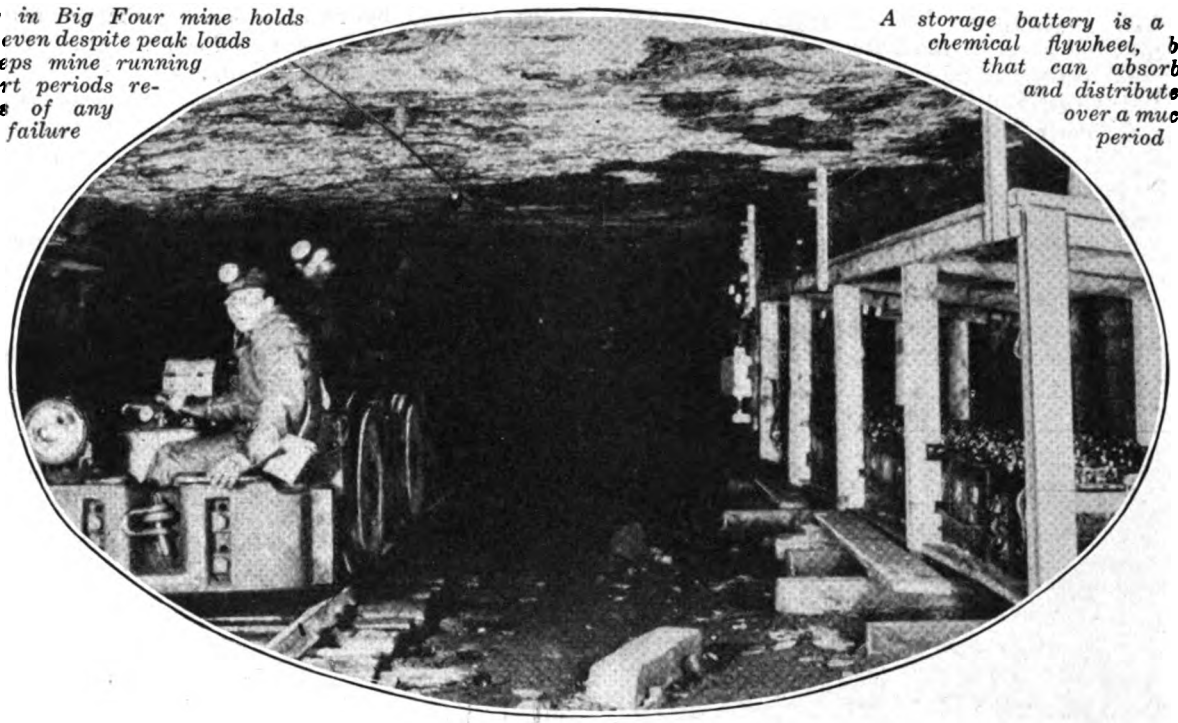
The comforting thought that it was never supposed that the coal miner and the wood chopper, along with the butcher, the baker and the candlestick maker, were to be drawn under the cloak of governmental regulation is less comforting than it was when some of the more recent decisions of the Supreme Court of the United States are examined.

Chief Justice Taft's opinion in *Stafford vs. Wallace*, in which the constitutionality of the Packers and Stockyards Act of 1921 was sustained gave to the implications of the interstate commerce clause a breadth which a few years ago would have been considered revolutionary. In *Avent vs. United States*, 226 U. S. 127, and in the still more recent companion case, *Koenig Coal Co. vs. United States* (decided April 12, 1926), the power of Congress to regulate the distribution of coal through a regulation of the instrumentalities of transportation was held not inconsistent with the Fifth Amendment. Moreover, *Wilson vs. New*, 243 U. S. 332, referred to in the first Kansas Industrial Court decision, *Wolff Packing Co. vs. Court of Industrial Relations*, 262 U. S. 522, as on the border line in upholding government interference, becomes only one of several cases cited in affirmation of federal power in the *Avent* case.

The real task confronting those who would keep business free from unreasonable interference is to teach the public the unwisdom of such restrictions. The successful accomplishment of that task calls for more than the establishment of the unconstitutionality of specific legislative proposals. It calls for more than a demonstration, however convincing, that these proposals, even if legal, are no adequate solution of the problems they purport to attack. The coal industry must be ready to offer a constructive program which will meet, insofar as it is humanely and legally possible, the problems which form the basis for the demand for legislative action. The coal industry should not only claim the right to self-government: it must be prepared to prove that it has the organization, the machinery and the program for the exercise of that right in the interest of the public—and the will to so exercise it.

"Open Confession—"

SOME HOMELY TRUTHS were told by C. Willing Hare, vice-president and general manager of the Anthracite Coal Service, in a recent talk to New England retailers. Discussing the competitive situation, he declared that other fuels, notably oil, had been making inroads upon anthracite, not because of any intrinsic superiority, but because of superior engineering salesmanship. It was to overcome that handicap that the Anthracite Coal Service was established. The fact that in the first nine months of its existence it was able to hold or regain 900,000 tons of business, stamps the wisdom of the undertaking.



Modern merchandising demands that the buyer shall receive the greatest possible value for his money. In coal that means selling him the size and grade best adapted to his plant and operating conditions. That, of course, presupposes an accurate knowledge of these conditions. But knowledge alone is not enough. To this the seller must add the engineering skill which can interpret the facts and the merchandising courage to apply them for the buyer's benefit. Sometimes that means recommending a cheaper coal, carrying a smaller profit to the seller.

Simple and elemental as these principles are, there has been a reluctance in some quarters to recognize them. There have been coal-company executives and subordinates who have clung to the theory of *laissez-faire* as the only workable rule. Fortunately the number who still insist that whatever was is right is diminishing and the number who, like Mr. Hare and his associates, are ready to frankly confess that outmoded ideas must yield to modern methods, is increasing. This change is a hopeful sign in a troubled industry.

Battery in Big Four mine holds voltage even despite peak loads and keeps mine running for short periods regardless of any power failure

A storage battery is a sort of chemical flywheel, but one that can absorb, store and distribute energy over a much longer period of time

Storage Battery Lowers Motor-Generator Peaks

Draws Current When Demand Is Low, Returning It When Peak Is Reached—Charging Method Almost Ideal—Power Cost per Ton Lowered—Battery Will Perform Light Duty When Substation Is Idle

By J. H. Edwards
Associate Editor, *Coal Age*, Huntington, W. Va.

MOMENTARY PEAKS rather than average loads usually limit the tonnage-producing capacity of direct-current generating equipment. It is not at all uncommon to find substations which are subjected to peaks 200 to 300 per cent above the nominal capacity and yet have an average day load less than one-half the rated capacity.

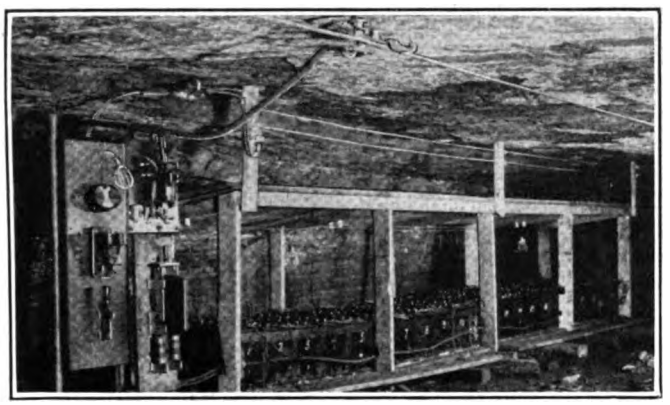
This condition has caused many engineers to dream of installing a battery to float across the line, taking energy from the substation when the mine load is below the generating capacity and discharging to the line during times of high demand, thus assisting the substation to carry the load. The ability of a battery to deliver energy at a tremendously high rate appeals to the imagination as a method of "chopping off" the high spots of the substation load curve.

In a few instances batteries have been utilized in this way, but for the most part, such installations were of a temporary nature using comparatively small batteries. Though the idea makes a strong appeal from one standpoint, it has never gained headway, because of two outstanding factors. First, there is a loss of approximately 20 per cent, or more, of the energy supplied to the battery, and second, every cycle of charge and discharge reduces the remaining battery life, and therefore, in a definite degree, destroys its value.

Despite these inherent disadvantages a large battery has been in regular use since last October, at Big Four, McDowell County, W. Va. This is arranged for taking the peaks imposed by the direct-current mine load. This mine is operated by the By-Products Pocahontas Co., a subsidiary of the Pond Creek Pocahontas Co., which latter firm has one of the few wireless or battery-operated mines of the country.

Escapes New Demand Charge

The conditions which prompted the installation of a "line-floating" battery at Big Four were: (1) The substation was overloaded, that is, it would not handle the peaks. It could, however, sustain a much higher average day load. (2) It was desirable to delay the installation of a new substation as long as possible in order to determine more definitely what size of unit to install and what would be the best location. (3) The mine served is of a limited size and production. (4) A new 110-cell cutting-machine battery was available from an associated mine and could be utilized there later, if desired. (5) It was estimated that if an additional substation unit was to be installed it should be of 200-kw. capacity. This would automatically add over $3,100 per year to the demand charge of the power company. The rate in this territory is $1.92 (less 10 per cent for cash) per month per half of the connected horsepower.



Other conditions, not influencing the decision to install a battery but having a bearing on the results obtained, were as follows:

(1) The opening is a slope. On account of the hoisting and pumping loads this mine requires inherently more power per ton of coal produced than does the

Digitized by Google

average mine in southern West Virginia. (2) The substation, which contains one 100-kw. induction motor-generator set, is located above ground. (3) All coal is undercut, the cutting being done at night with electric machines. Gathering is performed with cable-reel locomotives and haulage with 10-ton trolley locomotives. (4) The larger pumps are operated on alternating current, but several small gatherers are connected to the direct-current circuit.

The accumulator used is a 31-plate lead battery, having a capacity of approximately 91 kw.-hr. It is installed in a wide place on the main haulway and is connected to the 4/0 trolley (the main feeder from the substation) at a point 1,750 ft. from the motor-generator. W. F. Hossfield, chief electrician of the company, explains as follows his reason for setting this distance in seeking the proper location of the battery:

Battery Acts as Flywheel to Reduce Peaks

The 110-cell 31-plate battery is installed in a wide place on the main haulageway about 1,750 ft. from the substation. It is connected between the trolley line and the rail. Due to its closer proximity to the load than the substation, it relieves the motor-generator of the high peak demands and automatically recharges whenever the mine load drops below the full rated load of the substation.

"The full-load rating of the generator is 365 amp., so it was decided to allow it to carry 400 amp. continuously. The open-circuit voltage of a 110-cell lead battery is 220. This subtracted from 275, the full-load generator voltage, leaves 55 volts as the approximate drop desired between the generator and battery. The length of 4/0 copper circuit which gives this drop at 400 amp. is 1,450 ft. But as the battery voltage decreases as the rate of discharge increases, it evidently was necessary to have a drop somewhat greater than 55 volts. Twenty per cent was estimated as the increase necessary, so this added to the 1,450 ft. gave the distance as 1,750 ft.

BREAKER OPENS IN CASE OF NO VOLTAGE

The accompanying diagram shows the wiring arrangement. To the substation panel was added a voltage-failure relay *C* which causes the generator reclosing circuit breaker *A* to open in case of no voltage on the motor leads. This prevents motoring of the substation from the battery.

On the battery panel is mounted a relay *E* which prevents automatic reclosing of the breaker *B* in case of no voltage on the motor leads. The object of this is to prevent the draining of the battery at a high rate if the substation stops during the period of heavy load during the day.

As now arranged, the battery will continue to feed the mine if the motor-generator stops, but in case battery breaker *B* is opened by an overload it will have to be reclosed by hand unless in the meantime the motor-generator has been started, in which case this breaker will close automatically.

If the motor-generator stops, the relay *D* in the substation causes a bell to ring in the hoist house, 2,500 ft. distant. This provision is necessary because it might be some time before the men in the mine became aware that the motor-generator had stopped, and consequently the battery would lose an excessive quantity of energy before they could phone to the hoistman to have the substation started.

The only new equipment purchased for the control was the reclosing circuit breaker in the battery circuit. The relays, *C*, *D*, and *E* were made from old contactors, and the battery panel was assembled from old parts. The range of the volt-ammeter on this panel was changed and the current scale recalibrated with a zero center so as to indicate the rate of charge and discharge.

VOLTAGE DROPS A LITTLE AS LOAD INCREASES

On the motor-generator, several strips of German silver were added to the series-field shunt to reduce the tendency toward compounding. The voltage drops somewhat as the load increases. If the potential is adjusted to 275 volts at no load, it drops to approximately 265 volts at 400 amp., which is about 10 per cent overload.

As can be seen from one of the illustrations, the battery was installed in an inexpensive manner. The twenty-two trays of five cells each were placed side by side on a platform 36 in. wide by 24 ft. long. A wooden canopy cover was placed over this platform to protect the battery from small slate falls. The total installation cost was roughly $4,300.

This may seem like a large sum to put into a piece of equipment, the life of which is definitely determined by the quantity of work performed. The results obtained, however, have more than justified the installation

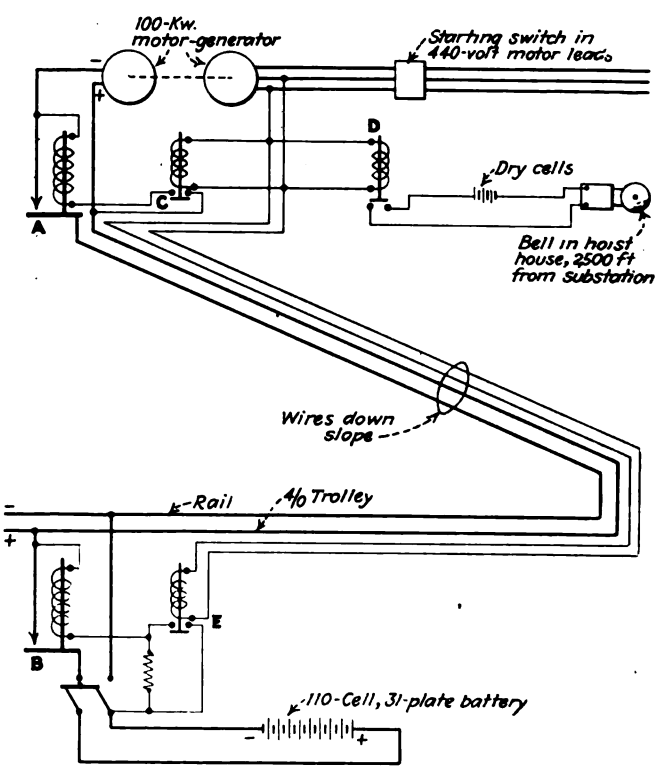


Diagram of Battery and Substation Connections

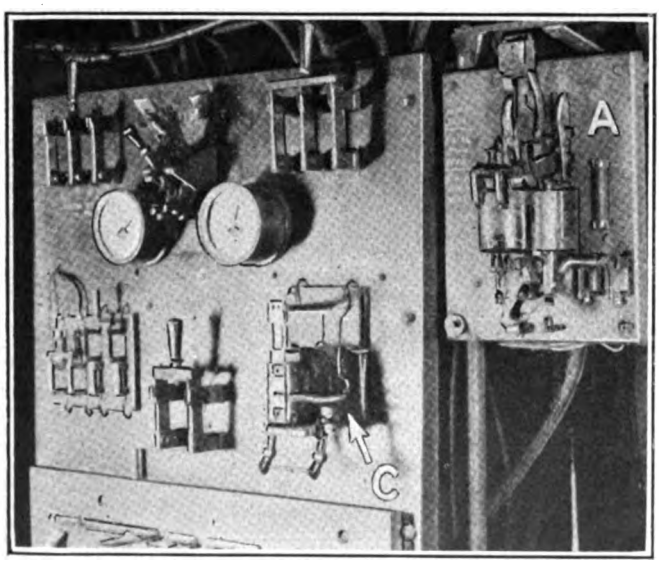
The only additional lines installed were those of the control circuit of the relay *E*. The battery is 1,750 ft. from the substation by way of the 4/0 feeder circuit. This provides sufficient voltage drop so that the battery will take the peak loads.

Digitized by Google

to the management of the mine. It is not known what will be the life of the battery in this service, but should it last only 17 months from the date of installation it will have paid for itself in the saving of the $3,100 per year extra demand charge which was in prospect.

Garner Fletcher, manager of the company, states that the 5 months of operation with this battery has revealed many advantages. There are few interruptions to the power supply on the direct-current mine circuit. The average voltage is greatly improved with the same quantity of copper in use, and this is reflected in a higher tonnage produced with the same equipment and at a relatively lower cost for maintenance.



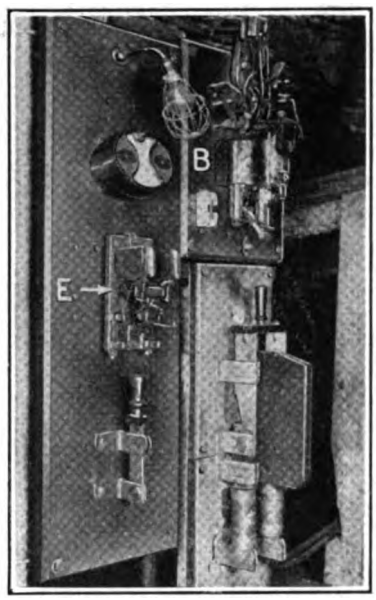
Power Failed, So Cut Coal with Battery

On two occasions prolonged failures of purchased power both occurring at night failed to prevent the cutting of all of the places for the next day's run. In one of these instances, however, before the cutting was finished the battery was discharged to a point far below that recommended as good practice.

Power and Production Data Before and After Installation of Storage Battery

1924	Kw.-Hr.	Production Tons	Kw.-Hr. Per Ton
October	98,760	13,753	7.2
November	96,850	12,298	7.9
December	105,350	12,410	8.5
1925			
January	104,964	12,288	8.5
February	109,230	12,828	8.5
July	107,150	14,929	7.2
August	118,930	16,619	7.1
September	113,710	15,923	7.1
October	112,210	17,859	6.3
(Battery put into use Nov. 1, 1925)			
November	123,340	18,212	6.8
December	127,860	18,976	6.7
1926			
January	135,230	20,968	6.5
February	127,160	18,700	6.8

The fact that a sizable proportion of all energy furnished to the battery is lost in heat, or by evaporation of the electrolyte, would indicate that perhaps the mine might require more power per ton of production after the battery was installed. The accompanying table indicates that this has not been the case at Big Four. The months of battery operation show a noticeable reduction in kilowatt-hour consumption per ton.



Motor-Generator Switchboard in the Substation

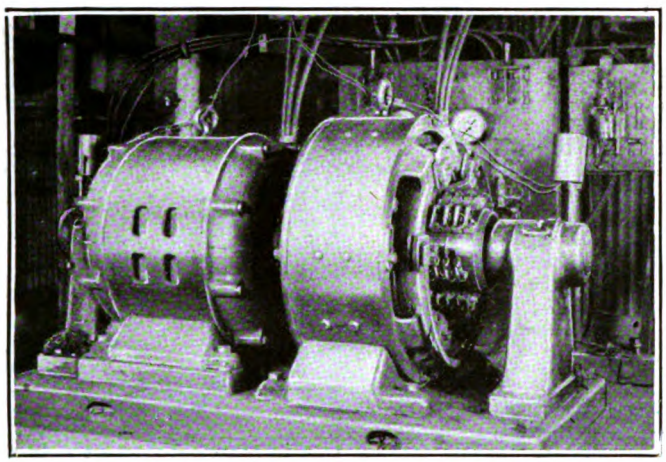
The only change made to the switchboard was to add the relay *C* in the right center which was built from an old contactor. In case of failure of the alternating current or in case the motor-generator starting switch is opened, this relay opens the reclosing circuit breaker on the little switchboard at the right, thus preventing the "motoring" of the power unit from the battery.

Battery Control

If the circuit breaker, *B*, has opened by reason of an overload, the relay *E*, will prevent it from closing if at the same time the substation stops. In such a case if the mine is to be operated from the battery, the breaker must be closed by hand.

It should be stated here that whenever a higher production is obtained from any given equipment, a decrease in power per ton can be expected. For this reason it is difficult to say just how much effect the battery has had in the reduction shown, especially as the months of battery operation are in the season of heavy pumping and lighting load, which condition tends to counteract any showing favorable to the accumulator.

The ammeter charts taken at the mine show the division of load between the substation and the battery. They show considerable similarity from day to day. Thus during an afternoon and evening, at about 4:15 p.m. when the day mine load falls off the battery begins to take a charging current sometimes amounting to as much as 180 amp., but by 6 p.m. this has decreased to about 60 amp.



The night load consisting as it does of pumps, mining machines and a few locomotives indicates that the battery is surprisingly active. It would appear that a more ideal arrangement would be to so adjust the installation at night as to make the substation take a larger part of the peaks, thereby somewhat relieving the battery. However, inasmuch as the loads are well proportioned during the day, it is presumed that to secure a different distribution at night would require the addition of expensive automatic apparatus or frequent hand adjustment.

Shut Down Sunday and Use Battery

Somewhat of a variation to the normal is introduced by the advent of Sunday which naturally is a day of little or no activity in the mine. By 6 a.m. the decreasing mine load allows the battery to charge to a point such that the voltage rises to approximately that of the substation, causing the battery to float on the line taking little current.

From 7 a.m. until about 9 a.m. the gathering-pump and mine-lighting load of 45 amp. is supplied by the motor generator. The presence of the battery makes it possible to shut the substation down on Sunday. This is done at about 9:20 a.m., after which time the small mine load is supplied by the battery. Being able to shut the substation down during periods of light load

Digitized by Google

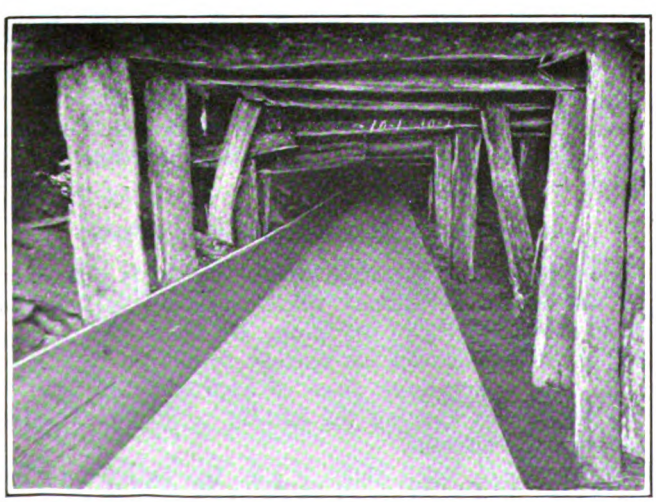
This Unit Supplies All the Direct-Current

The 100-kw. generator is driven by a 440-volt squirrel-cage induction motor. When the mine was producing 17,000 tons per month, overloads caused the circuit breaker to open frequently. After the battery was connected to the line the breaker seldom came out even though the equipment in the meantime had been speeded up to a production of 21,000 tons.

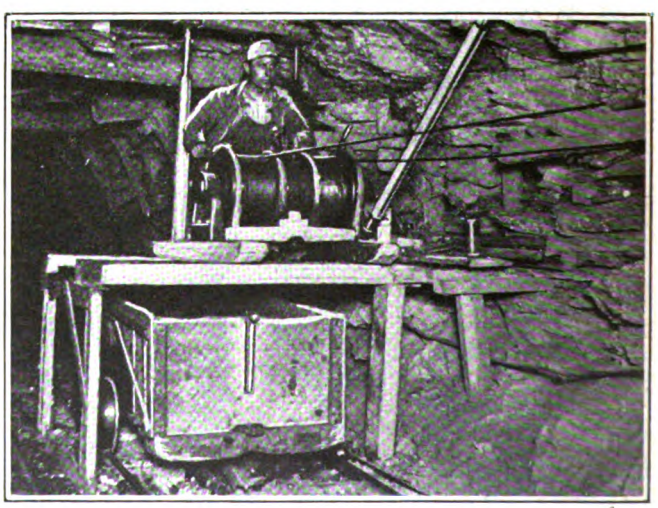
is an advantage from the standpoint of substation maintenance as well as from that of power consumption. Battery deterioration and loss is less than is incurred in operating the substation at extremely light loads.

Normally the substation is started at about 5:30 p.m. From this point onward the battery-charging current tapers off to zero. By about 8 p.m. both the battery and generator curves indicate the existence of a small fluctuating load in the mine.

Because of the resistance of the 4/0 circuit between the generator and battery, charging is accomplished practically by the modified constant-potential method, often recommended as being ideal. This condition coupled with the fact that the battery is located where it will require less attention and is more accessible than if it were installed in a locomotive or mining-machine power truck, point to the possibility of greater life.



Still another condition indicating greater longevity is that the battery is stationary and therefore free from jolting and vibration. Batteries of this size have lasted 20 to 24 months in every-day service on mining-machine power trucks where the rated capacity, or more, is put in and taken out every day.

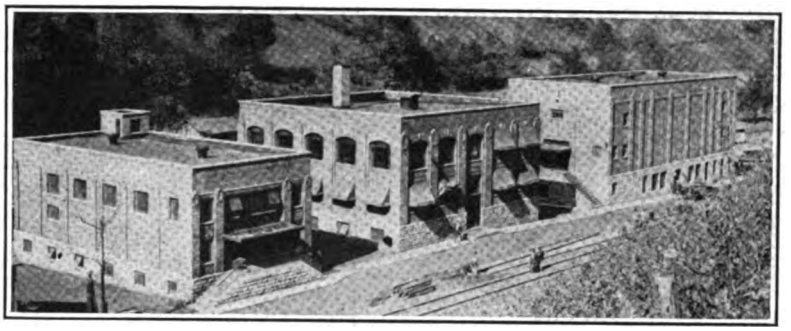


Although the battery at the Big Four mine was not installed as a permanent substitute for an additional substation, its performance to date indicates that its use will be continued for an indefinite time. It is seldom that a new item of mine equipment has "taken" so well as has this battery. Machinemen, motormen, the mine foreman, and in fact all concerned are loud in their praise of the better voltage and fewer interruptions experienced since its installation.

Gallup Coal District Half Century Old

THE COAL DEPOSITS and other mineral resources of the Gallup-Zuni Basin, in New Mexico, are the subject of a geologic report just issued by the Department of the Interior as Bulletin 767 of the Geological Survey, by J. D. Sears. This basin, which lies in McKinley and Valencia counties, has great economic value as well as geologic interest. Its commercial importance is at present centered in the Gallup coal district, the natural wealth of the rest of the basin having been almost untouched. The Gallup district, in which active mining has been carried on for nearly half a century, is now the second largest producing district in the State, and owing to the adaptability of the coal to certain uses, the convenient shipping facilities, and the nearness of the coal beds to the mining camps of Arizona it is one of the most important coal mining districts in the Southwest. The Gallup-Zuni report describes the geology and mineral resources of the whole basin in a general way, and the coal beds of the Gallup district and the Zuni Indian Reservation in greater detail.

GOLDEN AGE FOR COCKROACHES.—Sixty species of insects have been found in British coal measures, of which nearly twenty are cockroaches similar to those of today. Dr. Herbert Bolton has published a monograph on the fossil insects of the Carboniferous era.



Running the Hutch Conveyor in the Thin Coal of Spring Valley, Ill.

The picture at the left was taken along the conveyor—a trip of flat steel sheets on wheels, the sheets having 9¾-in. back plates, and coupled so closely as to constitute a continuous jointed surface—which was developed by the Spring Valley Coal Co. and used for a period with mechanical success, but without the co-operation of labor. The conveyor, on 19-in. track, was operated back and forth, shuttle-like, along a 400-ft. longwall face, discharging its load into cars on a depressed track at the midpoint. At the right is shown the hoist, located above the empty track of a double haulage line leading up to a turntable at the loading point. This installation was described in the Feb. 11, 1926, issue of *Coal Age*, Vol. 29, pages 225-229.

Ford Provides for Entertainment Of Employees

WHEN THE management of the Fordson Coal Co. decided to erect a new recreation building at its Stone plant in Kentucky, the following points were considered as bearing upon the design finally adopted and executed: Stone is the location of the general offices of the company, and the community included some forty officials' and office workers' families which might be expected to make use of the facilities of the recreation center to some extent, if it served the purpose for which it was planned. It was intended to be a meeting place for all the employees of the company where they could have amusement and relaxation and feel at home, whether they came in their Sunday best or in overalls.

At the Pond Creek mines of the company about 1,300 men were employed, the houses extending from Stone some four miles up the creek. The building had to accommodate everyone when necessary, though two smaller buildings of similar nature located on Pond Creek above Stone, were being used at the time.

In addition to the employees of the Fordson Coal Co. those of two other mines within half a mile employing about 425 men had to be considered, for the building was to be constructed not only for Fordson employees but also for the public in general.

The location available was alongside of, and in line with, recently constructed office and commissary buildings; hence the general type of structure and the style of architecture had to be in harmony. The two older buildings are fireproof—of concrete, brick and steel with the lower story of stone masonry. The demand, therefore, was for a theater of fireproof construction seating some 500 people with the usual auxiliary rooms on the lower floor and so designed that it could, and would, be kept absolutely clean.

Place for Correspondence

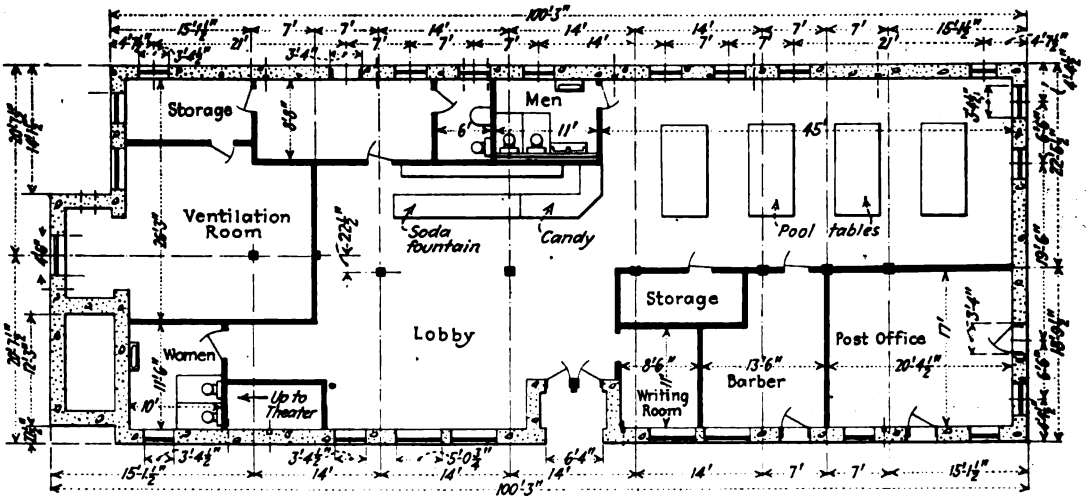
In addition to the theater, it was decided to include, on the lower floor, space for a post office, a two-chair barber shop and a writing room with desks where some place would be available at which stationery could be obtained and letters written. Such facilities for correspondence are usually not available in mine camp boarding houses. Furthermore, a lobby was to be provided with lounging chairs and a soda fountain, serving tables for ladies, places for selling magazines, candies and tobacco and a pool room, besides toilets, storage rooms and a room to hold the ventilating apparatus.

Much juggling was done with the lower floor to get a satisfactory arrangement of the rooms listed, and finally the plan shown was adopted. With this arrangement one man behind the fountain is able to handle everything in slack hours and has at all times everything under easy control.

The poolroom which has ample room for four tables is open to the lobby, yet it has the appearance of being separate. Being thus under full view the conduct of the players and spectators can be kept under proper control should any tendency toward rowdyism be manifested. The smoke also is kept out of the lobby by the location of the poolroom and by installing a ventilator so that the air will be drawn away instead of toward the lobby. "Old Hickory" furniture was installed in both lobby and poolroom, for all purposes. The serving tables of the soda fountain were, however, of another design. The writing room was furnished with three double desks, such as hotels use.

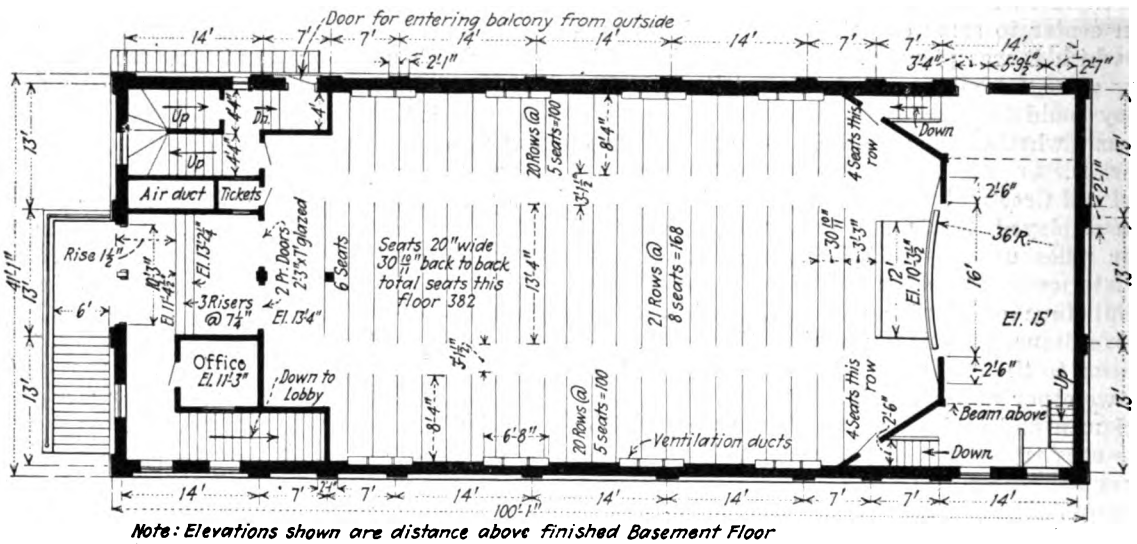
Dry and Clean Electric Refrigeration

The soda fountain, all white, was provided with electric refrigeration, thus the disorder consequent on the packing of cream was avoided. At the fountain everything is served which can be bought at similar places elsewhere. The floors of this lobby are made of tile in a combination design of brown, buff and ivory. The wainscot on all walls is of 4-in. ivory tile for a height of 56 in. above the floor. The toilet rooms have tile floors and glazed-tile wainscot. All radiators are placed near the ceiling so that the entire floor can be washed with a hose if necessary; thus there is no place to hold dirt.



When the design of the theater was discussed some proposed making the floor level with removable seats so that the room could be used as a gymnasium, but this idea was abandoned in favor of an elevated floor with easy vision from all seats, which were spaced for comfort rather than for maximum seating capacity. A stage was provided, of sufficient size to accommodate small companies, such as lyceum entertainers, lecturers, and such home-talent performances or church meetings as might need the theater from time to time. Two toilets and two dressing rooms were provided, one on each side above the stage. On this floor of the main auditorium are three hundred and eighty-two seats, as well as a manager's office and ticket seller's booth and a stairway to the balcony.

The balcony, having sixty-seven seats, is used for colored people, with a separate entrance at the side, but with provision for buying tickets from the one ticket seller. The projection booth has two motion-picture machines. The entrance to the theater is from



The headpiece shows, from left to right, the commissary, general offices and recreation building of the Fordson Coal Co., at Stone, Ky. Here is located the main operating office of the four divisions of the company.

Community Center Erected by the Fordson Coal Co. for Its Mining Force

(1) Electrically refrigerated soda fountain, all white. By eliminating the necessity for packing ice cream with salt and ice the slop and disorder is avoided that is so general in such places. All the newest sodas, drinks and combinations served at this fountain. (2) Pool hall with soda fountain and lobby in background. Note radiator at ceiling and tile wainscot 56 in. high. (3) Theater from stage. On main floor are 382 seats, spaced for comfort and in the balcony 67 seats for the colored population. Heating and ventilating provide for change of air every 10 min. (4) Theater from back. Back of motion-picture screen is a stage 15 ft. deep to accommodate lecturers and others. On the pilaster on right is one of ten openings to admit warm air when heat is necessary. Stale air is exhausted through 18 openings 6 in. above floor. (5) One side of lobby with pool room visible in background. Door at extreme right leads to writing room. Pool room is visible but seems separated from lobby. One man, in slack times, can tend the whole building. (6) Rear view of recreation building. The fire escape at the left serves also as a stage entrance and the door on right, which is on a level with the village street, is used for the handling of supplies at the soda fountain.

the end of the building or from the lobby by an inside stairway.

The auditorium is provided with sufficient direct radiation which heats the room when not being occupied. This is placed in locations away from the patrons and where dirt will not be collected. The remainder of the heat and ventilation is supplied by two multivane fans, each having a capacity of 5,000 cu.ft. per minute, one supplying fresh air and the other exhausting air which has become stale. The fresh air, being arranged to pass over steam coils and thus supply the additional heat needed, enters the auditorium through ten openings 8 ft. from the floor, each 24x30 in. The stale air is exhausted through eighteen openings 6 in. from the floor, each 14x22 in. The ducts are carried between the floor of the auditorium and the ceiling of the first story to the fans on the lower floor, and thence to the exterior of the building. The floors in the auditorium are of concrete, with rubber runners on the aisles. The stage floor is of wood resting on concrete. Lights are controlled from either the projection booth or the stage. Music is furnished by an ordinary player piano.

One manager and two men at the fountain operate the building. They devote their entire time to this work. In addition, a ticket seller, musician, ticket taker and operator are employed who are kept on duty only when shows are in progress.

The entire building was designed in the engineering department of the company and the building was erected by employees of the company under the supervision of the company's engineers except that contracts were let for the tile work, heating and ventilation. It was opened Aug. 1. The attendance at the building shows that the community is much pleased with the arrangements that have been made by the Fordson Coal Co. for its entertainment, comfort and convenience.

Why Don't Engineers Land Executive Positions?

Topic of Founder Societies—Not All Students Are Virtuosos—Engineers Have Their Full Proportion of Jobs—Some Won't Take Them When Offered

"TELLING THE STUDENT of engineering that executive ability is inborn and cannot be created out of nothing will no more discourage him than it does to tell a student of music that unless he has talent for music he cannot become a virtuoso or an operatic star," according to E. M. Herr, president of the Westinghouse Electric & Manufacturing Co. at a meeting of the Founders Societies in the Engineers' Societies' Building, New York City, April 14. Mr. Herr said that too materialistic and technical an education was dangerous, but colleges cannot build character without the student has the groundwork on which such a structure can be erected.

H. A. Guess, managing director, American Smelting and Refining Co., said that he believed that as engineers were not very numerous they were getting their due share of executive positions. Perhaps the engineers numerically are not as predominant as they would like to be. Still they did well enough as percentages ran. He assumed that there are three doctors to one engineer in this country and asked whether there were as many doctors in executive positions as engineers. He estimated that there were two lawyers to one engineer, yet he questioned if the number of lawyers in executive offices exceeded the number of engineers. He said that many business men who arrived at executive positions in companies were often college graduates themselves. On the whole he thought the engineer had more than his share of executive authority.

CHARACTER IS INBORN

Dr. F. B. Jewett, vice-president, of the American Telephone & Telegraph Co., said that character comes into the world with the man himself. It is part of his heritage. After all the fuss about the lack of recognition from which engineers are suffering, it must be admitted that some men don't want to leave technical work, but the number of engineers in executive positions is greater than the number of those from many of the other walks of life. Said Mr. Jewett, if a chief executive wants to train executives he must steer his technical assistants out of purely technical work. He believed that college too often laid too little stress on fundamentals and put too much emphasis on details. As many of the answers to business difficulties lay in the physics of the problems and not in business principles, the head of a large engineering corporation should be an engineer rather than a business man. A man had no chance if he had no knowledge of what might be at any time a matter of vital and major importance in solving his problems.

John C. Parker, vice-president and chief engineer, Brooklyn Edison Co., said that junior engineers were disposed to question whether engineers became executives because when the transformation took place it was so complete that the rank and file questioned whether the man so translated really ever had been an engineer; he no longer looked like one.

If engineers had no recognition, the fault was their own. They could, at least as a class, blame no one but themselves. Yet he thought engineers should make good executives, for an engineer could solve, by the processes he applied to technical questions, the economic problems with which he was confronted as an executive. Among those speaking extempore were, S. H. Libby, consulting hoist engineer, General Electric Co., and George L. Ray, chief engineer, Delaware, Lackawanna & Western R.R. The latter said that railroad practice varied greatly, some railroads advancing their engineers into all executive positions and others being disposed to leave them out of their calculations almost together. The operating men, who get in contact with the people have the best chance for advancement. He had in his employ a good railroad man, "who could lay out a switch so an engine could go over it without a derailment." He decided that this man should get away from the engineering department and he gave him a supervising job over the road foremen. The young man positively feared the job, and one year after he got it pleaded to be let off. But Ray made him stick it out, and he now is on his way up. Many technical men dread a transfer from the drafting room and the job of laying out tracks to a job of supervision, but therein lies the road to an executive position.

Even Coal Ash Has Its Industrial Uses

Dr. Lessing, in the Cantor lectures of the Royal Society of Arts, for 1925, "discoursed with his 'wonted fire' on his favorite topic" [the industrial wastes due to the presence of ash in coal], says *Fuel*. "He calculated that every year the [British] railway system is burdened with 25,000,000 tons of this useless material. It is indeed sad to think of so much waste labor but there are a few redeeming features about the situation even today. In the Portland cement industry, the coal ash increases the weight if not the quality of the product. Boiler clinker is useful for such purposes as making paths and on occasion as an ingredient of concrete. In the blast furnace any iron oxide or lime in the ash are turned to account and the slag is often converted into slag wool, which is useful as a heat-insulating material. Increasing quantities of quick-setting slag cement are also being made from it. Who knows what the future may bring forth? Perhaps the day will come when coal will be mined for the sake of its ash alone."

Main Office of Mines at Kemerova, Siberia

This property is owned by the Autonomous Industrial Colony, Kuzbas, a description of whose operations appeared in *Coal Age*, Nov. 26, 1925, and Jan. 28, 1926.

How Many Small Pipes Will Reservoir Keep Full?

A reservoir in the mine with which I am connected has a head of about 6 ft. with a 12-in. pipe taking the water off as fast as it enters. I want to replace this pipe with enough 2-in. pipes to carry this water for sprinkling purposes. How many such pipes will it supply? I estimate that it will fill 88 pipes basing my estimate on the fact that this is the square root of the fifth power of the ratio 6 between the pipes specified.

CHARLES J. LEWIS.
Reynoldsville, Pa.

Your method of calculating is quite correct providing your pipes are of the size stated. It must be remembered, however, that though a standard 12-in. pipe is exactly of 12-in. diameter, a standard 2-in. pipe has an actual inside diameter of 2.067 in.

$$\text{Ratio of capacities} = \sqrt[5]{\frac{12^5}{2.067^5}} = 81.2$$

Thus 81.2 standard 2-in. pipes would carry as much water under the same conditions as a 12-in. pipe when made of the same material. It is needless to say that the sprinkler discharge would greatly modify the resistance. Of course, if that resistance is sufficient there is no limit to the pipes that could be filled.

How Close May Head Sheave Be to Drum of Hoist?

Please advise the method of obtaining the distance a hoisting engine must be placed away from a sheave wheel in order to take care of the fleet of the rope, (1) when the top of the sheave wheel and the top of the drum are on the same level and (2) when they are on different levels?

The distance of the hoist drum from the sheave wheel should be the same whether the rope is horizontal or inclined. Experience has shown that the total angle between the two positions of the rope when leading toward the two extreme ends of the hoist drum should not exceed 3 deg. and this angle should be equally divided upon either side of the line between the center of the drum and the sheave wheel.

If the length of side travel on the drum is represented by l and the distance from the sheave center to the drum center by d and the fleet angle is 3 deg., then

$$\tan 1\tfrac{1}{2}^\circ = \tfrac{1}{2}\, l \div d$$
$$\text{or } 2d \tan 1\tfrac{1}{2}^\circ = l.$$

as $\tan 1^\circ 30' = 0.0262$; $d = 76.33$ ft., if the fleet of the rope is 4 ft.

Hydric Sulphide from Blasting Coal

What gases are formed by an explosion of powder and permissible explosive when fired in a borehole?

G. St. J. Perrott, assistant chief explosives chemist of the U. S. Bureau of Mines, answers this question as follows:

"The following is a typical analysis of the gases formed by the explosion of F granulation of black powder in the Bichel pressure gage:

		Per cent
Carbon dioxide	32.3	17.2
Carbon monoxide		8.6
Hydrogen		3.1
Nitrogen		30.4
Hydric sulphide		7.2

"The products of explosion of a permissible explosive may contain a trace of hydric sulphide, which comes from the sulphur in the electric detonators, as sulphur is not used in permissible explosives. The following analyses of samples from the Bichel gage show the variation in the gaseous products for different types of permissible explosives:

	Type A Per cent	Type B Per cent
Carbon dioxide	32.3	17.2
Carbon monoxide	3.5	36.3
Hydrogen	4.4	31.8
Methane	0.6	0.7
Nitrogen	59.2	14.0

"There are not sufficient data available to give the exact relation between gases formed in the greater confinement in mining operations and that obtained in the pressure gage.

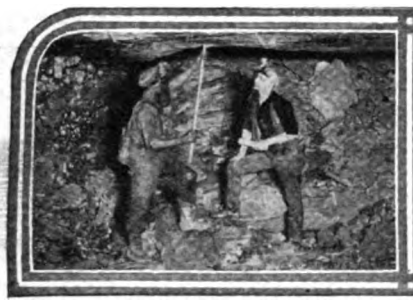
"There is so little iron sulphide present in coal that the possibility of an appreciable amount of hydrogen sulphide being formed with the small charges of explosives that are used, is very remote.

"We have not found oxides of nitrogen in any of our tests. Some observers have reported noting the odor of these oxides after large blasts, but there are no data available showing a measurable quantity present after blasting operations in coal mines."

It may be added that if the explosion takes place near a "sulphur ball" or a mass of pyrite or marcasite a small quantity of hydrogen sulphide conceivably might be formed, though apparently no tests which might bear on this supposition, other than some with gelatin dynamite and in the metal mines of Arizona, have been made by the U. S. Bureau of Mines.

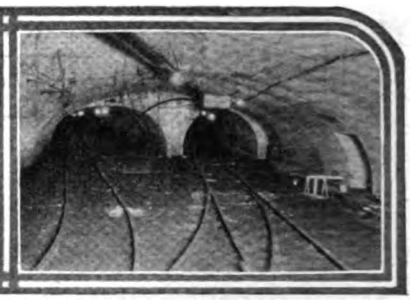
Coke Breeze Also Is Bettered By Air Cleaning

Do you know of any instance in which coke breeze is being cleaned by air or other dry method of separation?



Coke breeze has been treated by the regular pneumatic process on a coal-cleaning table at a testing plant and also at the Semet-Solvay Company's plant at Detroit, Mich. This commercial installation, we are informed has been in operation two years. It is believed to be giving entire satisfaction.

In treating, at the testing plant, coke breeze as received without any sizing and with the middlings mixed with the product, the ash was reduced from 17.37 to 9.34 per cent; that is, 47.2 per cent of the ash was removed. The refuse contained 75.23 per cent of incombustible.



In another instance in which coke breeze was received without sizing, the middlings were not returned and the following result was obtained: The ash was reduced from 17.12 to 9.06 per cent; that is, 47.1 per cent. The middlings contained 17.26 and the refuse 82.62 per cent of ash.

Coke breeze sized between ¼ and ⅜ in., with the middlings returned, had its ash content reduced from 16.87 to 9.24 per cent or 45.2 per cent. The ash in the refuse ran 81.96 per cent. With the material passing through a ⅜-in. mesh, with the middlings returned, the ash was reduced from 21.06 to 9.26 per cent or 56 per cent. The refuse contained 76.76 per cent of ash. These figures were obtained from a manufacturer of air-cleaner equipment, but are believed to accurately set forth the possibilities of air treating this material.

Underground Operation

Roof Control, the Big Problem in Mining; Some Factors in Its Solution

If the Mine Roof Rested on Red-Brick Masonry, If Its Thickness Was Not Less Than 100 Ft. and If the Open Area Was Half That of the Whole Mine Any Building Inspector Would Condemn the Structure

By Edward O'Toole
General Superintendent, U. S. Coal & Coke Co., Gary, W. Va.

To be successful in arranging that the pressure of the mine roof will break the coal loose from the seam of which it forms a part, the roof must be kept constantly under control. Roof control is the most difficult problem in mining and one of the most expensive and dangerous. It may be defined as holding up the roof of the mine during the process of mining and letting it down when its support is no longer necessary.

The problem is difficult of solution because the roof varies in composition and texture. The operation is dangerous, because at times the roof gets beyond control and falls without warning and injures the workmen. The control of roof is expensive because when the roof gets beyond control, it comes down before the mining of the coal is completed, and has to be moved or the covered coal is lost, adding to the expense. An additional expense is the cost of timber or other supports used for the roof control and the labor cost of placing and removing timber and other supports.

The strata overlying coal seams generally weigh about 160 lb. per cubic foot. Therefore, with a cover 100 ft. thick, the load on each square foot of the coal seam is 160x100 lb.; that is 16,000 lb., or 8 tons. This load would be increased in inverse proportion to the percentage of the coal left in the first workings. Thus if one-quarter of the coal is taken, three-quarters is left and this has to support the same weight as before, so the pressure is $\frac{4}{3}$ as great as at first; that is $\frac{1}{3}$ greater than its original value. If one-half of the coal in the bed is left in these preliminary operations this load will be doubled, which will give an average load of 16 tons per square foot, which exceeds the safe load for red brick in the wall of a building.

Safe Load Allowed on Brickwork

(Based on Chicago building ordinance quoted in Hool and Johnson's "Handbook of Building Construction," Vol. 1, page 611.)

Ordinary Construction	Lb. per sq. in	Tons per sq. ft.
Portland-cement mortar	175	12.6
Good lime and cement mortar	125	9.0
Good lime mortar	100	7.2

In operation the weight on the pillars left to support the roof becomes greater as mining progresses. The pressure per square foot on that portion of the coal seam adjacent to the open area will vary in proportion: (1) With the thickness of cover; (2) with the strength of the overlying strata; (3) with the distance between the pillars, for the pressure is carried from pillar to pillar, just as the weight of a bridge is carried on the piers and becomes greater as the length of the span or the distance between the supports becomes longer.

LIKE BRIDGE GIRDERS

The layers of the overlying strata are to the mine roof as the girders are to a bridge. They carry the weight from pillar to pillar over the excavated portion of the mine just as the girders of a bridge carry the weight and load of the bridge over the unsupported space between its abutments.

The strength of the strata overlying coal seams varies greatly in different localities. At places there are layers of massive sandstone 200 ft. thick overlying the coal seam. Where these occur a large area of the coal bed must be extracted before the weight of the stratum and the weight above it will break it down. The space between the mine pillars may have to be extended until it is three times as great as the thickness of the strongest band of rock in the overlying strata before the stratum will break and come down sufficiently to relieve the adjacent pillars from the weight of the roof above the excavated area.

THREE FOR ONE

For example: If the strongest band of rock overlying the coal is 200 ft. thick, the workings in the seam will have to be excavated for a width of about 600 ft. before the rock will break. If the thickness of the cover in such a case is 300 ft., the rupturing load on the coal pillars adjacent and surrounding the excavation would be as follows: 160 (the weight of strata per cubic foot) x300 (the thickness of the cover) x300 (one-half the distance from pillar to pillar) ÷ 2,000 lb. (one ton) = 7,200 tons, less the weight of the more friable portion of the strata lying between the coal seam and the predominating or load-carrying band of the overlying strata. This more friable material will fall to the height of the load-carrying band in the course of excavating in the seam an opening of the dimension stated.

When the girders of a bridge come to the rupturing point, the girder ruptures at, or about, the center, the ends bearing on the abutments rising in the air and drawing towards the center, so as to let the center go down; but in the rupturing of the roof of a coal mine, when the load on the stratum which is carrying the weight to the pillars becomes too great and reaches its rupturing point, the stratum cannot move towards the center of the opening as a bridge girder does, because it is held fast in place at both ends by the overlying strata on the unexcavated portion of the seam. As it must

Part of an address entitled "An Experiment in Combined Cutting, Mining and Loading in Coal Mines" delivered in New York City, March 11, at a meeting of the American Society of Mechanical Engineers, under the direction of the Materials Handling Section, the National Coal Association co-operating.

Digitized by Google

fracture when the stress becomes too great for its strength, the moment the load on the center produces a deflection at or near the edge of the pillar, the load-bearing stratum comes down, and the pressure on the pillars adjacent is then reduced to about what it was before operation commenced.

No Vertical Break

Just before the stratum breaks is the critical moment in roof control. Thereafter, the pressure will be approximately that due to the thickness of the overburden. It would be reduced to exactly that pressure were it not for the fact that the strata will not break vertically, but generally at an angle about 15 deg. from the vertical, and overhanging the open area.

It is under this overhang of the pillar that the O'Toole cutting-and-loading machine works, and it is the pressure due to this overhang that brings down the coal, at times fracturing it even before it is undercut. Thus it falls ahead of the coal cutters, and the only work the cutters of the machine have to do is to square up the bottom.

Roof control, more or less, affects all the branches of mining. If the roof can be controlled, all the pillars can be removed in their turn, thus reducing the open workings of the mine to a minimum. When this is done the territory to be ventilated, drained, timbered, etc., will be reduced. All the coal in the seam can be extracted and this complete extraction can be accomplished with slight damage to the surface ,as it will be let down more evenly and with fewer fractures.

Mud-Capped and Open Shots Dangerous in Coal Mines

I agree with Thomas F. Hoye that the method of shooting "coal bottoms" which he describes in his article in the "Underground Operation" department, March 25, entitled "Hazardous Way of Shooting Coal Bottoms," is ill-chosen and dangerous. In the first place there is no excuse for using a dynamite or any explosive other than a permissible in coal mines, because from among the various permissibles available one can be selected which will perform any specific job encountered in coal mines.

The U. S. Bureau of Mines has frequently pointed out the importance of property confining permissible explosives. This can be done only by charging the explosive in a hole and tamping it with clay or other non-combustible stemming. The explosive, even if mudcapped, cannot be properly confined in a notch cut in the bottom.

Shots Unsatisfactory

Much greater safety and efficiency can be attained by drilling holes and placing not more than half a stick in a hole and tamping the remaining portion of the hole with the non-combustible stemming. It is almost impossible, however, to place these holes so as to obtain high efficiency, because the average thickness of bottom is hardly ever greater than 6 in., but even so, at least 90 per cent of the explosive used by the other method will be saved. As a general rule as much of the bottom as possible should be pried loose with pick or bar, and the coal should be shot only in the tight places.

Now, a word as to the gases produced by permissible explosives and dynamites when detonated. The Bureau of Mines places on its list of permissible explosives only those that produce less than 158 liters (5½ cu.ft.) of permanent poisonous gases, as determined by tests in the Bichel pressure gage. Carbon monoxide is the most common poisonous gas produced by permissible explosive but sometimes small quantities of hydrogen sulphide are formed.

On the basis of the volume of poisonous gases, permissible explosives are placed in classes A, B. and C, in which the poisonous gases do not exceed 53, 106, and 158 liters respectively. They are also classified in accordance with their characteristic ingredient. The class of permissible explosive now largely used is of the ammonium-nitrate type, which comes within class A or B.

The quantity of poisonous gases produced by a dynamite would depend upon its class and grade. For example, gelatin dynamites produce small quantities of poisonous gases, whereas the grades of straight dynamite now manufactured rarely exceed 158 liters per 1½ lb. of explosive, the limit set by the Bureau of Mines for permissible explosives.

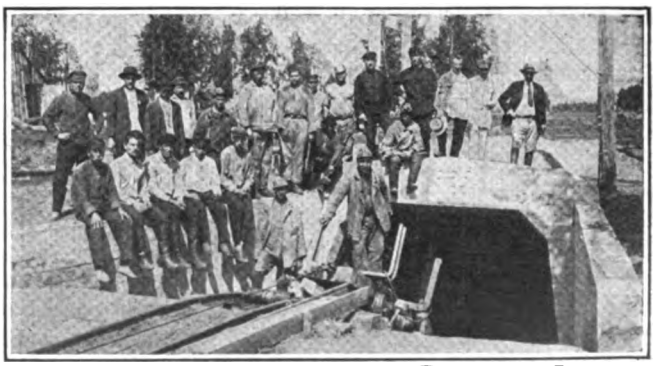
Explosives Testing Engineer
U. S. Bureau of Mines,
Pittsburgh, Pa.

By Monthly Mapping Check Loss of Coal Pillars

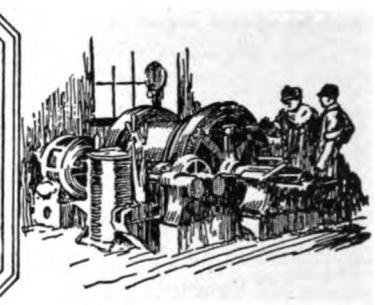


Distinctive crayon colors should be applied to mine maps to indicate progress on pillar extraction from month to month—say, yellow for one month, red for another, and so on. By this means coal pillars and stumps left in or abandoned cannot readily be camouflaged on the map as extracted coal. Not a few underground mine officials desirous of temporarily making a good showing abandon such pillars as can be recovered only at greater-than-average cost.

The failure to show clearly what coal is mined and what left makes it difficult for the company to justify the reported tonnage for royalty purposes where payment is made on the basis of actual coal mined. Where, on the other hand, payment is by the tonnage in the coal bed, the leaving of pillars involves the payment of royalty on coal left in the ground. The management should know just how much is left and why, so that it can enforce more complete extraction if that is desirable.

Moreover, the leaving of pillars causes an undue pressure on the pillar line if the abandoned pillars left are large enough to prevent the roof in the mined area from entire collapse. In consequence when pillars are left the management should have knowledge of that fact. Lost coal is not only a waste of coal and of development but often a source of further loss of coal and sometimes a menace to the section of the mine in which the pillars are abandoned.

Slope, Kemerova, Siberia



This slope is being sunk diagonally across the dip of the coal seam to the second level of the Central Shaft, a distance of 1,600 ft. on a grade of 25 deg.

Practical Pointers For Electrical And Mechanical Men

How to Install Shaft Cables Without Unequal Loading

Lowering electric cables down a mine shaft and fastening them in place is always a ticklish operation inasmuch as the cable sheathing should not be strained and consequently each support should take only the weight of cable between it and the next lower one. Where possible, it is advisable to place the cable reel on the cage allowing it to unwind as the cage is raised or lowered, a stop being made at each support while the cable is fastened securely in place.

In many instances, however, the electrical conductor must be installed in some other passage than the cage compartment and must accordingly be lowered from the top. In such a case, as described by the *Iron and Coal Trades Review* it is advisable to lower the electrical conductor by means of a steel rope, the two being lashed together at intervals of about 30 ft. The lashings are usually composed of rope yarns, and care must be taken to see that they bind properly on both cables. If the steel rope is greasy it is advisable not only to clean it but to chalk it as well so that the marline or twine lashing may secure an adequate, non-slipping grip. By this means each lashing supports only that length of the electrical conductor lying between it and the one next lower down.

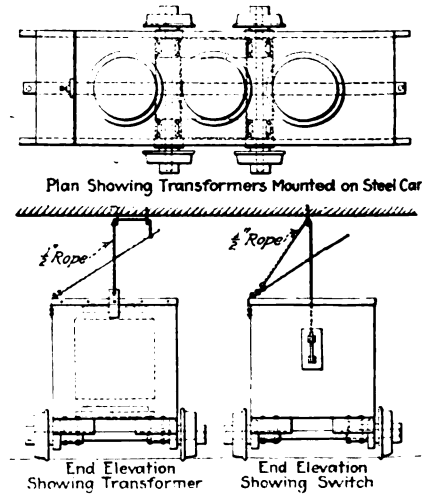
The electrical cable may be paid out from its reel under suitable tension. The steel cable, on the other hand, may well be wound upon the drum of a hoisting engine or capstan and be unwound therefrom either under the action of the driving engine or on the brake.

Fastening the Cable

When the electrical cable has been lowered to place it may be fastened in its supports successively beginning from the bottom and proceeding upward. If the lashings are properly spaced they should come immediately above or below the points of anchorage. As the cable is made fast to each permanent support the adjacent lashing may be cut loose. It has been found advisable to limit the weight of electrical conductor sustained by any one support to approximately 1,000 lb. By this means excessive weight is not thrown on the cable sheath which accordingly is not strained.

In leading the cable away from the top of the shaft also it has been found advisable to avoid sharp bends as well as sharp projections or corners in its holders. If handled and anchored carefully a cable of this kind will give excellent service and last almost indefinitely. If on the other hand it is handled roughly and installed carelessly it may give no end of trouble.

Sets Transformers in Tank Mounted on Wheels



In the accompanying illustration may be seen the portable transformer station installed at Mine No. 2 of the Francisco Mining Co., of Princeton, Indiana. This is a steel box fitted with a hinged cover and employed as a container for a set of three 15-kva. 2,500- to 250-volt, 60-cycle transformers and one 2,500-volt 200-ampere oil switch.

Mounted on a Truck

This box is 9 ft. long, 32 in. wide and 35 in. deep. It is mounted on an ordinary mine car truck. The bottom of the box consists of two 4x6x⅜-in. angle bars 9 ft. long forming the sides, and two 4x6x⅜-in. angle bars 32 in. long for ends. Upon this frame is placed a ⅜-in. boiler plate 32 in. wide and 9 ft. long. A 2x2x⅜-in. angle 35 in. in length forms each of the four corners, the sides, ends and cover being made of ¼-in. boiler plate. A ½-in. manila rope is attached at one inside end of the box extending directly over the top of the oil switch and transformers and then upward to the roof where it passes around a pulley, then down to the center of one side of the lid. Under normal conditions this lid is raised about 12 in. so as to allow ventilation over the transformers and switch. In case of fire the rope will burn in two, thus allowing the lid to fall inclosing the fire within the steel box where it will be smothered.

Switch Automatically Pulled

Another detail making for safety in this device is a steel rope attached to the oil switch lever. This extends over a pulley in the roof and thence downward, being fastened to the lid of the box in such a way as to cause the switch to be pulled out in case the lid falls. Dry sand to a depth of 2 in. is placed in the bottom of the box to absorb any oil that may leak from the transformers. This sand acts as a fire deterrent rather than a preventive.

Portable Transformer Station Has Steel Walls in Case of Fire

Three 15-kva. transformers are here shown inclosed in a steel box mounted on wheels. As may be seen the arrangement is such that should fire start within the box a manila rope will be burned off permitting the cover to fall. This not only totally encases the equipment and smothers the fire, but instantly jerks out the switch cutting off the current supply.

The chief advantages of this transformer station lie in its portability and durability. Thus it may be easily and quickly moved from place to place and its first cost is practically its last.

Six Motor Combinations for Six Reservoir Levels

An interesting system of pump-motor control was recently devised by the General Electric Co. It was developed for controlling three squirrel-cage pump motors used to maintain the water level in a reservoir. It was desired that standard automatic starting compensators be used, with an auxiliary control that would give six combinations of the pump motors at six different levels of the water in the reservoir. It was further desired that but one of the pumps operate during certain periods, the other two automatically shutting down to start again only at the end of a predetermined period.

In view of the fact that ice would foul the mechanism of a float switch during the winter months, it was decided to use a Ruggles-Klingemann regulator panel having six control points, each point to represent a definite level of the water in the reservoir. On this panel were mounted the regulator, a dial switch, a control circuit switch, a time switch and seven double-pole control relaying contactors. Rather than make up a new dial switch with six points, a field control switch with twenty-one buttons are utilized, the six points being obtained by wiring the twenty-one buttons into seven groups of three buttons each.

Pumps Start Successively

In use, a recession of the water in the reservoir causes the regulator to operate, moving the dial switch to the first control point, actuating contactor No. 1 and starting pump motor No. 1 by means of the first automatic compensator. As the water level continues to drop, additional contactors up to the sixth are actuated. The first pump motor is rated at 60 hp., the second at 100 hp. and the third at 150 hp. As each pump goes into operation on the first three points of the dial switch, the preceding one drops out. Pump No. 3 continues to operate on the fourth, fifth and sixth points, upon each of which additional pumps are picked up. On the fourth point, pump No. 1 is added; on the fifth this pump drops out and pump No. 2 is picked up, but on the sixth point, all three pumps go into operation.

In order to provide operation of but one of the pumps during certain periods, a time switch and one of the control relaying contactors were used. The normally closed tips of the time switch were wired in the coil circuit of the contactor. The control circuits of the two automatic starting compensator panels were likewise wired through this contactor. During normal operation this device is closed and all the pump motors start on their respective points. During the period of shut-down, however, the tips of the time switch open and the contactor drops out. As a result, only one pump motor operates, regardless of the position of the dial switch.

Interpoles Must Correspond With Required Rotation

In the "Practical Pointer" section of the Feb. 25 issue of *Coal Age*, J. A. Shaw describes safe practice in connecting the interpoles of direct-current motors. I am of the opinion that he has gone about the method backwards. He tells how to produce the proper rotation in relation to the interpole connections. The more practical need is to make the proper connections of the interpoles to correspond with the required rotation.

The more usual method is to connect the shunt and series fields properly, as determined by magnetic test if necessary, and then connect the interpoles in respect to the shunt and series field to correspond to the direction that the armature must rotate. Then, if on a trial, the armature does not rotate in the right direction, this can be corrected without disturbing the field relation, by reversing the two leads running to the brush holders.

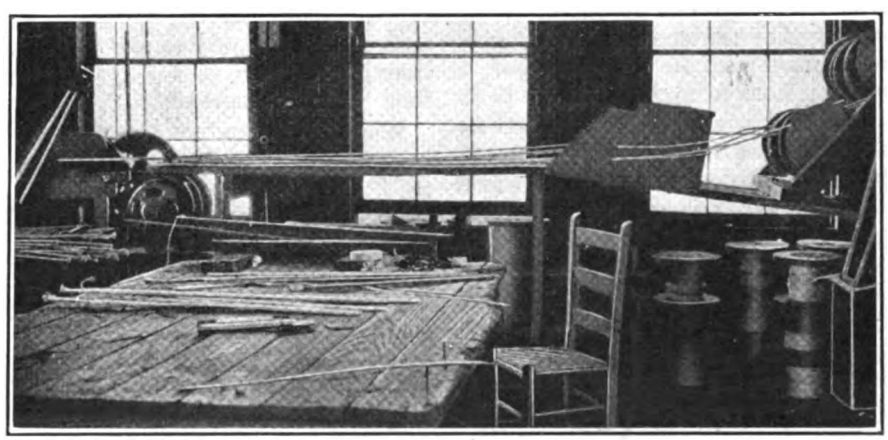
Weeksbury, Ky.

Coil Shop Should Be Clean, Light and Private



Coal companies in the last few years have shown a marked tendency to do less and less coil making in the mine repair shops. The smaller companies are, as a rule, sending their armatures away for rewinding, and the large companies which have their own winding shops are in many cases buying factory-made coils in preference to those of their own make.

An exception to the common practice is the Montevallo Coal Mining Co., of Aldrich, Ala. This mine produces only 600 tons per day, yet the armature winding is done at the mine and the coils are made there.

The coil shop is a room 16x20 ft. which forms the second story of a small store house. Windows on three sides let in an abundance of natural light. The equipment consists of a homemade motor-driven coil-winding machine, a homemade paper shear and a small dipping tank for individual coils. After being dipped in shellac the coils are pulled to shape by hand in a bench vise.

Light and Privacy Assured

The men at the mine state that this coil shop is, in a manner, a makeshift and that it is hoped that room will be provided in a proposed new repair shop for the work. Granted that it is a makeshift, this small coil shop has several desirable features. It is far enough away from the repair shop so that the man making coils is not bothered continually by visitors. The location is such that the place can be kept fairly clean, and the exposure and window location provides for an abundance of natural light.

Coil Shop of the Montevallo Coal Mining Co.

At the left is a homemade motor-driven winding machine. Mounted on the end of the bench is an improvised paper shear and at the lower right is a small tank in which the individual coils are dipped in shellac before being taped and pulled. The room, which is 16x20 ft. and is the second story of a small supply house, has windows on three sides.

Is the Fan with Backward-Curved Blades The Best Ventilating Unit?

Must Distinguish Intrinsic Resistance from That Due to Increased Volume — Laid-Back Blade Fan Has Twice Weight and Cost of One with Forward-Blades

By W. A. ROWE
American Blower Co., Detroit, Mich.

Several statements from which an entirely erroneous impression may be gained appeared in the article entitled "Operating Characteristics of Centrifugal Fans and Use of Fan-Performance Curve" delivered before the American Institute of Mining & Metallurgical Engineers and reprinted in *Coal Age*, March 18, pages 393 to 398. The first of these is that a fan with a forward-curved blade is so unstable that a "slight change in operating conditions when it is running at its point of maximum efficiency will cause the fan to operate very inefficiently." This is not so.

GREATER VOLUME OF AIR

The point which possibly has been overlooked is that a 10 per cent drop in the static pressure against which the fan is operating is not the same as a change of 10 per cent in the resistance of the mine. The author further states that it is guesswork to estimate the resistance a mine will offer to a certain volume of air within at least 10 per cent of the actual resistance and because that 10 per cent figure has been used, it is assumed that it was the intent of the author that the change in the mine resistance was 10 per cent *for a given volume* of air.

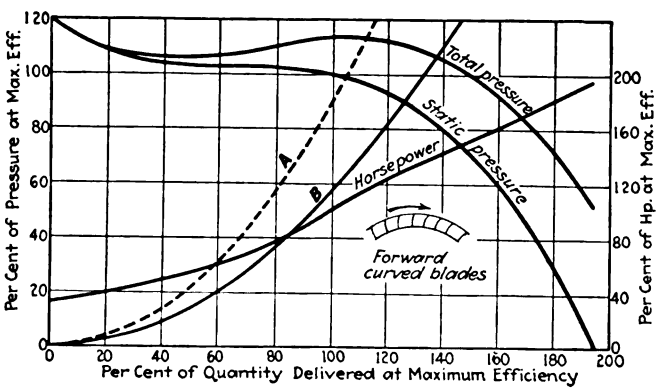
Take, for example, the first instance where it is stated that a 10 per cent drop in pressure would cause 26 per cent increase in volume and take also the example cited in the article of a fan designed to deliver 100,000 cu.ft. of air per minute against a 2-in. static pressure. A 26 per cent increase in the volume would represent 126,000 cubic ft. per minute at 1.8-in. water gage. We know from our mathematics of ventilation that the pressure necessary to cause ventilation varies directly as the square of the volume when conditions causing resistance remain unchanged.

NO SMALL MISCALCULATION

If the mine in its changed condition would handle 126,000 cu.ft. per minute at 1.8 in. water gage, it may be readily calculated that the resistance of the mine based on 100,00 cu.ft. per minute only being passed through it would correspond to a water gage of 1.13 in. This is not a 10 per cent change in the mine resistance. Had the actual resistance been 1.13 in. for 100,000 cu.ft. and the operator had calculated that the resistance would be 2 in. for that volume, he would have overestimated the mine resistance 77 per cent. It would not be correct to call that a "slight" difference in the resistance.

For an actual drop of 10 per cent in the resistance, it is easy to determine the condition at which the fan will operate by plotting the characteristics of the *mine* through a point corresponding to 90 per cent resistance for 100 per cent of capacity. Using the same fan characteristic charts of the forward-curved blade and the full backward-curved blade, which illustrate the author's article, we can plot the mine characteristic curve for that condition. This is marked *A*.

Where this mine characteristic curve crosses the static-pressure curve of the fan will establish the operating point, which is where the volume that a mine will pass at a given water gage equals the quantity of air a fan will handle against the same static pressure. This, it is apparent, will represent approximately 5 per cent increase in volume on the forward-curved blade, and 3 per cent increase in volume on the full backward-curved blade, with approximately 6 per cent and 2 per cent increase in the horsepower, respectively, for the two types.



The figures given in Table I, page 396, should show the effect of 10 per cent increase or decrease in resistance *for a given volume* of air and should be revised in accordance with these figures or an entirely erroneous impression will be conveyed.

If, for both types of fans mentioned, we plot the characteristics of the mine for a condition where the water gage at the fan at constant speed has dropped 10 per cent, then it will represent with the forward-curved blade a new condition in the mine where the mine would pass the original volume at approximately 57 per cent of the original water gage, whereas in the case of the full backward-curved blade, it will represent a water gage of 77 per cent of the original, the equivalent orifice being different in each case. These two conditions are shown by the solid characteristic line *B*.

WIDE RANGE OF EFFICIENCY

It is to be regretted that the efficiency curves were not also plotted as it would have been readily possible to show by the above means that with the forward-curved blade the efficiency of the fan is maintained over a much wider range of capacity than with the full backward-curved blade.

The second point in which it is impossible to accept the author's conclusions concerns the claim for high

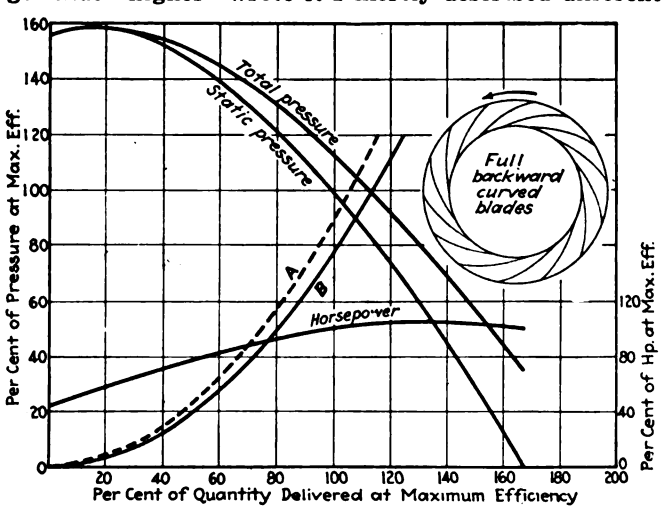
Forward-Curved Blade Fan

Graphs show results obtained when the larger or lesser quantity of air delivered at the changed pressure is taken into due consideration.

Digitized by Google

mechanical efficiency on fans having a full backward-curved blade. In Fig. 5, on p. 397 of the article quoted, is shown what purports to be a test of a high-speed fan, showing the mechanical efficiency above 80 per cent. Repeated tests of fans of the leading manufacturers of that type of equipment have never yet confirmed claims for efficiencies as high as this. The efficiency of this type of fan is more likely to be under 70 per cent than over 80 per cent and it is not as high as has been obtained with well-designed proportions of the fan with the forward-curved blades.

The characteristics which have been discussed have been unfortunately those of an academic rather than of a practical nature. Instead of focussing all our attention on the performance characteristics, it would be wise to give thought to the operating every-day characteristics of the different types of fans discussed.



TIP SPEED EXCESSIVE

The full backward-curved blade type of fan is not a new machine. It was described in text books over a generation ago. Though it is a good fan, its laid-back blades give a low manometric ratio, requiring an excessively high speed for a given water gage. For example, in the case of the fan duty previously mentioned, having a water gage of 2 in., this high-speed fan would have to operate at a peripheral velocity, or tip speed, of 7,000 ft. per minute. For the same duty the well-designed forward-curved blade would operate at a tip speed of 4,000 ft. per minute. Though the speed, first-mentioned, for the laid-back blade might not be considered objectionable for a 2-in. water gage, there are many of our mines today which are compelled to operate at water gages much higher than this. It is easy, therefore, to appreciate that when we apply such a fan to these higher water gages, the speed of this fan may be so high as to make its use seriously questionable. The preference of many mine operators for low speeds is therefore based on real reasons. If this is a "relic of the old days" it is a sample of good judgment used by the old timers founded on long practical experience.

Another disadvantage of the backwardly laid blade is that fans of that design are low in volumetric capacities. It is necessary to use a much larger fan in all its dimensions than with the forward-curved blade, for the maximum of efficiency of the high-speed fan occurs at a relatively much lower outlet velocity. The proportional dimensions for efficiencies anywhere near comparable would show lineal dimensions over 25 per cent greater than for the forward-curved blade. Experience has shown that the weight would be about double that of the forward-curved blade fan, and the cost in the same proportion.

Backward-Curved Blade Fan

Where the mine characteristic graph crosses the static-pressure curve of the fan establishes the operating point, which is where the volume that a mine will pass at a given water gage equals the quantity of air a fan will handle against the same static pressure. This shows for a curve of this type a 3-per cent increase in volume, with a 2-per cent increase in horsepower.

Snubbing More Effective Than Shearing

In the issue of March 11 Thomas Stroup comments on my article in your issue of Dec. 31, 1925, Mr. Stroup's comments being under the head "Shooting More Important Than Shearing." Among other matters he refers to a statement in the article to the effect that it is questionable if snubbing the face will be as efficient in increasing the percentage of lump coal as center shearing. I agree with him this is a surprising statement and was surprised when I read it. In the article as I wrote it I merely described different ways of obtaining larger coal, the important one of which was the snubbing of the face.

The title of my article was "Mining Lump Coal," and I described various ways and means of obtaining results, the more important of which was snubbing. The title of the article as printed reads, "Center Shearing Increases the Percentage of Lump," and so much was omitted from my article that by reading what was printed one would think my intention was to say that center shearing was the thing to do.

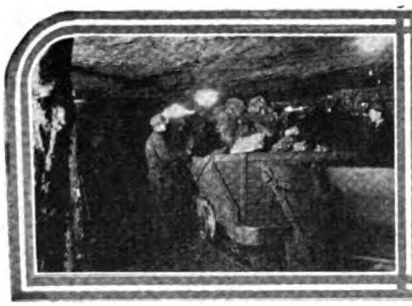
SNUB FACE AND SAVE POWDER

The article as I wrote it read in part as follows:

"Another method of mining coal so that it can be shot with a small quantity of explosives and few holes is to snub the face. After the undercut is made by an arcwall cutter the machine is pulled out from under the kerf, the cutterbar raised and a snubbing cut made.

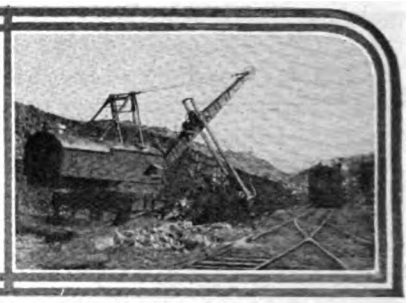
"If desirable, the snubbing can be made higher [than immediately over the undercut] leaving some coal between the two kerfs. This coal will break into good-sized lumps, and in some coal it is desirable to make the snubbing cut rather high. The same kind of cut can be made when the machine is used for slabbing on long faces. When the snubbing cut is made the coal rolls more freely from the face, requires less power to shoot, and a larger quantity of lump is obtained.

TURRET CUTTER PREFERABLE



"The arcwall machine is probably the best adapted of all machines to make a snubbing cut. There are no extra complications required on the machine to accomplish this. The standard machine will do the work.

"In some coal seams the saving in drilling holes and in powder will more than offset the cost of making the extra cut and whatever increase there might be in the percentage of lump coal is a clear gain.



"The shortwall machine has been equipped with a double cutter bar. The upper one, being shorter, does the snubbing. This type of shortwall machine has the disadvantage as compared with ordinary shortwall machines, that it is higher, heavier and a little more difficult to handle, and it is not recommended where there is sulphur, hard cutting or a rolling bottom." N. D. LEVIN.

Columbus, Ohio.

News Of the Industry

Union Balks at Arbitration in Any Form; Permanent Fact-Finding Bureau Conditionally Approved, Says Murray

Washington, D. C., April 20.—Unalterable opposition to any legislation "which spells arbitration" and conditional acceptance of the proposal to establish a permanent government fact-finding coal bureau mark the attitude of the United Mine Workers. This was made clear here yesterday when the House committee on interstate and foreign commerce resumed its hearings and invited Philip Murray, international vice-presdent, and Thomas Kennedy, international secretary-treasurer of the union, to present their views.

"Any kind of system" which has arbitration as its purpose would be unwelcome, declared Mr. Murray. This opposition extends not only to arbitration as a continuing policy but to any system of emergency control which would authorize the President to create a board that could investigate and report upon the issues in the wage controversy which gave birth to the emergency. If, however, the government should decide to set up some scheme of arbitration, then the union demands that the program be broadened to include government fixing of profits and prices as well as wages, and complete control of the industry.

The union will not oppose a compulsory fact-finding bureau provided the union has adequate representation in that bureau "in order that the American coal miner can rest assured that the statistics and information gathered shall be compiled from the standpoint of aiding in correcting the abuses and basic evils existing in the bituminous coal industry." Such a bureau should collect facts on:

(1) "The elimination of uneconomic and unscientific freight rates" on coal;

(2) Railroad coal purchases and alleged conspiracies to beat down prices on locomotive fuel;

(3) Alleged boycotts of union-mined coal by certain railroads and public utilities;

(4) Relative efficiency of all soft-coal mines;

(5) Physical conditions of mines as bearing upon introduction of new machinery and financial ability of producers to reduce costs by mechanization of such mines;

(6) Capital necessary to launch mining projects "based upon the utilization of modern mine practices in line with sound engineering principles";

(7) Sales costs, interlocking relationships of producers and sales agencies and actual profits;

(8) "All other facts which will enable collective bargaining and scientific management to remedy the evils of overproduction, unprofitable sales prices, promote efficiency and continuity of operations and in turn the lowest possible coal price to the consuming public, consistent with a wage rate to the miner compatible with American standards and a fair return upon the investment to the operator."

Congressman Lea wanted to know whether the fact-finding agency should not be empowered to compel the production of union records and testimony. Mr. Murray replied that the union did not want such power lodged with the fact-finding agency, but did not see how it could be avoided if such powers were exercised over the operators.

"The coal miner," asserted Mr. Murray, "has been the innocent victim of destructive mismanagement" and has learned by experience that it is unwise to take pot-luck in chance arbitration experiments.

Recounts Soft-Coal Evils

"Unprecedented overdevelopment, inequitable and unscientific freight rates, obsolete mining equipment, abrogation of wage contracts by cheating operators, halting of increased consumption and the inexpert management that persists throughout bituminous coal have all contributed to a period of cut-throat competition that is dissipating large pools of capital, wrecking entire mining communities and demoralizing the basic structure of the soft-coal industry."

Several times during the course of his testimony Mr. Murray attacked the companies which have broken away from the Jacksonville agreement. That agreement, he declared, had been made "at the behest of representatives of the United States Government" and the government has done nothing to brand those operators who repudiated their pledges.

Complete unionization, said the witness, would be a great stabilizing factor. Although closely questioned, he did not explain to the committee, however, how such complete unionization would eliminate the problem of the surplus mines and the surplus miners. His nearest approach was the contention that, with wages and working conditions equalized, the inefficient operation would be driven out of business by economic pressure. When asked how far the government should go in protecting the public against an interruption to its coal supply, Mr. Murray at first answered that he did not know and then parried by inquiring how far the government would go in interesting itself in the victims of contract "repudiation" in West Virginia and Pennsylvania.

Philip Murray

He admitted that if the government had emergency control powers and fixed wages high enough to induce strikers to return to work, there might be a willingness on the part of the workers to favor continued government operation. If, on the contrary, it "meant the same kind of wage regulation as in the postal service, the workers wouldn't be for it." He was not willing to concede that union and operator representation on the fact-finding agency would detract from the value and weight of such an agency's labors.

Mr. Murray accused the railroads of a deliberate campaign to break down coal prices in the union fields and to encourage non-union production to the detriment of roads serving union territory and the business and social life in that territory. President Atterbury of the Pennsylvania R.R., he said, was a leader in this movement. The purpose of this campaign, he insisted, was to wreck the Jacksonville agreement and force all wages down to $2.50@$3.50 levels. Discriminatory rate adjustments also are hurting the union fields.

Concluding the examination of Mr. Murray this morning, committee members again pressed him for an explanation of his statement that complete

Digitized by Google

unionization would be a stabilizing factor. The witness answered that the Central Competitive Field, paying a high wage rate, had efficient labor, skilled management, large operating units and lower production costs. He contended that these conditions were reversed in non-union West Virginia, although the physical conditions as to coal seams were comparable. The better relationships developed under union control would curb ruinous competition and promote mergers to eliminate uneconomic mines.

Mr. Murray denied that West Virginia coal was superior in quality to that mined in the Central Competitive Field and said operators in the latter territory had fallen down in salesmanship. The mine workers believe, he told representatives here, that the fact that the Southern fields were non-union has been considered in fixing rates to the Lakes. Increasing the differential in favor of Pittsburgh and eastern Ohio to 53c. would enable the union mines to compete against the lower wage scales in non-union districts. It might also have a tendency to close down some of the Southern mines.

Asked his authority for the statement that the Jacksonville agreement had been made at the request of the government, Mr. Murray said: "Prior to February, 1924, a joint call was issued for a conference of operators and mine workers in the Central Competitive Field. The Pittsburgh Coal Co. refused to participate. As a result of that refusal it seemed that there would be no conference, as other operators were about to decide on the same course. Mr. Hoover, in his anxiety to have industrial peace and to prevent an additional strike, asked W. K. Field to be represented at Jacksonville. Mr. Field then authorized Messrs. Donaldson and Armstrong to attend the Jacksonville meeting and participate on behalf of the Pittsburgh Coal Co.

Operators' Wants Differ

"During the conferences some of the operating interests were opposed to a three-year extension of the old agreement; some wanted a wage reduction, others wanted a one-year agreement, some two years, but Messrs. Donaldson and Armstrong insisted on a five-year contract at the old rates. Asked why, they said it was the desire of the government."

"But the government did not attempt to dictate the terms," said Mr. Herch.

"No, except that Mr. Hoover told the mine workers that it was the desire of the government that the contract be continued three or four years."

"All the government did was to urge an agreement," persisted Mr. Herch.

"It was suggested in a private conference between Mr. Hoover and Mr. Lewis, not at Jacksonville, that the old rates be continued," retorted the witness. There was, he admitted, no formal record of the government's interest except the annual report of the Department of Commerce and a letter from President Coolidge complimenting Mr. Lewis on the arrangement effected at Jacksonville.

Mr. Murray reiterated his opposition to compulsory arbitration and said the question of voluntary arbitration should be left to the industry. For that reason he rejected the suggestion that a bill along the lines of the Parker-Watson railroad labor bill would be a good thing, notwithstanding the fact that that measure makes the acceptance of arbitration optional. The union, he said, had no objection to mediation and conciliation. He declined to venture a prediction of what might happen at the expiration of the Jacksonville agreement.

Kennedy Launches Shafts

Mr. Kennedy, calling attention to bills providing for mediation and conciliation, testified that such powers already were lodged with the Department of Labor. To go beyond those powers, he argued, would in itself be creating some form of compulsion.

Expanding further on the union distaste for arbitration, Mr. Kennedy said that both the public and the anthracite operators wanted cheaper coal and continuity of supply. This meant that the representatives of the public and of the operators on an arbitration board would be arranged against the mine workers regardless of the justice of the mine workers' contentions.

The witness would not commit himself on the question of whether he favored legislation which would permit examination of the private records of industry in general, but said that was necessary in the coal industry to establish the facts. If the government could attack the royalty problem, it could reduce the price of coal. Mr Kennedy also assailed the state anthracite tax as put over by the selfish interests of manufacturers to avoid paying their proper share of taxation. He repeated the charge that the operators had encouraged the last anthracite suspension to destroy the union.

The committee adjourned the hearings this afternoon and will resume on April 26. Harry L. Gandy, executive secretary of the National Coal Association, probably will be the first witness heard next week.

Insurance Company Insists On Rock-Dusting

The Associated Companies, of Hartford, Conn., which write a large volume of compensation insurance business on coal mines throughout the United States, have come out strongly for rock-dusting. Carrying risks on gaseous as well as non-gaseous mines, the organization has been advocating rock-dusting of bituminous coal mines for the last two years, and a large number of operations have adopted the practice.

G. B. Butterfield, general manager of the Associated Companies, announced on April 10, however, that beginning Oct. 1, next, this organization will not insure any gaseous or dusty coal mine that is not rock-dusted, and in the event that any gaseous or dusty mine on the books has not adopted the practice by that time, its policy will be cancelled.

Penna Resigns, Then Accepts Another Term

After declining to accept another term as secretary of the Indiana Bituminous Coal Operators' Association at the regular election, April 17, Phil. H. Penna, who has held the office since 1900, consented to accept the position again Monday when the executive board met in an all-day session in Terre Haute and prevailed upon Mr. Penna to withdraw his resignation. While there were no comments Monday upon the situation which led Mr. Penna to refuse to accept the office at the annual meeting of the board, it was said that all difficulties had been satisfactorily settled and that Mr. Penna had been chosen by unanimous vote of the board.

David Ingle, of Evansville, Ind., president of the association, declared that Mr. Penna's name had been the only one under consideration by the executive board and in a statement following the meeting declared that "Mr. Penna's election was unanimous."

Mr. Penna first came into prominence in the mining industry when, as a miner, he was active in the organization of the present District No. 11, United Mine Workers. As a result of his activity he was elected in 1887 as the first president of the district organization and continued in his service with the miners' union until 1900.

His ability as an organizer brought an offer from the operators which was accepted by Mr. Penna in August, 1900. In the interim Mr. Penna not only has taken an active part in the development of the Indiana bituminous field but has become recognized nationally as a leader in the coal industry.

Montour 9 Opens; 2,200 at Work for Pittsburgh Co.

With the opening of Montour No. 9 mine, of the Pittsburgh Coal Co., at McDonald, Pa., on April 20, one-third of the mines of the company in the Pittsburgh district are operating on an open-shop basis. Montour No. 9 is the eleventh mine of the company to begin work on the November, 1917, scale, independent of the United Mine Workers. The company has a total of 33 mines in the Pittsburgh district, 22 of which are still idle. More than 50 men went to work at Montour No. 9 the first day. The company now has a total of almost 2,200 miners at work in the Pittsburgh district on the 1917 scale. Montour No. 9 had been closed since April 22, 1925.

Industrial Coal Stocks Ebb

Coal supplies on hand in various industries on March 1, according to the National Association of Purchasing Agents, were as follows: Steel plants, 24 days; electric utilities and goal-gas plants, 47 days; railroads, 23 days; by-product-coke plants, 21 days; miscellaneous industries, 42 days. This compares with these estimates by the government as of Feb. 1: Steel plants, 26 days; electric utilities and coal-gas plants, 50 days; railroads, 25 days; by-product-coke plants, 23 days; miscellaneous industries, 37 days.

Urges Subsidy to Encourage Nova Scotia Coal Industry

Establishment of coking plants in Montreal and other large central cities for converting Nova Scotia slack into domestic coal and the granting of a subsidy by the federal government for each ton of Nova Scotia coal sold to Montreal and points west, and for each ton of Alberta coal sold east of Winnipeg are suggested by Major Hume Cronyn, K. C., as means to enable Canada to become independent of the United States for coal supplies and to bring about relief from a perilous coal situation in Nova Scotia. These were submitted at a meeting of the Young Men's Canadian Club in the Windsor Hotel, Montreal, April 12. Mr. Cronyn, who is president of the Huron & Erie Mortgage Co. and the Mutual Life Insurance Co., was a member of the Duncan commission appointed to investigate Nova Scotia coal conditions.

Opposition was voiced against raising the Canadian tariff against American coals and against a reduction of rates for the transportation of coal east and west. The sale of byproducts, such as gas, from the coal converted in central coking plants, the speaker said, would lessen the cost of such fuel to the consumer. Expenses of establishing such plants would be heavy, he admitted, and he thought that the government should contribute.

Major Cronyn declared no betterment will come until the industry in Nova Scotia is placed on a firm economic basis and operators and miners forget their past bitterness and differences and prepare to co-operate in harmony for mutual benefit.

Break Off Wage Parley on Kansas Shovel-Mine Labor

Negotiations on a wage scale between District 14, United Mine Workers, and operators of half a dozen steam-shovel mines near Mulberry, Kan., were broken off the night of April 13. After the mines involved had been "marched" upon by union miners in motor cars several weeks ago, a truce was effected by entering negotiations for a contract. It was agreed at a preliminary conference that the miners should submit a written proposal. This was done and terms were presented similar to those of the Jacksonville agreement together with a tonnage rate on wagon hauls from the strip mines. The operators proposed a tonnage rate for a large part of the work in the pits, and the miners rejected this. The controversy hinges on wages for the common labor in the mines, as the cranemen, engineers and other skilled workers are paid the union scale.

Elk Horn Sells Oil Rights

All the undeveloped oil and gas rights in Kentucky and West Virginia belonging to the Elk Horn Coal Corporation have been sold to the Louisville Gas & Electric Co. for approximately $700,000. Elk Horn retains, under the terms of the sale, one-eighth interest in all oil found on the territory sold, without bearing any costs of development.

Thomas Kennedy

Miners' secretary-treasurer, who presented his views on coal legislation at the House hearing this week.

Alaska Colliery Destroyed In $500,000 Fire

The Alaska colliery of the Philadelphia & Reading Coal & Iron Co., at Mt. Carmel, Pa., was destroyed by fire last Saturday night, entailing a loss estimated unofficially at about $500,000. The fire broke out about 8 o'clock and had wrecked the structure within two hours. A night watchman who discovered the fire said there had been no explosion.

The colliery, which was comparatively new, was one of the largest in this section of the anthracite region and employed about 950 men. Officials said they were unable to explain the cause of the fire pending an investigation.

Since the resumption of hard-coal mining after the strike, the colliery had been operating at normal capacity.

C. & O. to Acquire Stock Of Island Creek R.R.

The Interstate Commerce Commission on April 16 authorized the Chesapeake & Ohio Ry. to acquire control of the Island Creek R.R. in Logan County, West Virginia, by purchase of its capital stock.

Since 1912 the Chesapeake & Ohio has been operating the Island Creek line under a 20-year lease. The main line of the Island Creek R.R., which was completed in 1904, extends from near Logan to Holden, a distance of about five miles, with several short branches which have an aggregate length of ten miles. The proposed purchase is to include the branch mileage.

The Logan & Southern R.R., a feeder line, owned by the Chesapeake & Ohio connects with the main line of the Island Creek at Monitor Junction, near Logan.

Commissioner Eastman, of the Commerce Commission, dissented from the report of the majority, declaring the acquisition of involved consolidation of roads into a single system for ownership and operation beyond their authority to approve. He also thought the price to be paid was too high.

Minto Board Report Tabled

The report of the Royal Commission appointed by the government to investigate the causes leading up to the troubles in the Minto (N. B.) coal field between the Minto Coal Co. and its miners was tabled in the Provincial Legislature April 9 by Dr. H. I. Taylor.

The Commission in the course of its duties acted as a board of conciliation and succeeded in bringing about an amicable and satisfactory settlement of the strike of the miners. The members of the Royal Commission were E. R. Teed, of Woodstock; Geo. A. Stone, of Moncton, and Luke S. Morrison, of Fredericton.

American Federation of Labor Opposes Plan For Federal Industrial Court to Settle Strikes

Discussion of proposal to establish a federal industrial court to settle strikes and other problems between capital and labor featured the hearing last week before the committee on commerce, trade and commercial law of the American Bar Association at 65 Liberty St., New York City. Chairman Province M. Pogue, of Cincinnati, presided.

Several bills are before Congress for establishment of a court of this sort, but the bar committee, it was learned, wants to formulate a bill of its own. The hearing was to study the various angles of public opinion as regards the formulation of such a bill, which would be equitable to both employer and employee.

The American Federation of Labor went on record as being unqualifiedly against establishment of such a court. Matthew Woll, vice-president of the federation, who appeared before the committee, declared such a measure "would destroy freedom of collective bargaining" between employer and employee and would furthermore be "unconstitutional as well as impracticable."

Murray T. Quigg, editor of *Law and Labor*, joined with Mr. Woll in the view that a national industrial court is unnecessary to settle strikes. He favored a Congressional bill to "define more clearly the private rights of disputants" and to provide changing of contracts by agreement in order to avoid strikes without "outside" interference in industry.

State Senator William R. Eaton of Colorado was the only advocate of the industrial court idea who was heard at the session. He favored a federal body similar to the Colorado Industrial Commission which, he said, has resulted in only two strikes being called in that state in three years.

Cabinet Confers with British Miners And Operators as Strike Impends; Commission Report Roundly Scored

When the situation in the British coal industry seemed likely to take an even more serious turn the government intervened. The Minister of Labor on April 14 had a conference with the representatives of the operators and the Prime Minister, Stanley Baldwin, interviewed the industrial committee of the General Council of the Trades Union Congress. The Premier did not commit himself to any action, but a special meeting of the Cabinet this week was expected to consider the matter.

The outlook seemed darkest at the close of the conference between the colliery owners and miners on April 13. Replying to the recent report of the Royal Coal Commission, the miners' representatives emphatically opposed several of the report's principal clauses, which were drafted by members of the commission as essential to bringing about peace and prosperity for the British coal industry.

The miners' leaders declared that no settlement would be acceptable that did not provide at least a wage enabling the miners to get a decent standard of living. The suggestion that "the minimum percentage" on wages should be settled in the various mining districts and not nationally also was objected to. Redistribution of present daily hours of labor over a week of five days instead of six, they pronounced impracticable.

The announced intention of the operators to endeavor to open district negotiations on the wage issue was construed by the miners as definite abandonment of the national wage negotiations. It brought the Industrial Committee of the General Council of the Trades Union Congress definitely into line behind the miners' executive.

Announce End of Old Contracts

In explaining their action the operators said that it would be necessary for them to terminate the existing contracts, and that notices to that effect would be posted at the pits this week, but this, they pointed out, did not imply termination of the negotiations. On the contrary, the mine owners were preparing a draft of a national wage agreement to embody the principles which they thought could appropriately be settled nationally.

Hope of an amicable settlement before May 1 has been held in some quarters because of the resistance on both sides to letting things get to the breaking point. It has been apparent all along that the miners, though objecting to portions of the Coal Commission's report, have not wished to go on record as repudiating it entirely.

The same is true regarding the coal owners. The extremists among them who are willing to go to the mat with the miners have so far been kept in the background by cooler heads, preferring argument to action.

Secretary Cook, of the Miners' Federation, announced that he had received a letter from the secretary of the International Transport Workers Federation promising all possible support to the miners should the conflict actually break out between them and the mine owners.

Support by every possible means, in the event of a strike, was promised April 16 by a committee of the International Miners' Federation at a meeting in Brussels. The decision means, according to the International Federation, that not only will efforts be made to stop the exportation of coal to Great Britain but the possibility of a general sympathetic strike on the Continent also is contemplated.

The support of the International Federation was gained only after concessions by the British leaders. It was agreed that in the event of a sympathetic strike on the Continent the direction of the British strike would pass from the British leaders to the international committee and that there should be no separate settlement in Britain.

Prime Minister Baldwin is devoting his energy to a plan for the settlement of wages, which is the most contentious point. It is expected that the operators will reluctantly consent to a national wage negotiation proceeding, but it is not known whether they will still desire to reserve some control of the wage settlements by districts, to which the miners are violently opposed.

Resumes Work of Unifying Electrical Terms

Nearly one hundred delegates with members of their families arrived on the "Andania" from Hamburg, Southampton and Cherbourg to attend the annual sessions of the International Electrotechnical Commission. Col. R. E. B. Crompton, of England, the honorary secretary of the commission, who is 81 years of age, was the official spokesman of the party. The commission will continue the work of the international standardization of electrical terms and ratings.

At the meeting of official welcome, held in the auditorium of the Engineers' Societies Building, New York City, April 13, John W. Lieb, vice-president of the New York Edison Co., acted as chairman of the meeting. Prof. Elihu Thompson welcomed the delegates on behalf of the U. S. National Committee, and Dr. H. T. Barnes, president, Canadian National Commission, added his felicitations. The principal speaker at the session was Guido Semenza, president of the commission. Others were E. Genissieu, of France; A. F. Enstrom, of Sweden; Carl Strecker, of Germany, and Prof. V. List, of Czechoslovakia. Thomas A. Edison sent a telegraphic greeting from Florida and Lord Balfour a cablegram from London. In his address Prof. Semenza declared that unifying the nomenclature in electrical science and manufacture and establishing unified ratings for machines will simplify production.

Open-Shop Miners Earn More Than Union Men

The claim that under what is known as the American plan, the coal miners are better paid in southern West Virginia than in union fields elsewhere, appears borne out by figures compiled by A. O. Wilson, statistician of the Kanawha Coal Operatives' Association.

A federal survey of fourteen states showed daily average pay of workers in 599 mines was $6.56. There were 198 working days in the year and it was possible to average $1,300 in twelve months. In the Kanawha district the average was $10.23 daily, working days 170 in the year, and the average earnings of 3,136 men was $1,739.93. Mr. Wilson points out that in 1921, when the Kanawha district was 100 per cent union, the average pay of 4,976 miners was $1,387.26.

Offer Coal Fellowships at University of Washington

The College of Mines of the University of Washington offers five fellowships for research in coal and clay in co-operative work with the U. S. Bureau of Mines. The fellowships are open to graduates of universities and technical colleges who are properly qualified to undertake research investigations. The value of each fellowship is $720 to the holder, for the twelve months beginning July 1. Fellowship holders pay tuition and laboratory fees, but are reimbursed for the amounts so expended; they register as graduate students and become candidates for the degree of Master of Science in the proper subject, unless an equivalent degree has previously been earned.

The following coal investigations have been selected for 1926-1927: (a) Beneficiation: Coal washing; application of ore dressing principles to cleaning of coal. (b) Utilization: Briquetting of low grade coals.

Each applicant should send a copy of his collegiate record from the registrar of the college where he has graduated, or will graduate in June. He also should send a photograph and a detailed statement of his professional experience, if any. Applications should be submitted as early as possible in order to allow ample time for consideration, and should be addressed to Dean Milnor Roberts, College of Mines, University of Washington, Seattle, Washington.

Will Report Fuel Sold to Ships

Coal totaling 304,946 tons, valued at $1,644,040, and bunker oil to a total of 3,231,616 barrels, valued at $4,904,974, was furnished at American ports during February to vessels of all nations engaged in foreign trade, according to a report issued by the Department of Commerce. This report is a new service of the department and will be issued monthly, it was stated.

Petroleum Institute Figures Reveal Influence of Oil Competition on Worldwide Slump in Coal Industry

By Paul Wooton
Washington Correspondent of *Coal Age*

A flood of light is thrown on the worldwide depression in the coal industry by the estimates of the American Petroleum Institute on oil output.

The world production of petroleum in 1925 was 1,066,220,000 barrels, a new high record and a total of 54,000,000 barrels larger than that of 1924. The figures show that the competition of fuel oil, which is such a factor in the United States, is worldwide and is the great underlying cause of the depression in the fields of Great Britain and the Continent.

In 1925 the world production of coal was 1,368,000,000 tons, only 26,000,000 tons greater than 1913. Prior to that time the average normal growth was 38,000,000 tons per year. Thus in a twelve-year period there has been less than one year's normal growth.

Some loss of coal consumption is chargeable to the industrial depression which has followed the war and to the fuel economies which were stimulated by higher prices, but these influences have not had a proportional influence on the consumption of energy. The production of natural gas has doubled since 1913, while the production of oil is 177 per cent greater. In 1913 oil and gas furnished only 7 per cent of the oil derived from mineral fuels. In 1925 they furnished 17 per cent.

Another factor which has had an influence is the increased use of waterpower. Scarcity of power during the war and the high price of coal stimulated waterpower development so that in 1920 this form of power was displacing 91,000,000 tons of coal. By 1923 further hydro development was resulting in the displacement of 116,000,000 tons of coal. Between 1913 and 1925 oil and waterpower displaced more than 200,000,000 tons of coal.

Use of Coal Reduced by Economy

At the same time that oil and waterpower have been obtaining a larger share of the total business, economies in the use of coal have reduced the quantity consumed. The electric utilities have reduced their unit consumption per kilowatt hour by 40 per cent. The railroads and steamship companies also have increased efficiency.

Had the bituminous coal industry in the United States been a static one like anthracite it could have met the decline with less difficulty. It had grown accustomed to rapid expansion and was so geared that it has been hard to adjust itself to the lessened demand.

Another study of current interest, using the statistics of the Engineering Valuation Committee of the Fuel Administration and of the Geological Survey, indicates that the industrial use of fuel oil in New England has reached and passed its maximum. Though it is expected that the relatively few remaining unutilized waterpower sites in that section of the country will be harnessed, coal operators do not expect much more competition than exists today. New England is expected, however, to increase its use of bituminous coal for industrial purposes as well as for domestic fuel. An extract from the report reads:

"According to the estimates of the U. S. Geological Survey the states of Pennsylvania, Maryland and West Virginia, from which New England draws bituminous fuel by both rail and water, contained deposits of coal amounts to no less than 285,193,000,000 net tons.

"The total quantity of low-volatile coal in reserve in West Virginia, Pennsylvania and Maryland is estimated to be 68,310,000,000 tons. These deposits all are within normal transportation radius of New England either by rail or water.

"Low-volatile coal is fragile in texture and frequent handling tends to reduce the quantity of lump. For that reason insistence upon low-volatile coal in domestic sizes has reduced greatly the percentage of the total output at the mines which can be used for household purposes. During the strike the Commission on the Necessaries of Life soon abandoned its emphasis upon sized smokeless coal and came out squarely for the use of run-of-mine. Sized smokeless coal has no advantage over run-of-mine coal and any preference shown for it by domestic users must be set down as almost entirely a matter of prejudice.

Low-Voltage Could Meet Demand

"The normal consumption of coal of all kinds in New England is 30,000,000 tons a year. Of that amount 10,000,000 tons have been anthracite. Even if anthracite were replaced entirely by bituminous coal, not all would be low-volatile, but even on the assumption that New England's entire fuel requirements were to be met with low-volatile coal the low-volatile mines would experience no difficulty in adapting themselves to that enlarged demand.

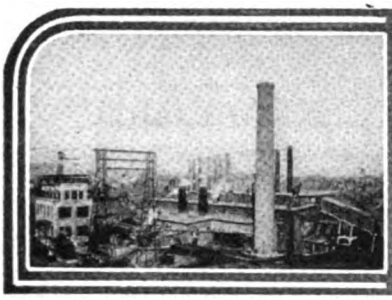
"As nearly as can be estimated, the output of low-volatile coal from Pennsylvania, Maryland and West Virginia in 1925 totaled 83,000,000 net tons. Of this 83,000,000 tons not less than 12,000,000 went to New England. Deducting this last quantity from the 30,000,000 tons annually required in New England the net addition to the output of low-volatile coal which would be required to meet New England's entire coal needs, would be only 18,000,000 tons. The best estimate that has been made of the equipped capacity of low-volatile mines is not less than 115,000,000 tons, which is 32,000,000 tons in excess of the 1925 output, which excess in turn is 14,000,000 tons more than the quantity necessary to replace New England's present consumption both of anthracite and of high-volatile coal."

Further Hearings Ordered in Lake Cargo Rate Cases

Further hearings in the Lake Cargo rate cases were ordered by the Interstate Commerce Commission on April 19. The dates and places at which such hearings will be held will be announced later.

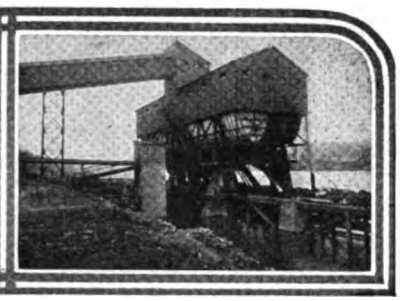
The question of the relative adjustment in rates from the Northern and Southern producing districts to Lake Erie ports for transshipment to the Northwest has been a subject of controversy for many years. In the most recent attack upon the adjustment the tentative opinion of the examiners of the Interstate Commerce Commission recommended a revision of rates which would have widened the spread between the transportation charges from Ohio, western Pennsylvania and northern West Virginia on the one hand and southern West Virginia and eastern Kentucky on the other. The Commission, however, refused to indorse those recommendations and dismissed the complaints.

Since that time the case has been the subject of heated discussion by Congressmen from the affected districts and by officials of the United Mine Workers. Senator Reed of Pennsylvania used the decision as a text in his drive to force the appointment of a Keystone State man to the Commission. On March 2 the commission announced that it would consider whether the case should be reopened for additional testimony and called upon the parties at interest to state their views.



The Northern railroads which, with the exception of the Wheeling & Lake Erie, had stood with the Southern lines in opposing any change when the original case was heard, abandoned that alliance.

Hearing on Permanent Rates From South to Northeast



The question of the establishment of permanent rates on bituminous coal from the Virginias, Pennsylvania, Maryland and eastern Kentucky and on coke from ovens in that territory to points in the New England and Middle Atlantic States where no joint through all-rail rates are now in effect will be considered by the Interstate Commerce Commission at a hearing before Examiner Koch at New York on June 7. The proceedings are part of the same docket under which the Commission established permanent rates on prepared low-volatile coal to part of the northern territory and emergency rates on high- and low-volatile coal to all destinations in the Northeast. The emergency rates expire on April 30 and the Commission recently refused the petition of the New England Governors' fuel committee and associated industrial interests to continue those rates until the question of permanent rates had been decided.

In a hearing before the same examiner, at Syracuse on June 28, the Commission will take up the adjustment of anthracite rates to stations in upper New York. The central and upstate New York rate structure on hard coal has been a bone of contention for several years.

News Items From Field and Trade

ALABAMA

The Tennessee Coal, Iron & Railroad Co., it is understood, will in the near future sink a shaft or slope in the Pratt division near its present No. 2 mine, which will be driven into the workings of the Hamilton slope.

The Alabama By-Product Corp. has been making a number of improvements in its Flat Creek division lately, 250 new houses of modern construction having been built for its employees. It is also stated that consideration is being given to the driving of a new slope at Praco, an extension is being made to the tipple building at Wegra and other improvements are under way to arrange for the handling of a larger tonnage at this mine. Installation of conveyor belts at some of the Flat Creek operations for bringing the coal to the surface also is contemplated.

Reports from New Orleans are to the effect that E. A. Martinez, of that city; A. A. Fendley, of Oneonta, and Messrs. Gay and Gillespie, of Biloxi, Miss., have taken over the properties of the Birmingham Coal & Iron Co. in Blount County, near Oneonta. J. O. Gillespie succeeds I. E. Boyette, of Birmingham, as president. Mines at Inland were developed a number of years ago, but have not been in operation in the past six years.

ARKANSAS

Thirty-two local unions of District No. 21, United Mine Workers, are enjoined permanently from interfering with employees or properties of the Bernice Anthracite Coal Co. at Russellville in a pro confesso decree issued in U. S. District Court at Little Rock by Judge Jacob Trieber. The order is directed against locals in Sebastian, Franklin, Logan, Johnson and Pope counties, which revolted against employment under the wage scale of 1917 placed in effect at the expiration of the 1924 scale.

ILLINOIS

The Consolidated Coal Co.'s Mine No. 7, at Herrin, has posted notice of an indefinite suspension of operations. Slack market and the need for a considerable amount of repair work are reasons assigned for the shutdown. Normally the mine employs 600 men.

The Cosgrove-Meehan Co. has announced that, due to new contracts, Franco mine No. 3, located at Paulton, seven miles east of Marion, will reopen at once and employ 300 men who have been idle two months.

The St. Louis & O'Fallon Coal Co. has discontinued the sale of coal from its own mine in Illinois. It will be handled in the future through the Meteor Coal Co., of St. Louis.

The Black Servant Coal Co., of Danville and Elkville, have established their own sales office in St. Louis under the name of the Black Servant Coal Sales Co.

The By-Products Coke Corp., Chicago, reports March net earnings of $292,633 before depreciation and federal taxes, against $150,642 in March, 1925. Net earnings for the first quarter of 1926, before depreciation and federal taxes, were $886,818, compared with $169,864 in the first quarter of the previous year.

The State Mine Examining Board, of which William Hall is president and John Mulligan is secretary, has announced its schedule for May as follows: Belleveille, 10th; Harrisburg, 11th; Herrin, 12th; Benton, 13th; Duquoin, 14th; Centralia, 15th; Staunton, 17th; Springfield, 18th; Taylorville, 19th; Danville, 20th; Farmington, 21st; Peoria, 22d.

INDIANA

The Carlisle mine, at Carlisle, owned by the Carlisle Coal Mining Co., has reopened after a two-months shutdown. It was closed about the middle of February when it failed to meet its payroll. Under the present arrangement whereby it was reopened miners will receive half their back pay and the remainder in instalments, money to be furnished by subscription of Carlisle business men. Three thousand dollars is on hand at present. By a new contract with the Carlisle Fifth Vein Coal Co., owners of the mine will buy its output from the Fifth Vein company, which will operate the pit. Will Cooper will be local superintendent under Wesley Harris, general superintendent of the Carlisle Coal Mining Co.

The Indiana Coal Co., of Sullivan, has filed a certificate of dissolution. Following the filing of this certificate, the same incorporators filed incorporation papers for the Indiana Coal Co., giving a capital stock of 300 shares of no par value. The company is formed primarily to enter the production end of the business. Among the incorporators are Will H. Hays, motion picture czar and former Postmaster General, whose home is in Sullivan, and his brother, Hinkle C. Hays, attorney of Sullivan. Joseph E. Hitt is given as the other incorporator.

KANSAS

Postpone Rescue Meet.—The Kansas mine-rescue and first-aid meet that was to have been held in Pittsburg on May 22, has been indefinitely postponed, it was announced after a meeting of the general arrangements committee. While the meet may be held in the late summer or early autumn it is probable that it will be deferred to next year, members said. The great expense of sending the winning team to the international meet in San Francisco, together with other outlays for the meet made it impossible to finance it at a time when the coal industry in this region is inactive, members of the committee stated.

Examinations of applicants for certificates as mine foremen, hoisting engineers, gas men and shotfirers were held in Pittsburg, on April 17 by the state mine examining board.

Jackson-Walker Lease 10 Mines.—The Jackson-Walker Coal & Mining Co. announced on April 5 that leases had been signed on ten of its mines in the Pittsburg district to ten different companies as follows: Pittsburg, Crawford County, Cayuga, Victor, Star, Wolfe & Linthicum, Moore, Wilbert & Schreeb, Dittman & Wachter and Gubbio coal companies. The leases run to March 31, 1927. The Jackson-Walker no longer operates any mines, leasing all its properties to operating companies and handling the greater part of their output.

Sixty-two miners who had completed their night class work in Scammon and West Mineral in the extension course in mining offered by the State Teachers College received their certificates April 6, short addresses being made by President W. A. Brandenburg, Prof. G. E. Abernathy and Prof. J. A. Yates, of the Teachers College; Matt L. Walters, president of District 14, United Mine Workers, and James Sherwood, state mine inspector. Similar exercises were conducted in Arma the night of April 8 for a large class of miners completing the course there.

KENTUCKY

William A. Schanzenbacher, manager of a Louisville yard of the St. Bernard Mining Co. division of the West Kentucky Coal Co., is in a serious condition at a local hospital as a result of having been shot by two would-be bandits on the evening of April 3. The gunmen trailed him in another machine from the coal company office to his home, and started shooting, one of the five bullets striking him in the abdomen. After the shooting the bandits jumped into their car and fled, without taking a box from him which contained nearly $300. In their excitement they failed to change a set of license tags, and were later picked up, and acknowledged the

Digitized by Google

plot. Schanzenbacher has a fair chance of recovery, the bullet having been removed in an operation the following day.

Work of stripping the Canoe Creek mine, located in Henderson County, has been started by A. D. Reed. The mine formerly was operated as a shaft mine. All cutting machines, motors and rails will be brought to the surface and sold at private sale, it was announced.

The Eastern Kentucky R.R., operating thirty-six miles of track from Webbville to Riverton, near Ashland, Ky., has petitioned the Interstate Commerce Commission for permission to abandon the road, which has lost money for several years. This road some three years ago was frequently mentioned in reports regarding an extension of the Detroit, Toledo & Ironton R.R. owned by Henry Ford, traffic men figuring that it might be bought up and used as a link in a proposed road to reach the eastern Kentucky coal fields.

Following the recent announcement that the Old Ben Coal Corporation, Chicago, had closed contracts for eastern Kentucky and western Kentucky coals it has been learned that the company arranged with the Hart Coal Corporation, Providence, for supplying western Kentucky fuel.

MINNESOTA

The Zenith Furnace Co., of Duluth, has awarded a contract for complete re-equipment of the section of the coal dock destroyed by fire last January. The dock uses the cable-drawn coal car system in which the cars dump into pockets for delivery to coke ovens or for outgoing car shipments.

MISSOURI

Miners of Bevier have reached an agreement to operate the Star coal mine on a co-operative basis, and will put the plant in shape to work soon. About 50 men will be given employment, the number to be increased as the demand develops. The mine suspended April 1, 1924. A co-operative coal mine at Macon has been doing well and from 75 to 100 men have found steady work there right along. It is operated in conformity with the union laws and union men have at all times been working in the pit.

The St. Louis Coal Club last week elected the following officers: President, Louis C. Meid; first vice-pres., Harry K. Pilkington; second vice-pres., Edw. D. Houlle; secretary, Joseph J. Harding; treasurer, Gregory W. Daues; directors, Geo. H. Martin, Arthur M. Hull, Henry C. Frier and Carl Stiefel.

Horace Whetsel, treasurer of the Home Coal Co., Macon, has announced that the company will open Mine No. 1 at once to supply the needs of patrons of the company and the Mulkey Block Co. The Mulkey Block company closed down March 31 to add some equipment to its mine.

NEW MEXICO

Form Institute Chapter.—At a recent meeting of foremen and officials of the Phelps Dodge Corp. held in Dawson, a chapter of the Rocky Mountain Coal Mining Institute was organized with twenty-five charter members. W. C. Holman, chief engineer, was elected president and Wm. Moorehead, assistant underground superintendent, was named secretary of the new organization. Various phases of the coal mining industry will be discussed at the monthly meetings of the chapter and membership will be open to all foremen, department heads and other executives.

NEW YORK

The city water works department of Buffalo on April 10 opened bids for furnishing three-quarter slack coal to the pumping station for a year, beginning July 1. The tenders were as follows: On $2.25 rate, Lake Erie Fuel Co., $1.44; Theo. Krug, $1.53; M. Balber & Son (Avella slack), $1.44; on $2.39 rate, Agnew-Smith Fuel Co., $1.30; Theo. Krug, $1.39. The Balber bid is regarded as irregular, making the Lake Erie Fuel Co. lowest, by one cent. No action was taken by the department.

NORTH DAKOTA

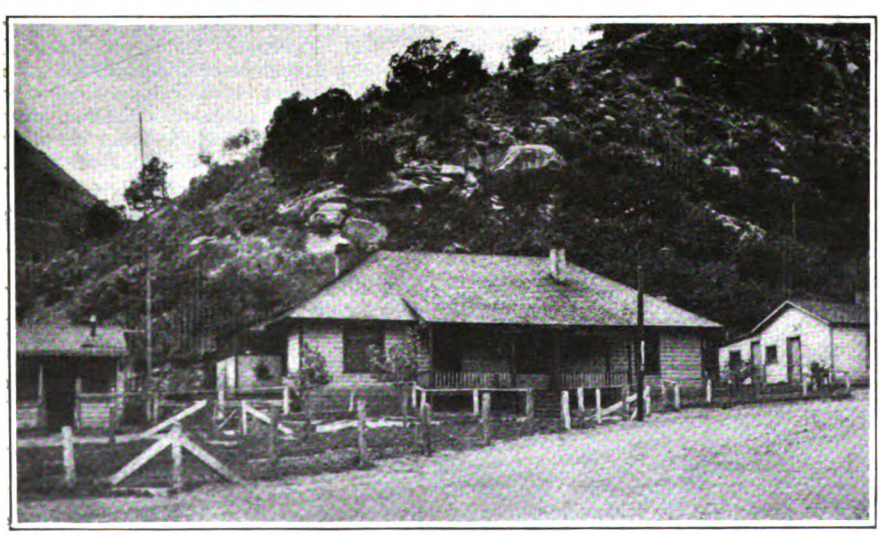
Records of the state Railroad Commission of North Dakota on lignite shipments show a slight gain for the first three weeks of March, 1926, as compared with the same month in 1925. Interstate shipments were 5,472 tons against 4,615 and intrastate were 53,289 against 51,285.

OHIO

Upon the application of John McMillen, president of the Big Bailey Mining Co., the Carr Run Coal Co., and the North Hill Coal Co., R. H. Jackson, of Nelsonville, was named receiver of the three companies by the common pleas court recently. The three companies have been operated by Mr. McMillen and C. C. Sharp, of Nelsonville, on property leased from the Sunday Creek Coal Co., upon a royalty and sales contract basis.

The Harbison-Walker Refractories Co., which has headquarters at Pittsburgh, has taken options on the clay rights of four large tracts of coal lands in Jackson County, and steps have been taken to make extensive tests for fine clays for refractories manufacture. Drilling machines will be used to determine the quality of the various clay seams. The company obtained the options from the Superior Colliery Co., of which U. S. Morris, Detroit, is president. In all about 6,000 acres are to be tested. In the mining operations in No. 2 seam the men exposed many fine clay seams.

Several thousand forest trees are being planted on the property of the Wayne Coal Co., near New Lexington. The reforestation is being supervised by F. W. Dean, of the Forestry Department of the Ohio Agricultural Experiment Station.



The Black Diamond, mines, near Glouster, will soon suspend operations, unless some change is made in the wage scale. The company has just completed the driving of a new entry 300 ft. long to open a new body of coal. About 250 men are habitually employed at the mine.

The Board of Education of Columbus will receive bids May 13 for approximately 15,000 tons of mine-run or lump coal and 2,000 tons of nut, pea and slack to be delivered to the various public schools of the city. The specifications provide for analysis of the coal offered by the various bidders.

PENNSYLVANIA

Plant 300,000 Trees.—The Berwind-White Coal Mining Co. and the Wilmore Coal Co. are each planting 100,000 trees on lands in Somerset County. The Wilmore Real Estate Co. also is planting 100,000 trees in the vicinity of Windber.

The sixth quarterly meeting of the Pittsburgh Coal Mining Institute was held in the Pittsburgh Chamber of Commerce, April 17. The institute is engaged in a general educational program involving the several successive steps

Official House or Club House of Carbon Fuel Co. at Rains, Utah

Though Rains is not named in recognition of the precipitation of moisture locally, but after L. F. Rains, of Salt Lake City, it shows clearly the advantage which rains afford. Much of Carbon County is arid and Rains itself is perhaps semi-arid, but the hills are clad with scrub vegetation.

Digitized by Google

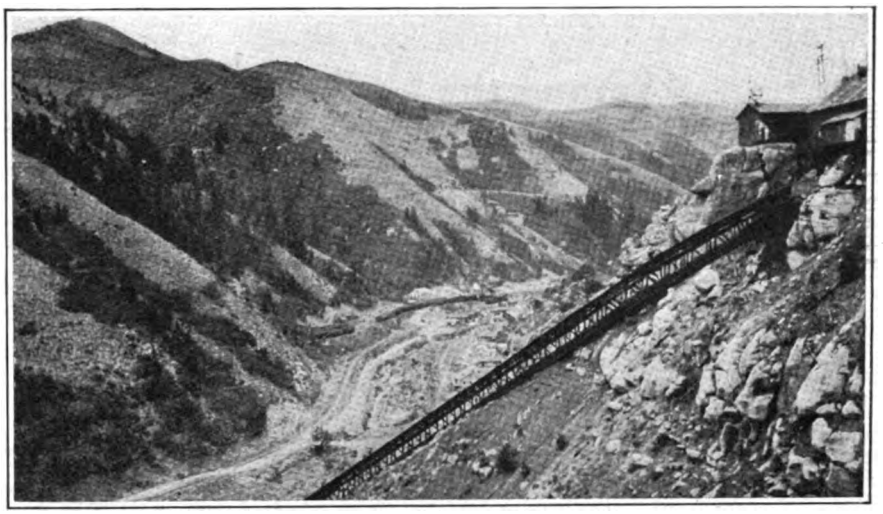
in the operation of a coal tract from the optioning, testing and prospecting to full development. The largest session dealt with the modern development stages. A. W. Hesse, chief engineer of the Buckeye Coal Co., Nemacolin, was the chief speaker. B. L. Lubelsky, explosives engineer of the Pittsburgh Coal Co., discussed the several types of explosives with respect to several methods of blasting coal. A question box was in charge of Hunter Klingensmith, safety director of the National Mining Co., Morgan, Pa.

The U. S. Engineer's report for March showed that 1,594,624 tons of coal and 30,224 tons of coke moved on the Monongahela River, 370,352 tons of coal moved on the Ohio and 64,100 tons of coal moved on the Allegheny River.

Open-shop miners of the Pittsburgh Coal Co. in the Pittsburgh district established a new record for a week's production during the week ended April 10, when 39,026 tons of coal was dumped through the tipples of 10 mines. This is the largest coal output in one week since the first mine was reopened independent of the United Mine Workers, in August, 1925. A new maximum number of men at work on any one day was reached during the week with 2,156, and a new daily output record was reached with 7,200 tons.

TENNESSEE

Tennessee mined 846,243 more tons of coal in 1925 than in 1924, at an increased value of $1,724,723, according to O. P. Pile, chief mine inspector. The average price was $1.90 or 14c. lower than 1924, while the wages increased $200,000.



UTAH

The Columbia Steel Corp., with offices in Salt Lake City and a plant at the new town of Ironton, Utah County, has taken up another 116 acres of land for the purpose, it is understood, of extending its coal operations.

WEST VIRGINIA

After an inspection trip covering their mines in Boone County, stockholders of the Coal River Collieries Co., controlled largely by members of the Brotherhood of Locomotive Engineers, held their annual meeting in Huntington, on April 6 but did not elect their directors at that time owing to the fact a majority of the stock was not represented at the meeting. The election was therefore deferred until May 15, and it is believed that the election will be conducted by ballots. At the conclusion of the two-day meeting stockholders heard the report of President J. T. Dunigan and discussed it informally.

It is reported in coal circles that J. S. Thurmond, son of the late Capt. W. D. Thurmond, has disposed of the three-fifths interests of the Thurmond heirs in 3,500 acres of smokeless coal land in the Minden section of Fayette County to the New River-Pocahontas Consolidated Coal Co. The company formerly owned a two-thirds interest. The sale followed action in federal courts, according to reports.

Scraper Conveyor at Rains, Carbon County, Utah

To the left can be seen Spring Canyon. Rains, operated by the Carbon County Coal Co., is the most northern of all the plants on the canyon except Mutual, which is operated by the Mutual Coal Co., of Salt Lake City.

The Black Betsy and Otto Marmet Coal Co. properties in the Black Betsy and Raymond City sections, respectively, in Putnam County, have been taken over by the Otto Marmet Coal Mining Co., the original company, it is reported. This followed federal court action in which the Johnson McKinley interests released the properties. It is reported that the company is considering a plan to consolidate the properties and probably spend from $100,000 to $200,000 in improvements.

Within six weeks the new rope and button conveyor being installed by the Forsdon Coal Co. at Nuttallburg mine, Nuttallburg, Fayette County, will be completed. The conveyor is 1,500 ft. long and will cost approximately $100,000.

Mines Nos. 5 and 6 of the Crab Orchard Improvement Co., at Eccles, Raleigh County, will be rock-dusted beginning this week.

J. D. Stoots and James Keath, who were among the entombed miners rescued March 8 from mine No. 5 of the Crab Orchard Improvement Co. at Eccles, addressed a meeting of the Fayette Mining Institute at Mount Hope Saturday night, April 10. Robert M. Lambie, chief of the state department of mines, also spoke.

Ground has been broken in Belle, 10 miles east of Charleston, for the new plant of the Sharpless Solvents Corporation, and W. H. Mason, formerly of the Winifrede Coal Co., is in charge of the work.

Rock-Dusting Spreads. — The state Department of Mines reports that these mines in southern West Virginia are being rock-dusted: Lake Superior mines Nos. 1 and 2 of the Lake Superior Coal Co., at Superior, McDowell County; the mine of the Landstreet Downey Coal Co. at Delbarton, Mingo County; a mine of the Elkhorn Piney Coal Mining Co. at Stanaford, Raleigh County; mines Nos. 21 and 22 of the Island Creek Coal Co., at Holden, Logan County.

Three prosecutions were made recently by the state Department of Mines against men charged with short-fusing, improper tamping, storing powder in the mine and other offenses. Each miner was fined $50 and costs by justices of the peace. The alleged offenses occurred at the Kingmont mine of the Virginia & Pittsburgh Coal Co. near Fairmont, and the J. D. Boone Coal Co. at Boonedale, Kanawha Falls, Fayette County.

The Paisley interests, of Cleveland, have issued instructions to the management of the company's four operations in the Monongalia field to keep the mines closed indefinitely instead of operating on a non-union basis. The management states it can buy non-union coal to fill orders at a lower price than it can be mined in Monongalia County.

CANADA

The British Empire Steel Corporation's coal mines produced 268,582 tons in March. Of this amount, 167,794 tons was hoisted in the Glace Bay and New Waterford district; 13,121 at Sydney Mines; 38,602 at Acadia Mines, and 49,065 at Springhill.

Bituminous coal has been discovered at Long Rapids, on the Mattagami River, northern Ontario, but whether it exists in commercial quantities has not as yet been ascertained. The occurrence of lignite in the locality has been known for some years, but a borehole through the lignite revealed a seam of bituminous coal. Work is now under way on the sinking of a shaft to the bituminous seam.

Coal operators of British Columbia are meeting with keen competition owing to large importations of British coal. This is due to the increase of grain exportations by the Pacific route, the grain-carrying ships bringing from England return cargoes of coal. The British coal can be sold on the western Canada market cheaper than the home product. This is made possible by the policy of the British government in subsidizing coal production in order to keep the British miner at work.

Digitized by Google

Among the Coal Men

Samuel W. Parr, professor of chemistry in the University of Illinois, who will receive the Chandler gold medal for 1926, will deliver a lecture on "The Constitution of Coal" in connection with the presentation, at Havemeyer Hall, Columbia University, New York City, at 8:15 p.m., April 23.

A. G. Johnson has been appointed as general superintendent of the Greenbrier Coal & Coke Co. in McDowell County, West Virginia, to succeed Charles L. Logan, who resigned. The appointment became effective April 1. Mr. Logan became superintendent of the Killarney Smokeless Coal Co., operating in Raleigh County, W. Va., on April 1.

Walter R. Thurmond, head of the Thurmond Consolidated Coal Co., with headquarters at Logan, W. Va., has announced the appointment of **H. A. McAllister**, formerly general superintendent of the Logan Division of the West Virginia Coal & Coke Co., as general manager of mines for the Thurmond interests.

J. B. McCune, of Bentleyville, Pa., general superintendent of the Bethlehem Mines Corporation in that district, was the principal speaker at the weekly luncheon of the Charleroi (Pa.) Rotary Club last week.

Charles O. Fowler, formerly of the Southern Coal Co., Chicago, distributors of western Kentucky coal, has become president of the Abbott-Irwin Coal Co., Chicago. Mr. Fowler was one of the first Illinois coal men to enter the western Kentucky field. He began in 1916 as vice-president of the Bickett Coal & Coke Co. In 1920 he went to the Monro-Warrior Coal Co. and two years later became president of the Southern Coal Co., selling coal which was recently taken over by the Peabody Coal Co. This change brought about Mr. Fowler's connection with the Abbott-Irwin Coal Co.

W. H. Grady, of New York, was recently appointed as consulting engineer of the West Virginia Coal & Coke Co., and is giving much attention to the operating affairs of that company. He also is consulting engineer for a number of other coal companies operating in different sections of West Virginia.

V. Y. Dallman, editor of the Illinois *State Register*, has been appointed receiver for the St. Louis Coke & Coal Co. by Federal Judge Fitz Henry. Mr. Dallman succeeds F. O'Donnell, Bloomington, who died recently. The new receiver says he will wind up the affairs of the receivership by disposing of claims pending.

Don D. Walker, manager in Louisville, Ky.; New Albany, Ind., and Jeffersonville, Ind., for the St. Bernard division, West Kentucky Coal Co., was recently elected a director of Post Q, Travelers Protective Association, at New Albany, Ind.

John Hays Hammond

When John Hays Hammond, eminent engineer and former chairman of the U. S. Coal Commission, arrived in New York last week after a trip to Europe he learned that a celebration had been arranged in honor of his seventy-first birthday, which occurred in March, when he was abroad. Mr. Hammond told some friends who met him at the pier that eating and drinking when he felt like it, and even worrying a little, had not proved a handicap in living to be 71.

Obituary

Abner Lunsford Succumbs To Pneumonia

Abner Lunsford, general manager of the Fordson Coal Co. (Henry Ford interests), with headquarters in Stone, Ky., who was well known to the coal trade of southern West Virginia, died in the Good Samaritan Hospital in Cincinnati, April 12, of the effects of an attack of pneumonia, following an operation for appendicitis.

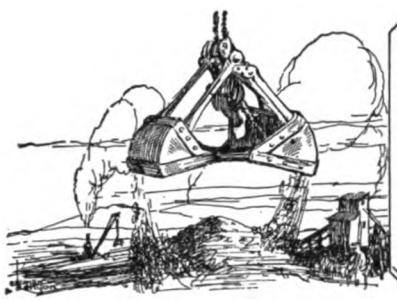
Mr. Lunsford formerly was general manager and part owner of the Banner Fork Coal Co. at Harlan, Ky., and when Mr. Ford purchased the mines he made Mr. Lunsford general manager with extended duties. Two of these mines are located in southern West Virginia, the Nuttallburg mine at Nuttallburg, Fayette County, and the Twin Branch plant at Twin Branch, McDowell County, along the Norfolk & Western Ry.

At one time Mr. Lunsford was connected with the Virginia Iron, Coal & Coke Co. in the Clinch Valley at Norton and at St. Paul. He was especially well known in operating circles in Charleston, and was highly regarded as a mining man.

John F. Fuller, 33 years old, part owner of the Sunflower Coal Co., Scammon, Kan., was killed by a fall of rock in the company's mine, near Columbus, Kan., on the afternoon of April 7. Mr. Fuller was working alone in a room when a 1,000-lb. slab fell on his shoulders, pinning him to the floor. His brother, Harry Fuller, associated with him in the company, heard the crash, but it was ten minutes before the rock could be broken by sledgehammers and the man removed. Mr. Fuller had lived in the southeastern Kansas field seven years.

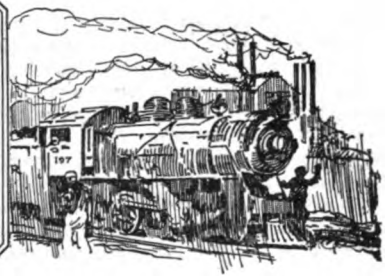
David William Jones, brother of John E. Jones, safety engineer of the Old Ben Coal Corp., Chicago, Ill., was fatally injured April 16 in a mine accident. The younger and only brother of the safety engineer was engaged in operating a small mine with his father, and according to the information received the wheel in the headframe broke, and Jones was killed outright. The shaft is 40 ft. in depth and is located at Spara, Ill. He is survived by a widow and two children.

George P. Pattison, 75 years old, a coal operator identified with the Piedmont field of West Virginia for 60 years, died suddenly April 6, as he was about to leave his home for Baltimore on business. Mr. Pattison had apparently recovered from grip. His wife died about three weeks ago. He leaves three sons, Carroll and Russell Pattison, well-known coal operators of Bloomington, and Dorsey Pattison of Westernport, manager of the Pattison store at Bloomington.



Traffic News

To Study Coke Rates from South



The Coal, Coke & Iron Ore Committee, Central Freight Association Territory, announces a public hearing on coke rates in general from Birmingham, Ala., to destinations in the State of Michigan. Application for extension of the basis covered by Committee Information Circular No. 1373 beyond April 30, 1926, for an indefinite period having been made by Southern coke producers and shippers through the Southern Freight Association, the committee will hold a session at Room 606 Chamber of Commerce Building, Pittsburgh, Pa., April 29, 1926, at 10 A.M., daylight saving time.

The Kanawha Coal Operators' Association was an intervener at the hearing of the Kalbaugh Coal Co. case, which was heard by an examiner of the Interstate Commerce Commission at Cumberland, Md., on April 16. The Kalbaugh Coal Co., which operates a mine at Barnum, Mineral County, W. Va., along the Baltimore & Ohio R.R., seeks to have its rate lowered under the so-called Myersdale (Pa.) group rate on the ground that as the coal from its mines does not have to be hauled over the Allegheny Mountains it should have a lower freight rate to the east than mines in the Preston County fields of northern West Virginia. The State of Maryland filed an amended complaint with the Commission designed to protect the several coal fields of that state. Southern West Virginia wants the present relativity to remain intact.

Production And the Market

Soft-Coal Market Suffers from Stand-Off Policy; Anthracite Demand Disappointing

Developments in the bituminous coal trade during the last week, as far as any approach to a firm footing is concerned, brought comparatively little comfort to anyone. Domestic business, it is true, felt the stimulus of a quickened demand brought about by unseasonably low temperatures, but orders were fitful, unevenly distributed and only in sufficient volume to tide over immediate requirements.

Steam-coal demand shows but little change, particularly in the contract situation. Large industrial consumers are reluctant to enter into agreements, the belief in some quarters being that the bottom of the market has not been reached. Some business is being closed quietly, of course, but most of the orders that are placed in the open are practically "bargain counter" deals. This condition does not seem to be confined to any section, a waiting game apparently having been adopted as the ruling policy. The utilities and railroads in all districts likewise are in no hurry to cover.

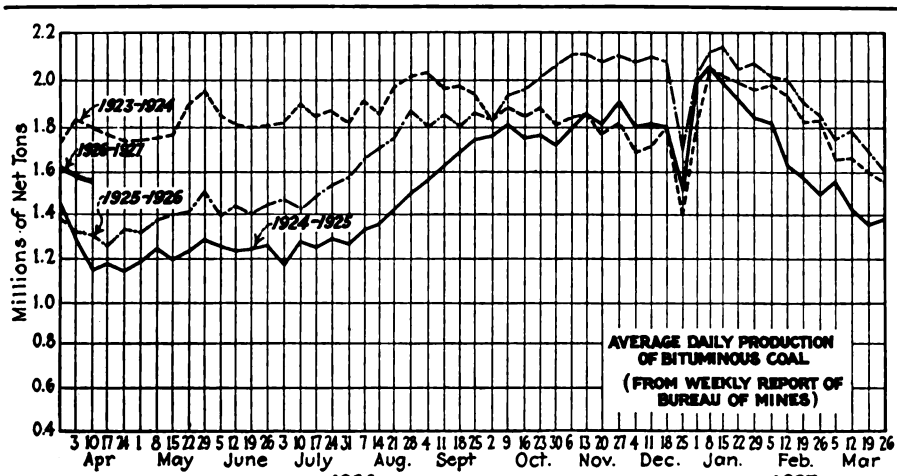
Lake Shipping Further Delayed

The backwardness of the lake season has been the chief unsettling influence, continued congestion between the mines and the docks at Toledo and Sandusky having made it necessary for the railroads to continue the embargo on shipments until the tracks have been cleared. The movement of a large tonnage of western Kentucky coal into channels served by Illinois and Indiana producers seems to be helping the general market situation in the Middle West. Price competition, which of late has been ruinous, will be less keen, it is hoped, and a further stabilizing influence is seen in the reports of more mergers.

Although production continues above the seasonal average of the preceding two years, the downward course of spot prices came to a halt this week. *Coal Age* Index on April 19 stood at a fraction over 158 and the corresponding price was $1.92. This was an advance of about 1c. compared with the preceding week.

Bituminous coal production during the week ended April 10 was estimated by the Bureau of Mines at 9,429,000 net tons. Output was partly curtailed by the observance of Easter Monday, though the total was 389,000 tons higher than for the preceding week.

Weak Retail Demand for Hard Coal



Domestic sizes of anthracite from company mines are moving with comparative freedom, pea continuing to show the greatest strength. Retail distributors, particularly in New York and Philadelphia, find the demand a distinct disappointment. Consumers in most cases are indifferent to efforts to induce them to place orders for next winter. The cool spell served to bring in only small orders for immediate consumption. Baltimore householders, on the other hand, are placing orders promptly for season's requirements, lest prices be increased later.

Considerable uneasiness has been expressed by retail distributors lest the anthracite operators reduce the prices on domestic sizes later in the season. The likelihood of any such action being taken is so extremely remote, however, that it may be ignored.

Premium prices on the larger domestic sizes are largely nominal as the market refuses to absorb any substantial tonnage at prices above company circulars.

The steam sizes are quiet, some industrial consumers holding out for lower prices on contracts.

In the Connellsville coke market there is practically no spot demand for any grade and output is declining slightly.

Estimates of Production

(Net Tons)

	1925	1926
BITUMINOUS		
March 27	8,353,000	9,626,000

Railroads Reluctant to Contract

Middle Western railroads still play a waiting game in the matter of contracts. Few, if any, of the big systems have covered for their requirements and the little buying being done is at low prices. One belt line, for example, closed for April delivery of western Kentucky coal at $1,10 for mine-run. A number of large industrial consumers also are fighting shy of contracts. Spot business is quiet, but fairly strong.

Another cold snap last week put life into the demand for domestic sizes, but orders are unevenly distributed. In the southern Illinois field, Carterville operators complain that business is backward, except at mines supplying railroad tonnage. Duquoin working time is down to three days a week and the number of idle mines is increasing. On the whole, steam business exceeds domestic in the Mt. Olive district. The only coal in the Standard district that is not backing up on producers is slack.

Eastern Kentucky and West Virginia are pounding the Chicago territory for tonnage. Coke also is making a drive to hold its position against anthracite. The failure of the anthracite producers to make the usual spring reduction has helped the coke market and many dealers are pushing the latter product much more actively. Aside from a weather domestic movement of the cheaper coals, the St. Louis local market is featureless.

Kentucky Competition Less Menacing

The passing of such a large tonnage of western Kentucky coal into the hands of Illinois and Indiana producers is having a favorable effect upon the general market situation in the Middle West. Ruinous price competition, the optimists believe, will be lessened. Talk of additional consolidations in the Middle Western fields also is looked upon as a stabilizing influence. Mines in western Kentucky are now operating at about one-third capacity.

The Louisville view of the railroad contract situation is happier than that prevailing at Chicago. However, the optimism rests more upon contracts that may be placed than on actual orders. The Illinois Central is reported to be buying in the open market at around $1.50, mine-run; the Louisville & Nashville, says rumor, is paying $1.40@$1.50 for western Kentucky coal and up to $1.60 for southeastern Kentucky and Tennessee mine-run.

Troublesome accumulations of "no bills" in the eastern Kentucky districts have disappeared. There is considerable dickering on lake business, but the situation is by no means clear as the late opening of the season relieves buyers of the necessity of closing. Utilities are contracting at a fair rate, but industrial consumers are holding back.

Western Kentucky Prices Firmer

On the whole, the tendency in western Kentucky prices is toward greater firmness. Actual realizations are ap-

proximately 25c. per ton better than a year ago although the price ranges show little change. Screenings are selling at 85c.@$1.15, with little tonnage moving under 90c. Some lots of mine-run have gone at $1.05 or less, but the average is $1.15@$1.35. Some eastern Kentucky mine-run has sold at $1.20; most shippers, however, ask $1.35@$1.60.

Cold weather came to the rescue of the trade at the Head of the Lakes last week and kept retailers over the Northwest busy delivering small lots to improvident consumers. As a result some of the accumulations of smokeless coals, domestic coke and briquets put in stock during the hard-coal strike have been diminishing. There is a fair demand for anthracite, but no great pressure to buy. Dock men, however, hold to the belief that the market will absorb 1,000,000 tons in 1926-27.

There has been practically no contracting for soft coal by industrials and public utilities. Activity in that direction waits upon the announcement of the new season prices. Owing to ice conditions, actual receipts from the East are not expected before the first week in May. In the meantime quotations on stocks now on the docks are steady except upon coals which have degraded badly in storage.

Northwestern Consumers Indifferent

Fluctuating temperatures have created an air of uncertainty in the domestic coal trade at Milwaukee, but business thus far this month has been good. Results in March were comparatively satisfactory. The call for steam coal has been surprisingly strong and dealers expect to see the docks pretty well cleaned up by the time navigation opens. Prices are steady and unchanged. Despite uncertain weather conditions, business in the Twin Cities is characterized by evasive tactics on the part of consumers. Demand has been only moderate. Prices now named are considered tempting, but consumers show no interest.

Kansas mines did not catch up with their orders until last week. There is still enough cold-weather business on the books of the companies working to assure steady operation for some days. The increase in domestic demand has made the screenings situation easier and there has been a slowing down in the crushing of mine-run for steam consumption.

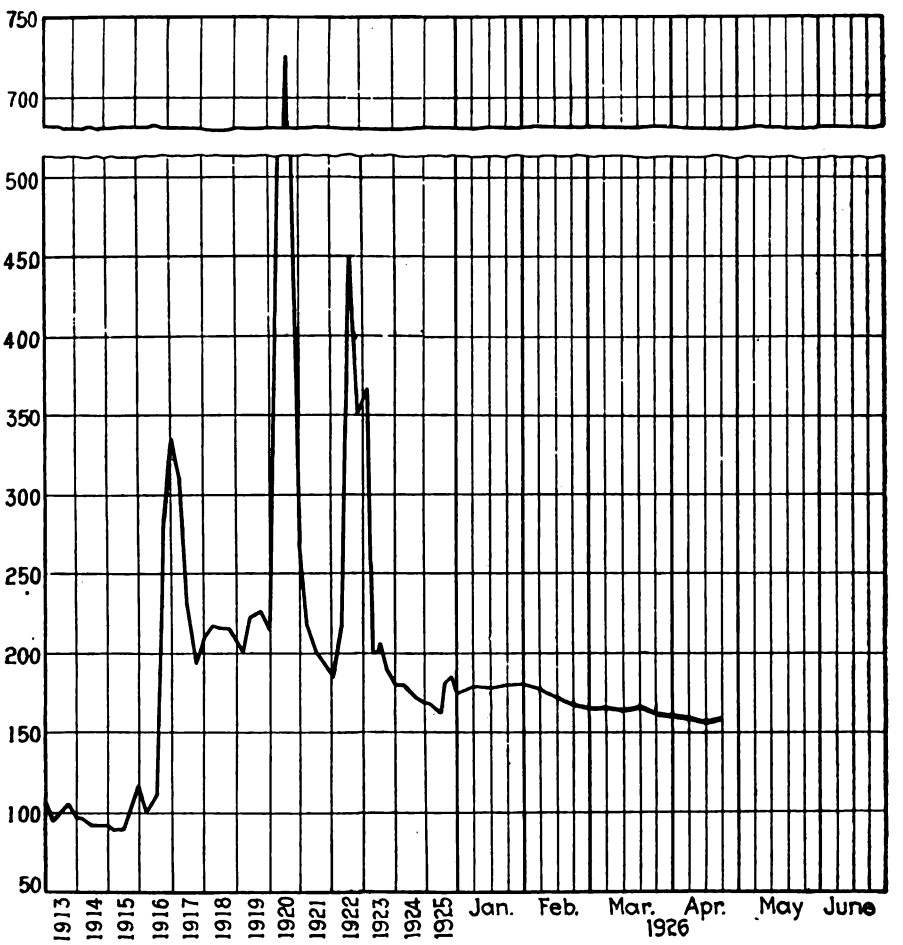
Colorado, too, is still enjoying a heavy demand for domestic sizes and running time has increased approximately 15 per cent. One of the largest producers has been so swamped with orders that it is now accepting business only for future delivery. Lump and nut are the sizes most called for, but there also is a fair movement of steam sizes.

Spring and summer storage prices have been announced. On Walsenburg domestic lump the base price is $4.25; on nut, $4; on anthracite, $6.75. These prices will be advanced 25c. per ton each month until August, making the August prices $1 higher. Trinidad coking coal is quoted at $2.75 for April delivery, $2.85 for May, $2.95 for June, $3.05 for July and $3.15 for August.

Utah mines again are complaining of poor business. Sales of prepared sizes are so small that it is difficult to take care of the orders for slack, which is firm at $1.50. "No bills" of lump and stove are waiting for buyers. The only real activity reported in the industrial field is in the buying by the smelters and the metal mines.

Smokeless Prices Continue Downward

Prices at Cincinnati continue on a downward course. Smokeless lump and egg were offered last week at $2.50, though the spread ranged up to $3. Mine-run dipped to $1.75. Screenings, however, maintain a firm front at $1.50.



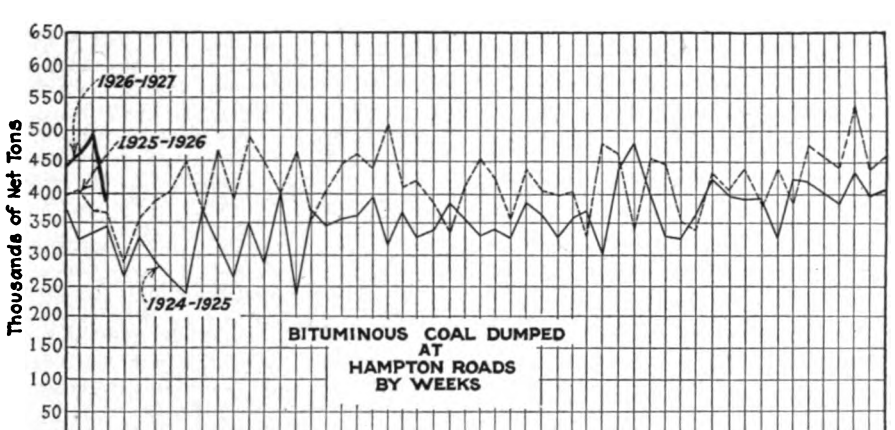
High-volatile mine-run is unsteady with a tendency to softness; 2-in. and egg are shaky, and screenings, which had been notably steady, are wobbling. Prepared lump sizes, on the other hand, are fairly firm, due to a decrease in the "make."

Overproduction is the principal cause of the difficulty, the latest report of coal movement through the Cincinnati gateway showing an increase of 1,545 carloads. Delay in the opening of lake navigation and embargoes at Toledo and Sandusky have intensified the dilemma.

Dealer demand is light, despite continued cold weather, buyers showing a disposition to "shop around," which is discouraging to sellers. Utilities and other large consumers are reluctant to close contracts, apparently being hopeful of a lower market. Retail trade has been unusually good for April on account of low temperatures.

The coal business in central and southern Ohio continues in a state of flux. There is little contracting by industrial consumers and the majority of the railroad contracts have not yet been placed. The slow start of the lake season also adds to the uncertainty and intensifies the pressure from the non-union fields. Lake business probably will be closed at $1.35@$1.50, mine-run. The bright spot in the lake situation is the possibility of a broader market for slack coal. Domestic trade is quiet.

At Cleveland an oversupply of bituminous coal from practically all fields that ship to this market coupled with an easing off in consumption of both steam and domestic grades has caused a pronounced depression. Slack and nut-and-slack are no longer scarce and prices have declined 5 to 15c. per ton in the last week.



Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1926				1925	1924
	Apr. 19	Apr. 12	Apr. 5	Mar. 29	Apr. 20	Apr. 21
Index	158	158	160	163	161	169
Weighted average price...	$1.92	$1.91	$1.93	$1.97	$1.95	$2.04

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke: 1913-1918," published by the Geological Survey and the War Industries Board.

Digitized by Google

Output in eastern Ohio during the week ended April 10 was 199,000 tons, or 28 per cent of capacity, compared with 191,000 tons in the preceding week, which was a 5-day week, and 211,000 tons in the corresponding week a year ago.

Price Slide Continues at Pittsburgh

Very little coal is moving on the open market in the Pittsburgh district. Prices are more or less nominal. There are 18 or 19 mines now running open-shop and their output probably represents half of the commercial production of the district. Output for the field as a whole is less than 25 per cent of capacity.

With 2,400 "no bills" in the field, central Pennsylvania is experiencing the dullest market so far encountered this year. Loadings for the first ten days of the month were approximately 34 per cent less than for the same period in March. Quotations have declined 5 to 40c. in a week. Pool 1 dropped to $2.40@$2.60; pool 71, $2.20 @$2.40; pool 9, $2@$2.15; pool 10, $1.75@$2 and pools 11 and 18, $1.65 @$1.75.

With the exception of some small-lot domestic business due to cold weather, the Buffalo market is as dead as ever. Nominal quotations on mine-run and lump are unchanged, but it is not unlikely that these figures could be shaded. Slack is 5@10c. stronger. All-rail demand for anthracite still is so heavy that lake loading may not begin for several weeks. In Buffalo local territory coke alone is proving an active competitor of hard coal.

New England Trade Inert

In New England there is practically no buying of steam coal in any quantity. Consumers feel it is much too early to take on supplies even for summer consumption, and present prices afford no inducement. Shippers report extremely light tonnages in every direction and the market seems certain to be more or less glutted for months to come.

Rehandling factors here have again modified prices for Pocahontas and New River for inland delivery; $5.50 is quoted as a top figure now per gross ton on cars, and at Providence spot coal can be covered at as low as $5.25. Even the smaller purchasers are counting upon lower prices later on.

On the other hand the Hampton Roads situation is under slightly better control than a week ago. Accumulations are not heavy; there appears more co-ordination on the part of producers, and in consequence there is less talk of distress prices. The agencies maintain $4.25 as a minimum f.o.b. vessel per gross ton for No. 1 Navy Standard, but naturally all the weak spots are not yet eliminated.

Coals from central Pennsylvania show no favorable signs whatever. Output is extremely light and prices are at production cost.

New York Situation Slightly Better

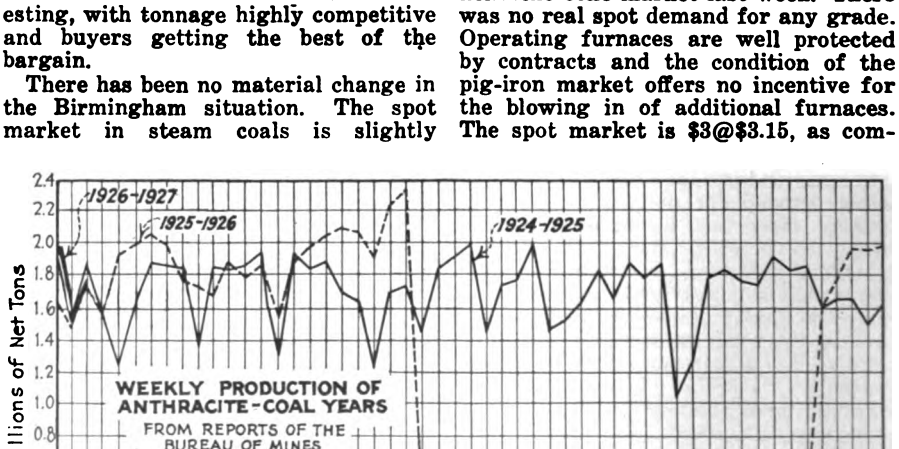
There was a slight improvement in the bituminous situation at New York last week, although the distress tonnage still is uncomfortably large. Some high-volatile coal was offered at $2.25 @$2.75 alongside. Buyers, for the most part, are deaf to pleas for contract renewals. Local exporters are watching the British situation closely.

The one show of seasonal activity in the Philadelphia market has been the solicitation of bids by various public institutions. Competition on this business has been so keen that some bargain-counter prices have been named. The railroads have not changed their policy of dictating prices and feign indifference as to the future. Prices are weak. Baltimore is another market where the situation is flat and uninteresting, with tonnage highly competitive and buyers getting the best of the bargain.

There has been no material change in the Birmingham situation. The spot market in steam coals is slightly stronger and there are no troublesome surpluses to depress prices. Industrial operations throughout the territory are on a good basis. A little spot tonnage of high-grade domestic coal is available, with demand negligible. Most of the output, however, is covered by contracts. Foundry coke is strong at $5.50@$6.50, spot or contract; egg and nut coke is weak at $4.50@$5, f.o.b. ovens.

Hard-Coal Buying Disappoints

April buying of anthracite at New York has been disappointing. Retailers find it hard to induce consumers to place orders for next winter's supply. Company domestic sizes are moving fairly well, but there is practically no market for premium coal, except pea, and quotations have been shaded. The maximum premium is 50c. and it is no secret that tonnage can be had at approximately company prices. Steam sizes are dragging and prices are weaker.



Were it not for the demand for coal for immediate consumption, the Philadelphia anthracite market would be weaker than it is. Some independents are experiencing difficulty in moving nut and some premium orders placed with middle houses have been canceled. In so far as movement at premium prices is concerned, pea coal is the strongest member of the hard-coal family.

The steam coal situation in unsatisfactory. Certain industrial consumers are holding out for lower prices on contracts. Independent No. 1 buckwheat has been offered for contract at $2.25. Buyers have no difficulty in picking up rice and barley at less than company circulars and the big producers are putting coal in storage.

Unlike the consumer at New York and Philadelphia, Baltimore householders are eager to place orders for their season's requirements. Some of the more forehanded are asking for April delivery, fearing an increase in prices later in the year.

Connellsville Coke Market Stagnant

Stagnation characterized the Connellsville coke market last week. There was no real spot demand for any grade. Operating furnaces are well protected by contracts and the condition of the pig-iron market offers no incentive for the blowing in of additional furnaces. The spot market is $3@$3.15, as com-

Freight-Car Loadings

	Cars Loaded—All Cars	Coal Cars
Week ended April 3, 1926	928,092	156,909
Preceding week	967,838	171,413
Week ended April 4, 1925	861,990	123,403

pared with $3@$3.25 a fortnight ago. Spot foundry coke is weak at $4.25@$4.75.

The decline in merchant-oven production which began with the end of the anthracite strike continues, but furnace-oven output during the week ended April 10 showed a sharp increase. The total output, according to the Connellsville *Courier*, was 179,730 tons, as compared with 180,850 tons in the preceding week and 148,490 tons a year ago. Furnace-oven output increased 4,300 tons over the preceding week and merchant-oven output declined 5,420 tons.

Coal Consumption by Utilities Continues to Decline

Public utility power plants in the United States consumed 3,357,808 net tons of coal in February, according to the U. S. Geological Survey. This compares with a consumption of 3,730,371 tons in the preceding month and 3,803,633 tons in December, 1925. Fuel-oil consumption by utilities in February totaled 703,947 barrels, as against 1,014,245 barrels in January and 810,980 barrels in December.

The daily production of electricity by public-utility power plants in February surpassed all previous records with an average rate for the month of 199,700,000 kw.-hr. The average daily production of electricity by the use of water power also exceeded all previous daily rates, with an average for the month of 67,600,000 kw.-hr.

The total output for January and February of this year was about 11 per cent larger than for the same months in 1925 and the output in 1925 was only 5½ per cent larger than the output for the same months in 1924.

Dutch Production Increases

Coal production in the province of Limburg, which produces practically all of the Netherlands coal output, was 6,848,000 metric tons in 1925, as compared with 5,882,000 in 1924, an increase of 16 per cent. In addition slack coal was produced to the amount of 269,000 tons in 1925, a decrease of 10 per cent from the production of 299,000 tons in the preceding year.

The greatest increase took place in the third quarter of 1925, when the output was 17 per cent more than in the previous quarter. The increase is attributed to several causes, chief among which are the gradual exploitation of one of the state-owned mines (Mannits), the extension of two other mines and the installation of improved mechanical devices underground.

On Jan. 1, 1926, 22,610 underground and 8,421 surface workers were employed in the Netherlands coal mines. The average number of workers during 1920, 1922, 1924 and 1925 was 24,944, 26,766, 29,957 and 30,390, respectively. The increase in the average number of workers is proportionately less than the increase in output.

Production of Briquets In 1925 Gained Impetus From Anthracite Strike

A marked increase occurred in the manufacture of fuel briquets during 1925, according to reports received by the U. S. Bureau of Mines. Production totaled 839,370 tons, an increase over 1924 of 258,900 tons, or 45 per cent. This is the highest production figure for the fuel briquet industry in this country, indicating not only substantial progress in the capacity of the operating plants but the possibilities in times of fuel shortage.

Fuel briquet manufacturing in 1925 received its great impetus from the suspension of the production of anthracite, which began Sept. 1 and continued through the end of the year. For the period January-August, 1925, the average production per month was 48,726 tons, as against 34,856 tons in the corresponding period in 1924. During September-December, 1925, however, when no domestic sizes of anthracite were being produced, briquet production per month averaged 112,780 tons. Some of this was due, obviously to the increased autumn and winter demand, but during the same four months in 1924 the average monthly production was only 77,905 tons.

The increased production for 1925 was general in the three grand subdivisions of the country. It was greatest in the Eastern States, where the tonnage was more than double that for 1924; increased 37 per cent in the Central States, and 8 per cent in the Pacific Coast States. The United States production and value of the fuel briquets for the years 1918-1925 is summarized in table I.

Table I—Fuel Briquets Produced in the United States, 1918-1925

Year	Net Tons	Value—Total	Value—Per Ton
1918	477,235	$3,212,793	$6.73
1919	295,734	2,301,054	7.78
1920	567,192	4,623,831	8.15
1921	398,949	3,632,301	9.10
1922	619,425	5,444,926	8.79
1923	696,810	5,898,698	8.47
1924	580,470	4,986,622	8.59
1925	839,370	7,128,404	8.49

The character of the raw material used as a fuel constituent by the 17 plants reporting production during 1925, is summarized in Table II.

Table II—Materials Used in Manufacture of Briquets in 1925

	Number of Plants
Anthracite culm	7
Semi-anthracite	1
Semi-anthracite and carbon	1
Mixture of anthracite fines and bituminous slack	2
Bituminous slack and sub-bituminous	1
Semi-bituminous slack	1
Semi-coke	1
Carbon residue from the manufacture of oil gas	3
	17

The total quantity of raw coal used was 844,590 net tons, an increase over 1924 of 261,225 net tons, or 45 per cent. Of the total used, 46 per cent was anthracite and semi-anthracite coal, 40 per cent semi-bituminous and bituminous slack, coke and semi-coke, and 14 per cent sub-bituminous coal and oil-gas residue.

During the year one plant in Pennsylvania, which had been idle during all of 1924, went out of business. There were added, however, during 1925 five others, located in California, Maryland, New Jersey, Pennsylvania and West Virginia.

Breaks Coal Loading Record At Curtis Bay Pier

In a space of 3 hours and 1 minute 11,353 tons of coal was put aboard the Str. "Lemuel Burrows" at the Curtis Bay coal pier of the Baltimore & Ohio R.R., at Baltimore, on April 13, according to the railroad company officials. This was an average of 62.7 tons a minute, or a little more than a ton a second.

This achievement by the pier broke the world's record for fast loading of coal into vessels, which it had held since 1920. The previous speed recorded was at the rate of 61.2 tons a minute, when the Str. "Malden" was loaded with 7,222 tons of coal in 1 hour and 58 minutes.

During the first hour and 58 minutes while the Str. "Lemuel Burrows" was being loaded, 73.5 tons a minute was the average speed at which the coal was handled on the pier, which was 12.3 tons a minute more than the "Malden" loading.

Strike Boosts C. & O. Profits

The cessation of operations in the anthracite mines during the latter half of 1925 enabled the Chesapeake & Ohio Ry. to report a gain of more than $8,000,000 in 1925 net income. After deductions of taxes and fixed charges net totaled $20,152,269, compared with $12,222,042 in 1924. This was equivalent to earnings of $21.32 a share on 906,912 shares of outstanding common stock, compared with $16.95 a share on 672,657 shares of common stock outstanding in 1924.

As the Chesapeake & Ohio serves some of the principal bituminous mines of West Virginia it came in for a good share of the bituminous coal traffic necessary to supply the Eastern markets during the anthracite strike. As a result the increase in net reported is the third largest of any railroad in the country, being exceeded only by the Pennsylvania and Norfolk & Western. Gross operating receipts were larger by $15,000,000 than in 1924.

Table III—Raw Fuels Used in Making Briquets in the United States, 1921-1925

In Net Tons

	1921	1922	1923	1924	1925
Anthracite culm and fine sizes and semi-anthracite	190,964	254,563	331,102	224,539	387,454
Semi-bituminous and bituminous slack, coke and semi-coke	a121,925	a235,542	a225,508	a297,814	a341,161
Sub-bituminous coal and oil-gas residue	85,352	123,339	125,880	b61,012	115,975
Total	398,241	613,444	682,490	583,365	844,590

a Includes no semi-coke in 1921 and 1922, no coke or semi-coke in 1923 and 1924, and no coke in 1925
b Includes no sub-bituminous coal.

Foreign Market And Export News

Sharp Pick-Up in Orders For Welsh Steam Coals; Spot Quotations Stiffen

London, England, April 6.—Conditions in the Welsh steam coal trade are stronger at the moment than at any time during the past two years. Inquiries from foreign buyers are very frequent and tonnage is arriving freely. More coal is being shipped now than at any time since the beginning of last year and the output is the highest for two years. Several pits which have been closed down since the end of 1924 are now reopening.

Buyers had been holding back to watch the action of the government over the Coal Commission report, but have now booked heavy quantities throughout April and into early May. Prices have stiffened a little and in some cases have advanced by a shilling or so.

According to the audit the actual loss per ton of coal for the quarter ended Dec. 31, 1925, was 3s. 3d., and operators are doing all they can to make selling prices cover as much of this loss as possible, though they cannot hope to retrieve all their losses on sales alone. At present most of the coal being delivered is on the low price rate and on contracts placed some weeks back, so there is little chance of any immediate cutting of losses.

The Newcastle market shows some improvement and European gas plants continue to favor British gas coals. Aside from these orders, which are mostly for comparatively small quantities, there is not very much doing.

Output by British collieries during the week ended April 3, according to a special cable to *Coal Age*, totaled 4,635,000 gross tons, compared with 5,415,000 tons the preceding week.

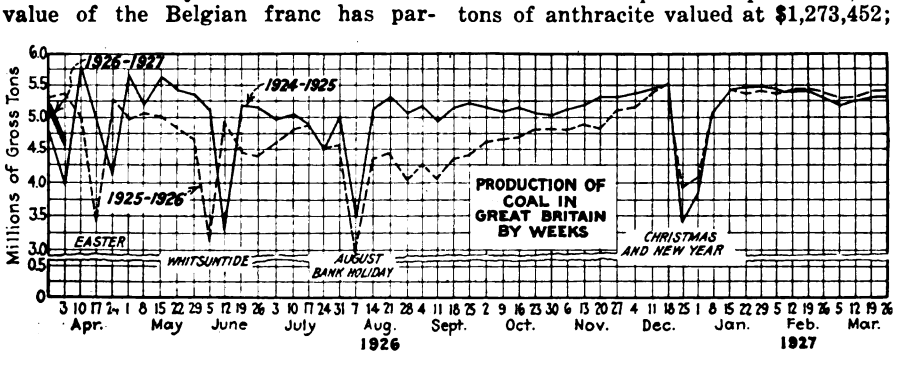
Belgian Market Quiet

Brussels, Belgium, March 31.—The Belgian coal market is devoid of a startling change. With the exception of greater firmness in quotations on fines for lime and brick-making, 70 fr., and coking smalls, 87 fr., prices are colorless. Industrial demand is far from satisfactory. The decline in the value of the Belgian franc has paralyzed foreign competition for local trade. Holland alone is meeting with success in the Belgian market.

During February Belgian mines produced 1,894,470 metric tons of coal, as compared with 1,976,320 tons in January and a monthly average of 1,928,000 tons in 1925. The pre-war monthly average was 1,902,460 tons. Coke output last month was 347,900 tons, as compared with 324,220 tons in January and monthly averages of 346,650 tons in 1925 and 293,480 tons in 1913. Briquet production, 203,370 tons, was approximately 36,000 tons greater than the 1925 average, but 14,000 tons less than the pre-war average.

Spring Reductions in Effect on French Coals

Paris, France, March 31.—The new schedule of prices effective April 1, published by the O. H. S., shows the following increases:



(1) For shipment by sea to French domestic and colonial ports, 5 fr.; (2) on trucks at the Franco-Belgian frontier, 15 and 10 fr. for anthracite, lean and semi-bituminous domestic coals; (3) on truck or canal barges in French ports of the Rhine, 5 fr. on industrial sizes, 10@15 fr. on sized coal and 20 fr. on lignite briquets.

A discount of 10 fr. will be given on April-May orders of coal, 6 fr. in June and July and 4 fr. in August. On lignite briquets a discount of 15 fr. will be made on April, May and June shipments and 10 fr. on July business.

The current market, particularly on industrial coals, is considered satisfactory. Stocks are low and the decline in the franc has helped the French producers by erecting a barrier against foreign competition.

As a result of the recent changes, April prices in the Paris district show reductions of 10@28 fr. when compared with March quotations on kitchen coals, 15@16 fr. on briquets and ovoids and 13@18 fr. on flaming coals. Belgian anthracite prices at retail are down 24 @30 fr.; British nuts and cobbles, 10@15 fr. and central heating coals, 22@28 fr.

During February the Custom House at New York reported imports 115,814 tons of anthracite valued at $1,273,452; 5 tons of bituminous coal and slack valued at $100 and 1,900 tons of coke valued at $9,404.

Coming Meetings

Chamber of Commerce of the United States. Fourteenth annual meeting, United States Chamber of Commerce Bldg., Washington, D. C., May 10-13.

Mine Inspectors' Institute of America. Annual meeting, Seventh Avenue Hotel, Pittsburgh, Pa., May 11-13. Secretary, G. B. Butterfield, Hartford, Conn.

International Railway Fuel Association. Eighteenth annual convention, Hotel Sherman, Chicago, Ill., May 11-14. Secretary, J. B. Hutchinson, Omaha, Neb.

National Retail Coal Merchants' Association. Ninth annual convention, New Willard Hotel, Washington, D. C., May 17-19. Resident vice-president, Joseph E. O'Toole, Transportation Bldg., Washington, D. C.

The American Mining Congress. Annual Exposition of Coal Mining Equipment, May 24-28, at Cincinnati, Ohio, in conjunction with the annual meeting of practical operating officials. Assistant secretary, E. R. Coombes, Washington, D. C.

International Geological Congress. The fourteenth congress will be held in Madrid, Spain, commencing May 24, 1926. Secretary of the organizing committee, Enrique Dupuy de Lome, Plaza de los Mostenses, 2, Madrid, Spain.

Midwest Retail Coal Merchants Association. Annual meeting, May 25 and 26, at Kansas City, Mo. Secretary, James P. Andriano, St. Joseph, Mo.

Pennsylvania Retail Coal Merchants' Association. Annual meeting, York, Pa., May 27 and 28. Secretary, W. M. Bertolet, Reading, Pa.

Western Canada Fuel Association. Annual meeting at Winnipeg, Manitoba, Can., May 27 and 28. Secretary, W. H. Morrison, Winnipeg.

West Virginia Coal Mining Institute. Annual meeting, June 1-2, Bluefield, W. Va. (tentative). Secretary, R. E. Sherwood, Charleston, W. Va.

American Wholesale Coal Association. Annual meeting at Toledo, Ohio, June 7-9. Treasurer, R. B. Starek, Union Fuel Bldg., Chicago, Ill.

Association of Iron & Steel Electrical Engineers. Exposition and convention at Hotel Sherman, Chicago, Ill., June 7-10. Secretary, J. F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

National Coal Association. Ninth annual meeting, June 9-11, at Drake Hotel, Chicago, Ill. Executive secretary, Harry L. Gandy, Southern Bldg., Washington, D. C.

American Institute of Electrical Engineers. Annual convention, White Sulphur Springs, W. Va., June 21-25. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Illinois Mining Institute. Annual summer meeting on board steamer "Cape Girardeau" to some point in Illinois on the upper Mississippi River, leaving St. Louis, Mo., June 24 and returning to St. Louis about noon, June 26. Secretary, Frank F. Tirre, Central National Bank Bldg., St. Louis, Mo.

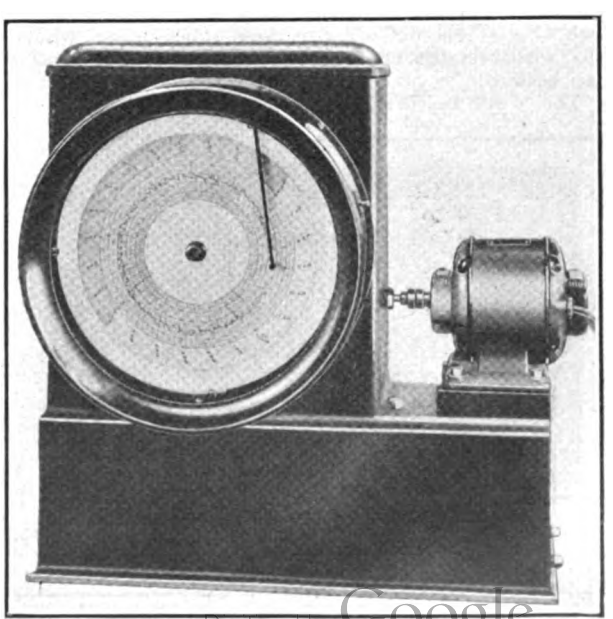
New Equipment

Carbon-Dioxide Recorder Is Motor-Driven

After many experiments, a new motor-driven carbon-dioxide recorder has been perfected and introduced on the market by the Republic Flow Meters Co., 2240 Diversey Parkway, Chicago, Ill. This recorder is shown in the illustration.

As it does not operate by water power, water conditions at the place of installation need no consideration whatever, the manufacturer claims. The mechanism of the instrument is completely submerged in oil, thus reducing wear to a minimum and eliminating corrosion, said to be the chief difficulty found in water-driven carbon-dioxide recorders.

The case of the instrument is dirtproof. It has been designed for appearance and easy vision as well as for accuracy and ruggedness. It is arranged so that it is easy to change both the oil and potash. All parts are interchangeable. A small motor is used to operate the instrument, and, though small, it is capable of handling a load two or three times that required.



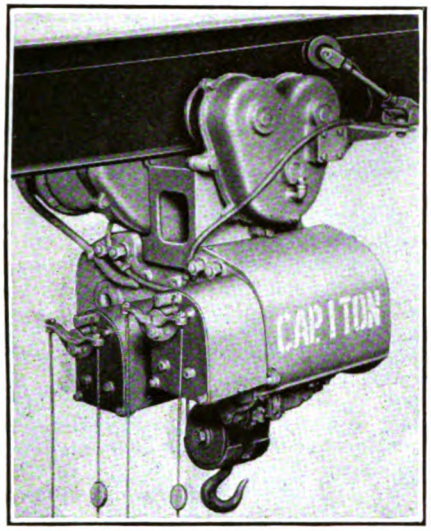
The operation of the recorder is as follows: When the gases are drawn through the furnace into the instrument they pass through a brass tubing immersed in oil. They then go through the pump and more brass tubing before passing to the measuring chamber. The gas in passing through the pump is divided into very fine particles and comes into close contact with the metal. This gives it the temperature of the pump and the surrounding oil. It then passes into the measuring chamber, which is immersed in the same oil and measured at a specific temperature. Next the gas passes through the potash chamber and then into the final measuring chamber, this last also being immersed in the same oil as in the first measuring chamber.

The oil chamber is directly above and in contact with the potash chamber, so that the oil and potash are at the same temperature or nearly so. If there is a difference in the temperatures of the oil and the potash, corrections will be made in the final measuring chamber, which also is surrounded by the oil. Therefore, no error can be caused by temperature irregularities.

The instrument requires about two gallons of ordinary machine lubricating oil, which should be changed every six months or every year. The potash chamber holds about three gallons and requires 12 lb. of dry potash. This will last from four to six months.

Mechanism Submerged in Oil

As no water is used corrosion is avoided. Ordinary machine lubricating oil is used which needs changing only once in six months or a year. Oil keeps potash at same temperature as measuring chambers so no error can be caused by irregularities of temperature. Other recorders are driven by water power and, hence, have trouble from rust.



Motor Trolley for Spotting Work Over Machine Tools

A new motor-driven trolley has been developed by the American Engineering Co., Philadelphia, Pa., for use with its ½-ton and 1-ton Class A, "Lo-Hed" electric hoists, which have been built, heretofore in bolt-suspension and plain trolley types only.

This trolley can be supplied with a travel speed of either 80 or 120 ft. per minute, so that the unit provides an inexpensive overhead system for handling loads of one ton or less at high speed, both in lifting and moving. Its accurate control makes it highly efficient in spotting work for machine-tool operations. It can be arranged for remote control, if desired. Any hoist of the type named now in service can be easily converted into a motor-trolley hoist by adding the new trolley.

Only 22-in. headroom is required for both hoist and trolley, which is small for a motor trolley hoist. The trolley is ruggedly built, and maximum traction is obtained by driving all four

Digitized by Google

Speedy Trolley Hoist

Around many plants, particularly machine and electric shops a unit of this kind is extremely handy. It may be built in either ½- or 1-ton capacity and the traversing speed may be made as much as 120 ft. per minute.

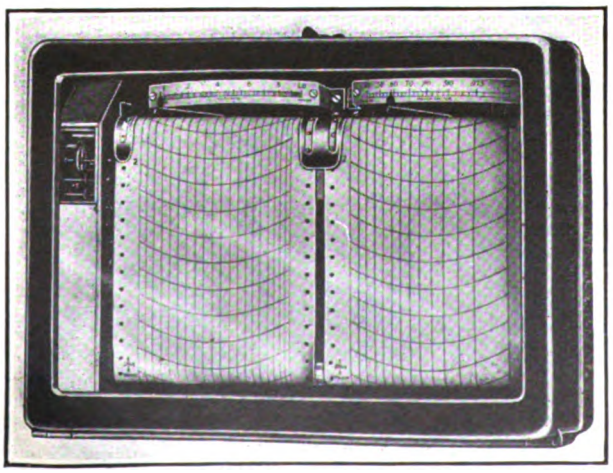
wheels. The three main castings, from which the hoist and the load are suspended, are made of steel. The spur-gear drive is totally inclosed and runs in an oil bath. Roller bearings are used on all shafts. The motor also is totally enclosed and has high-grade ball bearings. All parts are completely accessible and the motor can be removed readily when necessary. It can be furnished for either direct or alternating current, the latter either 2- or 3-phase.

Two Graphic Records Drawn Side by Side

The new "Twin-Type" graphic meter of the Esterline-Angus Co., Indianapolis, Ind., represents a logical development in meter construction. This model contains two metering elements which are mounted side by side and are driven by a common mechanism. The distinct advantages of the new meter are, (1) two quantities can be recorded simultaneously and on charts that are perfectly synchronized, (2) much less switchboard space is needed than when two single instruments are used, and (3) either daily or long-strip charts can be used.

The first feature will be specially useful in recording simultaneously the load in kilowatts and the voltage, the load and power factor, the line amperage and power factor, or other similarly related quantities, in a power plant, substation, or at any convenient metering point of a distribution system. The meter can be equipped with almost any combination of two of the various electrical measuring elements or with other units such as pressure and vacuum recorders.

The 12- or 24-hr. duplex charts are 11¼x26¼ in. overall. They are punched at one end so they can be placed in a standard loose-leaf file, and are of such dimensions that when folded, they will fit a standard letter-size drawer file.



In addition to the two standard types of clock drive, the instrument can be furnished with either an impulse-system electric drive or with a motor. The latter is recommended only when high chart speeds are desirable. While regularly made in the switchboard and wall types, instruments of this kind can be built in portable models for special requirements.

Affords Better Illumination

Recently the U. S. Bureau of Mines granted to the Koehler Mfg. Co. of Marlboro, Mass., an extension to Approval No. 17 covering improvements in the Wheat electric safety mine lamp. The principal feature of the improved lamp is a new higher candle-power bulb. This operates at 4 volts, has successfully passed the 300-hr. life test of the Bureau and when used in the improved mine lamp gives the greatest amount of light of any bulb having passed this test.

To produce this increased candle power a new design of battery plate has been used. This new plate is so constructed as to give not only increased power but longer life as well.

A new design of non-spilling device is also used. This employs tubes that carry the fumes produced by charging to the outside of the battery case free and clear of all working parts. The improved battery may be charged in the regular Wheat electric mine lamp charging equipment. In outward appearance the new lamp outfit is practically identical with the older equipment which has become familiar to most mining men during the past few years. It is not illustrated for this reason.

Meter Fitted with Strip Charts

The two scales can be printed on a single wide sheet and two graphs drawn simultaneously. The meter shown is fitted to record kilowatts and power factor side by side.

gathering pumps
small fans
blowers
room hoists
air compressors

Built to Start a New Chapter in Coal Mining History

This latest General Electric contribution to mine electrification is intended to reduce the danger arising from internal explosions. It is the first complete, self-contained motor and control unit approved for use in gaseous mines.

Both motor and controller are totally inclosed. The controller throws the motor across the line and protection to the motor is provided by a thermal overload relay which can be reset without dismantling the controller.

See this equipment at the G-E Exhibit. American Mining Congress Exposition, Cincinnati, May 24-29.

G-E Motorized Power is more than a motor or its control—it is a practical and economical application of electric power. "Built in" or connected to all types of industrial machines, G-E Motorized Power provides lasting assurance that you have purchased the best.

Speeding the empties in and the loads out

Miners seldom wait for empties when Exide-Ironclad Batteries are in the haulage motors. An Exide-Ironclad is not only full of pep and speed, but its speed holds up well all day long. It hustles the empties in and the loads out.

This motor is pulling a heavily loaded trip up a steep hill. Yet it moves right along without pause, for in the battery box is an Exide-Ironclad. This battery always carries power in reserve; and when extra power is needed, it delivers current much faster than the normal rate.

Noon hour, and while the motorman eats his lunch he is giving his battery a "boosting" charge. You can do this to an Exide-Ironclad Battery when rush of work makes you push the haulage motors extra-hard, for an Exide-Ironclad is so efficient on charge that it takes current in quickly, easily, and with little waste.

This motor has completed a week's work and is at the charging barn. The motorman is testing the specific gravity of his battery cells with a hydrometer. That, and an occasional flushing of the cells with pure water, is about all the attention an Exide-Ironclad Battery ever needs. It is built so rugged that it stays on the job month after month without needing repairs.

If you want your mine to ship as many cars a day as it is capable of producing, you've got to have a smooth-running haulage system. And one of the biggest helps in maintaining a speedy, efficient, trouble-free haulage system is to have your motors driven by Exide-Ironclad Batteries.

They Didn't Read

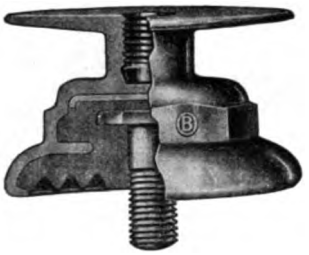
No one can but be impressed with the rapidity of modern progress as compared with that in earlier years when men didn't read and didn't travel. Once in a while populations got on the move, and by meeting other peoples learned new ideas. Then the world went a step forward, only to stop again. Then came printing. It developed mankind in mental and moral ways, but it really did not effect any active change in the arts and sciences till the technical journal came on the scene. Then the results were marvelous. Every month showed progress. There was no standing still so long as the technical magazine was devoured week by week.

Too Far Behind

Backward mines have not become obsolete in a day, but month by month they have gotten behind in condition and in practice. What was left one week or one month remains to be done the next. Soon there are several weeks' or several months' work to be done in one week or month, and the job is too big to be done and is not performed at all unless there is a new management and more money put in the plant.

The cure for this growing backwardness is to keep the mine always up to the minute, to read and to plan so that the burden of getting on an up-to-date basis will not be too big for accomplishment. Many an old mine, like many an old business, settles back like an old hulk on a sandy shore till it cannot be moved.

Our Mines and Our Minds



Coal Age has men gathering up-to-date ideas of operation around the country. Though its readers in some cases live where they have little chance to keep in touch with the current of affairs, they have an opportunity to travel with its pages over the length and breadth of the whole field of mining, geographically and technically speaking. But if we fail to read we come soon to a day when our mines and our minds need more replenishment than they can acquire in the time we have to bestow on them.

Standard—for roof
(renewable insulation)

Universal—for roof
or timber

K Type—for roof

Made of Dirigo Insulation and FLECTO IRON

ABOVE are popular types of hangers, all widely used.

The Standard is for roof. It has a removable insulator made of Dirigo. Made also in Universal and timber types.

The Universal is probably the most popular of O-B Hangers. It may be used for roof or timber support. Made in five styles.

The K type is for roof only. It is made in 5 styles.

WHEN it is said that O-B Insulated Hangers are made of Dirigo Insulation and Flecto Iron—you have the story of those qualities that save you money, not necessarily in first cost but in the extra service you realize.

FLECTO IRON—The O-B malleable iron that does not become brittle when hot-dip galvanized. It is never brittle—a tough metal with heavy galvanized coating that will give years of extra life.

DIRIGO INSULATION—The O-B molded insulation that withstands heat, cold, moisture, acid, time, mechanical stresses, electrical stresses—the balanced composition.

All O-B Insulated Hangers are made with these two materials and there is variety in design so you can make the correct application for your trolley.

Ohio Brass Company, Mansfield, Ohio
Dominion Insulator & Mfg Co., Limited
Niagara Falls, Canada

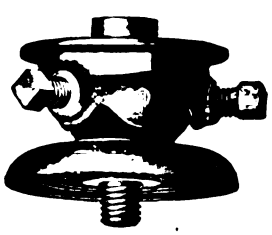
27M

Ohio Brass Co.

PORCELAIN INSULATORS, LINE MATERIALS, RAIL BONDS, CAR EQUIPMENT, MINING MATERIALS, VALVES

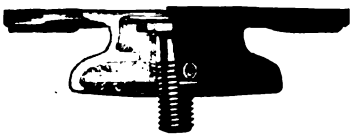
O-B Expansion Bolts are all made of O-B Flecto Iron.

BELOW are several special types of O-B Hangers — also made of Flecto Iron and Dirigo Insulation.



The SK—a swivel type for use on sloping roof.

The H—for timber or with special clamps it may be attached to I-beams. Has a long leakage path.



Pipe Hanger—one of several types designed for suspension from pole brackets or pipe frame.

O-B Expansion Bolt suitable for Standard, K, SK and Universal Hangers.

SK-Swivel for sloping roof

Problems of the Coal-Mining Industry

R. DAWSON HALL
Engineering Editor

Volume 29 NEW YORK, APRIL 29, 1926 Number 17

Preventing Substitution in Marketing Coal

COMMENT WAS MADE in a recent editorial on the evils of substitution in marketing coal and its unfortunate repercussions on the producer, wholesaler and retailer. No one in the industry can regard such practices with indifference even though his own practice is in every way honorable. A communication was received from George R. Pratt of *Coal Truth* in which he describes the means by which the Government of the Province of Alberta endeavors to establish fair-trade conditions in coal marketing. The foundation of these methods is fair price, high coal quality, consumer satisfaction and good will.

A special act called the Coal Sales Act of 1925 provides for registering the trade names of the coals which the several mines produce. No coal can be advertised or sold except under its registered trade name, and the invoices and shipping bills must give the name of the mine, the coal field in which it is located, the size of coal shipped and the registered trade name of the coal.

Every dealer is required to keep a record of his coal purchases whether from Alberta or outside sources. This record is open to inspectors who have the power to inspect invoices and shipping documents, and, where these do not conform to the coal in question, they may stamp upon the document a statement to that effect. A penalty is provided for failure to comply with the law or for false statements in the invoice documents.

In advices to the retail coal dealer the following excellent rules are offered for his adoption: That the value of the coal shall be equal to the advertised value; that in the event of dispute of value no rebate in money (unless a contract to the contrary has been made) shall be given but the offer shall be made to remove the coal within 24 hours and to refund the purchase money; that the Golden Rule shall govern in all dealings between dealer and consumer.

It is recognized that where the "quality first" dealer pays the price for quality coal and sells in competition with second-quality coal sold at the quality price, the result is a buying public dissatisfied with the price, dissatisfied with the quality and of critical mind toward all engaged in the industry. Advertising and selling efforts enhance coal values, but by supplying coal below the established quality standard, or of different sizes, or by substituting coals of different class, inferior to the promised standard and rebating to one customer out of ten who complains forcefully enough, good will and confidence are undermined.

To overcome the difficulty of the few dealers who do not wish to deal on the square, the government office offers to all dealers who agree to observe the foregoing rules the privilege of attaching a seal to each customer's delivery slip and supplies the seals to the dealers. The seals are about the size of a postage stamp and contain the words—"Coal on the Square."

Evidently the Alberta coal industry has worked out a practical method to insure satisfactory trade practice in distributing their product. No doubt other methods would serve the same ends but similar problems arise in many coal-distributing centers and need the attention of producers, wholesalers and retailers in establishing "coal on the square" practices.

Water on Cutter Bits

RAPID PROGRESS is being made in the application of jets of water to the bits of cutting machines, the purpose being to keep down coal dust which would otherwise be suspended in the air and carried considerable distances outby the face. Where places are wetted down by a hose and a waterline is therefore convenient the spray pipe of the cutting machine should, of course, be connected to the line. Absence of this last provision in the majority of mines should not retard the spread of bit sprinkling, for it is entirely practicable to carry a tank of water on a trailer truck, to which pressure may be applied by a small air compressor. In other cases a pump may be used.

At the last meeting of the Coal Mining Institute of America, Inspector E. Girod of the Twenty-third Bituminous District, part of the coke region of Pennsylvania, stated that five mines in his territory during the last ten months of 1925 adopted this measure. He added that he expected a rapid growth in the practice. Solely as a safeguard against the danger from coal dust, it ought to be regarded as being worth while but those not so strongly influenced by this safety feature should be won over by the pecuniary gain which might possibly accompany it.

A jet of water playing on the bits not only lays the dust but dissipates the heat generated during cutting. When the material cut is hard the temper within the pointed section of the bit is likely to be lost at least to skin depth by extreme rises of temperature, and the effectiveness of the tool may soon become lessened by the greater rate of wear of the cutting edge. Mining men generally, including several manufacturers of cutting machines and cutter-bit steel, say that this action does not take place. Their contention as applied to the absence of such action in bits made of alloy steel is no doubt true. However, are they even reasonably sure that their contention rests on solid ground as regards carbon steel, of which practically all the bits now in use are manufactured?

No scientific studies of the problem have yet been made, for which reason a positive opinion should be withheld. Already several manufacturers' engineers have withdrawn their adverse criticism to the suggestion and, after hearing the other side of the argument,

Digitized by Google

have taken a neutral stand. The very fact that alloy steel is admitted to be far superior to carbon steel in the use to which cutter bits are put casts a shadow of suspicion on the ability of the latter substance to retain its temper in cutting the harder coals. The few metallurgists who have been interested in the discussion are one in the opinion that hard cutting could draw the temper in a bit of carbon steel. The stand which they take, in view of their knowledge, should be considered with some deliberation, and the argument should be definitely decided one way or the other.

It may be found that bits of carbon steel are not likely to be fatigued and fractured by shock when a uniform low temperature is maintained. The sprinkling attachment may after all be the means by which the time lost in the frequent changing of bits may be retrieved; also it might enable the bits to cut coal at greater speed.

Limiting the Peak

PEAK LOADS are always to be avoided regardless of whether power for mine operation is purchased or generated. If current is purchased the peak load "sets the pace," that is, determines the demand charge paid for power for the month during which the peak occurred as well as in many instances for the eleven succeeding months as well. If power is generated the peak throws a heavy and usually an unnecessary load on the power-generating equipment.

In order to avoid high momentary peaks, especially where power is purchased various expedients have been employed. At one large mine in southern Illinois the present production of which is well below its demonstrated capacity and where consequently it is not necessary to hoist steadily throughout the entire shift in order to raise the day's output, a plainly visible indicating meter is placed near the hoist engineer's platform. This is marked with a predetermined peak load which is not to be exceeded. The hoistman watches this meter closely and when this maximum demand is approached hoisting is suspended until the demand subsides when it is again resumed.

Certain other mines are employing circuit breakers so arranged that when the total load reaches a predetermined value the breakers controlling one or more of the feeder circuits will kick out. These breakers will automatically reclose when the total demand has decreased to a predetermined level. This arrangement is extremely handy and effective possessing the marked advantage that it is automatic in operation, thus requiring no attendance.

Conservation in mine costs is a dominant trend in the coal industry today. Of course what all mine operators most desire is a means for materially lowering the major expense involved in coal production, namely the cost of loading, but advantage should be taken, nevertheless, of all other possibilities by which the cost of mining may be reduced, even though the reduction be small. Not allowing the power demand to exceed a predetermined amount is one means of accomplishing the desired result.

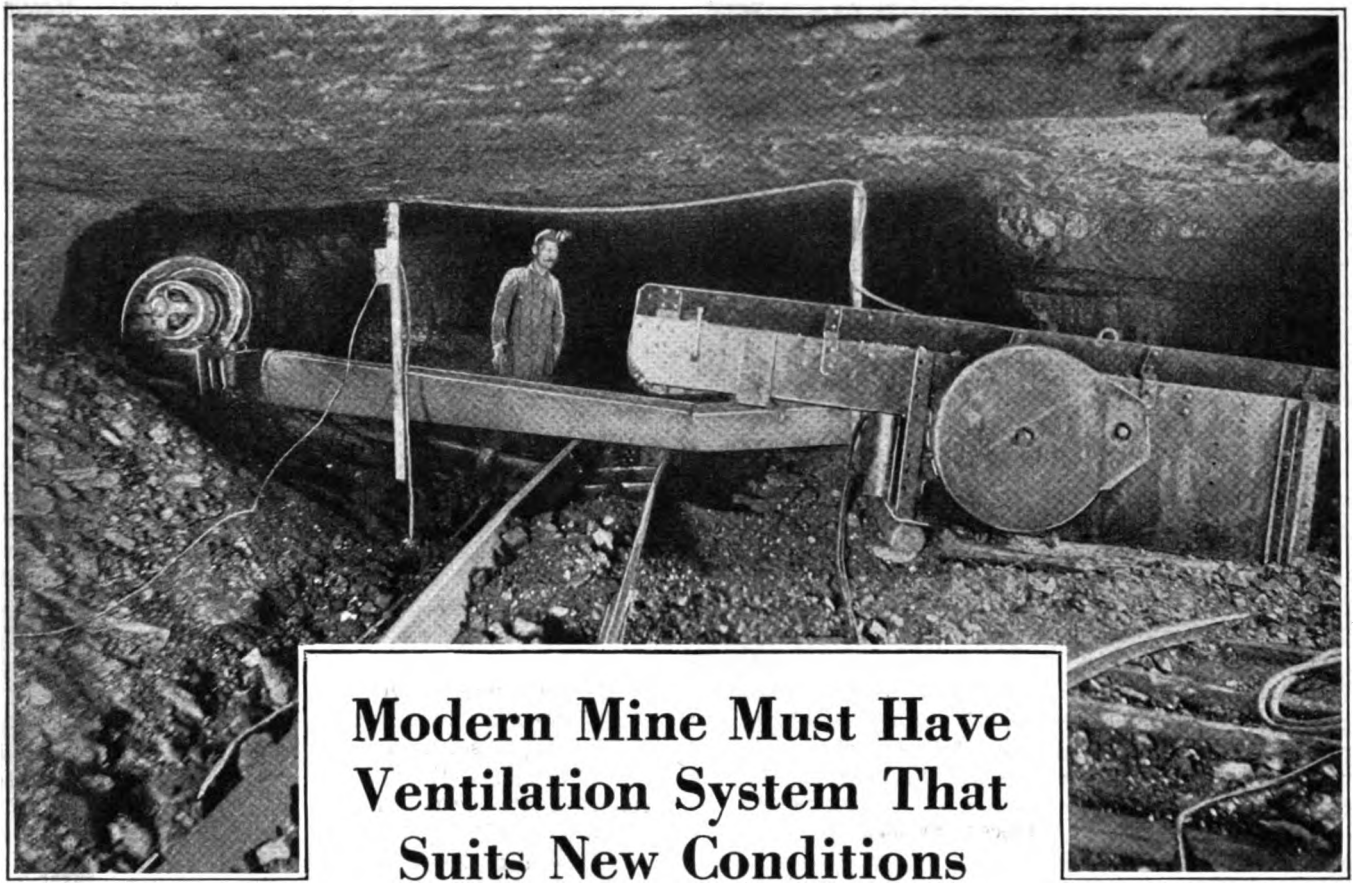
The time has passed in which the superintendent called for power, more power, regardless of the way in which it was used. He now tries to make his uses fit a certain definite hourly supply. He trims his power bills just as he has long limited his supply requisitions.

Substance and Shadows

HOW FUTILE the hope that Congress can guarantee the public an uninterrupted flow of coal is unblushingly revealed in the frank statements of international officers of the United Mine Workers before the House committee on interstate and foreign commerce. Organized labor in the coal industry is firmly opposed to compulsory arbitration. In that opposition the mine workers have the tacit or open support of the majority of the country. Raise the cry, as union leaders have done, that compulsory arbitration means enforced labor, and only a small minority will have either the courage or the desire to embrace that uncertain strike preventive.

The United Mines Workers, however, goes still further in fighting the suggestion that the federal government should have the power to intervene in times of emergency. The union objects to anything and everything that smells of arbitration. Mediation and conciliation it is ready to accept—possibly because they already are written into the Department of Labor law. Any proposal that the President be authorized to create a fact-finding agency with power to inquire into wage disputes and make public the results of its investigations is wholly unacceptable to the men who direct the destinies of the mine workers' organization.

Academic discussion of compulsory arbitration is beside the point. It is obvious that such compulsion is repugnant to the nation when the surface of industrial relations is reasonably calm. Congress does not intend to consider that question. The United Mine Workers, apparently, has no intention of viewing favorably any of the various half-steps proposed in the many "emergency control" bills which have been referred to the House committee. That Congress, of its own volition, will risk battle against a minority as effectively and vociferously organized as union labor upon an issue in which there is little present public interest is unlikely. Thus the chief excuse for federal regulation of the coal industry falls of its own weight.



Fire Will Build, Not Burn, Our Homes

PRINCIPAL AMONG the changes of the twentieth century is the tendency to build fireproof structures, and, strange to say, fire has a part in the manufacture of nearly all fireproof material—lime, cement, brick, tile, terracotta and steel—and in the formation in geologic time of granite and therefore of its reconstructed materials, sandstone and slate.

The coal industry will necessarily benefit in this movement and should foster it. There is no reason why the present heavy yearly loss from fire should be sustained. From the progress in the use of steel for schoolhouses, factories and dwellings, the coal industry may draw much help in the future. Unfortunately dwellings not entirely standard make it difficult to construct the great variety of shapes needed for residence construction. But the oxy-acetylene field welding apparatus will probably enable the architect to turn rigid standard forms into the shapes required by the eccentricities of home construction and to do it with as much ease as a woman can remodel a bonnet with a few deft touches.

The fireproof era will be one in which fire and therefore coal will have increased use. Fire will be more active in the building and less active in the burning of our homes.

Modern Mine Must Have Ventilation System That Suits New Conditions

Dead Ends Best Ventilated by Blowers and Canvas Tubing —Air Is Static in Wide Places—Sometimes a Fan Can Deliver More Air Than Mine Will Pass at Water Gage Provided

By Carl H. Trik
Mine Ventilation Engineer, Jeffrey Manufacturing Co., Columbus, Ohio

Carl H. Trik

IN ALL the studies of the mining of coal by mechanical cutters, loading devices, conveyors and other means, commonly designated as "concentrated mining," little has been written as to the effect of these new methods of "harvesting coal" by machinery on the ventilation problems at the working face. Is it not high time to consider the effect of these changes on the ventilation of the mine? What effect will they have on the quality and quantity of the air delivered to the face? How will it modify the mine resistance? What effect will it have on the fan and on the cost of operation? Let us consider each of these matters in turn. Theoretical discussion is of little value to the practical man, and empirical data are so far difficult to find. However, enough information is now available to allow anyone to arrive at certain definite conclusions.

Ventilation has, for instance, definitely divided itself into two parts, a primary and a secondary system to be compared aptly with the ventilation of a metal mine which has its gangways and tunnels ventilated by a primary system and its "dead ends" such as blank stopes and raises requiring secondary systems supplied with air drawn from the main, or primary, air current. In those states that permit the driving of a single entry for any number of feet without a crosscut, the problem of secondary ventilation is simply, if not always cheaply, solved. These "minor faces" must have air while they are being driven to open up a panel or block. As they receive conveyors, it will be well to name them "conveyor headings," or "conveyorways," though "development headings" would be an equally satisfactory term.

Judging by the number of companies using the small auxiliary blower and flexible canvas tubing, as compared with those using brattice cloth to conduct air to the face of these conveyor headings, the former method must be the best means of ventilating these minor faces. In fact, operators who have installed fans and tubing declare that this method of providing air is less costly by far than the erection of brattice cloth. Many operators would gladly adopt these fans in preference

Headpiece shows a fan delivering air to a "minor face." This face is being served by a sectional conveyor which brings the coal to another conveyor on the entryway of the panel. The blower is set on the opposite side of the main conveyorway from the narrow place or room, so that the air returning from the place will not enter the fan and be redelivered to the working face.

Digitized by Google

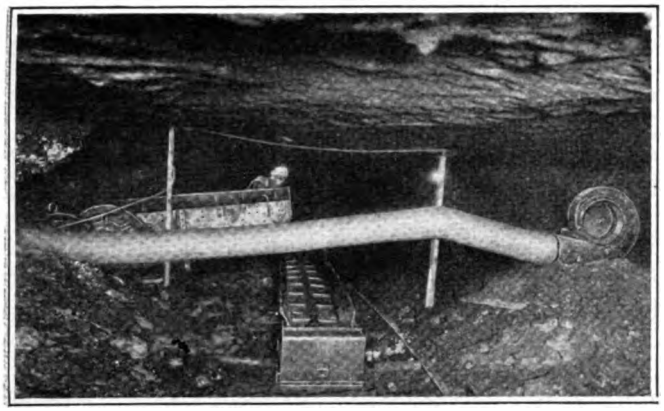

Fig. 1—Opposite View of Conveyor, Fan and Canvas Tubing Shown in Headpiece

Twelve-inch diameter tube delivering air to a minor face. The conveyor, being empty, its construction can readily be discerned. An electric lamp strung from the supports of the canvas tube lights up the conveyor and adds to the safety of the operation.

to older devices if the laws of the states in which they are operating would permit. They believe that these laws should be revised so as to be in harmony with changing conditions. Of course, there are those who object to the small blower, and they present many reasons for their opposition. But there are also many who take exception to the use of the brattice line, and they have just as many and as cogent reasons for the stand they take. Be that as it may, the conveyor headings must be ventilated. That is true regardless of the system of secondary ventilation that is adopted. Certainly this ventilation will not be as expensive as in those fields where the state laws and state inspectors insist on having a crosscut driven every 60 to 100 ft. Even when such rulings are obeyed the operator is left without anything that could be dignified with the term "secondary system."

When the decrees of such legislatures and inspectors are followed the resistance of the airways varies greatly according to the degree of their development, and the main current has to be regulated to suit the frictional losses of the most resistant entries. The ventilation is consequently uneconomical and not appreciably safer than when the small blower is used.

AUXILIARIES OR HIGH WATER GAGE

The headpiece of this article shows the method of setting the blower that one operator adopted when driving a single entry to connect up with another entry parallel to the one down which we are looking in the picture. The fan is set across the entry so that it will not recirculate the air as it returns from the conveyor heading. Here it is entirely out of the way.

A few inspectors have severely criticized the small blower as a source of danger declaring that with it the air might be recirculated. I have even heard one man state that he knew of a small fan handling nothing but gas between the fan inlet and the face. This may be true, it could easily happen, but I fail to see the logic in condemning the small blower. Rather should the operator be taken to task who was so utterly lax as to install a fan in such a position as to permit this to occur. Every tubing company makes right-angle bends of tubing to obviate this very condition. If these were used even the probability of recirculation would be eliminated so long as the main fan continued in operation.

After the narrow conveyor headings or the double entries, if these are driven, are completed and connected with each other so as to form a continuous working this section becomes "a major face" and a part of the primary ventilation system in that a true circuit or current is established which can be considered as a separate split of the main current passing to the return or being carried back to the intake air current, diluted and used again, all depending on local conditions. Many operators mining a large acreage on a continuous face (really consisting of a series of small faces *en échelon*) find themselves forced to consider one of the blocks as a separate split, the law of the state under which the operator is working limiting the number of men allowed on each split.

We are now ready to consider the ventilation of those working places which, for obvious reasons, we have termed "major faces." In a block consisting of a single face or a series of staggered faces, the conveying and haulage problems may be more or less intricate but the ventilation will be plain sailing from this point on, so that the old cry, "No air at the working face" will become a thing of the past.

We have all heard of operators who have been all too eager to get out coal and who in their mad dash for production have dug themselves in until their airways, especially on the return, are mere dog holes and the air current is so feeble that it cannot travel against the high resistance of the mine. But with concentrated mining systems we shall probably hear of them no longer.

Fig. 2—Looking Along Conveyorway Toward Fan

The canvas tubing naturally straightens itself and gives a fair passage for the air current. Resting on the floor of the roadway it requires no support. Note how large a capacity the conveyor provides.

Under the new system the ventilation should be much superior to that of the average mine under the old plan, and that is proved by the experience of many companies throughout the land. There is an "if," however, in this, as in every flat statement and that is "*if* the main airways, both intakes and returns, are

FIG. 3

Work in Good Air

Each man has about 25 ft. of face. Despite the absorption of light by the coal, six men can be seen at work on about 125 ft. of face. The photograph was taken with a flashlight, a testimony to the excellence of the ventilation due to the generous current that can be made to sweep a straight face.

kept free and clean and the sectional area is ample for the volume required."

When cutting begins on a major face, the current of air flows past the men working along it in a clean uncontaminated stream. Fig. 3 shows how pure the air is at one of these faces. This flashlight photograph reveals about 125 ft. of face. Six loaders can be distinctly seen through the clean air. Fig. 4 shows another face immediately after shooting. The air has rapidly swept away all fumes and smoke.

In fact, at some mines, as cutting proceeds and more and more coal is removed, the space between the working face and the gob increases to such an extent that the air is likely to become sluggish due to the greater increase in area. Plenty of air may be passing, but the area over which it travels is so wide that the speed will decline unless some means be taken to guide the air to the place in which its scouring effect is needed.

Putting Brattice Cloth Behind the Men

The best method is to line brattice cloth between the men and the gob at such a distance as will cause the air to travel along the face at the requisite speed. This, in no case, should exceed 500 ft. per minute nor be less than 50 ft. In fact 75 ft. per minute would be the preferable figure.

However, it will be found that in most mines the roof will have fallen shut practically up to the props or cribbing, and the air will now slow down so much as to make the use of brattice cloth necessary. Although the roof is down and loose rock is piled up to the rear line of props, the gob is not tight and the air will work its way through and around the caved area, which is as it should be. When the coal is mined out to the barrier pillar and the last cut has been taken, the entire area may be sealed off and forgotten so far as entering into the scheme of ventilation is concerned.

New Methods Lower Mine Resistance

From the foregoing it is apparent what a remarkable effect this will have in reducing the water gage, or mine resistance. This is what every conscientious manager is seeking, and this new method of operation will commend itself to him from this reason alone.

We have now seen the effect of the new methods of mining on the quality of the air and the resistance to its passage. It next behooves us to consider its effect on the fan. It is well known to ventilation and fan specialists that fully 80 per cent of the fans ventilating coal mines today are working below their true or normal capacity, for the water gage is higher than that for which the fan is designed.

The reasons for this condition are many, chief among them being that the mine manager oftentimes when ordering a fan, orders that it be built to afford "plenty of capacity" and he gets it *in the fan*, but he fails to live up to his end of the bargain, in that he does not give the fan a mine that will permit the normal capacity

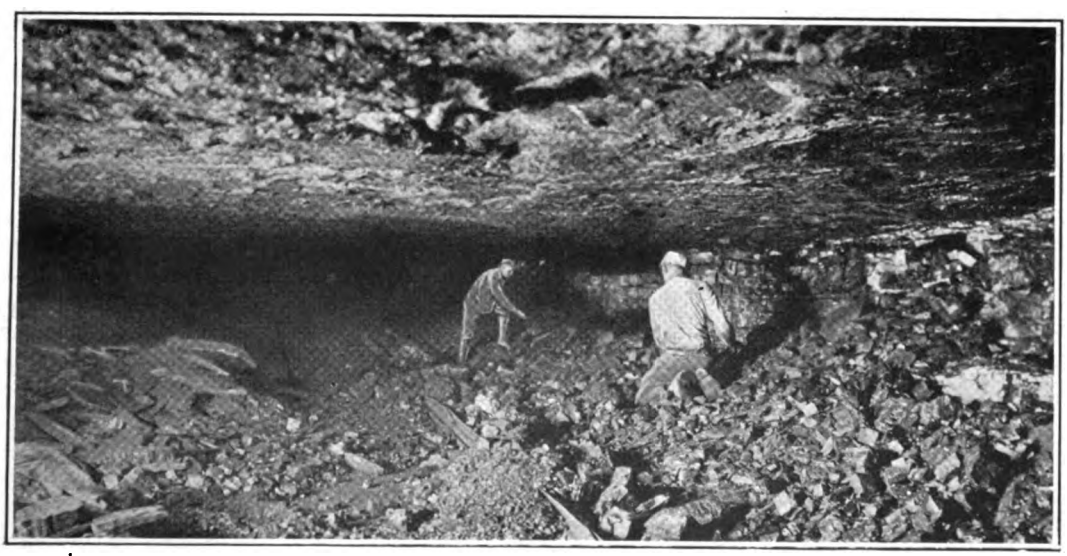

FIG. 4

After a Shot

Immediately after shooting, the men are able to resume work. The conveyor in any event does not need loading by hand, for it is already well-loaded by the effects of the shot. Much of the coal is above the conveyor and does not have to be raised. The work is that of lowering coal rather than of lifting it as in loading a mine car.

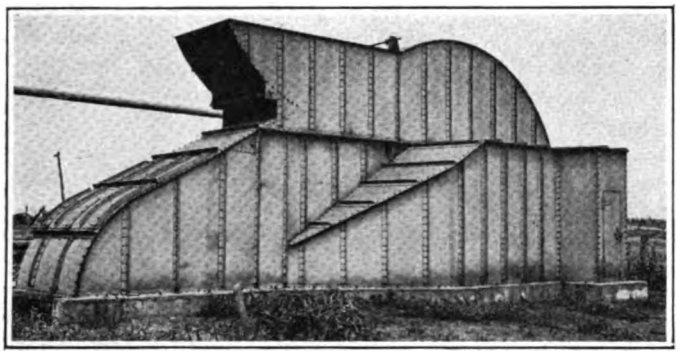

Fig. 5—Fan Makes More Air Than Mine Will Take

Always consider the mine wholly apart from the fan. Given a certain water gage and a certain resistance the mine will pass a certain quantity of air. The duty of the ventilating unit is to create that water gage. How much air must it thus compress? Just as much as, and no more than, the mine will take at that pressure.

of the ventilating unit to flow through the mine workings except at a water gage entirely out of all reason.

Again one finds at mines, fans that "fit" the mine conditions the first few years of their operation, but as time has passed the operator has been too optimistic as to his ability to keep down the resistance of the mine to the stated water gage, and as the workings develop the fan becomes more and more unsuited to the work it is required to perform. It is now too large and is able to deliver more air altogether than can pass through the aging mine at the original water gage. As retreating begins, of course, the fan is gradually brought up to capacity and operates more efficiently.

Fig. 5 shows a 12-ft. blowing reversible fan, the normal capacity of which is about 300,000 cu.ft. per minute. When the mine resistance is equal to 3 in. of water gage the fan is 75 per cent efficient mechanically and the brake horsepower required is 140. But the mine will only permit 200,000 cu.ft. per minute to pass with a 3-in. water gage. As a result 140 hp. is required to obtain this result.

By cleaning up the airways and otherwise relieving the restriction, the fan could be brought to efficiency and made to deliver the desired 300,000 cu.ft. of air per minute without a single additional revolution per minute, but this is exceedingly difficult and expensive to do once the airways throughout the mine have been allowed to become cluttered with roof falls.

Characteristic Curves of Multivane Fan

Fig. 6 shows the characteristic curves of a modern multivane fan of practically any standard make when running at constant speed. It will readily be seen that with the fan running at normal capacity it operates at a peak efficiency of 75 per cent delivering 150,000 cu.ft. per minute at 3.5-in. water gage. Should roof fall in the aircourses so as to restrict the air passing through the mine to one-half that volume, the water gage, as will be noted from the graph, will show a slight increase, but the efficiency of the fan will be reduced to about 58 per cent. Yet, its speed will have remained unchanged. The constant-speed curve illustrates clearly the important economy effected by operating a multiblade fan at ranges reasonably within its normal capacity.

Fig. 7 shows a small modern all-steel fan 5 ft. in diameter replacing a wooden fan of 20-ft. diameter. This substitution saved the operator about $3,000 a year in his power bills, because the new fan was operated at peak efficiency. Not so much of this trouble will be experienced in a mine that has introduced the new systems of mining, for the fan will be over- rather than underloaded. As most fans are underloaded the change to more modern methods of extracting coal, which will increase the load, will be favorable to greater mechanical efficiency.

What about the effect of this change on the cost of ventilation? My data, observation and experience lead me to the conclusion that ventilating cost will be materially reduced, particularly in those states permitting the driving of entries more than 80 ft. without a crosscut. The elimination of the driving of many crosscuts and of the building and maintenance of many stoppings will result in an important reduction of cost. A positive decrease in the cost of ventilation is assured because of the reduction in the resistance of the mine. The power required to drive a mine fan varies as the square of the pressure and increases, or decreases, as the cube of the volume, the velocity or the number of revolutions per minute of the fan.

If a mine needs 200,000 cu.ft. of air per minute and the water gage is 4.5 in. a 250-hp. motor is needed to ventilate it. The operation of the fan will cost about $25,000 a year, estimating the cost on the basis of a 24-hr. day, 300 days in the year, a 60-per cent overall efficiency and 2c. per kilowatt-hour. This figure will be about $19,200 a year with energy at 1½c. per unit. This is to run the fan alone.

Operator Saves $13,000 Yearly

Should the same mine be able to reduce its resistance to 2 in. of water gage for the same quantity of air, the power bill for the operation of the fan will be cut to $11,300 on a basis of 2c. per kilowatt-hour and to $8,500 if the cost of energy is only 1½c. per unit. It

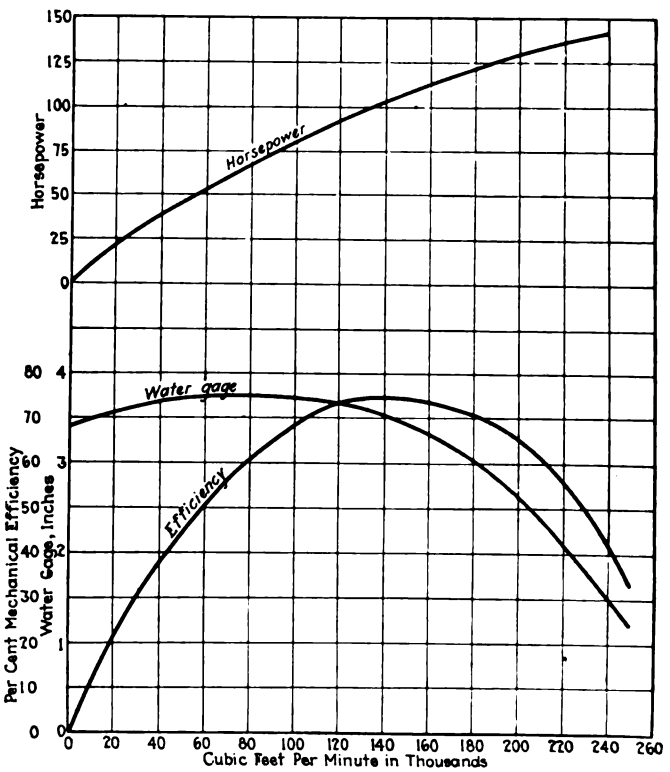

Fig. 6—Characteristics of Mine Fan Running at Constant Speed

The greatest water gage is not found at the point of maximum efficiency. If the mine demands the higher water gage the fan will furnish it in some degree but at a loss of capacity. If it demands less pressure more air will be delivered but at a lowered efficiency. As far as possible the mine should fit the fan and the fan the mine, but that fact is rarely understood.

Digitized by Google

is quite evident, therefore, that if the permanent airways are kept clean and open, under the new system, the ventilation cost, in so far as power bills are concerned, will be reduced appreciably. The company using this system of mining successfully should be able to show a saving in the cost of production per ton over its former system, and if it can achieve a saving of 25c. a ton on the mining alone, it is inclined to regard any saving in the cost of ventilation as so much "velvet."

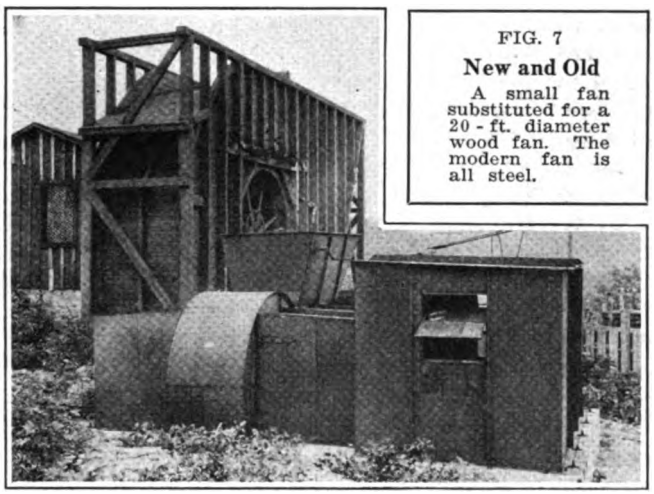

FIG. 7
New and Old
A small fan substituted for a 20-ft. diameter wood fan. The modern fan is all steel.

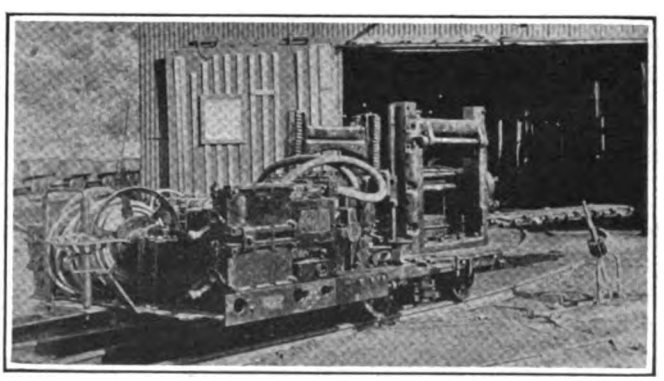
The ventilation of the working faces under various systems of concentrated mining presents problems all having the same physical aspects but though these aspects are alike they cannot all be solved in the same manner. The operator in one state may have clear sailing, whereas his neighbor across the state line may be hampered in many ways by the laws with which he is obliged to conform. One state will be found progressive and alive to what these new methods can do and in framing its legislation will give all reasonable assistance to its mining men. Another will be found to cling to laws made for a system of mining that is surely, but, of course, gradually, doomed to give place to a new order, the state being nevertheless unwilling to recognize this fact.

I refer, of course, to those states that bar the use of the small auxiliary blower with canvas tubing for ventilating minor faces and which do not permit an entry to be driven without making a crosscut every 60 or 80 ft. The last thing in my mind is to recommend a step backward or to undo any good practice already established, but the reader will surely agree that without jeopardizing the lives of the men employed, a mining code may be so framed and worded as to give progressive operators a chance to work their mines efficiently by one of the many systems of concentrated mining now receiving extended application.

Royalties Are Low in Southern Illinois

Investigations made by L. D. Tracy, a coal-mining engineer of the U. S. Bureau of Mines, show that since 1910 the average royalty in Williamson County in southern Illinois has gradually increased from about 3c. per ton for run-of-mine coal to about 6½c. In Franklin County, which is adjacent to Williamson and in the same state, during the same period the royalty has risen from about 1½c. to 5c. per ton.

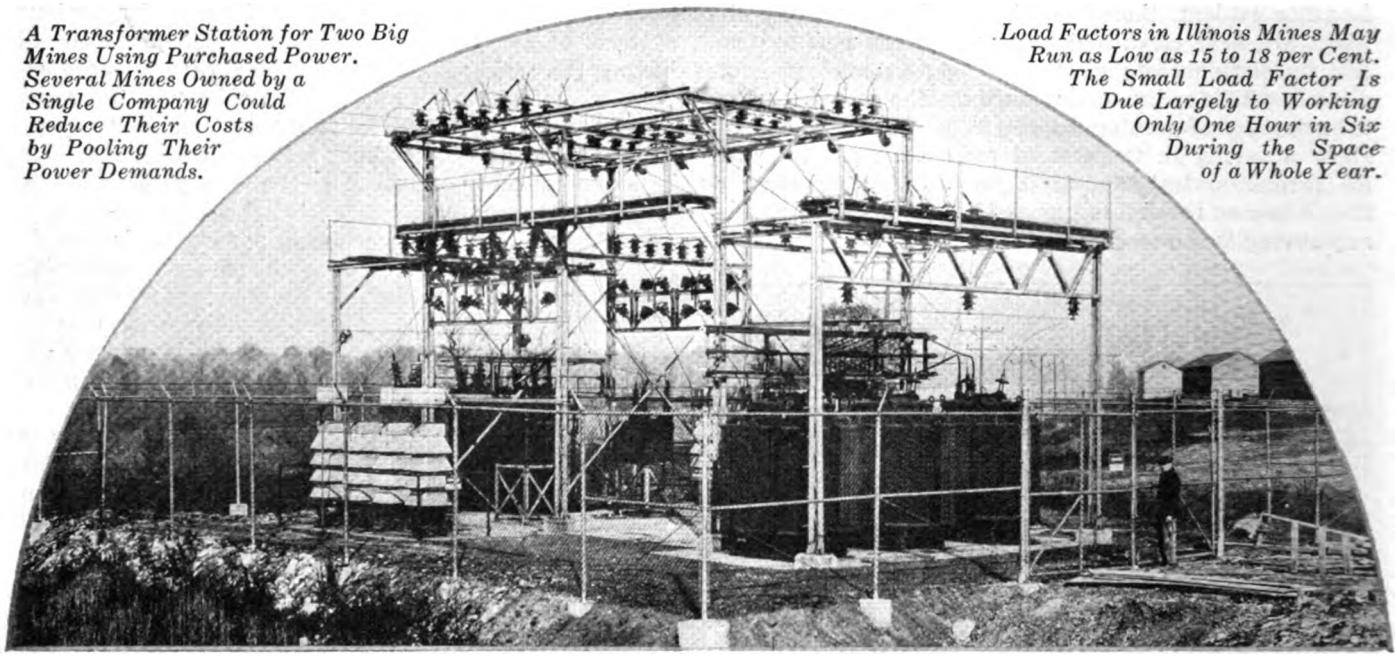
In normal times a piece of coal land in Williamson County brings about 8c. per ton royalty. This presupposes that all conditions as to mining, shipping and quality are favorable and that it will be mined in the course of the normal development of the field. In Franklin County the probabilities are that a slightly lower royalty would be asked than in Williamson, although royalties as high as 10c. per ton have been received. Surface options, as given in leases in this district, indicate the surface as valued at $85 per acre. General inquiry would indicate that from $50 to $75 per acre was a fair price for the surface and $100 to $125 per acre for the big seam, No. 6, without surface.



Formerly no mention of surface subsidence was made in coal leases, but in later years about 52 per cent of the leases in Williamson County and 37 per cent of those in Franklin County contain a clause which expressly releases the lessee from all liability for damages to the surface by subsidence caused by removing the underlying coal. No difference in the royalty appears to result from incorporating such a clause.

There are no recent figures at hand of royalties in other fields of the country but George H. Ashley gives a few as of 1910. However, comparing the average royalty in Franklin and Williamson as of 1923 with those in the coal fields as given by Ashley it would appear that southern Illinois coal is valued at a much lower figure by comparison.

As far back as 1910, Pittsburgh coal royalties ranged from 10 to 15c. per ton of run-of-mine coal. Hocking Valley, Ohio, coal brought 8c. per ton; Kanawha, W. Va., 5½ to 10c., Routt County, Colo., 8 to 10c. and Boulder County 8 to 27½c. These figures of fifteen years ago are higher than those of Williamson County which averaged a little over 6c. per ton or those of Franklin County that run from about 4 to 7c. per ton for the past few years. There does not seem to be any definite reason for this seeming discrepancy in values.



The highest price of Williamson and Franklin County coal land, is $125 per acre for coal and $75 per acre for surface, or a total of $200. The average thickness of the principal bed is given as 9.2 ft., and the average thickness mined as 7½ ft. These figures will give an approximate acre-foot value of $21.50 and $26 respectively.

Comparing Ashley's maximum acre-foot values of fifteen years ago: Pittsburgh coal is $110 to $170; Kanawha district $6 to $60; Pocahontas district $10 to $40; Colorado $23 to $60. And probably in none of those places does the surface value play as large a part as in the Illinois acre-foot value.

This Top Cutter Overcomes Obstacles
Turret machine with 8-ft. cutterbar is used by the Phelps Dodge Corp. for special cutting in 35-ft. rooms where faces slant at an angle of about 32 deg. The revolving cutting mechanism is self-propelling within its working area, maintaining contact with the nearest power line by means of a cable reel.

A Transformer Station for Two Big Mines Using Purchased Power. Several Mines Owned by a Single Company Could Reduce Their Costs by Pooling Their Power Demands.

Load Factors in Illinois Mines May Run as Low as 15 to 18 per Cent. The Small Load Factor Is Due Largely to Working Only One Hour in Six During the Space of a Whole Year.

Why Illinois Uses Purchased Power Extensively

Small Loads and Irregularity of Operation Favor Use of Purchased Power—Load Factor of Diversified Service Much Greater Than That of Any Single Mine

By J. Paul Clayton
Vice-President, Central Illinois Public Service Co., Springfield, Ill.

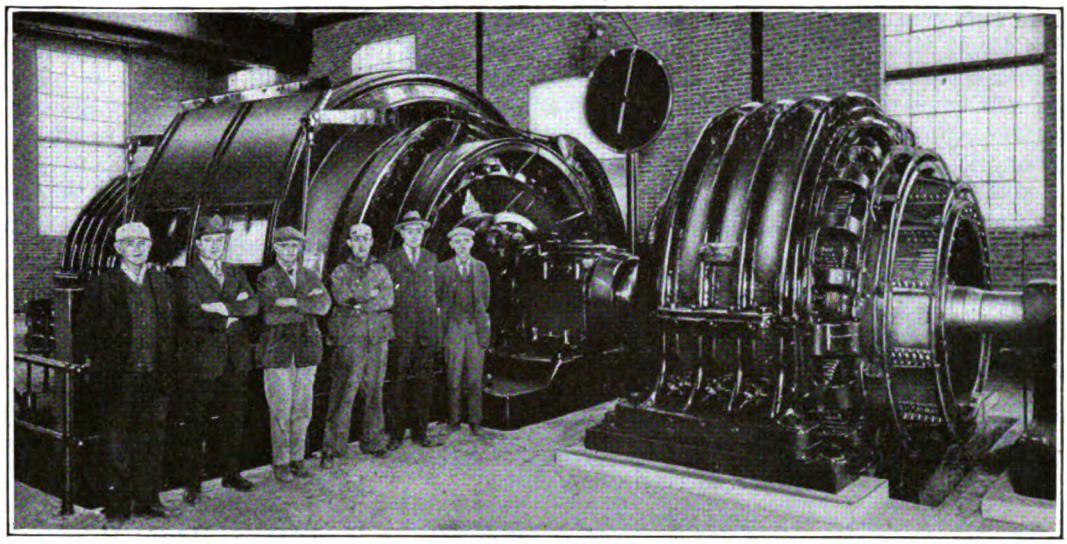
OUT of a total area of 56,000 square miles in the State of Illinois somewhat over 35,000 square miles are underlaid with bituminous coal. With an average yearly production of about 70,000,000 tons this state ranks third in the Union, being exceeded only by Pennsylvania and West Virginia. The beds of coal now worked vary from 3 to 14 ft. in thickness and lie at a depth ranging from nothing at certain outcrops to as much as 1,000 ft. below the surface. The average depth of the mines now working is approximately 400 ft. Little water is encountered in any of these operations.

Early development of the coal deposits of this state largely utilized hand labor, but as this became more and more expensive it has been gradually supplemented by mechanical energy until at the present time mechanical or electrical power is used for a great variety of operations. The early mines were supplied with mechanical or electrical energy from stations located near the shaft or other mine opening. These as a rule were small at the start and grew by accretion as power demands increased. As a result, many of these early mine power plants were woefully inefficient.

It was not until about 1912 that high-tension transmission lines furnishing power to the mines made their appearance in Illinois. At that time two large mines were built and completely electrified using purchased power for their operation. These two developments are still among the most efficient in the state from the standpoint of power consumption. They are likewise among the largest producers as regards annual tonnage. The extension of transmission lines steadily progressed until, at present, purchased power is available in almost all the coal fields of the state. Most of the power furnished to these fields is generated in large modern steam-turbine stations where it can be produced at low cost.

Electric service to the coal mines has steadily progressed from its humble beginning back in 1912 up to the present. Today not less than 200 coal operations purchase all or a substantial portion of their total power requirements. There are now about 338 shipping mines within the state, so that approximately 60 per cent buy part or all of their power. A majority of the fully electrified operations are of large capacity so that probably at least 75 per cent of the coal mined within the state borders is produced in whole or in part by the aid of power purchased from central station companies. Great progress has been made in the electrification of the mining industry of Illinois during the last fifteen years.

SERVICES POWER PERFORMS



The main purpose for which power is used at electrified mines are as follows: Hoisting, haulage, cutting, ventilating, pumping, preparation, shops, lighting and to a limited extent battery charging. In the larger fully electrified mines of Illinois practically all the hoisting is done by means of flywheel motor-generator sets which take energy from the alternating-current supply through an induction motor and generate direct-current power. A large flywheel is mounted on the same shaft with the motor and generator so that any sudden draft of power for hoisting is provided by both an increased input from the transmission line to

Abstract of a paper entitled "Purchased Power for Coal Mines in Illinois," presented before a meeting of the Mid-West Power Conference at Chicago, Jan. 26 to 28, 1926.

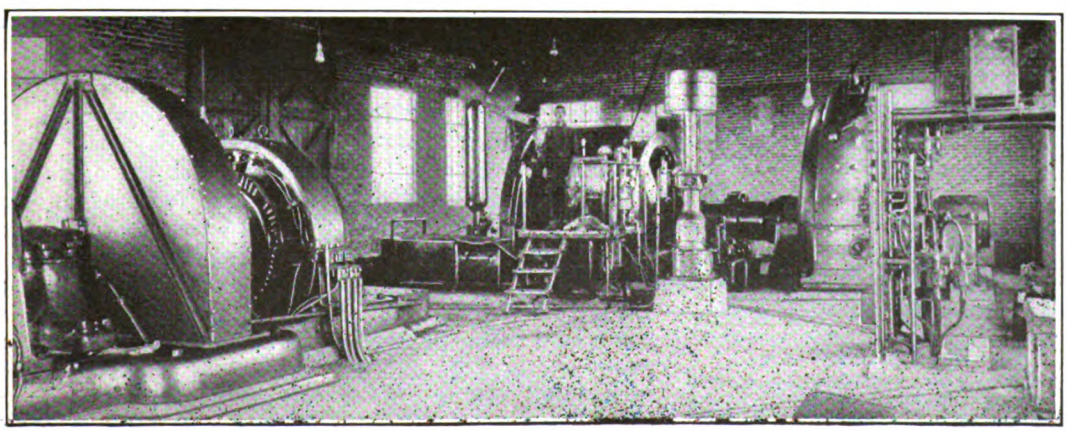
Double-Motored Hoist

At Orient, No. 2 Mine. In order to avoid the installation of a motor of excessive size two such machines are employed to operate a single hoist. Where large outputs must be attained speed and reliability are prime requisites in hoisting equipment. Such machinery must, therefore, be massive in design.

the motor and the stored energy of the flywheel. The hoist itself is driven by a motor drawing its current supply from the direct-current generator. An auxiliary alternating-current motor of relatively small capacity is provided for hoisting men and materials when the large motor-generator is not in operation.

This method of driving the hoist, variously known as the Ward-Leonard and Ilgner system of control, provides a fairly steady average load upon the alternating-current supply, simultaneously affording almost unlimited power for hoisting purposes. One of the advantages of this method of control is that in the event of an interruption to the power supply sufficient energy for hoisting is available for some time from the flywheel alone. This control also gives great refinement of manipulation in hoisting. It is undoubtedly the most satisfactory method yet devised for controlling mine hoists at operations of large capacity. In small mines or those that hoist only a short distance where the size of motor required does not exceed 300 to 500 hp. geared alternating-current motors are employed.

Haulage Uses 250-Volt Current



Power haulage in Illinois mines is performed entirely by means of direct current at approximately 250 volts. To furnish this energy synchronous motor-generator sets are employed. An Illinois law forbids the carrying of potentials exceeding 275 volts on exposed wires.

Cutting and mining machines are operated both by direct current from the haulage system at approximately 250 volts and by alternating current at about 220 volts. Alternating-current cutting machines were first introduced in this state in 1913 following the introduction of purchased power. Their use encouraged the practice of taking power at 2,300 volts underground by means of three-phase, lead-covered, armored cables to banks of transformers located adjacent to the working faces. This arrangement greatly reduced the losses experienced in the direct-current transmission and materially lessened repairs to the cutting machines themselves as full voltage was always supplied to them. The majority of new mines developed within this state during the last ten years have installed alternating-current cutting machines.

Pumps and Fans Use Alternating Current

Pumps used for voiding water from the mines are usually driven by alternating-current motors, although some are operated from the direct-current haulage circuits. Ventilating fans are usually driven by induction motors taking either 220, 440 or 2,300 volts. Many machines of this kind are operated at constant speed but others are connected to variable-speed motors obtaining this variation of speed either by means of pole-changing devices or by some form of mechanical equipment for altering the speed. Tipple motors at the majority of mines are operated on alternating current of 220 to 440 volts.

During the last two or three years a number of large strip mines have been developed in Illinois. Some entirely satisfactory beds of coal lie within 25 or 30 ft. of the surface. By the use of large power shovels it has been found possible to strip the overburden from these measures and lay the coal bare. Smaller shovels

Hoisting Electrically

Hoist at Valier. Raising coal entails a big demand for power. A flywheel motor-generator is interposed between the hoist and the line. The inertia of the flywheel takes part of the load when coal is being raised, thus cutting down demand peaks.

Digitized by Google

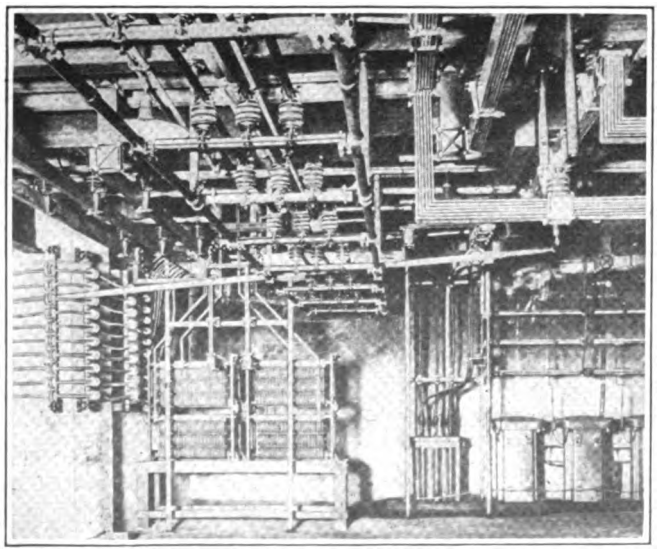
load this coal into cars by which it is transported to the tipple where it is prepared for market. In such mines electric power may be utilized for operating the shovels employed in both stripping and loading as well as for actuating the tipple. In some cases also this power is used for pumping if natural drainage is not available.

Power consumption in individual mines varies according to the depth of the operation, average length of haulage, volume of air furnished, quantity of water pumped, thickness of bed and other conditions of lesser importance. The actual power consumption for a year of operation, in two completely electrified mines producing approximately 1,000,000 tons of coal each from a depth of 400 ft. was as in Table I.

Table I—Power Used for Various Purposes and Its Percentage of Use as Related to Total Consumption

Operation Performed	Power Consumption Kw.-Hr. per Ton of Coal Hoisted	Percentage of Total Consumption
Hoisting	0.6	25.0
Haulage, gathering, cutting, pumping	1.4	58.3
Fan, tipple, shops	0.4	16.7
Total	2.4	100.0

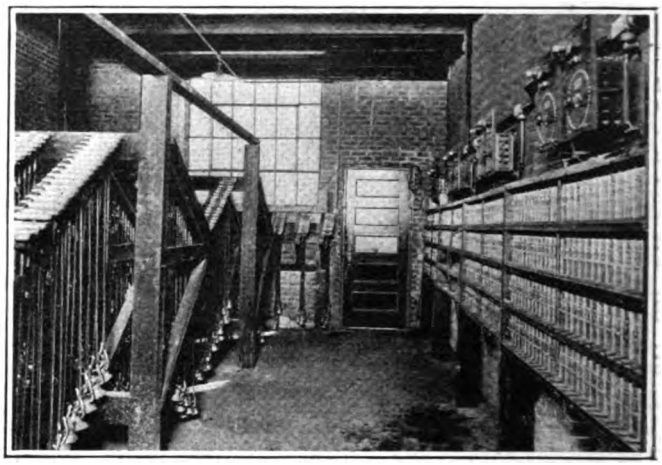
The total power consumption in completely electrified Illinois mines varies from a minimum of about 2.1 kw.-hr. per ton of coal produced under unusually favorable conditions of nearly continuous operation up to 4.5 kw.-hr. per ton of production under unfavorable conditions and operations considerably below normal. An average for the state would probably be about 3.5 kw.-hr. per ton under average prevailing conditions.



The total operating cost of power when purchased will vary between limits according to the conditions enumerated above. The actual cost of power from a year's operation of the two mines to which reference has been made was as in Table II.

Table II—Cost of Operating Mine Equipment

	Cost Cents per Ton of Coal Hoisted
Labor, including hoisting engineers, firemen, janitors, etc.	1.5
Purchased power, coal for heating water for wash house, lubricants, etc.	5.8
Repairs, supplies and miscellaneous	1.0
Total	8.3



The total operating cost for current where all power is purchased will vary from about 7c. per ton for highly favorable conditions such as large output and nearly continuous operation to about 10c. per ton for less favorable conditions and less constant operation. An average for the state would be about 8.5c. per ton under the conditions normally prevailing.

When compared with the other costs incurred in coal mining, particularly that of labor, it will be found that the item of purchased energy is the smallest of all the various components making up the total expense of producing a ton of coal.

In the Basement of a Big Electric Hoisthouse

This view taken at the Orient No. 2 plant of the Chicago, Wilmington & Franklin Coal Co., shows some of the elaborate wiring that supplies current to the diverse electrical equipment installed on the floor above.

Interior of Lamp-Charging Station

Charging storage batteries, regardless of whether they supply current to cap lamps, locomotives or other devices, is one of the few operations about the mines, aside from pumping and ventilation, that can be done at night.

The total operating cost of power generated in privately owned plants will vary because the same conditions affect it that affect the cost of purchased energy. Actual average costs for several mines having fairly efficient steam plants and operating about the average number of days that mines work in this state in normal times, are as in Table III.

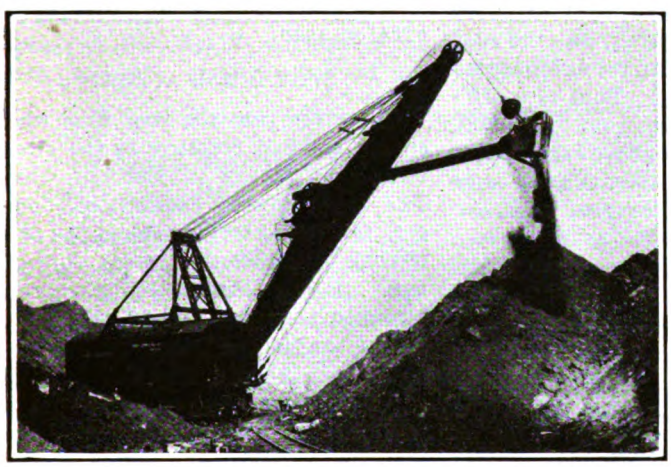
Table III—Operating Cost of Privately Owned Plants

	Cost Cents per Ton of Coal Hoisted
Labor, including hoisting engineers, firemen, coal passers, oilers, janitors, etc.	3.6
Coal, water supply, operating supplies, lubricants, etc.	4.5
Repairs, repair labor, supplies and miscellaneous	2.2
Total	10.3

The total operating cost of power produced in privately owned steam generating plants varies from about 10c. per ton for efficient installations at mines of large output to approximately 15c., or even 20c. per ton in many mines operating under less favorable conditions. An average for the mines of the state where generated power is used for all purposes would be about 12c. per ton.

FIVE HOURS IN EVERY SIX IDLE

Under normal conditions the average coal mine in Illinois operates about 180 eight-hour days per year. In other words, a full power supply for the operation of the average mine in this state is required during slightly less than one-sixth of the total number of hours in the year. The power necessary for hoisting, haulage, cutting and preparation has an annual load factor of about 15 to 18 per cent. That required for ventilation has a load factor of from 50 to 100 per cent, depending upon whether the fan is operated at constant speed throughout the year or is run at reduced speed when coal is not being mined. As a result the total load



Digitized by Google

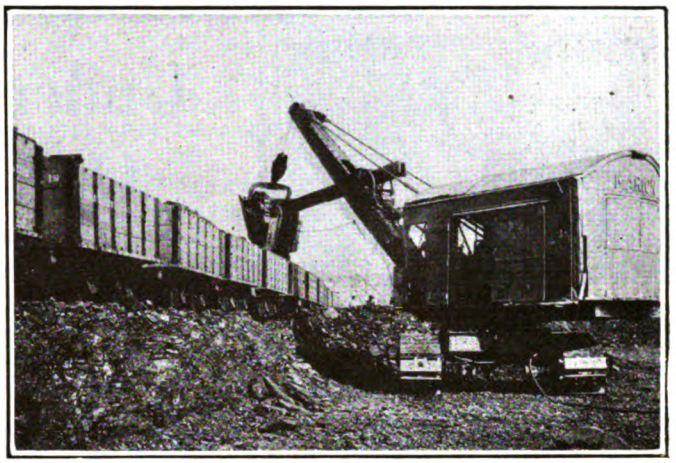
factor for all the power requirements of Illinois coal mines varies from a minimum of about 20 per cent up to a maximum of approximately 35 per cent in mines requiring large volumes of air and operating much more constantly than the average working time of the state. It is difficult to design a steam-power plant that will generate current efficiently under such conditions. The losses from banked fires are relatively large, and the labor cost incident to operating the boiler plants are high. Bearing in mind that the mines are working for only about one-sixth of the total time throughout the year, the unit costs of producing the small quantity of power required during their active periods are relatively extreme.

The reasons why it is best for coal mines to buy their power instead of generating it are as follows:

(1) Because the concentration of large production in big generating stations, serving a large lighting and industrial load as well as mines, affords a high load factor with resultant economy in current generation.

(2) Because the large diversity factor between the maximum loads of individual coal mines and the maximum load of a large transmission system serving many

Stripping Coal Electrically at Cuba, Ill.



Many coal beds lie close enough to the surface to be mined by the stripping method. For this purpose the electric shovel possesses many advantages over its steam-actuated predecessor. This illustration shows the United Electric Coal Co.'s stripping.

such mines, as well as other industries and large lighting loads reduces the peaks that would otherwise overload the equipment or make undue expenditures on equipment necessary.

(3) Because coal mining loads in Illinois, excepting only those for ventilation, pumping and lighting, occur between the hours of 7:30 a.m. and 4 p.m., whereas the lighting loads of central-station systems develop after 4 p.m.

(4) Because the grouping of many coal mines lowers the peaks, because the coal-mining loads occur only in the daytime, and because of the further consideration that the same central stations furnishing these requirements supply also large lighting demands, result in a system load factor at the generating stations of from 45 to 60 per cent as compared with those of individual mining plants of from 20 to 35 per cent. The generating equipment installed in central stations serving such diversified loads is, therefore, used for a variety of purposes, and the high load factors of such systems greatly aid in reducing the production costs.

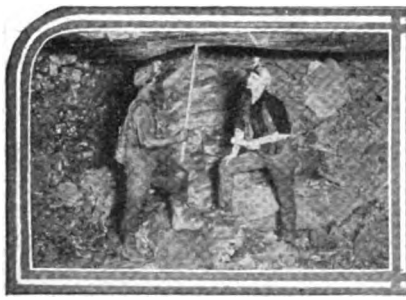
Even if a generating station were established for a group of mines, it would not be possible to obtain the low cost of investment and production which occurs with

Loading Out Stripped Coal by Power

The advantages of electrical operation in the strip pit need not be confined to the earth-moving shovel. This shows a small power shovel loading out coal that has been uncovered by the big stripper.

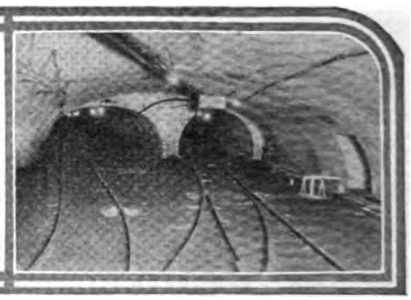
a modern central-station transmission system, because the load factor of a group of mines, at least in Illinois, cannot well exceed 35 per cent as compared with load factors of from 45 to 60 per cent for central-station systems. In addition, all the capacity can be used only for mine operation so that the investment costs are relatively high. It is true that a power plant serving a group of mines secures some of the economies inherent to a central station, but full advantage cannot be taken of the diversity of demand and high load factors of these latter systems.

WHAT PURCHASED POWER AFFORDS



The chief advantages to mine operators accruing from the purchase of power are approximately as follows: (1) Elimination of power-plant investment. (2) Reduced cost of purchased power as compared with that generated. (3) Independence of the water supply which is necessary if a power plant is located at the mine. (4) Reliable power supply available during strikes and periods when the the mine is not being operated; this results in a saving in labor costs. (5) Great flexibility in the supply of power necessary for increasing the output of the mine from time to time upon short notice. (6) Ability to locate motor-generator sets near the working face.* (7) The purchase of energy enables all the men at the mine to devote their undivided attention to the production of coal without being distracted by the generation of power.

When it is considered that only about fifteen years ago there were no mines in Illinois purchasing their power and that at present purchased current is used wholly or in part for the production of at least 75 per cent of the state's output, it is immediately apparent that central-station energy is the most important factor entering into the production of coal within this state. Most of the new large mines sunk during the past few years have been constructed for complete electrification with purchased energy from the start.



In many coal fields throughout the United States as much as 90 per cent of all of the power required is purchased. Undoubtedly a similar result will be attained in Illinois within the comparatively near future now that it has adequate power systems everywhere.

*This advantage can be secured by any mine generating its own power. In Illinois, however, about 90 per cent of all the installations of this kind were made at the time purchased power was adopted and are now used in connection with this source of energy.

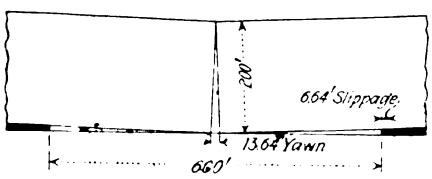
Underground Operation

When Mine Roof Breaks, Can It Fall?

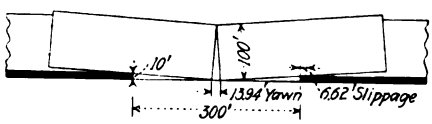


If a Free Piece of Roof Resting on Ribs Breaks and Tries to Tilt Into the Mine Workings It Must Open a Wide Crevice and Slide Up on the Pillar

By R. D. Hall
Engineering Editor, *Coal Age*

Last week appeared in this department of *Coal Age*, Edward O'Toole's interesting and illuminating remarks on roof control and incidentally on roof failure also. If more persons would study the roof as a girder or rather as a continuous beam, many strange fallacies, now widely current, would be exploded.

Mr. O'Toole puts all his confidence in the main resisting stratum. However, it must be remembered that the materials near the neutral axis are subject to but little compression or tension (according as they are above or below the axis respectively) and only the outer fibers of the girder experience the maximum stress—until the girder breaks and begins to fall. Then the neutral axis rises higher and higher, finally reaching the top of the girder, all the unbroken parts progressively becoming in tension.



Because the load, when within the sustaining limits of the girder, brings little stress on the material near the neutral axis, girders are made light at this point and heavy at the parts more distant therefrom. In the case of the roof if the material near the neutral axis is weak it may nevertheless be strong enough to meet the stress laid on it. This fact may explain why roofs give extraordinary resistance, so long as one layer cannot slide on another.

How the Roof Would Break If Free at Its Edges

A vertical crevice opening from the bottom up would divide the slab in two and with the dimensions of span, thickness and fall as shown, the opening or "yawn" of the crevice would be over 13 ft. wide.

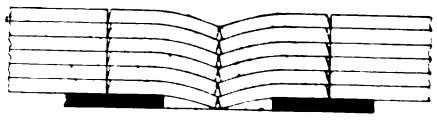
Mr. O'Toole says that a girder will fail more readily than a mine roof because in failing it can be drawn into the opening, but the roof being held by the surrounding areas cannot be so drawn. That is a difficult saying. The roof probably breaks somewhat above the pillar when it fails for as Mr. O'Toole says there is stress in the roof over the pillar, but it is interesting to note that the *bottom flange* of a girder which fails and drops does not slide *into* the opening but rather slides *out* of it during the early part of its fall.

Note What Happens Over Rib

In order to open the crevice, the bottom of the slab must slide upward on the rib and that will push back the unbroken measures about 6 ft. But these will not go back, so there is something wrong in the assumption that the slab is free to fall as it pleases.

YAWNS MORE THAN IT FALLS

Let us take Mr. O'Toole's example: Suppose the beam is 200 ft. deep and the span is 600 ft. The girder tears and ultimately opens up as if there were a hinge in the upper flange at midspan. The fracture yawns and that yawn if the fall is 10 ft. is 13.64 ft.



It is easy to calculate that the slant distance to the pier along the lower flange is no longer 300 ft. but 293.36 ft. so that motion of the point in the lower flange over the edge of the pier is backward toward the pier and the measure of it is 6.64 ft. It is because this movement in the case of the roof is prevented that the roof shows much strength. It is a thrust and not a pull that is being resisted by the adjacent strata.

Changing the thickness of the girder to 100 ft. and the span to 300 ft., using Mr. O'Toole's factor of three and assuming the roof to fall 10 ft., the yawn will be 13.94 ft. and the slide at the edge of the pier 6.62 ft. and in the same direction, backward toward the pier as in the previous case. The figures are naturally much the same as for the greater span.

WHY BREAK AT RIB?

But given that the roof falls what should make it fracture at the ribs? It is easy to say it does but why? The weak layers between the coal and the load-carrying band, as Mr. O'Toole significantly terms it, may fail. Being beams of no great strength they are nipped off. They are of the nature known as *encastré* or built-in beams, one end possibly on the floor and the other nipped in between the load-carrying band and the coal. Possibly these weaker layers, which are all that can be seen, do break on a line inclined 15 deg. to the vertical as Mr. O'Toole has noted, the ends projecting over the broken area, but it is difficult to see what should break off the load-carrying band unless it be the dynamic effect of the fall. The strain of the drop, most of which is almost instantaneous, must be enormous and perhaps Mr. O'Toole is correct in saying the rock breaks near the pillar, but it must be dynamic and not static strain that causes the break. More will be said about that later.

Now looking at the size of the

What Really Happens to Slab

The solid roof splits horizontally into a series of drawrocks, that is, rocks that are free of each other and which no longer act as a single integral slab, or monolith. These fit themselves to the space afforded them, pressing back the side rocks a little, but not six feet as the other illustrations show.

Digitized by Google

yawns between the fractured rocks and at the movements at the edge of the pillar no one can deny that they are unbelievably large. They surely do not occur in any such measure or the rocks would be thrust several feet into the air. What really happens is that the roof fractures not only vertically but horizontally. Each stratum in the load-carrying band slips a little past its neighbor. The hinge effect is not achieved; the yawn is not nearly what the figures purport to show, the distortion by horizontal shear between layers making it possible for the rock to fail without the fracture opening in the manner of a hinge on a door. The rectangles lose their rectangular form and become rhomboids, or possibly, rather slightly distorted rectangles of relatively shallow depth.

When All Is Drawrock

This horizontal movement that separates all the layers and makes of them separate small beams of no great strength is doubtless the cause of the failure at the rib. This is aided by the dynamic effect of the roof fall. The load-carrying band is no longer a unit. It has become a series of drawrocks that have no strength and are easy prey to the stresses involved in roof motion.

These considerations, perhaps, show why sandstone is so strong. It does not have much greater tensile strength than a good slate. But tension only opens the way to failure. The roof fails mainly from a yielding to compression, within the elastic limits, of the fractured member and of the measures surrounding it and from the sliding of one stratum on another. Consequently the important elements of strength are the ability to resist compression and horizontal shear, two qualities that in general discussion have always been overlooked. Tension and vertical shear are usually held exclusively accountable for roof failure, but is that view tenable?

How to Make Machine Loader A Popular Innovation

In discussing with coal operators the application of mechanical shoveling to coal mining, few, to date, have put due emphasis on the human element which is so necessary to the success of the undertaking. The miner, naturally, by means of the "grape-vine telegraph" gets early advice that the staff at the mine is discussing an addition to the equipment.

He knows that the purchase of more mine cars or more locomotives or additional cutting machines means, generally, that he will get better service and that he will be able to load more coal or, perhaps, will be enabled to load what he feels like loading in a shorter time. He does not entertain for a moment the thought that he will have to take less per ton or per yard for his services. The new equipment seems likely to increase the tonnage he will be able to get out and to make jobs for a few more motormen and cutters. That's fine. He likes to see things on the jump. It adds to the excitement of camp life, and it indicates, to him, that the rumors of a shutdown, perhaps, are not true.

Loaders, That's Different

Then comes the rumor that the company is considering the use of shoveling machines. That's different. That means cheaper coal, and he argues that cheaper coal means lower rates or wages for him. Nobody corrects that erroneous impression, and a machine is brought to the mine and put to work.

The man on the machine and those working about it, laying track, drilling holes and shooting them and generally preparing the working places are getting as good wages as they formerly got at other work but no more. Why then "cut loose" to get more coal and cheaper coal when it means no increase in the loader's earnings. But suppose, and why not, the loaders are, in due time, appraised of an arrangement whereby they will have a chance to make more money by the use of the large capacity of the machine. That again is different!

Interesting Labor

Suppose they are grouped about a shoveling machine in an ample, well-defined and compact territory, embracing rooms and narrow work, eleven men, including the group foreman. These men take care of the entire preparation, loading and haulage to the nearest lieway, including all dead work. Give them the wages that are current for the various classes of work for an output that profitably warrants the purchase of the machine.

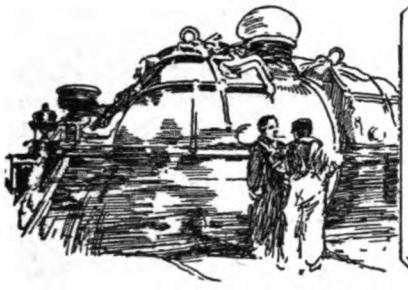
This is all right as far as it goes, but the worker's psychology has not yet been taken into account. How are we to make a fair arrangement whereby the interested capital and the partially interested worker can both be interested to the fullest extent?

The plan that would at once suggest itself, is that of paying in specified amounts for each unit of increase in joint performance, above the base production. It is a system of more pay for more coal, and more coal is what cuts the mine overhead. Such an arrangement honestly undertaken and fairly administered will surely be productive of enthusiastic team work which is so vital to the largest output at the smallest cost.

Everyone a Handyman

It is fair to say that under this group system of operation, no man is a specialist but that each man will do a fair day's work at whatever the foreman directs him to do. For example, if the cutting is completed and the drilling lags behind, the cutters will help in the drilling and so on. In a short season, under this plan the work would not suffer because one group failed to report.

It will be surprising and gratifying to note the increased *esprit de corps* that will permeate the whole organization. From a study of men in coal mines over a period of twenty-five years, it is my belief that mechanical shoveling is destined to show only mediocre results just so long as the men are not allowed to share, to a proper extent, in the benefits made possible by the shoveling machine.



Free Miners from Precedent

The sooner, be it said, the mining of a ton of coal is regarded less as an established practice and more as a problem of excavation and delivery, the sooner will the benefits from mechanical shoveling accrue. Another advantage, which does not generally show itself as an item on the cost sheet is the greater safety of the men. Our casualty list is a serious blot on the history of American coal mining. With mechanical loading fewer men are necessary for a given tonnage and a complete supervision of such men as are employed is rendered comparatively simple. The introduction of machines is bound to result in a great saving of life and limb. Experience has proved this to be true where machines have been introduced.

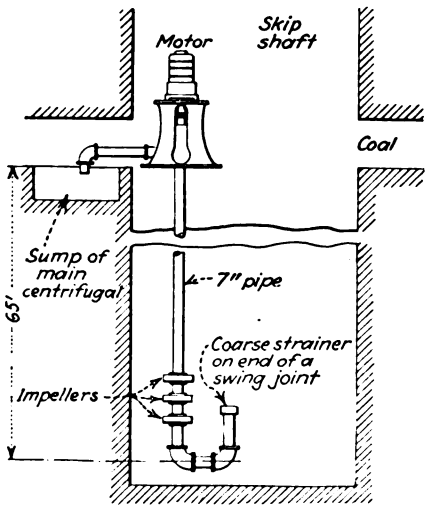
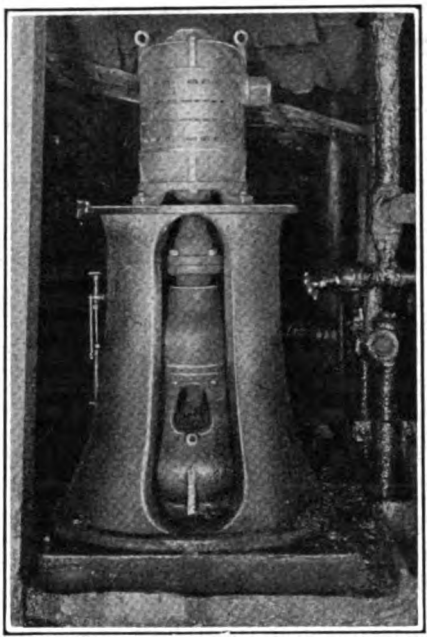
Practical Pointers For Electrical And Mechanical Men



Vertical Pump Driven by Motor at Lower Landing Lifts Sludge from Sump

Removing the water and sludge from the sump at the bottom of a skip shaft in many cases is a somewhat annoying operation. It is annoying rather than difficult because the liquid is laden with an appreciable quantity of solid matter and the ordinary horizontal direct-connected centrifugal pump, if placed in the sump would be subjected to the action not only of drip but that of the skip spillage sifting down upon it as well. This probably represents the hardest kind of conditions under which an electric motor can be called upon to work.



At the Bartley mine of the Pond-Creek Pocahontas Coal Co., near English, W. Va., these various difficulties are surmounted by placing a vertical centrifugal pump near the bottom of the sump and driving it with a motor installed at the level of the coal. By this means the pump is placed down close to its work, whereas the motor is up in a really accessible position, one that frees it from the action of both water and fine coal.

As may be seen from the accompanying drawing, the pump intake

How Sump Pump Is Installed

Making the pump vertical and driving it through a long shaft from a motor installed at the level of the coal bed removes the motor from the harmful action of both excessive dampness and dirt.

Pump Motor Works in the Dry

This motor is mounted on a substantial foundation approximately 65 ft. above the motor that it drives. It is thus well removed from the dirt and dampness of the skip pump.

or suction opening is approximately 65 ft. below the level of the coal bed. The suction pipe is turned upward at its extremity which is further protected by means of a coarse strainer. The pump itself is a three-stage machine, the diameter of the impellers being about 12 in. The discharge pipe is of 7-in. diameter, and delivery is made to the sump of the main mine drainage pump. The 10-hp. vertical driving motor operating at 440 volts, alternating current, is shown in the photographic illustration.

This pump, which is of Layne & Bowler type, was put into service, July 1, 1925, and so far has handled the sump sludge without difficulty and apparently without much wear. The chief advantage of this type of unit, however, as already pointed out is that the motor and working head are above the sump and consequently up out of both water and dirt. A further advantage is ease of access. Neglect usually follows where a piece of equipment cannot be reached readily or only with discomfort.

Grinding Valves Eliminate Pump Difficulties

Much trouble and expense was experienced in the upkeep of the boiler-feed pump in our 1,000-kw. power plant. The main troubles were these: The pump ran too fast, water-valve seats were continually being knocked out, valve stems broke frequently, and there was much wear on the rocker arms and on the rods of the steam valves.

New Valves No Better

New brass water valves and seats, in the condition in which they came from the factory were installed, but this did not seem to help matters. The first step taken was to determine what speed the pump should run to supply the proper quantity of water for the boilers. This was determined easily from readings of a feed-water meter which is a part of the regular equipment of the water line. By calculating the displacement of the pump plungers it was found that the pump should be making five to six strokes per minute instead of twenty-four to twenty-five strokes, which it was actually making. The natural deduction was, "leaky water valves."

Valve Ill-Seated

A new seat and valve were closely examined. It was found that the valve touched the seat only in spots. To the eye it appeared to seat well, but by using a feeler gage as much as 0.005 and 0.006 in. opening was found in spots between the valve and its seat. A new set of valves and seats were made up by grinding the valve to the seat, with valve grinding compound, until there was a good seat over the entire bearing surface. After the new seats had been placed in the pump, the valves were given a final grinding to their seats. When the pump was again started, all troubles had disappeared. The pump carried the load by operating at a speed of six strokes per minute and ran that way without any further expense for over eighteen months.

Digitized by Google

As a result of the above experience the same practice was followed with brass-valve mine pumps. These pumps would deliver a much greater quantity of water, after the valves were ground to their respective seats.

Counterweight on Hillside Balances Slope Trips

Hoisting in balance is to be preferred to unbalanced hoisting. On slopes a counterweight within the slope itself can sometimes be used. This should equal the weight of the cars and half the weight of the coal in the trip to be hoisted. The machine thus consumes as much power in lowering a trip of empties into the mine as it does in bringing out a string of loads. Some mines are so located that a counterweight may be used on the surface.
